9.3 Framework

create_dl_layer_activation (: : DLLayerInput, LayerName, ActivationType, GenParamName, GenParamValue : DLLayerActivation)

Create an activation layer.

The operator create_dl_layer_activation creates an activation layer whose handle is returned in DLLayerActivation.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter ActivationType sets the type of the activation. Supported activation types are:

'relu': Rectified linear unit (ReLU) activation. By setting a specific ReLU parameter, another type can be specified instead of the standard ReLU:

- Standard ReLU, defined as follows:

$$ReLU(x) := \max(0, x)$$

- Bounded ReLU, defined as follows:

$$ReLU(x) := \begin{cases} 0 & \text{if } x \leq 0, \\ x & \text{if } 0 < x \leq \beta, \\ \beta & \text{else.} \end{cases}$$

  Setting the generic parameter *'upper_bound'* will result in a bounded ReLU and determines the value of β.

- Leaky ReLU:, defined as follows:

$$ReLU(x) := \begin{cases} \alpha x & \text{if } x \leq 0, \\ x & \text{else.} \end{cases}$$

  Setting the generic parameter *'leaky_relu_alpha'* results in a leaky ReLU and determines the value α.

'sigmoid': Sigmoid activation, which is defined as follows.

$$Sigmoid(x) := \frac{1}{1 + e^{-x}}$$

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

'upper_bound': Float value defining an upper bound for a rectified linear unit. If the activation layer is part of a model which has been created using create_dl_model, the upper bound can be unset. To do so, use set_dl_model_layer_param and set an empty tuple for *'upper_bound'*.
Default: *[]*

'leaky_relu_alpha': Float value defining the alpha parameter of a leaky ReLU.

Restriction: The value of *'leaky_relu_alpha'* must be positive or zero.

Default: *0.0*

Certain parameters of layers created using this operator `create_dl_layer_activation` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Layer Parameters	set	get
'activation_type' (`ActivationType`)	x	x
'input_layer' (`DLLayerInput`)		x

create_dl_layer_batch_normalization (: : DLLayerInput, LayerName, Momentum, Epsilon, Activation, GenParamName, GenParamValue : DLLayerBatchNorm)

Create a batch normalization layer.

The operator create_dl_layer_batch_normalization creates a batch normalization layer whose handle is returned in DLLayerBatchNorm. Batch normalization is used to improve the performance and stability of a neural network during training. The mean and variance of each input activation are calculated for each batch and the input values are transformed to have zero mean and unit variance. Moreover, a linear scale and shift transformation is learned. During training, to take all samples into account, the batch-wise calculated mean and variance values are combined with a Momentum into running mean and running variance, where i denotes the iteration index:

$$\begin{aligned} running\_mean(i) &= (1 - \texttt{Momentum}) * mean(i) + \texttt{Momentum} * running\_mean(i-1), \\ running\_variance(i) &= (1 - \texttt{Momentum}) * variance(i) + \texttt{Momentum} * running\_variance(i-1). \end{aligned}$$

To affect the mean and variance values you can set the following options for Momentum:

Given number: For example: *0.9*. This is the default and recommended option.
Restriction: $0 \leq \texttt{Momentum} < 1$

'auto': Combines mean and variance values by a cumulative moving average. This is only recommended in case the parameters of all previous layers in the network are frozen, i.e., have a learning rate of *0*.

'freeze': Stops the adjustment of the mean and variance and their values stay fixed. In this case, the mean and variance are used during training for normalizing a batch, analogously to how the batch normalization operates during inference. The parameters of the linear scale and shift transformation, however, remain learnable.

Epsilon is a small offset to the variance and used to control the numerical stability. Usually its default value should be adequate.

The parameter DLLayerInput determines the feeding input layer.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter Activation determines whether an activation is performed after the batch normalization in order to optimize the runtime performance.

- *'relu'*: perform a ReLU activation after the batch normalization.
  It is possible to specify an upper bound to the ReLU operation (see create_dl_layer_activation) via the generic parameter *'upper_bound'*.
- *'none'*: no activation operation is performed.

It is not possible to specify a leaky ReLU or a sigmoid activation function. Use create_dl_layer_activation instead.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'bias_filler': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
List of values: *'xavier'*, *'msra'*, *'const'*.
Default: *'const'*

'bias_filler_const_val': Constant value.
Restriction: *'bias_filler'* must be set to *'const'*.
Default: *0*

'bias_filler_variance_norm': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
List of values: *'norm_out'*, *'norm_in'*, *'norm_average'*, or constant value (in combination with *'bias_filler'* = *'msra'*).
Default: *'norm_out'*

'bias_term': Determines whether the created batch normalization layer has a bias term (*'true'*) or not (*'false'*).

Default: *'true'*

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).

Default: *'false'*

'learning_rate_multiplier': Multiplier for the learning rate for this layer that is used during training. If *'learning_rate_multiplier'* is set to *0.0*, the layer is skipped during training.

Default: *1.0*

'learning_rate_multiplier_bias': Multiplier for the learning rate of the bias term. The total bias learning rate is the product of *'learning_rate_multiplier_bias'* and *'learning_rate_multiplier'*.

Default: *1.0*

'upper_bound': Float value defining an upper bound for a rectified linear unit. If the activation layer is part of a model, which has been created using `create_dl_model`, the upper bound can be unset. To do so, use `set_dl_model_layer_param` and set an empty tuple for *'upper_bound'*.

Default: *[]*

'weight_filler': See `create_dl_layer_convolution` for a detailed explanation of this parameter and its values.

List of values: *'xavier'*, *'msra'*, *'const'*.

Default: *'const'*

'weight_filler_const_val': See `create_dl_layer_convolution` for a detailed explanation of this parameter and its values.

Default: *1.0*

'weight_filler_variance_norm': See `create_dl_layer_convolution` for a detailed explanation of this parameter and its values.

List of values: *'norm_in'*, *'norm_out'*, *'norm_average'*, or constant value (in combination with *'weight_filler'* = *'msra'*).

Default: *'norm_in'*

Certain parameters of layers created using this operator `create_dl_layer_batch_normalization` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Layer Parameters	set	get
'activation_mode' (`Activation`)		x
'epsilon' (`Epsilon`)		x

'weight_filler_variance_norm'	x	x

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **Momentum** (input_control) . . . . . string ⇝ *string* / real
Momentum.
Default: 0.9
List of values: Momentum ∈ {0.9, 0.99, 0.999, 'auto', 'freeze'}

▷ **Epsilon** (input_control) . . . . . number ⇝ *real*
Variance offset.
Default: 0.0001

▷ **Activation** (input_control) . . . . . string ⇝ *string*
Optional activation function.
Default: 'none'
List of values: Activation ∈ {'none', 'relu'}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'bias_filler', 'bias_filler_variance_norm', 'bias_filler_const_val', 'bias_term', 'is_inference_output', 'learning_rate_multiplier', 'learning_rate_multiplier_bias', 'upper_bound', 'weight_filler', 'weight_filler_variance_norm', 'weight_filler_const_val'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'xavier', 'msra', 'const', 'nearest_neighbor', 'bilinear', 'norm_in', 'norm_out', 'norm_average', 'true', 'false', 1.0, 0.9, 0.0}

▷ **DLLayerBatchNorm** (output_control) . . . . . dl_layer ⇝ *handle*
Batch normalization layer.

Example

```
create_dl_layer_input ('input', [224,224,3], [], [], DLLayerInput)
* In practice, one typically sets ['bias_term'], ['false'] for a convolution
* that is directly followed by a batch normalization layer.
create_dl_layer_convolution (DLLayerInput, 'conv1', 3, 1, 1, 64, 1, \
                             'none', 'none', ['bias_term'], ['false'], \
                             DLLayerConvolution)
create_dl_layer_batch_normalization (DLLayerConvolution, 'bn1', 0.9, \
                                     0.0001, 'none', [], [], \
                                     DLLayerBatchNorm)
```

Execution Information

create_dl_layer_class_id_conversion (: : DLLayerInput, LayerName, ConversionMode, GenParamName, GenParamValue : DLLayerClassIdConversion)

Create a class ID conversion layer.

The operator create_dl_layer_class_id_conversion creates a class ID conversion layer whose handle is returned in DLLayerClassIdConversion. The layer converts between the IDs used internally by the network and the target / output class IDs.

The network internally uses consecutive integer values starting from 0 as IDs (the number of values depends on the model type). In case the target / output class IDs differ from the internal IDs, this layer can be used to convert between them. The target / output class IDs are stored in the model parameter *'class_ids'* (see get_dl_model_param for more information on this parameter). If no *'class_ids'* are set, this layer copies the input to the output.

The parameter ConversionMode specifies the conversion direction and accepts the following values:

- *'from_class_id'*: Convert target / output class IDs into internal IDs. This mode is typically used after a target input layer.
- *'to_class_id'*: Convert internal IDs into target / output class IDs. This mode is typically used after an inference output layer.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_class_id_conversion can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

create_dl_layer_concat (: : DLLayerInputs, LayerName, Axis, GenParamName, GenParamValue : DLLayerConcat)

Create a concatenation layer.

The operator create_dl_layer_concat creates a concatenation layer whose handle is returned in DLLayerConcat.

The parameter DLLayerInputs determines the feeding input layers. This layer expects multiple layers as input.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

A concatenation layer concatenates the data tensors of the input layers in DLLayerInputs and returns a single data tensor DLLayerConcat. The parameter Axis specifies along which dimension the inputs should be concatenated. The supported options for Axis are:

'batch': Concatenation is applied along the batch-dimension.
Example: if you concatenate two inputs *A* and *B* of shape (h, w, d, b) = (1, 1, 1, 2), where *A* = [*A0*, *A1*] and *B* = [*B0*, *B1*], you obtain the output [*A0*, *A1*, *B0*, *B1*] with shape (1, 1, 1, 4).

'batch_interleaved': Concatenation is applied along the depth-dimension, but the output is reshaped as if the data was concatenated along the batch-dimension. For this dimension, all inputs need to have exactly the same shape.
Note that when the input batch_size is *1*, the concatenation is identical for *'batch'* and *'batch_interleaved'*.
Example: if you concatenate two inputs *A* and *B* of shape (h, w, d, b) = (1, 1, 1, 2), where *A* = [*A0*, *A1*] and *B* = [*B0*, *B1*], you obtain the output [*A0*, *B0*, *A1*, *B1*] with shape (1, 1, 1, 4).

'depth': Concatenation is applied along the depth-dimension.
Example: if you concatenate two inputs *A* and *B* of shape (h, w, d, b) = (1, 1, 1, 2), where *A* = [*A0*, *A1*] and *B* = [*B0*, *B1*], you obtain the output [*A0*, *A1*, *B0*, *B1*] with shape (1, 1, 2, 2).

'height': Concatenation is applied along the height-dimension.

'width': Concatenation is applied along the width-dimension.

Note that all non-concatenated dimensions must be equal for all input data tensors.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_concat can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

create_dl_layer_convolution (: : DLLayerInput, LayerName, KernelSize, Dilation, Stride, NumKernel, Groups, Padding, Activation, GenParamName, GenParamValue : DLLayerConvolution)

Create a convolutional layer.

The operator create_dl_layer_convolution creates a convolutional layer with NumKernel kernels in Groups filter groups whose handle is returned in DLLayerConvolution.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter KernelSize specifies the filter kernel in the dimensions width and height.

The parameter Dilation specifies the factor of filter dilation in the dimensions width and height.

The parameter Stride specifies how the filter is shifted.

The values for KernelSize, Dilation, and Stride can be set as

- a single value which is used for both dimensions
- a tuple [width, height] and [column, row], respectively.

The parameter Groups specifies the number of filter groups.

The parameter NumKernel specifies the number of filter kernels. NumKernel must be a multiple of Groups.

The parameter Padding determines the padding, thus how many pixels with value 0 are appended on the border of the processed input image. Supported values are:

- *'half_kernel_size'*: The number of appended pixels depends on the specified KernelSize. More precisely, it is calculated as $\lfloor \texttt{KernelSize}/2 \rfloor$, where for the padding on the left / right border the value of KernelSize in dimension width is regarded and for the padding on the upper / lower border the value of KernelSize in height.
- *'none'*: No pixels are appended.
- Number of pixels: Specify the number of pixels appended on each border. To do so, the following tuple lengths are supported:
  - Single number: Padding in all four directions left/right/top/bottom.
  - Two numbers: Padding in left/right and top/bottom: [l/r, t/b].
  - Four numbers: Padding on left, right, top, bottom side: [l,r,t,b].
    Restriction: *'runtime' 'gpu'* does not support asymmetric padding, i.e., the padding values for the left and right side must be equal, as well as the padding values for the top and bottom side.

  Restriction: The integer padding values must be smaller than the value set for KernelSize in the corresponding dimension.

The output dimensions of the convolution layer are given by

$$output\_dim = \left\lfloor \frac{input\_dim + 2(padding\_begin + padding\_end)}{\texttt{Stride}} - \frac{\texttt{KernelSize} + (\texttt{KernelSize} - 1)(\texttt{Dilation} - 1)}{\texttt{Stride}} \right\rfloor + 1$$

Thereby we use the following values: $output\_dim$: output width/height, $input\_dim$: input width/height, $padding\_begin$: number of pixels added to the left/top of the input image, and $padding\_end$: number of pixels added to the right/bottom of the input image.

The parameter Activation determines whether an activation is performed after the convolution in order to optimize the runtime performance. The following values are supported:

- *'relu'*: perform a ReLU activation after the convolution.
  It is possible to specify an upper bound to the ReLU operation (see create_dl_layer_activation) via the generic parameter *'upper_bound'*. Note: It is not possible to specify a leaky ReLU.
- *'none'*: no activation operation is performed.

We refer to the "Solution Guide on Classification" for more general information about the convolution layer and the reference given below for more detailed information about the arithmetic of the layer.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'bias_filler': See *'weight_filler'* for an explanation of the values.
List of values: *'xavier'*, *'msra'*, *'const'*.
Default: *'const'*

'bias_filler_variance_norm': See *'weight_filler_variance_norm'* for an explanation of the values.
List of values: *'norm_in'*, *'norm_out'*, *'norm_average'*.
Default: *'norm_out'*

'bias_filler_const_val': Specifies the constant bias term initialization value if *'bias_filler'* has been set to *'const'*.
Restriction: Ignored for other values of *'bias_filler'*.
Default: *0*

'bias_term': Determines whether the created convolutional layer has a bias term (*'true'*) or not (*'false'*).
Default: *'true'*

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).

Default: *'false'*

'learning_rate_multiplier': Multiplier for the learning rate for this layer that is used during training. If *'learning_rate_multiplier'* is set to *0.0*, the layer is skipped during training.

Default: *1.0*

'learning_rate_multiplier_bias': Multiplier for the learning rate of the bias term. The total bias learning rate is the product of *'learning_rate_multiplier_bias'* and *'learning_rate_multiplier'*.

Default: *1.0*

'upper_bound': Float value, which defines the upper bound for ReLU. To unset the upper bound, set *'upper_bound'* to an empty tuple.

Default: *[]*

'weight_filler': This parameter defines the mode how the weights are initialized. The following values are supported:

- *'const'*: The weights are filled with constant values.
- *'msra'*: The weights are drawn from a Gaussian distribution.
- *'xavier'*: The weights are drawn from a uniform distribution.

Default: *'xavier'*

'weight_filler_const_val': Specifies the constant weight initialization value.

Restriction: Only applied if *'weight_filler'* = *'const'*.

Default: *0.5*

'weight_filler_variance_norm': This parameter determines the value range for *'weight_filler'*. The following values are supported:

- *'norm_average'*: the values are based on the average of the input and output size
- *'norm_in'*: the values are based on the input size
- *'norm_out'*: the values are based on the output size.

Default: *'norm_in'*

Certain parameters of layers created using `create_dl_layer_convolution` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **KernelSize** (input_control) . . . . . number(-array) ⇝ *integer*
Width and height of the filter kernels.
Default: 3

▷ **Dilation** (input_control) . . . . . number(-array) ⇝ *integer*
Amount of filter dilation for width and height.
Default: 1

▷ **Stride** (input_control) . . . . . number(-array) ⇝ *integer*
Amount of filter shift in width and height direction.
Default: 1

▷ **NumKernel** (input_control) . . . . . number ⇝ *integer*
Number of filter kernels.
Default: 64

▷ **Groups** (input_control) . . . . . number ⇝ *integer*
Number of filter groups.
Default: 1

▷ **Padding** (input_control) . . . . . number(-array) ⇝ *string* / integer
Padding type or specific padding size.
Default: 'none'
List of values: `Padding` ∈ {'none', 'half_kernel_size', [all], [width,height], [left,right,top,bottom]}
Suggested values: `Padding` ∈ {'none', 'half_kernel_size'}

▷ **Activation** (input_control) . . . . . number ⇝ *string*
Enable optional ReLU or sigmoid activations.
Default: 'none'
List of values: `Activation` ∈ {'none', 'relu', 'sigmoid'}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: `GenParamName` ∈ {'weight_filler', 'weight_filler_variance_norm', 'weight_filler_const_val', 'bias_filler', 'bias_filler_variance_norm', 'bias_filler_const_val', 'bias_term', 'is_inference_output', 'learning_rate_multiplier', 'learning_rate_multiplier_bias', 'upper_bound'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: `GenParamValue` ∈ {'xavier', 'msra', 'const', 'nearest_neighbor', 'bilinear', 'norm_in', 'norm_out', 'norm_average', 'true', 'false', 1.0, 0.9, 0.0}

▷ **DLLayerConvolution** (output_control) . . . . . dl_layer ⇝ *handle*
Convolutional layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_dl_layer_dense (: : DLLayerInput, LayerName, NumOut, GenParamName, GenParamValue : DLLayerDense)

Create a dense layer.

The operator create_dl_layer_dense creates a dense or fully connected layer (sometimes also called gemm) with NumOut output neurons whose handle is returned in DLLayerDense.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'bias_filler': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
List of values: *'xavier'*, *'msra'*, *'const'*.
Default: *'const'*

'bias_filler_const_val': Constant value if *'bias_filler'* = *'const'*.
Default: *0*

'bias_filler_variance_norm': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
List of values: *'norm_out'*, *'norm_in'*, *'norm_average'*, or constant value (in combination with *'bias_filler'* = *'msra'*).
Default: *'norm_out'*

'bias_term': Determines whether the created dense layer has a bias term (*'true'*) or not (*'false'*).
Default: *'true'*

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

'learning_rate_multiplier': Multiplier for the learning rate for this layer that is used during training. If *'learning_rate_multiplier'* is set to *0.0*, the layer is skipped during training.
Default: *1.0*

'learning_rate_multiplier_bias': Multiplier for the learning rate of the bias term. The total bias learning rate is the product of *'learning_rate_multiplier_bias'* and *'learning_rate_multiplier'*.
Default: *1.0*

'weight_filler': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
List of values: *'xavier'*, *'msra'*, *'const'*.
Default: *'xavier'*

'weight_filler_const_val': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.

Default: *0.5*

'weight_filler_variance_norm': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.

List of values: *'norm_in'*, *'norm_out'*, *'norm_average'*, or constant value (in combination with *'bias_filler'* = *'msra'*).

Default: *'norm_in'*

Certain parameters of layers created using create_dl_layer_dense can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

create_dl_layer_depth_max (: : DLLayerInput, LayerName, DepthMaxMode, GenParamName, GenParamValue : DLLayerDepthMaxArg, DLLayerDepthMaxValue)

Create a depth max layer.

The operator create_dl_layer_depth_max creates a depth max layer.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

There are two possible output layers depending on DepthMaxMode:

- DLLayerDepthMaxArg: Handle to a depth max layer with mode *'argmax'*.
- DLLayerDepthMaxValue: Handle to a depth max layer with mode *'value'*.

Note, these parameters only need to be set in case such an output layer is requested (see DepthMaxMode).

The parameter LayerName defines the name of the output layer(s) depending on DepthMaxMode:

- *'argmax'*: name of DLLayerDepthMaxArg.
- *'value'*: name of DLLayerDepthMaxValue.
- *'argmax_and_value'*: name of DLLayerDepthMaxArg, while the layer DLLayerDepthMaxValue receives the same name with the suffix string *'_value'* appended to it.

Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The mode DepthMaxMode indicates which depth max value is actually returned as output. The following values are supported:

'argmax': *newline* The depth index of the maximal value is returned in DLLayerDepthMaxArg.

'value': *newline* The maximal value itself is returned in DLLayerDepthMaxValue.

'argmax_and_value': *newline* Both are returned, the depth index of the maximal value in the output layer DLLayerDepthMaxArg, and the maximal value itself in the output layer DLLayerDepthMaxValue.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_depth_max can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'input_layer' (DLLayerInput)		x
'mode' (DepthMaxMode)	x	x
'name' (LayerName)	x	x
'output_layer' (DLLayerDepthMaxArg and/or DLLayerDepthMaxValue)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'		x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **DepthMaxMode** (input_control) . . . . . string ⇝ *string*
Mode to indicate type of return value.
Default: 'argmax'
List of values: DepthMaxMode ∈ {'argmax', 'value', 'argmax_and_value'}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerDepthMaxArg** (output_control) . . . . . dl_layer(-array) ⇝ *handle*
Optional, depth max layer with mode *'argmax'*.

▷ **DLLayerDepthMaxValue** (output_control) . . . . . dl_layer(-array) ⇝ *handle*
Optional, depth max layer with mode *'value'*.

Module

Deep Learning Professional

```
create_dl_layer_depth_to_space ( : : DLLayerInput, LayerName,
    BlockSize, Mode, GenParamName,
    GenParamValue : DLLayerDepthToSpace )
```

Create a depth to space layer.

The operator create_dl_layer_depth_to_space creates a depth to space layer whose handle is returned in DLLayerDepthToSpace.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

This layer rearranges the elements of the feeding tensor of shape $(N, C*r^2, H, W)$ to a tensor of shape $(N, C, H*r, W*r)$. Thereby r can be considered an upscale factor, which is set with BlockSize.

The output element $(depth, row, col)$ is mapped from the input element $(depth * r^2 + (row\%r) * r + col\%r, row/r, col/r)$.

With Mode the ordering in the output tensor is set. Currently only the *'column_row_depth'* order described above is available.

Certain parameters of layers created using this operator create_dl_layer_depth_to_space can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'input_layer' (DLLayerInput)		x
'name' (LayerName)	x	x
'block_size' (BlockSize)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

- ▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
  Feeding layer.
- ▷ **LayerName** (input_control) . . . . . string ⇝ *string*
  Name of the output layer.
- ▷ **BlockSize** (input_control) . . . . . number ⇝ *integer*
  Block size (i.e., upscale factor).
  Default: 3
- ▷ **Mode** (input_control) . . . . . string ⇝ *string*
  Ordering mode.
  Default: 'column_row_depth'
- ▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
  Generic input parameter names.
  Default: []
  List of values: GenParamName ∈ {'is_inference_output'}
- ▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
  Generic input parameter values.
  Default: []
  Suggested values: GenParamValue ∈ {'true', 'false'}
- ▷ **DLLayerDepthToSpace** (output_control) . . . . . dl_layer ⇝ *handle*
  Depth to space layer.

Example

```
InputShape := [16, 16, 3]
Upscale := 2
*
create_dl_layer_input ('input', InputShape, [], [], DLLayerInput)
* Create a convolutional layer, that generates Upscale^2*NumChannel feature maps.
create_dl_layer_convolution (DLLayerInput, 'conv1', 3, 1, 1,\
                             Upscale * Upscale * InputShape[2],\
                             1, 'half_kernel_size', 'none',\
                             [],  [], DLLayerConvolution)
* Use a depth to space layer to combine Upscale^2 feature maps to upscale.
create_dl_layer_depth_to_space (DLLayerConvolution, 'upscaled', Upscale,\
                                'column_row_depth',[], [],\
                                DLLayerDepthToSpace)
* The output shape of DLLayerDepthToSpace is now [16*Upscale, 16*Upscale, 3].
create_dl_model (DLLayerDepthToSpace, DLModel)
```

create_dl_layer_dropout (: : DLLayerInput, LayerName, Probability, GenParamName, GenParamValue : DLLayerDropOut)

Create a DropOut layer.

The operator create_dl_layer_dropout creates a DropOut layer with probability Probability and returns the handle DLLayerDropOut.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

During training, activations within DLLayerInput are set to zero with probability Probability. All other activations are rescaled with (1 - Probability).

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_dropout can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get

Module

Deep Learning Professional

```
create_dl_layer_elementwise ( : : DLLayerInputs, LayerName,
    Operation, Coefficients, GenParamName,
    GenParamValue : DLLayerElementWise )
```

Create an elementwise layer.

The operator create_dl_layer_elementwise creates an element-wise layer whose handle is returned in DLLayerElementWise.

An elementwise layer applies a certain operation to every data tensor of the input layers handles and to each element of the data tensor. As a consequence, all input data tensors should be of the same shape and the output tensor has the same shape as the first input tensor.

The parameter DLLayerInputs determines the feeding input layers. This layer expects multiple layers as input. For Operation = *'division'* exactly two input layers are expected.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter Operation specifies the operation that is applied. Depending on Operation, the layer supports implicit broadcasting. I.e., if one of the shape dimensions (batch_size, depth, height, width) of the second or any of the following input tensors is 1, the values are implicitly multiplied along that dimension to match the shape of the first input. The supported values are:

- *'division'*: Element-wise division. Broadcasting is fully supported.
- *'maximum'*: Element-wise maximum. Broadcasting is fully supported.
- *'minimum'*: Element-wise minimum. Broadcasting is fully supported.
- *'product'*: Element-wise product. Broadcasting is supported, but all inputs following the second input must have the same shape as the second input.
- *'sum'*: Element-wise summation. Broadcasting is not supported.

The optional parameter Coefficients determines a weighting coefficient for every input tensor. The number of values in Coefficients must match the number of feeding layers in DLLayerInputs. Set Coefficients equal to *[]* if no coefficients shall be used in the element-wise operation.

Restriction: No coefficients can be set for Operation = *'product'*.

Example: for Operation = *'sum'*, the i-th element of the output data tensor is given by

$$output[i] = \sum_{n=0}^{N-1} \texttt{Coefficients}[n] \cdot \texttt{DLLayerInputs}_n[i],$$

where N is the number of input data tensors.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'div_eps': Small scalar value that is added to the elements of the denominator to avoid a division by zero (for Operation = *'division'*).
Default: *1e-10*

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_elementwise can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'coefficients' (Coefficients)		x
'input_layer' (DLLayerInputs)		x
'name' (LayerName)	x	x
'operation' (Operation)		x
'output_layer' (DLLayerElementWise)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'div_eps'	x	x
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInputs** (input_control) . . . . . dl_layer(-array) ⇝ *handle*
Feeding input layers.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **Operation** (input_control) . . . . . string ⇝ *string*
Element-wise operations.
Default: 'sum'
List of values: `Operation` ∈ {'division', 'maximum', 'minimum', 'product', 'sum'}

▷ **Coefficients** (input_control) . . . . . number(-array) ⇝ *real*
Optional input tensor coefficients.
Default: []

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: `GenParamName` ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: `GenParamValue` ∈ {'true', 'false'}

▷ **DLLayerElementWise** (output_control) . . . . . dl_layer ⇝ *handle*
Elementwise layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Deep Learning Professional

create_dl_layer_identity (: : DLLayerInput, LayerName, GenParamName, GenParamValue : DLLayerIdentity)

Create an identity layer.

The operator `create_dl_layer_identity` creates an identity layer whose handle is returned in `DLLayerIdentity`.

The parameter `DLLayerInput` determines the feeding input layer and expects the layer handle as value.

The parameter `LayerName` sets an individual layer name. Note that if creating a model using `create_dl_model` each layer of the created network must have a unique name.

The following generic parameters `GenParamName` and the corresponding values `GenParamValue` are supported:

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator `create_dl_layer_identity` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Layer Parameters	set	get
'input_layer' (DLLayerInput)		x
'name' (LayerName)	x	x
'output_layer' (DLLayerIdentity)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerIdentity** (output_control) . . . . . dl_layer ⇝ *handle*
Identity layer.

Example

```
* Create a model that concatinates the output of a convolution layer.
create_dl_layer_input ('input', [10,10,3], [], [], DLLayerInput)
create_dl_layer_convolution (DLLayerInput, 'conv', 3, 1, 1, 8, 1, 'none', \
                             'none', [], [], DLLayerConvolution)
* Using the same layer multiple times as input does not work, so make a copy.
create_dl_layer_identity (DLLayerConvolution, 'conv_copy', [], [], \
                          DLLayerIdentity)
create_dl_layer_concat ([DLLayerConvolution, DLLayerIdentity], 'concat', \
                        'depth', [], [], DLLayerConcat)
create_dl_model (DLLayerConcat, DLModelHandle)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

create_dl_layer_elementwise, create_dl_layer_concat

Module

Deep Learning Professional

create_dl_layer_input (: : LayerName, Shape, GenParamName, GenParamValue : DLLayerInput)

Create an input layer.

The operator create_dl_layer_input creates an input layer with spatial dimensions given by Shape whose handle is returned in DLLayerInput.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

When the created model is applied using e.g., apply_dl_model or train_dl_model_batch, it must be possible to map an input with its corresponding input layer. Operators applying a model expect a feeding dictionary DLSample, see Deep Learning / Model. The mentioned mapping is done using dictionary entries, where the key matches the input layer name. Thus, for an input of this layer a sample dictionary will need an entry with the key LayerName (except if the *'input_type'* is set to *'constant'*, see below).

The parameter Shape defines the shape of the input values (the values given in the feeding dictionary DLSample) and must be a tuple of length three, containing width, height, and depth of the input. The tuple values must be given as integer values and have have different meaning depending on the input type:

- for an input image the layer Shape defines the image size. Images shall be given with type real (for information on image types see Image).
- for an input tuple its length will need to match the product of the individual values in Shape, i.e., width × height × depth.

  Tuple values are distributed along the column- (width), row- (height), and depth-axes in this order. Input tuple values can be given either as integer or real.

The batch size has to be set later with set_dl_model_param, once the model has been created by create_dl_model.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'allow_smaller_tuple': For tuple inputs, setting *'allow_smaller_tuple'* to *'true'* allows to have an input tuple with less values than the total dimension given by Shape. E.g., this can be the case if an input corresponds to the number of objects within one image and the number of objects changes from image to image. If fewer than the maximum number of values given by the total dimension of Shape are present, the remaining values are set to zero.

Shape should be set such that it fits the maximum expected length. For the example above this would be the maximum number of objects within one image present in the whole dataset.

Default: *'false'*.

'const_val': Constant output value.

Restriction:

Only an integer or float is settable. This value is only settable or gettable if *'input_type'* is set to *'constant'*.

Default: *0.0*.

'input_type': Defines the type of input that is expected. The following values are possible:

'default': The layer expects a number of input images corresponding to the batch size.

'region_to_bin': The layer expects a tuple of regions as input and internally converts it to a binary image where each region is encoded in one depth channel. Regions reaching out of the given dimensions are clipped to the width and height given by Shape. The maximum number of regions is defined by the depth of Shape. If fewer than the maximum number of regions are given, the output is filled up with empty (zero) images. For example, this can be the case if the regions are corresponding to objects within an image and the number of objects changes from image to image.

'constant': The layer does not expect any key value pair in the input dictionary. Instead all entries within the output of this layer are filled with the value given by *'const_val'*.

Default: *'default'*.

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).

Default: *'false'*

Certain parameters of layers created using create_dl_layer_input can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'input_layer'		x
'name' (LayerName)	x	x
'output_layer' (DLLayerInput)		x
'shape' (Shape)		x
'type'		x

Generic Layer Parameters	set	get
'allow_smaller_tuple'		x
'const_val'	(x)	(x)
'input_type'		x
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **Shape** (input_control) . . . . . number-array ⇝ *integer*
Dimensions of the input (width, height, depth).
Default: [224,224,3]

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'allow_smaller_tuple', 'const_val', 'input_type', 'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {0.0, 'constant', 'default', 'false', 'region_to_bin', 'true'}

▷ **DLLayerInput** (output_control) . . . . . dl_layer ⇝ *handle*
Input layer.

Example

```
* Create a model for summation.
create_dl_layer_input ('input_a', [2, 3, 4], [], [], DLLayerInputA)
create_dl_layer_input ('input_b', [2, 3, 4], [], [], DLLayerInputB)
create_dl_layer_elementwise ([DLLayerInputA, DLLayerInputB], 'sum', \
                             'sum', [], [], [], DLLayerElementWise)
create_dl_model (DLLayerElementWise, DLModel)
set_dl_model_param (DLModel, 'runtime', 'cpu')
*
* Add 'input_a' as an inference model output.
set_dl_model_layer_param (DLModel, 'input_a', 'is_inference_output', 'true')
*
* Feed input data as tuple (a) or image (b).
create_dict (Sample)
set_dict_tuple (Sample, 'input_a', [1:(2*3*4)])
gen_empty_obj (InputB)
for I := 1 to 4 by 1
    gen_image_const (Channel, 'real', 2, 3)
    get_region_points (Channel, Rows, Cols)
    set_grayval (Channel, Rows, Cols, gen_tuple_const(|Rows|, I))
    append_channel (InputB, Channel, InputB)
endfor
set_dict_object (InputB, Sample, 'input_b')
*
```

```
* Apply the model for summation and get results.
set_dl_model_param (DLModel, 'batch_size', 2)
apply_dl_model (DLModel, [Sample,Sample], [], Result)
get_dict_object (Sum, Result[0], 'sum')
get_dict_object (TupleInputA, Result[1], 'input_a')
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Deep Learning Professional

create_dl_layer_loss_cross_entropy (: : DLLayerInput, DLLayerTarget, DLLayerWeights, LayerName, LossWeight, GenParamName, GenParamValue : DLLayerLossCrossEntropy)

Create a cross entropy loss layer.

The operator create_dl_layer_loss_cross_entropy creates a cross entropy loss layer whose handle is returned in DLLayerLossCrossEntropy. This layer computes the two dimensional cross entropy loss on the input (provided by DLLayerInput) given the corresponding target (provided by DLLayerTarget) and weight (provided by DLLayerWeights).

Cross entropy is commonly used to measure the similarity between two vectors.

Example: Illustrative example, where we have a pixel-level classification problem with three classes.

The input vector for a single pixel is $\mathbf{x} = [0.7, 0.1, 0.2]$ (e.g., the output of a softmax layer) which means that the predicted value (e.g., probability) is 0.7 for the class at index 0, 0.1 for the class at index 1 and 0.2 for the class at index 2.

The target vector is $\mathbf{t} = [1.0, 0.0, 0.0]$ with a probability of 1.0 for the actual class and 0.0 else. Entropy is calculated by the dot product of these two vectors. Since the target vector has only one non-zero entry, it can be given by the index of the actual class instead of a vector, in this case $t = 0$.

The cross entropy is then simply the value of the input vector at the target class index, hence $\mathbf{x}[t] = 0.7$. Using this simplification, the cross entropy loss function over an input image can be defined by

$$L_{cross\_entropy}(\mathbf{x}, \mathbf{t}, \mathbf{w}) \quad := \quad -\frac{1}{W} \sum_{i=0}^{N-1} w_i \cdot \mathbf{x}_i[t_i],$$

where the input $\mathbf{x}$ consists of one prediction vector $\mathbf{x}_i$ for each pixel, the target $\mathbf{t}$ and weight $\mathbf{w}$ consist of one value t_i and w_i for each input pixel, N is the number of pixels and $W = \sum_{i=0}^{N-1} w_i$ is the sum over all weights.

Hence, this layer expects multiple incoming layers:

- DLLayerInput: Specifies the prediction (e.g., a softmax layer, commonly with logarithmized results).
- DLLayerTarget: Specifies the target sequences (originating from the ground truth information).
- DLLayerWeights: Specifies the weight sequences. This parameter is optional. If an empty tuple *[]* is passed for all values the weighting factor *1.0* is used.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter LossWeight determines the scalar weight factor with which the loss, calculated in this layer, is multiplied. This parameter can be used to specify the contribution of the cross entropy loss to the overall network loss in case multiple loss layers are used.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_loss_cross_entropy can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'input_layer' (DLLayerInput, DLLayerTarget, and/or DLLayerWeights)		x

'output_layer' (DLLayerLossCrossEntropy)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) ..... dl_layer ⇝ *handle*
Input layer.

▷ **DLLayerTarget** (input_control) ..... dl_layer ⇝ *handle*
Target layer.

▷ **DLLayerWeights** (input_control) ..... dl_layer ⇝ *handle*
Weights layer.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **LossWeight** (input_control) ..... number ⇝ *real*
Overall loss weight if there are multiple losses in the network.
Default: 1.0

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerLossCrossEntropy** (output_control) . . . . . dl_layer ⇝ *handle*
Cross entropy loss layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Deep Learning Professional

create_dl_layer_loss_ctc (: : DLLayerInput, DLLayerInputLengths, DLLayerTarget, DLLayerTargetLengths, LayerName, GenParamName, GenParamValue : DLLayerLossCTC)

Create a CTC loss layer.

The operator create_dl_layer_loss_ctc creates a Connectionist Temporal Classification (CTC) loss layer whose handle is returned in DLLayerLossCTC. See the reference cited below for information about the CTC loss.

With this loss layer it is possible to train sequence to sequence models (Seq2Seq). E.g., it can be used to train a model that is able to read text in an image. In order to do so, the sequences are compared, thus the determined network prediction DLLayerInput with sequence length DLLayerInputLengths to the given DLLayerTarget with sequence length DLLayerTargetLengths.

The following variables are important to understand the input shapes:

- *T:* Maximum input sequence length (i.e., width of DLLayerInput)
- *S:* Maximum output sequence length (i.e., width of DLLayerTarget)
- *C:* Number of classes including 0 as the blank class ID (i.e., depth of DLLayerInput)

This layer expects multiple layers as input:

- DLLayerInput: Specifies the network prediction.
  Shape: [*T*,1,*C*]
- DLLayerInputLengths: Specifies the input sequence length of each item in the batch.
  Shape: [1,1,1]
- DLLayerTarget: Specifies the target sequences.
  Shape: [*S*,1,1]
- DLLayerTargetLengths: Input layer which specifies the target sequence length of each item in the batch.
  Shape: [1,1,1]

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The CTC loss is typically applied in a CNN as follows. The input sequence is expected to be encoded in some CNN layer with the output shape [width: *T*, height: 1, depth: *C*]. Typically the end of a large fully convolutional classifier is pooled in height down to 1 with an average pooling layer. It is important that the last layer is wide enough to hold enough information. In order to obtain the sequence prediction in the output depth a 1x1 convolutional layer is added after the pooling with the number of kernels set to *C*. In this use case the CTC loss obtains this convolutional layer as input layer DLLayerInput. The width of the input layer determines the maximum output sequence of the model.

The CTC loss can be applied to a batch of input items with differing input and target sequence lengths. T and S are the maximum lengths. In DLLayerInputLengths and DLLayerTargetLengths the individual length of each item in a batch needs to be specified.

Restrictions

- A model containing this layer cannot be trained on a CPU.
- A model containing this layer cannot be trained with a *'batch_size_multiplier'* != 1.0.
- The input layer DLLayerInput must not be a softmax layer. The softmax calculation is done internally in this layer. For inference, there should be an extra softmax layer connected to the DLLayerInput (see create_dl_layer_softmax).

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_loss_ctc can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'input_layer' (DLLayerInput, DLLayerInputLengths, DLLayerTarget, and/or DLLayerTargetLengths)		x
'name' (LayerName)	x	x
'output_layer' (DLLayerLossCTC)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) ..... dl_layer ⇝ *handle*
Input layer with network predictions.

▷ **DLLayerInputLengths** (input_control) ..... dl_layer ⇝ *handle*
Input layer which specifies the input sequence length of each item in the batch.

▷ **DLLayerTarget** (input_control) ..... dl_layer ⇝ *handle*
Input layer which specifies the target sequences. If the input dimensions of the CNN are changed the width of this layer is automatically resized to the same width as the DLLayerInput layer.

▷ **DLLayerTargetLengths** (input_control) ..... dl_layer ⇝ *handle*
Input layer which specifies the target sequence length of each item in the batch.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerLossCTC** (output_control) ..... dl_layer ⇝ *handle*
CTC loss layer.

Example

```
* Create a simple Seq2Seq model which overfits to a single output sequence.

* Input sequence length
T := 6
* Number of classes including blank (blank is always class_id: 0)
C := 3
* Batch Size
N := 1
* Maximum length of target sequences
S := 3

* Model creation
create_dl_layer_input ('input', [T,1,1], [], [], Input)
create_dl_layer_dense (Input, 'dense', T*C, [], [], DLLayerDense)
create_dl_layer_reshape (DLLayerDense, 'dense_reshape', [T,1,C], [], [],\
                         ConvFinal)

* Training part

* Specify the shapes without batch-size
* (batch-size will be specified in the model).
create_dl_layer_input ('ctc_input_lengths', [1,1,1], [], [],\
                       DLLayerInputLengths)
create_dl_layer_input ('ctc_target', [S,1,1], [], [], DLLayerTarget)
create_dl_layer_input ('ctc_target_lengths', [1,1,1], [], [],\
                       DLLayerTargetLengths)
* Create the loss layer
create_dl_layer_loss_ctc (ConvFinal, DLLayerInputLengths, DLLayerTarget,\
                          DLLayerTargetLengths, 'ctc_loss', [], [],\
                          DLLayerLossCTC)

* Get all names so that users can set values
get_dl_layer_param (ConvFinal, 'name', CTCInputName)
get_dl_layer_param (DLLayerInputLengths, 'name', CTCInputLengthsName)
get_dl_layer_param (DLLayerTarget, 'name', CTCTargetName)
get_dl_layer_param (DLLayerTargetLengths, 'name', CTCTargetLengthsName)

* Inference part
create_dl_layer_softmax (ConvFinal, 'softmax', [], [], DLLayerSoftMax)
create_dl_layer_depth_max (DLLayerSoftMax, 'prediction', 'argmax', [], [],\
                           DLLayerDepthMaxArg, _)

* Setting a seed because the weights of the network are randomly initialized

create_dl_layer_loss_distance (: : DLLayerInput, DLLayerTarget, DLLayerWeights, LayerName, DistanceType, LossWeight, GenParamName, GenParamValue : DLLayerLossDistance)

Create a distance loss layer.

The operator create_dl_layer_loss_distance creates a distance loss layer whose handle is returned in DLLayerLossDistance.

This layer expects multiple layers as input:

- DLLayerInput: Specifies the prediction (e.g., a softmax layer).
- DLLayerTarget: Specifies the target sequences (originating from the ground truth information).
- DLLayerWeights: Specifies the weight sequences. This parameter is optional. If an empty tuple *[]* is passed for all values the weighting factor *1.0* is used.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter LossWeight is an overall loss weight if there are multiple losses in the network.

The parameter DistanceType determines which distance measure is applied. Currently, *'l2'* and *'l1'* are implemented. Depending on the generic parameter *'reduce'* this results in

- L2 loss distance as a tensor:

$$\begin{aligned}\texttt{DLLayerLossDistance}[i] &= 0.5 \cdot \texttt{LossWeight} \cdot \texttt{DLLayerWeights}[i] \\ &\cdot(\texttt{DLLayerInput}[i] - \texttt{DLLayerTarget}[i])^2,\end{aligned}$$

  in this case loss is the tensor of the same size as DLLayerInput.

- L2 loss distance as a scalar:

$$\texttt{DLLayerLossDistance} = \frac{\sum_{i=0}^{N-1} \texttt{DLLayerLossDistance}[i]}{\sum_{i=0}^{N-1} \texttt{DLLayerWeights}[i]},$$

  where N is a number of elements in DLLayerInput.

- L1 loss distance as a tensor:

$$\begin{aligned}\texttt{DLLayerLossDistance}[i] &= \texttt{LossWeight} \cdot \texttt{DLLayerWeights}[i] \\ &\cdot|\texttt{DLLayerInput}[i] - \texttt{DLLayerTarget}[i]|,\end{aligned}$$

  in this case loss is the tensor of the same size as DLLayerInput.

- L1 loss distance as a scalar:

$$\texttt{DLLayerLossDistance} = \frac{\sum_{i=0}^{N-1} \texttt{DLLayerLossDistance}[i]}{\sum_{i=0}^{N-1} \texttt{DLLayerWeights}[i]},$$

  where N is a number of elements in DLLayerInput.

Thus DLLayerInput, DLLayerTarget and DLLayerWeights should have the same size. Setting the weights in DLLayerWeights to *1* will result in a loss normalized over the number of elements.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).
Default: *'false'*

'reduce': Determines whether the output of the layer is reduced:

- *'true'*: The output is reduced to a scalar.
- *'false'*: The output of the layer is a tensor, where each element is a 'per-pixel' loss (squared differences).

Default: *'true'*.

Certain parameters of layers created using this operator `create_dl_layer_loss_distance` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Layer Parameters	set	get
'input_layer' (`DLLayerInput`, `DLLayerTarget`, and/or `DLLayerWeights`)		x
'loss_weight' (`LossWeight`)	x	x
'name' (`LayerName`)	x	x
'output_layer' (`DLLayerLossDistance`)		x
'shape'		x
'type'		x
'distance_type' (`DistanceType`)		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x
'reduce'	x	x

Parameters

▷ **DLLayerInput** (input_control) ..... dl_layer ⇝ *handle*
Input layer.

▷ **DLLayerTarget** (input_control) ..... dl_layer ⇝ *handle*
Target layer.

▷ **DLLayerWeights** (input_control) ..... dl_layer ⇝ *handle*
Weights layer.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **DistanceType** (input_control) ..... string ⇝ *string*
Type of distance.
Default: 'l2'
List of values: `DistanceType` ∈ {'l2', 'l1'}

▷ **LossWeight** (input_control) ..... number ⇝ *real*
Loss weight. Applies to all losses, if several losses occur in the network.
Default: 1.0

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: `GenParamName` ∈ {'is_inference_output', 'reduce'}

▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *string*
Generic input parameter values.
Default: []
Suggested values: `GenParamValue` ∈ {'true', 'false'}

▷ **DLLayerLossDistance** (output_control) ..... dl_layer ⇝ *handle*
Distance loss layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

Deep Learning Professional

create_dl_layer_loss_focal (: : DLLayerInput, DLLayerTarget, DLLayerWeights, DLLayerNormalization, LayerName, LossWeight, Gamma, ClassWeights, Type, GenParamName, GenParamValue : DLLayerLossFocal)

Create a focal loss layer.

The operator create_dl_layer_loss_focal creates a focal loss layer whose handle is returned in DLLayerLossFocal. See the reference cited below for further information about its definition and parameter meanings.

This layer expects multiple layers as input:

- DLLayerInput: Specifies the prediction (e.g., a sigmoid or softmax layer).
- DLLayerTarget: Specifies the target sequences (originating from the ground truth information).
- DLLayerWeights: Specifies the weight sequences. This parameter is optional. If an empty tuple *[]* is passed for all values the weighting factor *1.0* is used.
- DLLayerNormalization: Specifies the factor to normalize the loss. This parameter is optional, it can be given by the layer handle as value or ignored handing over an empty tuple *[]*.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter LossWeight is a overall loss weight if there are multiple losses in the network.

The parameter Gamma is the exponent of the focal factor.

The parameter ClassWeights defines class specific weights. All loss contributions of foreground samples of a class are weighted with the given factor. The background samples are weighted by 1 - ClassWeights. Typically, this is set to *1.0/(Number of samples of the class)*. Note, the length of this array has to be either 1, then its broadcasted to the number of classes, or it has to correspond to the number of classes. The default value *[]* corresponds to a factor of *0.5* for all classes. Note, if the number of classes are changed on a network then the number of class specific weights are also adapted and reset with the default value *0.5* for each class.

The parameter Type sets the focal loss options:

'focal_binary': Focal loss.
'sigmoid_focal_binary': Focal loss fused with sigmoid.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_loss_focal can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'focal_type' (Type)		x
'gamma' (Gamma)	x	x
'input_layer' (DLLayerInput, DLLayerTarget, DLLayerWeights, and/or DLLayerNormalization)		x
'loss_weight' (LossWeight)	x	x
'name' (LayerName)	x	x
'output_layer' (DLLayerLossFocal)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Input layer.

▷ **DLLayerTarget** (input_control) . . . . . dl_layer ⇝ *handle*
Target layer.

▷ **DLLayerWeights** (input_control) . . . . . dl_layer ⇝ *handle*
Weights layer.

▷ **DLLayerNormalization** (input_control) . . . . . dl_layer ⇝ *handle*
Normalization layer.
Default: []

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **LossWeight** (input_control) . . . . . number ⇝ *real* / integer
Overall loss weight if there are multiple losses in the network.
Default: 1.0

▷ **Gamma** (input_control) . . . . . number ⇝ *real* / integer
Exponent of the focal factor.
Default: 2.0

▷ **ClassWeights** (input_control) . . . . . number(-array) ⇝ *real* / integer
Class specific weight.
Default: []

▷ **Type** (input_control) . . . . . string ⇝ *string*
Focal loss type.
Default: 'focal_binary'
List of values: Type ∈ {'focal_binary', 'sigmoid_focal_binary'}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string*
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerLossFocal** (output_control) . . . . . dl_layer ⇝ *handle*
Focal loss layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Deep Learning Professional

create_dl_layer_loss_huber (: : DLLayerInput, DLLayerTarget, DLLayerWeights, DLLayerNormalization, LayerName, LossWeight, Beta, GenParamName, GenParamValue : DLLayerLossHuber)

Create a Huber loss layer.

The operator create_dl_layer_loss_huber creates a Huber loss layer whose handle is returned in DLLayerLossHuber. The Huber loss is defined by

$$\begin{aligned} L_{Huber}(x,t,w,n) &:= \frac{\alpha}{n}\sum_{i=0}^{N-1} w_i l(x_i - t_i), \quad \text{with} \\ l(y) &:= \begin{cases} 0.5y^2/\beta & \text{if } |y| < \beta \\ |y| - 0.5\beta & \text{else.} \end{cases} \end{aligned}$$

This layer expects multiple layers as input:

- DLLayerInput: Specifies x (usually a softmax layer).
- DLLayerTarget: Specifies the targets t.
- DLLayerWeights: Specifies the weights w.

The underlying data tensors are assumed to be of the same shape with a total number of N elements.

The parameter DLLayerNormalization can be used to determine the normalization factor n. If DLLayerNormalization is set to an empty tuple, the sum over all weights is used for the normalization n.

The parameter LossWeight determines the scalar weight factor α.

The parameter Beta sets the value for β in the formula. If Beta is set to *0*, the Huber loss is equal to an L1-loss.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_loss_huber can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get

create_dl_layer_lrn (: : DLLayerInput, LayerName, LocalSize, Alpha, Beta, K, NormRegion, GenParamName, GenParamValue : DLLayerLRN)

Create a LRN layer.

The operator create_dl_layer_lrn creates a local response normalization layer which performs normalization over a local window and whose handle is returned in DLLayerLRN. Currently, for NormRegion only *'across_channels'* can be set, which results in a normalization across the channel dimension. More detailed, a value x_c located in a channel with index c is normalized with a scale factor depending on a local window,

$$LRN(x_c) = x_c \cdot \left(\mathtt{K} + \frac{\mathtt{Alpha}}{n} \sum_{c'=\max(0,c-n/2)}^{\min(N-1,c+n/2)} x_{c'}^2 \right)^{-\mathtt{Beta}},$$

where n is the size of the local window given by LocalSize, N is the total number of channels, Alpha is the scaling parameter (used as a normalization constant), Beta is the exponent used as a contrast constant, and K is a constant summand, which is used to avoid any singularities.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_lrn can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'alpha' (Alpha)		x
'beta' (Beta)		x
'input_layer' (DLLayerInput)		x
'k' (K)		x
'local_size' (LocalSize)		x
'name' (LayerName)	x	x
'norm_region' (NormRegion)		x
'output_layer' (DLLayerLRN)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **LocalSize** (input_control) . . . . . number ⇝ *integer*
Size of the local window.
Default: 5

▷ **Alpha** (input_control) . . . . . number ⇝ *real*
Scaling factor in the LRN formula.
Default: 0.0001

▷ **Beta** (input_control) . . . . . number ⇝ *real*
Exponent in the LRN formula.
Default: 0.75

▷ **K** (input_control) . . . . . number ⇝ *real*
Constant summand in the LRN formula.
Default: 1.0

▷ **NormRegion** (input_control) . . . . . string ⇝ *string*
Normalization dimension.
Default: 'across_channels'

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerLRN** (output_control) . . . . . dl_layer ⇝ *handle*
LRN layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

create_dl_layer_matmul (: : DLLayerA, DLLayerB, LayerName, GenParamName, GenParamValue : DLLayerMatMul)

Create a MatMul layer.

The operator create_dl_layer_matmul creates a MatMul layer whose handle is returned in DLLayerMatMul.

A MatMul layer multiplies the 2D matrices, given in the latter two dimensions (H, W) of input DLLayerA, with the corresponding 2D matrices of input DLLayerB, also given in the latter two dimensions (H, W). The output in DLLayerMatMul is hence given by $C = A \cdot B$.

The MatMul layer supports broadcasting for the first input DLLayerA. That means, if the batch size or the number of channels in DLLayerA equals one then the first batch item or channel of DLLayerA is multiplied with all batch items or channels of DLLayerB, respectively.

To make the multiplication work, the width of DLLayerA must be equal to the height of DLLayerB.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).
Default: *'false'*

'num_trainable_params': Number of trainable parameters (weights and biases) of the layer.

'transpose_a': Matrices of input `DLLayerA` are transposed: $C = A^T \cdot B$.
Default: *'false'*

'transpose_b': Matrices of input `DLLayerB` are transposed: $C = A \cdot B^T$.
Default: *'false'*

Certain parameters of layers created using this operator `create_dl_layer_matmul` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Layer Parameters	set	get
'input_layer'		x
'name' (`LayerName`)	x	x
'output_layer' (`DLLayerMatMul`)		x
'shape'		x
'transpose_a'		x
'transpose_b'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerA** (input_control) . . . . . dl_layer ⇝ *handle*
Input layer A.

▷ **DLLayerB** (input_control) . . . . . dl_layer ⇝ *handle*
Input layer B.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: `GenParamName` ∈ {'is_inference_output', 'num_trainable_params', 'transpose_a', 'transpose_b'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: `GenParamValue` ∈ {'true', 'false'}

▷ **DLLayerMatMul** (output_control) . . . . . dl_layer ⇝ *handle*
MatMul layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Deep Learning Professional

create_dl_layer_permutation (: : DLLayerInput, LayerName, Permutation, GenParamName, GenParamValue : DLLayerPermutation)

Create a permutation layer.

The operator create_dl_layer_permutation creates a permutation layer whose handle is returned in DLLayerPermutation.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter Permutation determines the new order of the axes of DLLayerInput, to which the input axes should be permuted.

Permutation has the form [index width, index height, index depth, index batch], where the indices are corresponding to the dimensions of the input. For example, *[0, 1, 3, 2]* leads to swapping the depth and the batch axes. Therefore, each index must be unique and be taken from the set $0, 1, 2, 3$.

Using a CPU device, for some values of Permutation the internal code can not be optimized which can lead to an increased runtime. In this case, the layer parameter *'fall_back_to_baseline'* is set to *'true'*.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_permutation can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'fall_back_to_baseline'		x
'input_layer' (DLLayerInput)		x
'name' (LayerName)	x	x
'permutation' (Permutation)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) ..... dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **Permutation** (input_control) ..... number-array ⇝ *integer*
Order of the permuted axes.
Default: [0,1,2,3]

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerPermutation** (output_control) . . . . . dl_layer ⇝ *handle*
Permutation layer.

Example

```
* Swap the batch and depth axes with a permutation layer.
create_dl_layer_input ('input_a', [1, 1, 4], ['input_type', 'const_val'], \
                       ['constant', 1.0], DLLayerInputA)
create_dl_layer_input ('input_b', [1, 1, 4], ['input_type', 'const_val'], \
                       ['constant', 2.0], DLLayerInputB)
create_dl_layer_concat ([DLLayerInputA, DLLayerInputB], 'concat', 'batch', \
                        [], [], DLLayerConcat)
create_dl_layer_permutation (DLLayerConcat, 'permute', [0,1,3,2], \
                             [], [], DLLayerPermute)
create_dl_layer_depth_max (DLLayerPermute, 'depth_max', 'value', \
                           [], [], _, DLLayerDepthMaxValue)
create_dl_model (DLLayerDepthMaxValue, DLModel)
* The expected output values in DLResultBatch.depth_max are [2.0,2.0,2.0,2.0]
query_available_dl_devices (['runtime'], ['cpu'], DLDeviceHandles)
set_dl_model_param (DLModel, 'device', DLDeviceHandles[0])
apply_dl_model (DLModel, dict{}, [], DLResultBatch)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_dl_layer_pooling (: : DLLayerInput, LayerName, KernelSize, Stride, Padding, Mode, GenParamName, GenParamValue : DLLayerPooling)

Create a pooling layer.

The operator create_dl_layer_pooling creates a pooling layer whose handle is returned in DLLayerPooling.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter KernelSize specifies the filter kernel in the dimensions width and height.

The parameter Stride specifies how the filter is shifted.

The values for KernelSize and Stride can be set as

- a single value which is used for both dimensions
- a tuple [width, height] and [column, row], respectively.

The parameter Padding determines the padding, thus how many pixels with value 0 are appended on the border of the processed input image. Supported values are:

- *'half_kernel_size'*: The number of appended pixels depends on the specifies KernelSize. More precisely, it is calculated as $\lfloor \texttt{KernelSize}/2 \rfloor$, where for the padding on the left / right border the value of KernelSize in dimension width is regarded and for the padding on the upper / lower border the value of KernelSize in height.
- *'implicit'*: No pixels are appended on the left or on the top of the input image. The number of pixels appended on the right or lower border of the input image is $\texttt{Stride} - (input\_dim - \texttt{KernelSize}) \% \texttt{Stride}$, or zero if the kernel size is a divisor of the input dimension. $input\_dim$ stands for the input width or height.
- *'none'*: No pixels are appended.
- Number of pixels: Specify the number of pixels appended on each border. To do so, the following tuple lengths are supported:
  - Single number: Padding in all four directions left/right/top/bottom.
  - Two numbers: Padding in left/right and top/bottom: [l/r, t/b].
  - Four numbers: Padding on left, right, top, bottom side: [l,r,t,b].
    Restriction: *'runtime' 'gpu'* does not support asymmetric padding, i.e., the padding values for the left and right side must be equal, as well as the padding values for the top and bottom side.

  Restriction: The integer padding values must be smaller than the value set for KernelSize in the corresponding dimension.

The output dimensions of the pooling layer are given by

$$output\_dim = \left\lfloor \frac{input\_dim + padding\_begin + padding\_end - \texttt{KernelSize}}{\texttt{Stride}} \right\rfloor + 1$$

Thereby we use the following values: $output\_dim$: output width, $input\_dim$: input width, $padding\_begin$: number of pixels added to the left/top of the input image, and $padding\_end$: number of pixels added to the right/bottom of the input image.

The parameter Mode specifies the mode of the pooling operation. Supported modes are:

'average': The resulting pixel value is the average of all pixel values in the filter.

'maximum': The resulting pixel value is the maximum of all pixel values in the filter.

'global_average': Same as mode *'average'*, but without the knowledge of the spatial dimensions of the input, it is possible to define the desired output dimensions via the parameter KernelSize. E.g., if the average over all pixel values of the input shall be returned, set the KernelSize to *1* and the output width and height is equal to 1. The internally used kernel size and stride are calculated as follows:

- If KernelSize is a divisor of the input dimensions: The internally used kernel size and stride are both set to the value $input\_dim / \texttt{KernelSize}$.
- If KernelSize is not a divisor of the input dimension: The calculation of the internally used kernel size and stride depend on the generic parameter *'global_pooling_mode'*:

  'overlapping': The internally used $stride$ is set to $\lfloor input\_dim / \texttt{KernelSize} \rfloor$. The internally used kernel size is then computed as $input\_dim - (\texttt{KernelSize} - 1) \cdot stride$. This leads to overlapping kernels but the whole input image is taken into account for the computation of the output.

  'non_overlapping': The internally used kernel size and stride are set to the same value $\lfloor input\_dim / \texttt{KernelSize} \rfloor$. This leads to non-overlapping pooling kernels, but parts of the input image at the right or bottom border might not be considered when computing the output. In this mode, due to rounding the output size is not always equal to the size given by KernelSize.

'adaptive': In this mode, for each pixel (k, l) of the output, the size of the corresponding pooling area within the input is computed adaptively, where k are the row and l are the column indices of the output. The row indices of the pooling area for pixels of the k-th output row are given by $[\lfloor k \cdot input\_dim/\texttt{KernelSize} \rfloor, \lceil (k+1) \cdot input\_dim/\texttt{KernelSize} \rceil)$, where in this case the height of the `KernelSize` is used. The computation of the column coordinates is done analogously. This means that neighboring pooling areas can have a different size which can lead to a less efficient implementation. However, the pooling areas are only overlapping by one pixel which is generally less overlap than for *'global_pooling_mode' 'overlapping'*. The whole input image is taken into account for the computation of the output. For this mode, the parameter `Padding` must be set to *'none'*.

For this mode the parameter `Stride` is ignored and calculated internally as described above.

'global_maximum': Same as mode *'global_average'*, but the maximum is calculated instead of the average.

For more information about the pooling layer see the "`Solution Guide on Classification`".

The following generic parameters `GenParamName` and the corresponding values `GenParamValue` are supported:

'global_pooling_mode': Mode for calculation of the internally used kernel size and stride in case of global pooling (`Mode` *'global_average'* or *'global_maximum'*). See description above. In case of a non-global pooling the parameter is set to the value *'undefined'*.

Default: *'overlapping'*

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).

Default: *'false'*

Certain parameters of layers created using this operator `create_dl_layer_pooling` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **KernelSize** (input_control) . . . . . number-array ⇝ *integer*
Width and height of the filter kernels.
Default: [2,2]

▷ **Stride** (input_control) . . . . . number-array ⇝ *integer*
Bi-dimensional amount of filter shift.
Default: [2,2]

▷ **Padding** (input_control) . . . . . number(-array) ⇝ *string* / integer
Padding type or specific padding size.
Default: 'none'
Suggested values: Padding ∈ {'none', 'half_kernel_size', 'implicit'}

▷ **Mode** (input_control) . . . . . number ⇝ *string*
Mode of pooling operation.
Default: 'maximum'
List of values: Mode ∈ {'maximum', 'average', 'global_maximum', 'global_average'}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'global_pooling_mode', 'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'adaptive', 'non_overlapping', 'overlapping', 'true', 'false', 1.0, 0.9, 0.0}

▷ **DLLayerPooling** (output_control) . . . . . dl_layer ⇝ *handle*
Pooling layer.

Module

Deep Learning Professional

create_dl_layer_reduce (: : DLLayerInput, LayerName, Operation, Axes, GenParamName, GenParamValue : DLLayerReduce)

Create a reduce layer.

The operator create_dl_layer_reduce creates a reduce layer whose handle is returned in DLLayerReduce.

A reduce layer applies a given operation to the input data tensor to reduce it along one or multiple axes to a single value. Hence, the output tensor has the same shape as the input tensor, but at the axes given by Axes the dimension equals one.

The parameter DLLayerInput determines the feeding input layer. This layer expects a single layer as input.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter Operation specifies the operation that is applied. The operation is applied to the values along the axes given by Axes of the input tensor and the result is written to the corresponding position in the output tensor. The supported values for Operation are:

- *'norm_l2'*: Computes the L2 norm of the input values.
- *'sum'*: Computes the sum of the input values.

The following generic parameters `GenParamName` and the corresponding values `GenParamValue` are supported:

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).
Default: *'false'*

'div_eps': Small scalar value that is used to stabilize the training. I.e., in case of a division, the value is added to the denominator to prevent a division by zero.
Default: *1e-10*

Certain parameters of layers created using this operator `create_dl_layer_reduce` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Parameters

▷ **`DLLayerInput`** (input_control) ..... dl_layer ⇝ *handle*
Feeding input layer.

▷ **`LayerName`** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **`Operation`** (input_control) ..... string ⇝ *string*
Reduce operation.
Default: 'norm_l2'
List of values: `Operation` ∈ {'norm_l2', 'sum'}

▷ **`Axes`** (input_control) ..... integer(-array) ⇝ *integer* / string
Axes to which the reduce operation is applied.
Default: [2,3]
List of values: `Axes` ∈ {1, 2, 3, 'width', 'height', 'depth'}

▷ **`GenParamName`** (input_control) ..... attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: `GenParamName` ∈ {'div_eps', 'is_inference_output'}

▷ **`GenParamValue`** (input_control) ..... attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: `GenParamValue` ∈ {1e-10, 'true', 'false'}

▷ **`DLLayerReduce`** (output_control) ..... dl_layer ⇝ *handle*
Reduce layer.

Example

```
* Minimal example for reduce-layer.
create_dl_layer_input ('input', [64, 32, 10], [], [], DLLayerInput)
create_dl_layer_reduce (DLLayerInput, 'reduce_width', 'sum', 'width', [], [], \
                        DLLayerReduceWidth)
create_dl_layer_reduce (DLLayerReduceWidth, 'reduce_height_depth', 'norm_l2',  [1,2], []
                        [], DLLayerReduceHeightDepth)
* Create a model and change the batch-size.
create_dl_model (DLLayerReduceHeightDepth, DLModel)
set_dl_model_param (DLModel, 'batch_size', 2)
get_dl_model_layer_param (DLModel, 'reduce_height_depth', 'shape', ShapeReduceHeightWidt
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_dl_layer_input`

Possible Successors

`create_dl_model`

Module

Deep Learning Professional

create_dl_layer_reshape (: : DLLayerInput, LayerName, Shape, GenParamName, GenParamValue : DLLayerReshape)

Create a reshape layer.

The operator `create_dl_layer_reshape` creates a reshape layer whose handle is returned in `DLLayerReshape`.

The parameter `DLLayerInput` determines the feeding input layer and expects the layer handle as value.

The parameter `LayerName` sets an individual layer name. Note that if creating a model using `create_dl_model` each layer of the created network must have a unique name.

The parameter `Shape` determines the output shape, into which the input data is converted.

The value of `Shape` has to be given in the form [`width`, `height`, `depth`, `batch_size`], where the fourth value for the batch size is optional (see below). The overall size of the data has to remain constant, i.e., `width_out * height_out * depth_out * batch_size_out = width_in * height_in * depth_in * batch_size_in`.

The following options are available for setting the values of `Shape`:

- Setting a value for each of the four dimensions,
- One or several values are set to *0* in order to keep the value of the input dimension,
- By setting a maximum of one value to *-1*, this value will be determined automatically. It will be calculated in a way that the overall size remains constant. Note that this is only possible if the computed value is an integer.

For a model that was created using `create_dl_model` the model's batch size should always be settable with `set_dl_model_param`. Hence, either the output batch size of the reshape layer equals the batch size of the model (batch size in `Shape` set to *0*), or at least one reshape dimension should be calculated automatically (one value in `Shape` set to *-1*).

If the batch size is specified and it is not set to *0*, at least one dimension of Shape must be set to *-1*. This is necessary, because for a model created with create_dl_model, the model's batch size should always be settable with set_dl_model_param. Hence, either the output batch size of the reshape layer equals the batch size of the model (batch size in Shape set to *0*), or at least one reshape dimension should be calculated automatically (one value in Shape set to *-1*). In case the batch size is not specified it is set to *0*, which leads to an output batch size equal to the input one.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_reshape can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'input_layer' (DLLayerInput)		x
'name' (LayerName)	x	x
'output_depth' (Shape)		x
'output_height' (Shape)		x
'output_layer' (Shape)		x
'output_width' (Shape)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **Shape** (input_control) . . . . . number-array ⇝ *integer*
Shape of the output graph layer data.
Default: [224,224,3]

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerReshape** (output_control) . . . . . dl_layer ⇝ *handle*
Reshape layer.

Example

```
* Minimal example for reshape-layer.
create_dl_layer_input ('input', [64, 32, 10], [], [], DLLayerInput)
create_dl_layer_reshape (DLLayerInput, 'reshape_wh', [32, 64, 0], [], [], \
                         DLLayerReshapeWH)
create_dl_layer_reshape (DLLayerInput, 'reshape_bs', [64, 32, 1, -1], [], \
                         [], DLLayerReshapeBS)
* DLLayerReshapeBS has batch size 10 and depth 1.
get_dl_layer_param (DLLayerReshapeBS, 'shape', ShapeReshapeBS)
* Create a model and change the batch-size.
create_dl_model (DLLayerReshapeBS, DLModel)
set_dl_model_param (DLModel, 'batch_size', 2)
* DLLayerReshapeBS has batch size 20 now.
get_dl_model_layer_param (DLModel, 'reshape_bs', 'shape', ShapeReshapeBS)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Possible Successors

create_dl_layer_convolution, create_dl_layer_dense

Module

Deep Learning Professional

create_dl_layer_softmax (: : DLLayerInput, LayerName, GenParamName, GenParamValue : DLLayerSoftMax)

Create a softmax layer.

The operator create_dl_layer_softmax creates a softmax layer whose handle is returned in DLLayerSoftMax.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The softmax layer applies the softmax function which is defined for each input x_i as follows:

$$Softmax(x_i) = \frac{\exp(x_i)}{\sum_{j=0}^{N-1} \exp(x_j)}$$

where N is the number of inputs. During training, the result of the softmax function is transformed by a logarithm function, such that the values are suitable as input to e.g., a cross entropy loss layer. This behavior can be changed by setting the generic parameter *'output_mode'*, see below.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'output_mode': This parameter determines if and in which case the output is transformed by a logarithm function:

- *'default'*: During inference, the result of the softmax function is returned as output while during training, the softmax is further transformed by a logarithm function.
- *'no_log_training'*: During training the result of the softmax function is not transformed by a logarithm function.

- *'log_inference'*: The logarithm of the softmax is calculated during inference in the same way as during training.

Default: *'default'*.

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).

Default: *'false'*

Certain parameters of layers created using this operator `create_dl_layer_softmax` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

- Processed without parallelization.

Module

Deep Learning Professional

create_dl_layer_transposed_convolution (: : DLLayerInput, LayerName, KernelSize, Stride, KernelDepth, Groups, Padding, GenParamName, GenParamValue : DLLayerTransposedConvolution)

Create a transposed convolution layer.

The operator create_dl_layer_transposed_convolution creates a transposed convolution layer whose handle is returned in DLLayerTransposedConvolution.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter KernelSize specifies the filter kernel in the dimensions width and height. So far, only quadratic kernels are supported.

Restriction: This value must be a tuple of length 1.

The parameter Stride determines how the filter is shifted in row and column direction.

Restriction: This value must be a tuple of length 1.

The parameter KernelDepth defines the depth of the output feature maps.

Restriction: This value must be a tuple of length 1.

The parameter Groups determines the amount of filter groups. So far, only a single filter group is supported.

Restriction: This value must be a tuple of length 1.

The parameter Padding effectively appends $\texttt{KernelSize} - 1 - \texttt{Padding}$ pixels with value 0 to each border of the input. This is set so that a convolutional layer and a transposed convolution layer with the same KernelSize, Stride and Padding values are inverses of each other regarding their input and output shapes. Supported Padding values are:

- *'half_kernel_size'*: The integer value of Padding in the formula above depends on the specified KernelSize. More precisely, it is calculated as $\lfloor \texttt{KernelSize}/2 \rfloor$.
- *'none'*: The value of Padding in the formula above is 0.
- Number of pixels: Specify the integer value of Padding in the formula above for each border. To do so, the following tuple lengths are supported:
  - Single number: Padding value for all four directions left/right/top/bottom.
  - Two numbers: Padding value for left/right and top/bottom: [l/r, t/b].
  - Four numbers: Padding value for left, right, top, bottom side: [l,r,t,b].
    Restriction: *'runtime' 'gpu'* does not support asymmetric padding, i.e., the padding values for the left and right side must be equal, as well as the padding values for the top and bottom side.

  Restriction: The integer padding values must be smaller than the value set for KernelSize.

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'bias_term': Determines, whether the layer has bias terms.
Default: *'true'*

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

'learning_rate_multiplier': Learning rate multiplier for this layer that is used during training. If *'learning_rate_multiplier'* is set to *0.0*, the layer is skipped during training.
Default: *1.0*

'output_padding': Can be used to resolve ambiguities in the output shape for KernelSize and Stride larger than *1*. As mentioned above in the description of the parameter Padding, with respect to the input and output shapes a transposed convolution layer can be seen as the inverse of a convolution layer if they have the same settings for KernelSize, Stride, and Padding (and dilation). However, a convolution layer can map several shapes to the same output spatial dimensions. E.g., for KernelSize *3*, Padding *1*, and Stride *2*, both inputs with spatial dimensions (H, W) = *'(4, 4)'* and (H, W) = *'(3, 3)'* are mapped to an output shape with (H, W) = *'(2, 2)'*. To get back to *'(4, 4)'* using a transposed convolution (with the same settings for KernelSize, Stride, and Padding) *'output_padding'* must be set to *1*. *'output_padding'* must not be larger than the bottom and right Padding and can only be set larger than *0* if Stride is larger than *1*.
Default: *0*

'weight_filler': Defines the mode how the weights are initialized. See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
List of values: *'xavier'*, *'msra'*, *'const'*
Default: *'xavier'*

'weight_filler_const_val': See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
Default: *0.5*

'weight_filler_variance_norm': Value range for *'weight_filler'*. See create_dl_layer_convolution for a detailed explanation of this parameter and its values.
List of values: *'norm_average'*, *'norm_in'*, *'norm_out'*, constant value (in combination with *'weight_filler'* = *'msra'*)
Default: *'norm_in'*

Certain parameters of layers created using this operator create_dl_layer_transposed_convolution can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Module

Deep Learning Professional

create_dl_layer_zoom_factor (: : DLLayerInput, LayerName, ScaleWidth, ScaleHeight, Interpolation, AlignCorners, GenParamName, GenParamValue : DLLayerZoom)

Create a zoom layer using size factors.

The operator `create_dl_layer_zoom_factor` creates a zoom layer using size factors and returns the layer handle in `DLLayerZoom`.

The parameter `DLLayerInput` determines the feeding input layer and expects the layer handle as value.

The parameter `LayerName` sets an individual layer name. Note that if creating a model using `create_dl_model` each layer of the created network must have a unique name.

The parameters `ScaleWidth` and `ScaleHeight` specify the ratio between the output and the corresponding input dimension. Together they define the output size of the zoom layer `DLLayerZoom`.

The parameter `Interpolation` defines the interpolation mode. Currently only the mode *'bilinear'* is supported.

The parameter `AlignCorners` defines how coordinates are transformed from the output to the input image:

'true': The transformation is applied in the HALCON Non-Standard Cartesian coordinate system (edge-centered, with the origin in the upper left corner, see chapter Transformations / 2D Transformations). Using the x axis as an example, this leads to:

$$x_{input} = x_{output} * (length_{input} - 1)/(length_{output} - 1)$$

'false': The transformation is applied in the HALCON standard coordinate system (pixel centered, with the origin in the center of the upper left pixel, see chapter Transformations / 2D Transformations). Using the x axis as an example, this leads to:

$$x_{input} = (x_{output} + 0.5) * length_{input}/length_{output} - 0.5$$

The following generic parameters `GenParamName` and the corresponding values `GenParamValue` are supported:

'is_inference_output': Determines whether `apply_dl_model` will include the output of this layer in the dictionary `DLResultBatch` even without specifying this layer in `Outputs` (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator `create_dl_layer_zoom_factor` can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using `set_dl_model_layer_param` and which ones can be retrieved using `get_dl_model_layer_param` or `get_dl_layer_param`. Note, the operators `set_dl_model_layer_param` and `get_dl_model_layer_param` require a model created by `create_dl_model`.

Layer Parameters	set	get
'align_corners' (`AlignCorners`)	x	x
'input_layer' (`DLLayerInput`)		x
'interpolation_mode' (`Interpolation`)		x
'name' (`LayerName`)	x	x
'output_layer' (`DLLayerZoom`)		x
'scale_params' (`ScaleWidth` and `ScaleHeight`)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **`DLLayerInput`** (input_control) ..... dl_layer ⇝ *handle*
Feeding layer.

▷ **`LayerName`** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **`ScaleWidth`** (input_control) ..... number ⇝ *real* / integer
Ratio output/input width of the layer.
Default: 2.0

▷ **`ScaleHeight`** (input_control) ..... number ⇝ *real* / integer
Ratio output/input height of the layer.
Default: 2.0

▷ **`Interpolation`** (input_control) ..... string ⇝ *string*
Mode of interpolation.
Default: 'bilinear'
List of values: `Interpolation` ∈ {'bilinear'}

▷ **`AlignCorners`** (input_control) ..... string ⇝ *string*
Type of coordinate transformation between output/input images.
Default: 'false'
List of values: `AlignCorners` ∈ {'true', 'false'}

▷ **`GenParamName`** (input_control) ..... attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: `GenParamName` ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerZoom** (output_control) . . . . . dl_layer ⇝ *handle*
Zoom layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

create_dl_layer_zoom_size, create_dl_layer_zoom_to_layer_size

Module

Deep Learning Professional

create_dl_layer_zoom_size (: : DLLayerInput, LayerName, Width, Height, Interpolation, AlignCorners, GenParamName, GenParamValue : DLLayerZoom)

Create a zoom layer using an absolute output size.

The operator create_dl_layer_zoom_size creates a zoom layer using an absolute output size and returns the layer handle in DLLayerZoom.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameters Width and Height define the absolute output size of the zoom layer DLLayerZoom.

The parameter Interpolation defines the interpolation mode. Currently only the mode *'bilinear'* is supported.

The parameter AlignCorners defines how coordinates are transformed from the output to the input image:

'true': The transformation is applied in the HALCON Non-Standard Cartesian coordinate system (edge-centered, with the origin in the upper left corner, see chapter Transformations / 2D Transformations). Using the x axis as an example, this leads to:

$$x_{input} = x_{output} * (length_{input} - 1)/(length_{output} - 1)$$

'false': The transformation is applied in the HALCON standard coordinate system (pixel centered, with the origin in the center of the upper left pixel, see chapter Transformations / 2D Transformations). Using the x axis as an example, this leads to:

$$x_{input} = (x_{output} + 0.5) * length_{input}/length_{output} - 0.5$$

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_zoom_size can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'align_corners' (AlignCorners)	x	x
'input_layer' (DLLayerInput)		x
'interpolation_mode' (Interpolation)		x
'name' (LayerName)	x	x
'output_layer' (DLLayerZoom)		x
'scale_params' (Width and Height)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) ..... dl_layer ⇝ *handle*
Feeding layer.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **Width** (input_control) ..... number ⇝ *integer*
Absolute width of the output layer.
Default: 100

▷ **Height** (input_control) ..... number ⇝ *integer*
Absolute height of the output layer.
Default: 100

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Mode of interpolation.
Default: 'bilinear'
List of values: Interpolation ∈ {'bilinear'}

▷ **AlignCorners** (input_control) ..... string ⇝ *string*
Type of coordinate transformation between output/input images.
Default: 'false'
List of values: AlignCorners ∈ {'true', 'false'}

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: GenParamName ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **DLLayerZoom** (output_control) ..... dl_layer ⇝ *handle*
Zoom layer.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

create_dl_layer_zoom_factor, create_dl_layer_zoom_to_layer_size

Module

Deep Learning Professional

create_dl_layer_zoom_to_layer_size (: : DLLayerInput, DLLayerReference, LayerName, Interpolation, AlignCorners, GenParamName, GenParamValue : DLLayerZoom)

Create a zoom layer using the output size of a reference layer.

The operator create_dl_layer_zoom_to_layer_size creates a zoom layer using the output size of a reference layer and returns the layer handle in DLLayerZoom.

The parameter DLLayerInput determines the feeding input layer and expects the layer handle as value.

The parameter DLLayerReference is used to define the output size of the zoom layer DLLayerZoom: the size is adapted to the output size of DLLayerReference.

The parameter LayerName sets an individual layer name. Note that if creating a model using create_dl_model each layer of the created network must have a unique name.

The parameter Interpolation defines the interpolation mode. Currently only the mode *'bilinear'* is supported.

The parameter AlignCorners defines how coordinates are transformed from the output to the input image:

'true': The transformation is applied in the HALCON Non-Standard Cartesian coordinate system (edge-centered, with the origin in the upper left corner, see chapter Transformations / 2D Transformations). Using the x axis as an example, this leads to:

$$x_{input} = x_{output} * (length_{input} - 1)/(length_{output} - 1)$$

'false': The transformation is applied in the HALCON standard coordinate system (pixel centered, with the origin in the center of the upper left pixel, see chapter Transformations / 2D Transformations). Using the x axis as an example, this leads to:

$$x_{input} = (x_{output} + 0.5) * length_{input}/length_{output} - 0.5$$

The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'is_inference_output': Determines whether apply_dl_model will include the output of this layer in the dictionary DLResultBatch even without specifying this layer in Outputs (*'true'*) or not (*'false'*).
Default: *'false'*

Certain parameters of layers created using this operator create_dl_layer_zoom_to_layer_size can be set and retrieved using further operators. The following tables give an overview, which parameters can be set using set_dl_model_layer_param and which ones can be retrieved using get_dl_model_layer_param or get_dl_layer_param. Note, the operators set_dl_model_layer_param and get_dl_model_layer_param require a model created by create_dl_model.

Layer Parameters	set	get
'align_corners' (AlignCorners)	x	x
'input_layer' (DLLayerInput)		x
'interpolation_mode' (Interpolation)		x
'name' (LayerName)	x	x
'output_layer' (DLLayerZoom)		x
'scale_params' (DLLayerReference)		x
'shape'		x
'type'		x

Generic Layer Parameters	set	get
'is_inference_output'	x	x
'num_trainable_params'		x

Parameters

▷ **DLLayerInput** (input_control) . . . . . dl_layer ⇝ *handle*
Feeding layer.

▷ **DLLayerReference** (input_control) . . . . . dl_layer ⇝ *handle*
Reference layer to define the output size.

▷ **LayerName** (input_control) . . . . . string ⇝ *string*
Name of the output layer.

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Mode of interpolation.
Default: 'bilinear'
List of values: `Interpolation` ∈ {'bilinear'}

▷ **AlignCorners** (input_control) . . . . . string ⇝ *string*
Type of coordinate transformation between output/input images.
Default: 'false'
List of values: `AlignCorners` ∈ {'true', 'false'}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Generic input parameter names.
Default: []
List of values: `GenParamName` ∈ {'is_inference_output'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Generic input parameter values.
Default: []
Suggested values: `GenParamValue` ∈ {'true', 'false'}

▷ **DLLayerZoom** (output_control) . . . . . dl_layer ⇝ *handle*
Zoom layer.

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`create_dl_layer_zoom_size`, `create_dl_layer_zoom_factor`

Module

Deep Learning Professional

create_dl_model (: : OutputLayers : DLModelHandle)

Create a deep learning model.

The operator `create_dl_model` creates a deep learning model from a graph and returns its handle in `DLModelHandle`.

A deep learning model in HALCON mainly consists of a directed acyclic graph that defines the networks architecture. Further components of a deep learning model in HALCON are parameters as *'class_names'*, *'class_ids'*, and many others, or hyperparameters that are needed to train a model, as for example the *'learning_rate'*. While parameters and hyperparameters can be set after creation of the model using `set_dl_model_param`, the model itself can only be created using `create_dl_model` if its network architecture is given in form of a graph.

To build a graph that defines the models network architecture, one needs to put together the networks layers. In general, a graph starts with an input layer. A subsequent layer that follows after the input layer uses the input layer as feeding layer, and the new layer itself might be used as a feeding layer for the next layer, and so on. This is repeated until the graphs output layers (e.g., softmax or loss layers) are appended to the graph. To create a layer, use its specified creation operator, e.g., an input layer is created using `create_dl_layer_input`, a convolution layer is created using `create_dl_layer_convolution`, and so on.

When the graph is defined, a model can be created using `create_dl_model` by passing over the graphs output layer handles in `OutputLayers`. Note that the output layer handles save all other layers that directly or indirectly serve as feeding input layers for the output layers during their creation. This means that the output layer handles keep the whole network architecture necessary for the creation of the model using `create_dl_model`.

The type of the created model, hence the task the model is designed for (classification, object detection, segmentation), is only given by the networks architecture. However, if the networks architecture allows it, the type of the model, *'type'*, can be set using `set_dl_model_param`. A specified model type allows a more user friendly usage in the HALCON deep learning workflow. Supported types are:

'generic': This is the default model type. The task the model's neuronal network can solve is defined by its architecture. When `apply_dl_model` is applied for inference, the operator returns the activations of the output layers. To train the model using `train_dl_model_batch`, the underlying graph requires loss layers.

'classification': The model is specified for classification and all layers required for training the model are adapted to the model. When `apply_dl_model` is applied for inference, the output is adapted according to the type, see `apply_dl_model` for more details. See Deep Learning / Classification for further information.

In addition, the operator `gen_dl_model_heatmap` can be used to display the models heatmap.

'detection': The model is specified for object detection and instance segmentation and all layers and anchors required for training the model are adapted to the model. When `apply_dl_model` is applied for inference, the output is adapted according to the type, see `apply_dl_model` for more details. See Deep Learning / Object Detection and Instance Segmentation for further information.

'multi_label_classification': The model is specified for multi-label classification and all layers required for training the model are adapted to the model. When `apply_dl_model` is applied for inference, the output is adapted according to the type, see `apply_dl_model` for more details. See Deep Learning / Multi-Label Classification for further information.

'segmentation': The model is specified for semantic segmentation or edge extraction respectively and all layers required for training the model are adapted to the model. When `apply_dl_model` is applied for inference, the output is adapted according to the type, see `apply_dl_model` for more details. See Deep Learning / Semantic Segmentation and Edge Extraction for further information.

Furthermore, many deep learning procedures provide more functionality for the model if its type is set. As an example, `dev_display_dl_data` can be used to display the inferred results more nicely.

Note that setting a model type requires that the graph fulfills certain structure conditions. We recommend to follow the architecture of our delivered neuronal networks if the model type should be set to one of these types.

Parameters

▷ **`OutputLayers`** (input_control) ..... dl_layer(-array) ⇝ *handle*
Output layers of the graph.

▷ **`DLModelHandle`** (output_control) ..... dl_model ⇝ *handle*
Handle of the deep learning model.

Result

If the parameters are valid, the operator `create_dl_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`create_dl_layer_softmax`, `create_dl_layer_loss_cross_entropy`, `create_dl_layer_loss_focal`, `create_dl_layer_loss_huber`

Possible Successors

`set_dl_model_param`

Module

Deep Learning Professional

get_dl_layer_param (: : DLLayer, GenParamName : GenParamValue)

Return the parameters of a deep learning layer.

The operator get_dl_layer_param returns the parameter GenParamName of the deep learning layer DLLayer in GenParamValue.

Depending on the type of the layer, different parameter names are valid. Which generic and layer-specific parameters can be queried is described in the specific references of the operators used for layer creation (create_dl_layer_*).

Parameters

▷ **DLLayer** (input_control) . . . . . dl_layer ⇝ *handle*
Layer.

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Parameter to query.
Default: 'shape'
List of values: GenParamName ∈ {'input_layer', 'name', 'shape', 'type'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string / handle
Value of the queried parameter.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Deep Learning Professional

get_dl_model_layer (: : DLModelHandle, LayerNames : DLLayers)

Create a deep copy of the layers and all of their graph ancestors in a given deep learning model.

The operator get_dl_model_layer creates a deep copy of every layer named in LayerNames and all their graph ancestors in the deep learning model DLModelHandle. You can retrieve the unique layer names using get_dl_model_param with its option *'summary'*.

You might use the output layers returned in DLLayers as inputs to the create_dl_layer_* and create_dl_model operators in order to create novel model architectures based on existing models.

If you want to get multiple layers of a single model, these layers have to be specified as a LayerNames tuple in a single call to get_dl_model_layer. Doing so, you avoid multiple deep copies of graph ancestors that are potentially shared by the layers.

Example:

```
get_dl_model_layer(DLModelHandleOrig, ['layer_name_3',
'layer_name_6'], DLLayersOutput)
create_dl_model([DLLayersOutput], DLModelHandle)
```

Please note, that the output layers are copies. They contain the same weights and settings as in the given input model but they are unique copies. You cannot alter the existing model by changing the output layers.

Parameters

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Deep learning model.

▷ **LayerNames** (input_control) ..... string(-array) ⇝ *string*
Names of the layers to be copied.

▷ **DLLayers** (output_control) ..... dl_layer(-array) ⇝ *handle*
Copies of layers and all of their ancestors.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

read_dl_model

Possible Successors

create_dl_model, create_dl_layer_activation, create_dl_layer_batch_normalization, create_dl_layer_class_id_conversion, create_dl_layer_class_id_conversion, create_dl_layer_concat, create_dl_layer_convolution, create_dl_layer_dense, create_dl_layer_depth_max, create_dl_layer_dropout, create_dl_layer_elementwise, create_dl_layer_loss_cross_entropy, create_dl_layer_loss_ctc, create_dl_layer_loss_distance, create_dl_layer_loss_focal, create_dl_layer_loss_huber, create_dl_layer_lrn, create_dl_layer_pooling, create_dl_layer_reduce, create_dl_layer_reshape, create_dl_layer_softmax, create_dl_layer_transposed_convolution, create_dl_layer_zoom_factor, create_dl_layer_zoom_size, create_dl_layer_zoom_to_layer_size

Module

Deep Learning Professional

get_dl_model_layer_activations (: Activations : DLModelHandle, LayerName :)

Get the activations of a Deep Learning model layer.

The operator get_dl_model_layer_activations returns in Activations the activations of the specified LayerName of the model DLModelHandle.

Activations is a tuple of batch_size many objects, where every object is an image having the size (width, height, depth) of the given LayerName.

Parameters

▷ **Activations** (output_object) ..... image(-array) ⇝ *object :* real
Output activations.

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Handle of the deep learning model.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the layer to be queried.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Deep Learning Professional

get_dl_model_layer_gradients (: Gradients : DLModelHandle, LayerName :)

Get the gradients of a Deep Learning model layer.

The operator get_dl_model_layer_gradients returns in Gradients the gradients of the specified LayerName of the model DLModelHandle.

Gradients is a tuple of batch_size many objects, where every object is an image having the size (width, height, depth) of the given LayerName.

Parameters

▷ **Gradients** (output_object) ..... image(-array) ⇝ *object :* real
Output gradients.

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Handle of the deep learning model.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the layer to be queried.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Deep Learning Professional

get_dl_model_layer_param (: : DLModelHandle, LayerName, ParamName : ParamValue)

Retrieve parameter values for a given layer.

The operator get_dl_model_layer_param returns for a layer the value of the parameter ParamName in ParamValue. The layer is referred by its name LayerName in the model DLModelHandle. You can retrieve the layer names using get_dl_model_param with its option *'layer_names'* or *'summary'*.

Which generic and layer-specific parameters can be queried is described in the specific operator references (create_dl_layer_*).

Parameters

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Deep learning model.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **ParamName** (input_control) ..... string ⇝ *string*
Name of the queried parameter.
Default: 'type'
List of values: ParamName ∈ {'bias_filler', 'bias_filler_variance_norm', 'bias_filler_const_val', 'bias_term', 'input_layer', 'is_inference_output', 'leaky_relu_alpha', 'learning_rate_multiplier', 'learning_rate_multiplier_bias', 'name', 'num_trainable_params', 'output_layer', 'shape', 'type', 'upper_bound', 'weight_filler', 'weight_filler_const_val', 'weight_filler_variance_norm'}
Restriction: length(ParamName) > 0

▷ **ParamValue** (output_control) . . . . . tuple(-array) ⇝ *string* / real / integer
Value of the queried parameter.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology, OCR/OCV, Deep Learning Professional

get_dl_model_layer_weights (: Weights : DLModelHandle, LayerName, WeightsType :)

Get the weights (or values) of a Deep Learning model layer.

The operator get_dl_model_layer_weights returns in Weights the values of a LayerName of the model DLModelHandle.

The parameter WeightsType determines which type of layer values are retrieved. The following values are supported for WeightsType:

- *'batchnorm_mean'*: Batch-wise calculated mean values to normalize the inputs. For further information, please refer to create_dl_layer_batch_normalization.
  Restriction: This value is only supported if the layer is of type *'batchnorm'*.
- *'batchnorm_mean_avg'*: Average of the batch-wise calculated mean values to normalize the inputs. For further information, please refer to create_dl_layer_batch_normalization.
  Restriction: This value is only supported if the layer is of type *'batchnorm'*.
- *'batchnorm_variance'*: Batch-wise calculated variance values to normalize the inputs. For further information, please refer to create_dl_layer_batch_normalization.
  Restriction: This value is only supported if the layer is of type *'batchnorm'*.
- *'batchnorm_variance_avg'*: Average of the batch-wise calculated variance values to normalize the inputs. For further information, please refer to create_dl_layer_batch_normalization.
  Restriction: This value is only supported if the layer is of type *'batchnorm'*.
- *'bias'*: Biases of the layer.
- *'bias_gradient'*: Gradients of the biases of the layer.
- *'bias_gradient_norm_l2'*: Gradients of the biases of the layer in terms of L2 norm.
- *'bias_norm_l2'*: Biases of the layer in terms of L2 norm.
- *'bias_update'*: Update of the biases of the layer. This is used in e.g., a solver which uses the last update.
- *'bias_update_norm_l2'*: Update of the biases of the layer in terms of L2 norm. This is used in a solver which uses the last update.
- *'weights'*: Weights of the layer.
- *'weights_gradient'*: Gradients of the weights of the layer.
- *'weights_gradient_norm_l2'*: Gradients of the weights of the layer in terms of L2 norm.
- *'weights_norm_l2'*: Weights of the layer in terms of L2 norm.
- *'weights_update'*: Update of the weights of the layer. This is used in a solver which uses the last update.
- *'weights_update_norm_l2'*: Update of the weights of the layer in terms of L2 norm. This is used in a solver which uses the last update.

The following tables give an overview, which parameters for WeightsType can be set using set_dl_model_layer_weights and which ones can be retrieved using get_dl_model_layer_weights.

Layer Parameters	set	get
'batchnorm_mean'	x	x
'batchnorm_mean_avg'	x	x
'batchnorm_variance'	x	x
'batchnorm_variance_avg'	x	x
'bias'	x	x
'bias_gradient'		x
'bias_gradient_norm_l2'		x
'bias_norm_l2'		x
'bias_update'		x
'bias_update_norm_l2'		x
'weights'	x	x
'weights_gradient'		x
'weights_gradient_norm_l2'		x
'weights_norm_l2'		x
'weights_update'		x
'weights_update_norm_l2'		x

Attention

The operator get_dl_model_layer_weights is only applicable to self-created networks. For networks delivered by HALCON, the operator returns an empty tuple.

Parameters

▷ **Weights** (output_object) ..... image(-array) ⇝ *object :* real
Output weights.

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Handle of the deep learning model.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the layer to be queried.

▷ **WeightsType** (input_control) ..... string ⇝ *string*
Selected type of layer values to be returned.
Default: 'weights'
List of values: WeightsType ∈ {'weights', 'weights_norm_l2', 'weights_update', 'weights_update_norm_l2', 'weights_gradient', 'weights_gradient_norm_l2', 'bias', 'bias_norm_l2', 'bias_update', 'bias_update_norm_l2', 'bias_gradient', 'bias_gradient_norm_l2', 'batchnorm_mean', 'batchnorm_variance', 'batchnorm_mean_avg', 'batchnorm_variance_avg'}

Alternatives

get_dl_model_layer_activations, get_dl_model_layer_gradients

Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
Deep Learning Professional

load_dl_model_weights (: : DLModelHandleSource, DLModelHandleTarget : ChangesByLayer)

Load the weights of a source model into a target model.

The operator load_dl_model_weights loads weights of a source model DLModelHandleSource into a target model DLModelHandleTarget. Thereby applies for every layer in the target model: Its weights are only changed if there is a layer in the source model having the same name and the same weight-shape. Note that DLModelHandleSource must be different from DLModelHandleTarget, i.e., you cannot use the same model handle as source and target.

ChangesByLayer is a tuple indicating for every target layer how many weights changed. Its entries are sorted by ascending layer IDs. The layer IDs can be queried via the operator get_dl_model_param with the parameter *'summary'*.

Note, that 'weights' means all weights and biases for all layers which can have such values (e.g., convolutional layer, batch normalization layer, etc.).

Parameters

▷ **DLModelHandleSource** (input_control) ..... dl_model ⇝ *handle*
Handle of the source deep learning model.

▷ **DLModelHandleTarget** (input_control) ..... dl_model ⇝ *handle*
Handle of the target deep learning model.

▷ **ChangesByLayer** (output_control) ..... integer(-array) ⇝ *integer*
Indicates for every target layer how many weights changed.

Result

If the parameters are valid, the operator `load_dl_model_weights` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Deep Learning Professional

set_dl_model_layer_param (: : DLModelHandle, LayerName, ParamName, ParamValue :)

Set parameter values of a given layer.

The operator `set_dl_model_layer_param` sets the value `ParamValue` of the parameter `ParamName` for a layer. The layer is referred to by its name `LayerName` in the model `DLModelHandle`. You can retrieve the layer names using `get_dl_model_param` with its option *'layer_names'* or *'summary'*.

Which generic and layer-specific parameters can be set is described in the entries of the operators (`create_dl_layer_*`), which are used for creating the layer.

Parameters

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Deep learning model.

▷ **LayerName** (input_control) ..... string ⇝ *string*
Name of the output layer.

▷ **ParamName** (input_control) ..... attribute.name ⇝ *string*
Name of the set parameter.
Default: []
List of values: `ParamName` ∈ {'bias_filler', 'bias_filler_variance_norm', 'bias_filler_const_val', 'is_inference_output', 'leaky_relu_alpha', 'learning_rate_multiplier', 'learning_rate_multiplier_bias', 'name', 'upper_bound', 'weight_filler', 'weight_filler_const_val', 'weight_filler_variance_norm'}

▷ **ParamValue** (input_control) ..... attribute.value(-array) ⇝ *string* / integer / real
Value of the set parameter.
Default: []
List of values: `ParamValue` ∈ {'xavier', 'msra', 'const', 'norm_in', 'norm_out', 'norm_average', 'true', 'false'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology, OCR/OCV, Deep Learning Professional

set_dl_model_layer_weights (Weights : : DLModelHandle, LayerName, WeightsType :)

Set the weights (or values) of a Deep Learning model layer.

The operator set_dl_model_layer_weights sets for the model DLModelHandle the given Weights in the specified LayerName.

The parameter WeightsType determines which type of layer values are set. Which values can be set, please refer to the get_dl_model_layer_weights documentation.

Attention

The operator set_dl_model_layer_weights is only applicable to self-created networks. For networks delivered by HALCON, the operator does have no impact.

Parameters

- ▷ **Weights** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* real
  Input weights.
- ▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
  Handle of the deep learning model.
- ▷ **LayerName** (input_control) ..... string ⇝ *string*
  Name of the layer, whose weights are to be set.
- ▷ **WeightsType** (input_control) ..... string ⇝ *string*
  Selected type of layer values to be set.
  Default: 'weights'
  List of values: WeightsType ∈ {'weights', 'bias', 'batchnorm_mean', 'batchnorm_variance', 'batchnorm_mean_avg', 'batchnorm_variance_avg'}

Example

```
* Create weights for a convolution layer.
gen_image_const (Weights, 'real', 1, 1)
paint_region (Weights, Weights, Weights, 1, 'fill')
gen_empty_obj (WeightsArray)
for Index := 0 to 10 by 1
    concat_obj (WeightsArray, Weights, WeightsArray)
endfor
*
* Input image with rows consisting of 1s to 10s.
gen_image_const (Image, 'real', 10, 10)
for Index := 0 to 9 by 1
    gen_rectangle1 (Rectangle, Index, 0, Index, 9)
    paint_region (Rectangle, Image, Image, Index + 1, 'fill')
endfor
*
* Create a small model network.
create_dl_layer_input ('image', [10, 2, 1], [], [], ImageNode)
create_dl_layer_convolution (ImageNode, 'conv', 1, 1, 2, 11, 1, 'none', \
                             'none', [], [], ConvNode)
create_dl_layer_zoom_factor (ConvNode, 'zoom', 2, 2, 'bilinear', 'true', [],\
                             [], ZoomNode)
create_dl_model (ZoomNode, DLModelHandle)
set_dl_model_param (DLModelHandle, 'runtime', 'cpu')
*
```

```
* Set the weights to the convolution layer.
set_dl_model_layer_weights (WeightsArray, DLModelHandle, 'conv', 'weights')
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

9.4 Model

This chapter explains the general concept of the deep learning (DL) model in HALCON and the data handling.

By concept, a deep learning model in HALCON is an internal representation of a deep neural network. Each deep neural network has an architecture defining its function, i.e., the tasks it can be used for. There can be several possible network architectures for one functionality. Currently, networks for the following functionalities are implemented in HALCON as model:

- 3D Gripping Point Detection, see 3D Matching / 3D Gripping Point Detection.
- Anomaly detection and Global Context Anomaly Detection, see Deep Learning / Anomaly Detection and Global Context Anomaly Detection.
- Classification, see Deep Learning / Classification.
- Deep OCR, see OCR / Deep OCR.
- Multi-Label Classification, see Deep Learning / Multi-Label Classification.
- Object detection and instance segmentation see Deep Learning / Object Detection and Instance Segmentation.
- Semantic segmentation and edge extraction, see Deep Learning / Semantic Segmentation and Edge Extraction.

Each functionality is identified by its unique model type. For the implemented methods you can find further information about the specific workflow, data requirements, and validation measures in the corresponding chapters. Information to deep learning in general are given in the chapter Deep Learning.

In this chapter you find the information, which data a DL model needs and returns as well as how this data is transferred.

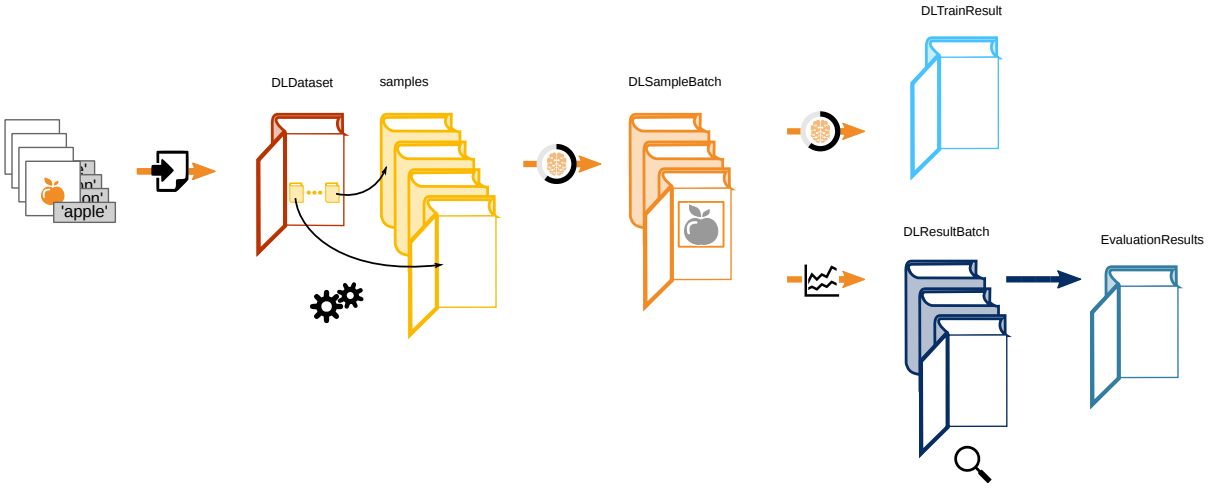
Data

Deep Learning applications have different types of data to be distinguished. Roughly spoken these are: The raw images with possible annotations, data preprocessed in a way suitable for the model, and output data.

Before the different types of data and the entries of the specific dictionaries are explained, we will have a look how the data is connected. Thereby, symbols and colors refer to the schematic overviews given below.

In brief, the data structure for training or evaluation starts with the raw images and their ground truth annotations (gray frames). With the read data the following dictionaries are created: A dictionary `DLDataset` (red), which serves as database and refers to a specific dictionary (yellow) for every input image. The dictionary `DLSample` (orange) contains the data for a sample in the way the network can process it. A batch of `DLSample` is handed to the model in `DLSampleBatch`. For evaluation, `DLResultBatch` is returned, a tuple of dictionaries `DLResult` (dark blue), one for every sample. They are needed to obtain the evaluation results `EvaluationResult`. For training, the training results (e.g., loss values) are returned in the dictionary `DLTrainResult` (light blue). The most important steps concerning modifying or creating a dictionary:

- reading the raw data (symbol: paper with arrow)
- preprocessing the data (symbol: cogs)
- training (symbol: transparent brain in an arc)
- evaluation of the model (symbol: graph)
- evaluation of a sample (symbol: magnifying glass)



Schematic overview of the data structure during training and evaluation.

For inference no annotations are needed. Thus, the data structure starts with the raw images (gray frames). The dictionary `DLSample` (orange) contains the data for a sample in the way the network can process it. The results for a sample are returned in a dictionary `DLResult` (dark blue). The most important steps concerning modifying or creating a dictionary:

- reading the raw data (symbol: paper with arrow)
- preprocessing the data (symbol: cogs)
- inference (symbol: brain in a circle)
- evaluation of a sample (symbol: magnifying glass)

Schematic overview of the data connection during inference.

In order for the model to process the data, the data needs to follow certain conventions about what is needed and how it is given to the model. As visible from the figures above, in HALCON the data is transferred using dictionaries.

In the following we explain the involved dictionaries, how they can be created, and their entries. Thereby, we group them according to the main step of a deep learning application they are created in and whether they serve as input or output data. The following abbreviations mark for which methods the entry applies:

- 'Any': any method
- '3D-GPD': 3D Gripping Point Detection
- 'AD': anomaly detection
- 'CL': classification
- 'MLC': multi-label classification
- 'OCR-D': Deep OCR detection component
- 'OCR-R': Deep OCR recognition component
- 'GC-AD': Global Context Anomaly Detection
- 'OD': object detection

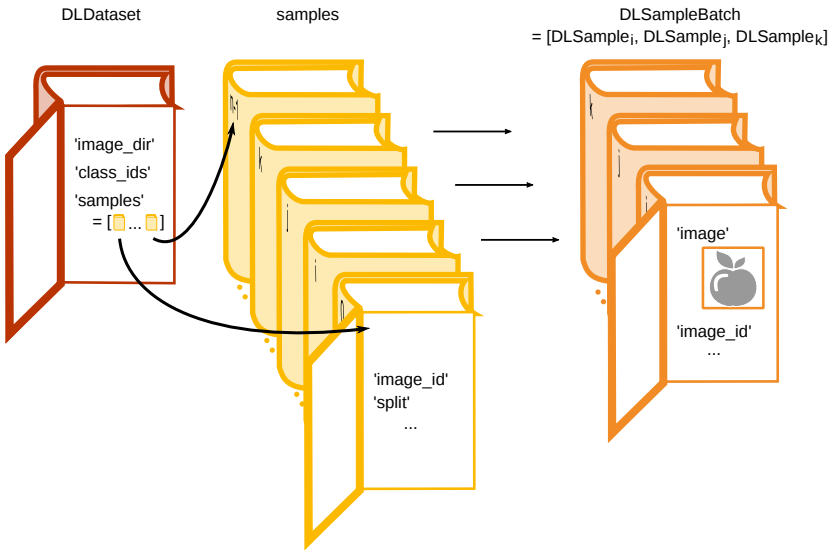
  In case the entry is only applicable for a certain *'instance_type'*, the specification 'r1': *'rectangle1'*, 'r2': *'rectangle2'* is added.

  For entries only applicable for instance segmentation the specification 'is' is added.
- 'SE': semantic segmentation

The entries only applicable for certain methods are described more extensively in the corresponding chapter.

Training and evaluation input data The dataset consists of images and corresponding information. They have to be provided in a way the model can process them. Concerning the image requirements, find more information in the section "Images" below.

The information about the images and the dataset is represented in a dictionary `DLDataset`, which serves as a database. More precisely, it stores the general information about the dataset and the dictionaries of the individual samples collected under the key `samples`. When the actual image data is needed, a dictionary `DLSample` is created (or read if it already exists) for each image required. The relation of these dictionaries is illustrated in the figure below.



Schematic illustration of the different dataset dictionaries used for training and evaluation. For visibility purpose only few entries are registered and `BatchSize` is set to three. In this example we have n samples. Thereof three samples are chosen randomly: i,j, and k. The corresponding dictionaries `DLSample` are created and joined in the tuple `DLSampleBatch`.

In the following we look at these dictionaries.

DLDataset The dictionary `DLDataset` serves as a database. It stores general information about the dataset and collects the dictionaries of the individual samples. Thereby iconic data is not included in `DLDataset` but the paths to the respective images. The dictionary `DLDataset` is used by the training and evaluation procedures. It is not necessary for the model, but we highly recommend to create it. Its necessary entries are described below. This dictionary is either created directly when labeling your data using the MVTec Deep Learning Tool or it is created by one of the following method-specific procedures:

- `read_dl_dataset_3d_gripping_point_detection` (3D Gripping Point Detection)
- `read_dl_dataset_anomaly` (anomaly detection, Global Context Anomaly Detection)
- `read_dl_dataset_classification` (classification)
- `read_dl_dataset_ocr_detection` (Deep OCR - detection component)
- `read_dl_dataset_ocr_recognition` (Deep OCR - recognition component)
- `read_dl_dataset_from_coco` (object detection with *'instance_type' = 'rectangle1'*)
- `read_dl_dataset_segmentation` (semantic segmentation).

Please see the respective procedure documentation for the requirements on the data in order to use these procedures. In case you create `DLDataset` in an other way, it has to contain at least the entries not marked with a number in the description below. During the preprocessing of your dataset the respective procedures include the further entries of the dictionary `DLDataset`.

Depending on the model type, this dictionary can have the following entries:

image_dir: Any
Common base path to all images.
format: string

dlsample_dir: Any [1]
Common base path of all sample files (if present).
format: string

class_names: Any except OCR-R
Names of all classes that are to be distinguished.
format: tuple of strings

class_ids: Any except OCR-R
IDs of all classes that are to be distinguished (range: 0-65534).
format: tuple of integers

preprocess_param: Any [1]
All parameter values used during preprocessing.
format: dictionary

samples: Any
Collection of sample descriptions.
format: tuple of dictionaries

normals_dir: 3D-GPD
Optional. Common base path of all normals images.
format: string

xyz_dir: 3D-GPD
Common base path of all XYZ-images.
format: string

anomaly_dir: AD, GC-AD
Common base path of all anomaly regions (regions indicating anomalies in the image).
format: string

class_weights: CL, SE [1]
Weights of the different classes.
format: tuple of reals

segmentation_dir: SE, 3D-GPD
Common base path of all segmentation images.
format: string

This dictionary is directly created when labeling your data using the MVTec Deep Learning Tool. It is also created by the procedures mentioned above for reading in your data. The entries marked with [1] are added by the preprocessing procedures.

samples The `DLDataset` key `samples` gets a tuple of dictionaries as value, one for each sample in the dataset. These dictionaries contain the information concerning an individual sample of the dataset. Depending on the model type, this dictionary can have the following entries:

image_file_name: Any
File name of the image and its path relative to `image_dir`.
format: string

image_id: Any
Unique image ID (encoding format: UINT8).
format: integer

split: Any [2]
Specifies the assigned split subset (*'train'*,*'validation'*,*'test'*).
format: string

dlsample_file_name: Any [3]
File name of the corresponding dictionary `DLSample` and its path relative to `dlsample_dir`.
format: string

normals_file_name: 3D-GPD
Optional. File name of the normals image and its path relative to `normals_dir`.
format: string

segmentation_file_name: 3D-GPD, SE
File name of the ground truth segmentation image and its path relative to `segmentation_dir`.
format: string

xyz_file_name: 3D-GPD
File name of the XYZ-image and its path relative to `xyz_dir`.
format: string

anomaly_file_name: AD, GC-AD
Optional. Path to region files with ground truth annotations (relative to `anomaly_dir`).
format: string

anomaly_label: AD, GC-AD
Ground truth anomaly label on image level (in the form of `class_names`).
format: string

image_label_id: CL
Ground truth label for the image (in the form of `class_ids`).
format: tuple of integers

image_label_ids: MLC
Ground truth labels for the image (in the form of `class_ids`).
format: tuple of integers

image_id_origin: OCR-R
ID of the original image the sample was extracted from.
format: integer

word: OCR-D, OCR-R
Ground truth word.
format: string

bbox_label_id: OD, OCR-D
Ground truth labels for the bounding boxes (in the form of `class_ids`).
format: tuple of integers

bbox_row1: OD:r1 [4]
Ground truth bounding boxes: upper left corner, row coordinate.
format: tuple of reals

bbox_col1: OD:r1 [4]
Ground truth bounding boxes: upper left corner, column coordinate.
format: tuple of reals

bbox_row2: OD:r1 [4]
Ground truth bounding boxes: lower right corner, row coordinate.
format: tuple of reals

bbox_col2: OD:r1 [4]
Ground truth bounding boxes: lower right corner, column coordinate.
format: tuple of reals

coco_raw_annotations: OD:r1
Optional. It contains for every bbox_label_id within this image a dictionary with all raw COCO annotation information.
format: tuple of dictionaries

bbox_row: OCR-D, OCR-R, OD:r2 [4]
Ground truth bounding boxes: center point, row coordinate.
format: tuple of reals

bbox_col: OCR-D, OCR-R, OD:r2 [4]
Ground truth bounding boxes: center point, column coordinate.
format: tuple of reals

bbox_phi: OCR-D, OCR-R, OD:r2 [4]
Ground truth bounding boxes: angle phi.
format: tuple of reals

bbox_length1: OCR-D, OCR-R, OD:r2 [4]
Ground truth bounding boxes: half length of edge 1.
format: tuple of reals

bbox_length2: OCR-D, OCR-R, OD:r2 [4]
Ground truth bounding boxes: half length of edge 2.
format: tuple of reals

mask: OD:is
Ground truth mask marking the instance regions.
format: tuple of regions

These dictionaries are part of DLDataset and thus they are created concurrently. An exception are the entries with a mark in the table, [2]: the procedure split_dl_dataset adds split, [3]: the procedure preprocess_dl_samples adds dlsample_file_name. [4]: Used coordinates: Pixel centered, subpixel accurate coordinates.

DLSample The dictionary DLSample serves as input for the model. For a batch, they are handed over as the entries of the tuple DLSampleBatch for apply_dl_model or train_dl_model_batch. They are created out of DLDataset for every sample by the procedure gen_dl_samples followed by preprocess_dl_samples. Note, preprocess_dl_samples will update the corresponding DLSample dictionary. If preprocessing is done using the standard procedure preprocess_dl_dataset, the preprocessed samples are stored on the file system. Afterwards they need to be retrieved with the procedure read_dl_samples.

DLSample contains the preprocessed image and, in case of training and evaluation, all ground truth annotations. Depending on the model type, it can have the following entries:

anomaly_ground_truth: AD, GC-AD
Anomaly image or region, read from anomaly_file_name.
format: image or region

anomaly_label: AD, GC-AD
Ground truth anomaly label on image level (in the form of class_names).
format: string

anomaly_label_id: AD, GC-AD
Ground truth anomaly label ID on image level (in the form of class_ids).
format: integer

bbox_label_id: OD
Ground truth labels for the image part within the bounding box (in the form of class_ids).
format: tuple of integers

bbox_row1: OD:r1 [4]
Ground truth bounding boxes: upper left corner, row coordinate.
format: tuple of reals

bbox_col1: OD:r1 [4]
Ground truth bounding boxes: upper left corner, column coordinate.
format: tuple of reals

bbox_row2: OD:r1 [4]
Ground truth bounding boxes: lower right corner, row coordinate.
format: tuple of reals

bbox_col2: OD:r1 [4]
Ground truth bounding boxes: lower right corner, column coordinate.
format: tuple of reals

bbox_row: OCR-D, OD:r2 [4]
Ground truth bounding boxes: center point, row coordinate.
format: tuple of reals

bbox_col: OCR-D, OD:r2 [4]
Ground truth bounding boxes: center point, column coordinate.
format: tuple of reals

bbox_phi: OCR-D, OD:r2 [4]
Ground truth bounding boxes: angle phi.
format: tuple of reals

bbox_length1: OCR-D, OD:r2 [4]
Ground truth bounding boxes: half length of edge 1.
format: tuple of reals

bbox_length2: OCR-D, OD:r2 [4]
Ground truth bounding boxes: half length of edge 2.
format: tuple of reals

image: Any
Input image.
format: image

image_label_id: CL
Ground truth label for the image (in the form of `class_ids`).
format: integer

image_label_ids: MLC
Ground truth labels for the image (in the form of `class_ids`).
format: tuple of integers

mask: OD:is
Ground truth mask marking the instance regions.
format: tuple of regions

normals: 3D-GPD
2D mappings (3-channel image)
format: image

segmentation_image: SE, 3D-GPD
Image with the ground truth segmentations, read from `segmentation_file_name`.
format: image

weight_image: SE [5]
Image with the pixel weights.
format: image

target_orientation: OCR-D
Orientation target image for the word orientation.
format: image

target_text: OCR-D
Text target image for the character detection.
format: image

target_link: OCR-D
Link target image for the connection of detected character centers to a connected word.
format: image

target_weight_orientation: OCR-D
Weight with respect to `target_orientation`.
format: image

target_weight_link: OCR-D
Weight with respect to `target_link`.
format: image

target_weight_text: OCR-D
Weight with respect to target_text.
format: image

word: OCR-D, OCR-R
Ground truth word.
format: string

x: 3D-GPD
X-image (values need to increase from left to right).
format: image

y: 3D-GPD
Y-image (values need to increase from top to bottom).
format: image

z: 3D-GPD
Z-image (values need to increase from points close to the sensor to far points; this is for example the case if the data is given in the camera coordinate system).
format: image

These dictionaries are created by the procedure gen_dl_samples followed by preprocess_dl_samples. An exception is the entry marked in the table above, [5]: created by the procedure gen_dl_segmentation_weights. [4]: Used coordinates: Pixel centered, subpixel accurate coordinates.

Inference input data The inference input data consists of a single DLSample dictionary or a tuple of such. In contrast to training and evaluation, only the following keys are used:

image: Any
Input image
format: image

normals: 3D-GPD
2D mappings (3-channel image).
format: image

x: 3D-GPD
X-image (values need to increase from left to right).
format: image

y: 3D-GPD
Y-image (values need to increase from top to bottom).
format: image

z: 3D-GPD
Z-image (values need to increase from points close to the sensor to far points; this is for example the case if the data is given in the camera coordinate system).
format: image

Concerning the image requirements, find more information in the subsection "Images" below.

For the inference, such a dictionary containing only the image data can be created using the procedure gen_dl_samples_from_images or gen_dl_samples_3d_gripping_point_detection (only for 3D Gripping Point Detection). These dictionaries can be passed one at a time or within a tuple DLSampleBatch.

Training output data The training output data is given in the dictionary DLTrainResult. Its entries depend on the model and thus on the operator used (for further information see the documentation of the corresponding operator):

3D-GPD, CL, MLC, OCR-D, OCR-R, GC-AD, OD, SE:
The operator train_dl_model_batch returns

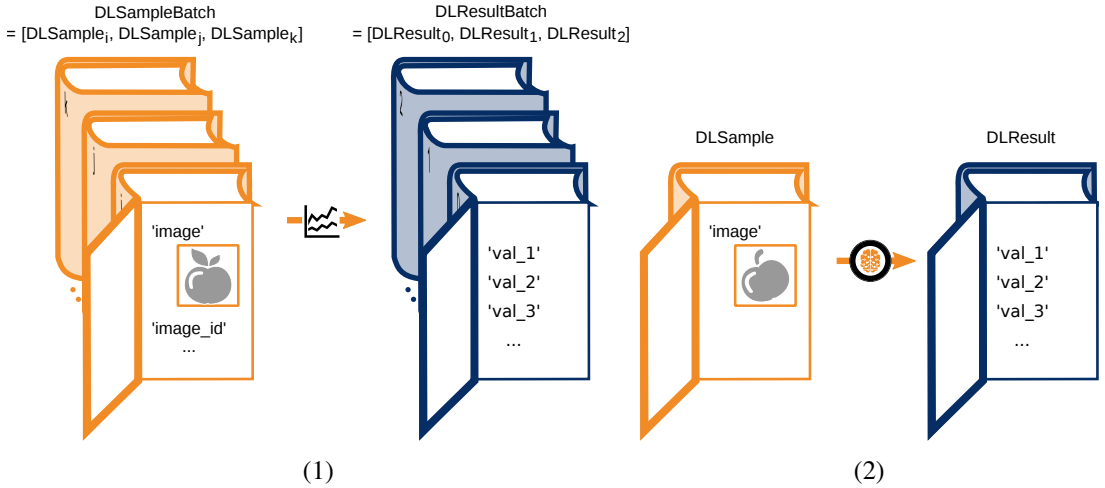
- total_loss
- possible further losses included in your model

AD:

The operator `train_dl_model_anomaly_dataset` returns

- `final_error`
- `final_epoch`

Inference and evaluation output data As output from the operator `apply_dl_model`, the model will return a dictionary `DLResult` for each sample. An illustration is given in the figure below. The evaluation is based on these results and the annotations. Evaluation results are stored in the dictionary `EvaluationResult`.



Schematic illustration of the dictionaries serving as model input: (1) Evaluation: `DLSample` includes the image as well as information about the image and its content. This data serves as basis for the evaluation. For visibility purpose `BatchSize` is set to three (containing the randomly chosen samples i,j,and k, see above) and only few entries are registered. (2) Inference: `DLSample` contains only the image. These dictionaries can be passed one at a time or within a tuple.

Depending on the model type, the dictionary `DLResult` can have the following entries:

`gripping_confidence`: 3D-GPD
Image, containing raw, uncalibrated confidence values for every point in the scene.
format: image

`gripping_map`: 3D-GPD
Binary image, indicating for each pixel of the scene whether the model predicted a gripping point (pixel value = *1.0*) or not (*0.0*).
format: image

`anomaly_image`: AD, GC-AD
Single channel image whose gray values are scores, indicating how likely the corresponding pixel in the input image belongs to an anomaly.
format: image

`anomaly_image_combined`: GC-AD
Single channel image whose gray values are scores, indicating how likely the corresponding pixel in the input image belongs to an anomaly. Calculated by combining the *'local'* and *'global'* subnetworks of the model.
Format: Bild

`anomaly_image_global`: GC-AD
Single channel image whose gray values are scores, indicating how likely the corresponding pixel in the input image belongs to an anomaly. Calculated by the *'global'* subnetwork of the model.
format: image

`anomaly_image_local`: GC-AD
Single channel image whose gray values are scores, indicating how likely the corresponding pixel in the input image belongs to an anomaly. Calculated by the *'local'* subnetwork of the model.
format: image

anomaly_score: AD, GC-AD
Anomaly score on image level calculated from anomaly_image.
format: real

anomaly_score_local: GC-AD
Anomaly score on image level calculated from anomaly_image_local.
format: real

anomaly_score_global: GC-AD
Anomaly score on image level calculated from anomaly_image_global.
format: real

classification_class_ids: CL
Inferred class ids for the image sorted by confidence values.
format: tuple of integers

classification_class_names: CL
Inferred class names for the image sorted by confidence values.
format: tuple of strings

classification_confidences: CL
Confidence values of the image inference for each class.
format: tuple of reals

class_ids: MLC
Inferred class ids for the image sorted by confidence values.
format: tuple of integers

class_names: MLC
Inferred class names for the image sorted by confidence values.
format: tuple of strings

confidences: MLC
Confidence values of the image inference for each class.
format: tuple of reals

selected_class_ids: MLC
Class ids for the image selected by the confidence threshold(min_confidence).
format: tuple of integers

selected_class_names: MLC
Class names for the image selected by the confidence threshold (min_confidence).
format: tuple of strings

selected_confidences: MLC
Confidence values of the image selected by the confidence threshold for each class.
format: tuple of reals

char_candidates: OCR-R
Candidates for each character of the word and their confidences.
format: tuple of dictionaries

word: OCR-R
Recognized word.
format: string

score_maps: OCR-D Scores given as image with four channels:

- Character score: Score for the character detection.
- Link score: Score for the connection of detected character centers to a connected word.
- Orientation 1: Sine component of the predicted word orientation.
- Orientation 2: Cosine component of the predicted word orientation.

format: image

words: OCR-D Dictionary containing the following entries. Thereby, the entries are tuples with a value for every found word.

- row: Localized word: Center point, row coordinate.

- `col`: Localized word: Center point, column coordinate.
- `phi`: Localized word: Angle phi.
- `length1`: Localized word: Half length of edge 1.
- `length2`: Localized word: Half length of edge 2.
- `line_index`: Line index of localized word if *'detection_sort_by_line'* set to *'true'*.

format: dictionary with tuples of reals and strings

word_boxes_on_image: OCR-D Dictionary with the word localization on the coordinate system of the preprocessed images placed in `image`. The entries are tuples with a value for every found word.

- `row`: Localized word: Center point, row coordinate.
- `col`: Localized word: Center point, column coordinate.
- `phi`: Localized word: Angle phi.
- `length1`: Localized word: Half length of edge 1.
- `length2`: Localized word: Half length of edge 2.

format: dictionary with tuples of reals

word_boxes_on_score_maps: OCR-D Dictionary with the word localization on the coordinate system of the score images placed in `score_maps`. The entries are the same as for `word_boxes_on_image` above. *format:* dictionary with tuples of reals

bbox_class_id: OD
Inferred class for the bounding box (in the form of `class_ids`).
format: tuple of integers

bbox_class_name: OD
Name of the inferred class for the bounding box.
format: tuple of strings

bbox_confidence: OD
Confidence value of the inference for the bounding box.
format: tuple of reals

bbox_row1: OD:r1 [6]
Inferred bounding boxes: upper left corner, row coordinate.
format: tuple of reals

bbox_col1: OD:r1 [6]
Inferred bounding boxes: upper left corner, column coordinate.
format: tuple of reals

bbox_row2: OD:r1 [6]
Inferred bounding boxes: lower right corner, row coordinate.
format: tuple of reals

bbox_col2: OD:r1 [6]
Inferred bounding boxes: lower right corner, row coordinate.
format: tuple of reals

bbox_row: OD:r2 [6]
Inferred bounding boxes: center point, row coordinate.
format: tuple of reals

bbox_col: OD:r2 [6]
Inferred bounding boxes: center point, column coordinate.
format: tuple of reals

bbox_phi: OD:r2 [6]
Inferred bounding boxes: angle phi.
format: tuple of reals

bbox_length1: OD:r2 [6]
Inferred bounding boxes: half length of edge 1.
format: tuple of reals

bbox_length2: OD:r2 [6]
Inferred bounding boxes: half length of edge 2.
format: tuple of reals

mask: OD:is
Inferred mask marking the instance regions.
format: tuple of regions

mask_probs: OD:is
Image with the confidence values of the inferred mask.
format: image

segmentation_image: SE
Image with the segmentation result.
format: image

segmentation_confidence: SE
Image with the confidence values of the segmentation result.
format: image

[6]: Used coordinates: Pixel centered, subpixel accurate coordinates.

For a further explanation to the output values we refer to the chapters of the respective method, e.g., Deep Learning / Semantic Segmentation and Edge Extraction.

Images Regardless of the application, the network poses requirements on the images. The specific values depend on the network itself and can be queried using `get_dl_model_param`. In order to fulfill these requirements, you may have to preprocess your images. Standard preprocessing of the entire dataset and therewith also the images is implemented in `preprocess_dl_samples`. In case of custom preprocessing this procedure offers guidance on the implementation.

add_dl_pruning_batch (: : DLModelHandleToPrune, DLPruningHandle, DLSampleBatch :)

Calculate scores to prune a deep learning model.

`add_dl_pruning_batch` calculates pruning scores for the deep learning model `DLModelHandleToPrune`. More precisely, the scores are calculated on the images given in `DLSampleBatch` and internally accumulated by each call of `add_dl_pruning_batch` in the pruning data handle `DLPruningHandle`.

The parameter `DLModelHandleToPrune` specifies the deep learning model to use. Note that `add_dl_pruning_batch` supports only deep learning models of type *'classification'*.

The parameter `DLPruningHandle` specifies the pruning data handle, which is used to pass information as e.g., the accumulated scores or the pruning mode. See `create_dl_pruning` for further information about implemented pruning modes.

The parameter `DLSampleBatch` specifies the batch with input images based on which the scores are calculated. Note that the number of images in the tuple `DLSampleBatch` needs to be equal to the value set for the model parameter *'batch_size'*.

For an explanation of the concept of deep learning see the introduction of chapter Deep Learning.

Parameters

▷ **DLModelHandleToPrune** (input_control) . . . . . dl_model ⇝ *handle*
Handle of a deep learning model to prune.

▷ **DLPruningHandle** (input_control) . . . . . dl_pruning ⇝ *handle*
Pruning data handle.

▷ **DLSampleBatch** (input_control) . . . . . dict-array ⇝ *handle*
Tuple of dictionaries with input images.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_dl_model, create_dl_pruning, set_dl_pruning_param

Possible Successors

get_dl_pruning_param, gen_dl_pruned_model

Module

Deep Learning Professional

apply_dl_model (: : DLModelHandle, DLSampleBatch, Outputs : DLResultBatch)

Apply a deep-learning-based network on a set of images for inference.

apply_dl_model applies the deep-learning-based network given by DLModelHandle on the batch of input images handed over through the tuple of dictionaries DLSampleBatch. The operator returns DLResultBatch, a tuple with a result dictionary DLResult for every input image.

Please see the chapter Deep Learning / Model for more information on the concept and the dictionaries of the deep learning model in HALCON.

In order to apply the network on images, you have to hand them over through a tuple of dictionaries DLSampleBatch, where a dictionary refers to a single image. You can create such a dictionary conveniently using the procedure gen_dl_samples_from_images. The tuple DLSampleBatch can contain an arbitrary number of dictionaries. The operator apply_dl_model always processes a batch with up to *'batch_size'* images simultaneously. In case the tuple contains more images, apply_dl_model iterates over the necessary number of batches internally. For a DLSampleBatch with less than *'batch_size'* images, the tuple is padded to a full batch which means that the time required to process a DLSampleBatch is independent of whether the batch is filled up or just consists of a single image. This also means that if fewer images than *'batch_size'* are processed in one operator call, the network still requires the same amount of memory as for a full batch. The current value of *'batch_size'* can be retrieved using get_dl_model_param.

Note that the images might have to be preprocessed before feeding them into the operator apply_dl_model in order to fulfill the network requirements. You can retrieve the current requirements of your network, such as e.g., the image dimensions, using get_dl_model_param. The procedure preprocess_dl_dataset provides guidance on how to implement such a preprocessing stage.

The results are returned in DLResultBatch, a tuple with a dictionary DLResult for every input image. Please see the chapter Deep Learning / Model for more information to the output dictionaries in DLResultBatch and their keys. In Outputs you can specify, which output data is returned in DLResult. Outputs can be a single string, a tuple of strings, or an empty tuple with which you retrieve all possible outputs. If apply_dl_model is used with an AI^2-interface, it might be required to set *'is_inference_output'* = *'true'* for all requested layers in Outputs before the model is optimized for the AI^2-interface, see optimize_dl_model_for_inference and set_dl_model_layer_param for further details. The values for Outputs depend on the model type of your network:

Models of *'type'*=*'3d_gripping_point_detection'*

- Outputs=*'[]'*: DLResult containing:
  - 'gripping_map': Binary image, indicating for each pixel of the scene whether the model predicted a gripping point (pixel value = *1.0*) or not (*0.0*).
  - 'gripping_confidence': Image, containing raw, uncalibrated confidence values for every point in the scene.

Models of *'type'*=*'anomaly_detection'*

- Outputs=*'[]'*: DLResult contains an image where each pixel has the score of the according input image pixel. Additionally it contains a score for the entire image.

Models of *'type'='counting'*

This model type cannot be run with the operator `apply_dl_model`.

Models of *'type'='gc_anomaly_detection'*

For each value of `Outputs`, `DLResult` contains an image where each pixel has the score of the according input image pixel. Additionally it contains a score for the entire image.

- `Outputs`=*'[]'*: The scores of each input image pixel are calculated as a combination of all available networks.
- `Outputs`=*'anomaly_image_local'*: The scores of each input image pixel are calculated from the *'local'* network only. If the *'local'* network is not available, an error is raised.
- `Outputs`=*'anomaly_image_global'*: The scores of each input image pixel are calculated from the *'global'* network only. If the *'global'* network is not available, an error is raised.
- `Outputs`=*'anomaly_image_combined'*: The scores of each input image pixel are calculated by combining the *'global'* and the *'local'* networks. If one or both of the networks are not available, an error is raised.

Models of *'type'='classification'*

- `Outputs`=*'[]'*: `DLResult` contains a tuple with confidence values in descending order and tuples with the class names and class IDs sorted accordingly. If Out-of-Distribution Detection is available, `DLResult` additionally contains the out-of-distribution score, the out-of-distribution result and the threshold that was used for the prediction.

Models of *'type'='multi_label_classification'*

- `Outputs`=*'[]'*: `DLResult` contains a tuple with the selected class names, class IDs and the corresponding confidence values according to the model parameter *'min_confidence'*. Additionally, it contains tuples with all class names, class IDs and corresponding confidence values.

Models of *'type'='detection'*

- `Outputs`=*'[]'*: `DLResult` contains the bounding box coordinates as well as the inferred classes and their confidence values resulting from all levels.
- `Outputs`= *'[bboxhead + level + _prediction, classhead + level + _prediction]'*, where *'level'* stands for the selected level which lies between *'min_level'* and *'max_level'*: `DLResult` contains the bounding box coordinates as well as the inferred classes and their confidence values resulting from specific levels.

Models of *'type'='ocr_recognition'*

- `Outputs`=*'[]'*: `DLResult` contains the recognized word. Additionally it contains candidates for each character of the word and their confidences.

Models of *'type'='ocr_detection'*

- `Outputs`=*'[]'*: `DLResult` contains the bounding boxes coordinates of localized words.

Models of *'type'='segmentation'*

- `Outputs`=*'segmentation_image'*: `DLResult` contains an image where each pixel has a value corresponding to the class its corresponding pixel has been assigned to.
- `Outputs`=*'segmentation_confidence'*: `DLResult` contains an image where each pixel has the confidence value out of the classification of the according pixel.
- `Outputs`=*'[]'*: `DLResult` contains all output values.

Attention

System requirements: To run this operator on GPU by setting *'device'* to *'gpu'* (see `get_dl_model_param`), cuDNN and cuBLAS are required. For further details, please refer to the "`Installation Guide`", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

▷ **DLModelHandle** (input_control) . . . . . dl_model ⇝ *handle*
Handle of the deep learning model.

▷ **DLSampleBatch** (input_control) . . . . . dict-array ⇝ *handle*
Input data.

▷ **Outputs** (input_control) . . . . . string-array ⇝ *string*
Requested outputs.
Default: []
List of values: `Outputs` ∈ {[], 'segmentation_image', 'segmentation_confidence', 'bboxhead2_prediction', 'classhead2_prediction'}

▷ **DLResultBatch** (output_control) . . . . . dict-array ⇝ *handle*
Result data.

Result

If the parameters are valid, the operator `apply_dl_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`read_dl_model`, `train_dl_model_batch`, `train_dl_model_anomaly_dataset`, `set_dl_model_param`

Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
3D Metrology, OCR/OCV, Deep Learning Enhanced, Deep Learning Professional

clear_dl_model (: : DLModelHandle :)

Clear a deep learning model.

`clear_dl_model` clears the handle of the deep learning model given by `DLModelHandle` and frees all memory required for the model. After calling `clear_dl_model`, the model can no longer be used and the handle `DLModelHandle` becomes invalid.

For further explanations to deep learning models in HALCON, see the chapter Deep Learning / Model.

Parameters

▷ **DLModelHandle** (input_control) . . . . . dl_model(-array) ⇝ *handle*
Handle of the deep learning model.

Result

If the parameters are valid, the operator `clear_dl_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DLModelHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

read_dl_model, apply_dl_model, train_dl_model_batch, train_dl_model_anomaly_dataset

Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
3D Metrology, OCR/OCV, Matching, Deep Learning Enhanced, Deep Learning Professional

create_dl_pruning (: : DLModelHandle, Mode, GenParam : DLPruningHandle)

Create a pruning data handle.

The operator create_dl_pruning creates a handle DLPruningHandle. This handle is used to pass information when pruning a deep learning model.

Mode specifies the pruning method. The mode implies what will be removed and also which scores are needed. Currently only the following *'mode'* is implemented:

'oracle': Kernels of convolution layers are removed. In order to do so, a score is calculated for every (potentially removable) kernel, indicating its importance within the given network for the images used. See the given reference for details.

GenParam is a dictionary for setting generic parameters. Currently no generic parameters are supported.

For an explanation of the concept of deep learning see the introduction of chapter Deep Learning.

Parameters

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Handle of a deep learning model.

▷ **Mode** (input_control) ..... string ⇝ *string*
Pruning method.
Default: 'oracle'
List of values: Mode ∈ {'oracle'}

▷ **GenParam** (input_control) ..... dict ⇝ *handle*
Dictionary with generic parameters.
Default: []

▷ **DLPruningHandle** (output_control) ..... dl_pruning ⇝ *handle*
Pruning data handle.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

read_dl_model

Possible Successors

get_dl_pruning_param, set_dl_model_param

Module

Deep Learning Professional

deserialize_dl_model (: : SerializedItemHandle : DLModelHandle)

Deserialize a deep learning model.

deserialize_dl_model deserializes the deep learning model defined by the handle SerializedItemHandle and previously serialized by serialize_dl_model.

The operator acts the same as read_dl_model except that the input is a serialized item instead of a file. For a detailed description please refer to the documentation of read_dl_model.

For further explanations to deep learning models in HALCON, see the chapter Deep Learning / Model.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **DLModelHandle** (output_control) ..... dl_model ⇝ *handle*
Handle of the deep learning model.

Result

If the parameters are valid, the operator deserialize_dl_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_dl_model

Possible Successors

apply_dl_model, train_dl_model_batch, train_dl_model_anomaly_dataset, set_dl_model_param, get_dl_model_param

serialize_dl_model

Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
3D Metrology, OCR/OCV, Matching, Deep Learning Enhanced, Deep Learning Professional

gen_dl_model_heatmap (: : DLModelHandle, DLSample, HeatmapMethod, TargetClasses, GenParam : DLResult)

Infer the sample and generate a heatmap.

The operator gen_dl_model_heatmap infers the sample given by DLSample and generates a heatmap for the class specified by TargetClasses. DLSample can be a single dictionary or a tuple of dictionaries for different samples. To do so, the operator uses the deep learning model given by DLModelHandle. The parameter HeatmapMethod determines, which method is used to calculate the heatmap. The operator returns DLResult with a result dictionary for every given sample. Note, DLResult will be newly created and already existing parameters with this name will be overwritten.

A heatmap can be useful to analyze which parts of an image have a strong influence for the inference into a certain class. Shape and area of these parts and therewith the heatmaps may vary widely for differing networks especially if their architectures differ. There are different methods how a heatmap is calculated. The following ones can be selected using HeatmapMethod:

'grad_cam': Provides region-based heatmap information based on Gradient-weighted Class Activation Mapping (Grad-CAM). For a more detailed description refer to the referenced paper below.

'guided_grad_cam': Provides pixel-based heatmap information based on Guided gradient-weighted Class Activation Mapping (Guided Grad-CAM). For a more detailed description refer to the referenced paper below.

The input parameter TargetClasses determines the target class, the class for which the heatmap is generated. As value the class ID has to be set. Alternatively, an empty tuple can be handed over. In this case, the heatmap is calculated for the class with the highest confidence value, thus the top inferred class. Currently, TargetClasses only supports a single value or an empty tuple.

The following entries can be set in the dictionary GenParam:

target_conv_layer: Specifies the convolution layer whose activation and gradient are used for the heatmap. The convolution layer can be specified using its NAME, as returned using *'summary'* in get_dl_model_param, e.g., *'conv10'*. As default, the last (deepest) convolution layer of the network with a non-trivial activation (width and height not equal to 1) is used. As a general rule, the activation of the deepest convolution layer is most suitable for calculating the heatmap, therefore it is recommended to keep the default layer.

use_conv_only: In case the convolution layer (selected with target_conv_layer) is fused with a directly following ReLU activation layer, this parameter can be used to determine, from which of these layers the activation and gradient will be used for the heatmap. The following values are supported:

'true': convolution layer

'false': ReLU layer

Restriction: Only applicable if HeatmapMethod is set to *'grad_cam'*.

Default: use_conv_only = *'true'*.

scaling: Sets the scaling method for the heatmap. The following values are supported:

'scale_after_relu': Negative values of the heatmap are set to 0 and then all values are scaled within the range [0,1]. As a consequence, areas within the heatmap can attain very high values close to 1 although their contribution to the classification result might be small.

'scale_before_relu': All values of the heatmap are divided by the maximum absolute value and then negative values are set to 0. This leads to values for the heatmap in [0,1]. However, areas of less activation (and hence with a small contribution to the classification result) may not tend to attain values near 1.

'none': The heatmap values are not scaled.

Restriction: Only applicable if HeatmapMethod is set to *'grad_cam'*.

Default: scaling = *'scale_after_relu'*.

Every output dictionary in DLResult contains the inference results as obtained using apply_dl_model. Additionally it includes a nested dictionary under the key heatmap_method, where method is the name of the specified method as given in HeatmapMethod. In this nested dictionary the heatmap is saved under the key heatmap_image_class_classID, in case of *'guided_grad_cam'* the key is guided_grad_cam_image_class_classID, where classID is the ID of the target class.

Attention

System requirements: This operator performs a backward pass. As a consequence the same system requirements apply as for the training of deep-learning-based models. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

The heatmap should be used as a tool for visualizing and better understanding classification results. It is not intended as a segmentation tool. Moreover, gen_dl_model_heatmap currently only supports models with *'type'='classification'*.

Parameters

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Handle of a Deep learning model.

▷ **DLSample** (input_control) ..... dict(-array) ⇝ *handle*
Dictionaries with the sample input data.

▷ **HeatmapMethod** (input_control) ..... string ⇝ *string*
Method to be used for the heatmap calculation.
Default: 'grad_cam'
List of values: `HeatmapMethod` ∈ {'grad_cam', 'guided_grad_cam'}

▷ **TargetClasses** (input_control) ..... tuple ⇝ *integer*
ID of the target class.
Default: []

▷ **GenParam** (input_control) ..... dict ⇝ *handle*
Dictionary for generic parameters.
Default: []

▷ **DLResult** (output_control) ..... dict(-array) ⇝ *handle*
Dictionaries with the result data.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`apply_dl_model`

Module

Deep Learning Enhanced

gen_dl_pruned_model (: : DLModelHandleToPrune, DLPruningHandle : DLModelHandlePruned)

Prune a deep learning model.

The operator `gen_dl_pruned_model` copies the input model `DLModelHandleToPrune` and returns the pruned copy in `DLModelHandlePruned`. Note that `gen_dl_pruned_model` supports only deep learning models of *'type'='classification'*.

The parameter `DLPruningHandle` provides the necessary information as e.g., the selected pruning mode, the percentage or the kernel scores. See `create_dl_pruning` for further information about implemented pruning modes.

Behavior in special cases:

- In case the set amount of pruning *'percentage'* is too small to result in any removals, the returned model `DLModelHandlePruned` is simply a copy of the input model `DLModelHandleToPrune`.
- In case the model could not be pruned successfully, an empty handle is returned.

Parameters

▷ **DLModelHandleToPrune** (input_control) . . . . . dl_model ⇝ *handle*
Input model.

▷ **DLPruningHandle** (input_control) . . . . . dl_pruning ⇝ *handle*
Pruning data handle.

▷ **DLModelHandlePruned** (output_control) . . . . . dl_model ⇝ *handle*
Pruned model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

add_dl_pruning_batch, set_dl_pruning_param

Module

Deep Learning Professional

get_dl_model_param (: : DLModelHandle,
GenParamName : GenParamValue)

Return the parameters of a deep learning model.

get_dl_model_param returns the parameter values GenParamValue of GenParamName for the deep learning model DLModelHandle.

For a deep learning model, parameters GenParamName can be set using set_dl_model_param or create_dl_model_detection, depending on the parameter and the model type. With this operator, get_dl_model_param, you can retrieve the parameter values GenParamValue. Below we give an overview of the different parameters and an explanation, except of those you can only set. For latter ones, please see the documentation of corresponding operator. The parameters are listed corresponding to the deep learning model methods:

To mark which operators are available for the methods, we use the following notations:

- set: The parameter can be set using set_dl_model_param.
- get: The parameter can be retrieved using get_dl_model_param.
- create: The parameter can be set using create_dl_model_detection.
- Certain parameters are set as non-optional parameters, the corresponding notation is given in brackets.

In the following we list and explain the parameters `GenParamName` for which you can retrieve their value using this operator, `get_dl_model_param`. Note, that only parameters that do not change the model architecture can be set after the model has been optimized with `optimize_dl_model_for_inference`. A list of these parameters can be found at `optimize_dl_model_for_inference`. Thereby, the following symbols denote the model type for which the parameter can be get:

- 'Any': any method
- '3D-GPD': *'type'='3d_gripping_point_detection'*
- 'AD': *'type'='anomaly_detection'*

- 'CL': *'type'='classification'*
- 'MLC': *'type'='multi_label_classification'*
- 'DC': *'type'='counting'*
- 'OCR-D': *'type'='ocr_detection'*
- 'OCR-R': *'type'='ocr_recognition'*
- 'GC-AD': *'type'='gc_anomaly_detection'*
- 'OD': *'type'='detection'*
- 'SE': *'type'='segmentation'*
- 'Gen': *'type'='generic'*

'adam_beta1': **3D-GPD CL OCR-D OCR-R GC-AD OD SE Gen**

This value defines the moment for the linear term in Adam solver. For more information we refer to the documentation of `train_dl_model_batch`.

Restriction: Only applicable for *'solver_type'* = *'adam'*.

Default: *'adam_beta1'* = *0.9*

'adam_beta2': **3D-GPD CL OCR-D OCR-R GC-AD OD SE Gen**

This value defines the moment for the quadratic term in Adam solver. For more information we refer to the documentation of `train_dl_model_batch`.

Restriction: Only applicable for *'solver_type'* = *'adam'*.

Default: *'adam_beta2'* = *0.999*

'adam_epsilon': **3D-GPD CL OCR-D OCR-R GC-AD OD SE Gen**

This value defines the epsilon in the Adam solver formula and is purposed to guarantee the numeric stability. For more information we refer to the documentation of `train_dl_model_batch`.

Restriction: Only applicable for *'solver_type'* = *'adam'*.

Default: *'adam_epsilon'* = *1e-08*

'alphabet': **OCR-R**

The character set that can be recognized by the Deep OCR model.

It contains all characters that are not mapped to the Blank character of the internal alphabet (see parameters *'alphabet_mapping'* and *'alphabet_internal'*).

The alphabet can be changed or extended if needed. Changing the alphabet with this parameter will edit the internal alphabet and mapping in such a way that it tries to keep the length of the internal alphabet unchanged. After changing the alphabet, it is recommended to retrain the model on application specific data (see the HDevelop example `deep_ocr_recognition_training_workflow.hdev`). Previously unknown characters will need more training data.

Note, that if the length of the internal alphabet changes, the last model layers have to be randomly initialized and thus the output of the model will be random strings (see *'alphabet_internal'*). In that case it is required to retrain the model.

'alphabet_internal': **OCR-R**

The full character set which the Deep OCR recognition component has been trained on.

The first character of the internal alphabet is a special character. In the pretrained model this character is specified as Blank (U+2800) and is not to be confused with a space. The Blank is never returned in a word output but can occur in the reported character candidates. It is required and cannot be omitted. If the internal alphabet is changed, the first character has to be the Blank. Furthermore, if *'alphabet'* is used to change the alphabet, the Blank symbol is added automatically to the character set.

The length of this tuple corresponds to the depth of the last convolution layer in the model. If the length changes, the last convolution layer and all layers after it have to be resized and potentially reinitialized randomly. After such a change, it is required to retrain the model (see HDevelop example `deep_ocr_recognition_training_workflow.hdev`).

It is recommended to use the parameter *'alphabet'* to change the alphabet, as it will automatically try to preserve the length of the internal alphabet.

'alphabet_mapping': **OCR-R**

Tuple of integer indices.

It is a mapping that is applied by the model during the decoding step of each word. The mapping overwrites a character of *'alphabet_internal'* with the character at the specified index in *'alphabet_internal'*.

In the decoding step each prediction is mapped according to the index specified in this tuple. The tuple has to be of same length as the tuple *'alphabet_internal'*. Each integer index of the mapping has to be within *0* and |*'alphabet_internal'*|-1.

In some applications it can be helpful to map certain characters onto other characters. E.g. if only numeric words occur in an application it might be helpful to map the character "O" to the "0" character without the need to retrain the model.

If an entry contains a *0*, the corresponding character in *'alphabet_internal'* will not be decoded in the word.

'anchor_angles': **OD**

The parameter *'anchor_angles'* determines the orientation angle of the anchors for a model of *'instance_type'* = *'rectangle2'*.

Thereby, the orientation is given in arc measure and indicates the angle between the horizontal axis and `Length1` (mathematically positive). See the chapter Deep Learning / Object Detection and Instance Segmentation for more explanations to anchors.

You can set a tuple of values. A higher number of angles increases the number of anchors which might lead to a better localization but also increases the runtime and memory-consumption.

Value range:

'anchor_angles' $\in (-\pi, \pi]$ for *'ignore_direction'* = *'false'*, *'anchor_angles'* $\in (-\pi/2, \pi/2]$ for *'ignore_direction'* = *'true'*

Default: *'anchor_angles'* = *[0.0]*

'anchor_aspect_ratios' **(legacy:** *'aspect_ratios'***): OD**

The parameter *'anchor_aspect_ratios'* determines the aspect ratio of the anchors. Thereby, the definition of the ratio depends on the *'instance_type'*:

- *'rectangle1'*: height-to-width ratio
- *'rectangle2'*: ratio length1 to length2

E.g., for instance type *'rectangle1'* the ratio 2 gives a narrow and 0.5 a broad anchor. The size of the anchor is affected by the parameter *'anchor_num_subscales'* and with its explanation we give the formula for the sizes and lengths of the generated anchors. See the chapter Deep Learning / Object Detection and Instance Segmentation for more explanations to anchors.

You can set a tuple of values. A higher number of aspect ratios increases the number of anchors which might lead to a better localization but also increases the runtime and memory-consumption.

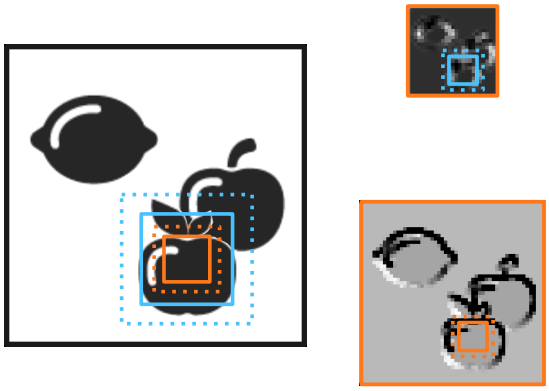
For reasons of backward compatibility, the parameter name *'aspect_ratios'* can be used instead of *'anchor_aspect_ratios'*.

Default: *'anchor_aspect_ratios'* = *[1.0, 2.0, 0.5]*

'anchor_num_subscales' **(legacy:** *'num_subscales'***): OD**

This parameter determines the number of different sizes with which the anchors are generated at the different levels used.

In HALCON for every anchor point, thus every pixel of every feature map of the feature pyramid, a set of anchors is proposed. See the chapter Deep Learning / Object Detection and Instance Segmentation for more explanations to anchors. Thereby the parameter *'anchor_num_subscales'* affects the size of the anchors. An example is shown in the figure below.



With *'anchor_num_subscales'*=2 we generate for every aspect ratio 2 anchors of different size on each level: One with the base length (solid line) and an additional, larger one (dotted line). Thereby, in the image these additional anchors of the lower level (orange) converge to the anchor of the next higher level (blue).

An anchor of level l has by default a edge lengths of $b \cdot 2^l$ in the input image, whereby the parameter has the value $b = 4$. With the parameter *'anchor_num_subscales'* additional anchors can be generated, which converge in size to the smallest anchor of the level $l + 1$. More precisely, these anchors of level l have in the input image the edge lengths

$$scale_{li} = b \cdot 2^{l+i/'anchor\_num\_subscales'}$$

where $i \in [0, 'anchor\_num\_subscales' - 1]$. For subscale i, this results on level l in an anchor of height h and width w equal

$$h_{lij} = scale_{li} \cdot \sqrt{r_j}, \qquad w_{lij} = scale_{li} \cdot \frac{1}{\sqrt{r_j}}$$

where r_j is the ratio of this anchor (see *'anchor_aspect_ratios'*).

A larger number of subscales increases the number of anchors and will therefore increase the runtime and memory-consumption.

For reasons of backward compatibility, the parameter name *'num_subscales'* can be used instead of *'anchor_num_subscales'*.

Default: *'anchor_num_subscales' = 3*

'anomaly_score_tolerance': **GC-AD**

The image-level anomaly score is calculated internally such that a certain fraction of the pixel-level anomaly scores in `anomaly_image` is greater or equal to the image-level anomaly score. The value of this fraction can be set by *'anomaly_score_tolerance'* and has to be in the interval *[0.0, 1.0]*. For example, for *'anomaly_score_tolerance'=0.01*, 1 percent of the pixel anomaly scores are larger or equal to the image anomaly score. This can be used to suppress outliers that might appear in the pixel anomaly scores.

Default: *'anomaly_score_tolerance' = 0.0*

'backbone': **OD**

The parameter *'backbone'* is the name (together with the path) of the backbone network which is used to create the model. A list of the delivered backbone networks can be found under `create_dl_model_detection`.

'backbone_docking_layers': **CL**

The parameter *'backbone_docking_layers'* specifies which layers of the backbone are to be used as docking layers by the feature pyramid. Thereby the layers are referenced by their names.

The docking layers can be specified for every classifier, also without using them as backbone. The specification is only considered for object detection backbones. When selecting the docking layers, consider that the feature map lengths have to be halved from one docking layer to the other. Rule of thumb: Use the deepest layers for every (lateral) resolution in the backbone (corresponding to one of the required levels for your object detection task).

Information about the names and sizes of the layers in a model can be enquired using *'summary'*.

Default: For the pretrained backbones delivered by HALCON the defaults depend on the classifier. Other classifiers do not have any docking layers set by default and therefore need to have this parameter set before they can be used as backbone.

'batch_size': **Any**

Number of input images (and corresponding labels) in a batch that is transferred to device memory.

For a training using `train_dl_model_batch`, the batch of images which are processed simultaneously in a single training iteration contains a number of images which is equal to *'batch_size'* times *'batch_size_multiplier'*. Please refer to `train_dl_model_batch` for further details.

For inference, the *'batch_size'* can be generally set independently from the number of input images. See `apply_dl_model` for details on how to set this parameter for greater efficiency.

Models of *'type'*='*classification*':

The parameter *'batch_size'* is stored in the pretrained classifier. Per default, the *'batch_size'* is set such that a training of the pretrained classifier with up to `100` classes can be easily performed on a device with `8` gigabyte of memory.

For the pretrained classifiers, the default values are hence given as follows:

pretrained classifier	default value of *'batch_size'*
'pretrained_dl_classifier_alexnet.hdl'	*230*
'pretrained_dl_classifier_compact.hdl'	*160*
'pretrained_dl_classifier_enhanced.hdl'	*96*
'pretrained_dl_classifier_mobilenet_v2.hdl'	*40*
'pretrained_dl_classifier_resnet18.hdl'	*24*
'pretrained_dl_classifier_resnet50.hdl'	*23*

Models of *'type'='counting'***:** The parameter *'batch_size'* has no effect.

*'batch_size_multiplier'***: Any**

Multiplier for *'batch_size'* to enable training with larger numbers of images in one step which would otherwise not be possible due to GPU memory limitations. This model parameter does only affect `train_dl_model_batch` and thus has no impact during evaluation and inference. For detailed information see `train_dl_model_batch`.

Models of *'type'='anomaly_detection'***:** The parameter *'batch_size_multiplier'* has no effect.

Models of *'type'='counting'***:** The parameter *'batch_size_multiplier'* has no effect.

Models of *'type'='ocr_recognition'***:** The parameter *'batch_size_multiplier'* has no effect.

Default: *'batch_size_multiplier' = 1*

'bbox_heads_weight', *'class_heads_weight'***: OD**

The parameters *'bbox_heads_weight'* and *'class_heads_weight'* are weighting factors for the calculation of the total loss. This means, when the losses of the individual networks are summed up, the contributions from the bounding box regression heads are weighted by a factor *'bbox_heads_weight'* and the contributions from the classification heads are weighted by a factor *'class_heads_weight'*.

Default: *'bbox_heads_weight' = 1.0*, *'class_heads_weight' = 1.0*

*'capacity'***: OD**

This parameter roughly determines the number of parameters (or filter weights) in the deeper sections of the object detection network (after the backbone). Its possible values are *'high'*, *'medium'*, and *'low'*.

It can be used to trade-off between detection performance and speed. For simpler object detection tasks, the *'low'* or *'medium'* settings may be sufficient to achieve the same detection performance as with *'high'*.

Default: *'capacity' = 'high'*

*'class_ids'***: 3D-GPD CL MLC OD SE**

Unique IDs of the classes the model shall distinguish. The tuple is of length *'num_classes'*.

We stress out the slightly different meanings and restrictions depending on the model type:

Models of *'type'='3d_gripping_point_detection'***:**

Two classes, in fixed order [*'gripping_map'*, *'background'*], are supported for this model. Therefore, for such a model the tuple has a fixed length of 2. Thereby, you can set any integer within the interval $[0, 65534]$ as class ID value.

Models of *'type'='classification'***:**

The IDs are unique identifiers, which are automatically assigned to each class. The ID of a class corresponds to the index within the tuple *'class_names'*.

Models of *'type'='multi_label_classification'***:**

The IDs are unique identifiers of the classes to be detected. Thereby, you can set any integer as class ID value.

Value range: $[0, 65534]$.

Models of *'type'='detection'***:**

Only the classes of the objects to be detected are included and therewith no background class. Thereby, you can set any integer within the interval $[0, 65534]$ as class ID value.

Note that the values of *'class_ids_no_orientation'* depend on *'class_ids'*. Thus if *'class_ids'* is changed after the creation of the model, *'class_ids_no_orientation'* is reset to an empty tuple.

Default: *'class_ids' = '[0,...,num_classes-1]'*

Models of *'type'='segmentation'***:**

Every class used for training has to be included and therewith also the class ID of the 'background' class. Therefore, for such a model the tuple has a minimal length of 2. Thereby, you can set any integer within the interval $[0, 65534]$ as class ID value.

'class_ids_no_orientation': **OD**

With this parameter you can declare classes, for which the orientation will not be considered, e.g., round or other point symmetrical objects. For each class, whose class ID is present in *'class_ids_no_orientation'*, the network returns axis-aligned bounding boxes.

Note, this parameter only affects networks of *'instance_type'* = *'rectangle2'*.

Note that the values of *'class_ids_no_orientation'* depend on *'class_ids'*. Thus if *'class_ids'* is changed after the creation of the model, *'class_ids_no_orientation'* is reset to an empty tuple.

Default: *'class_ids_no_orientation'* = *[]*

'class_names': **3D-GPD CL MLC OD SE**

Unique names of the classes the model shall distinguish. The order of the class names remains unchanged after the setting. The tuple is of length *'num_classes'*.

Restriction: For a *'3d_gripping_point_detection'* model, the *'class_names'* tuple has a fixed length of 2, with constant value [*'gripping_map'*, *'background'*].

'class_weights': **CL OD**

The parameter *'class_weights'* is a tuple of class specific weighting factors for the loss. Giving the unique classes a different weight, it is possible to force the network to learn the classes with different importance. This is useful in cases where a class dominates the dataset. The weighting factors have to be within the interval $(0, 1)$. Thereby a class gets a stronger impact during the training the larger its weight is. The weights in the tuple *'class_weights'* are sorted the same way as the classes in the tuple *'class_ids'*. We stress out the slightly different meanings and restrictions depending on the model type:

Models of *'type'*=*'classification'*:
Default: *'class_weights'* = *1.0* for each class.

Models of *'type'*=*'detection'*:
Default: *'class_weights'* = *0.25* for each class.

'clear_ood': **CL**

This parameter deactivates the out-of-distribution detection of a deep learning model. All related information will be deleted. `fit_dl_out_of_distribution` can be called to fit the out-of-distribution detection again.

Default: *'true'*

'complexity': **AD**

This parameter controls the capacity of the model to deal with more complex applications. A higher value allows for the model to represent images showing more complexity. Increasing the parameter leads to higher runtimes during training and inference. Please note that this parameter can only be set before the model is trained. Setting *'complexity'* on an already trained model would render this model useless. When trying to do so, an error is returned but the model itself is unchanged.

Default: *'complexity'* = *15*

'device': **Any**

Handle of the device on which the deep learning operators will be executed.

If the model was already optimized for a device, setting *'device'* might not be necessary anymore, see `optimize_dl_model_for_inference` for details.

To get a tuple of handles of all available potentially deep-learning capable hardware devices use `query_available_dl_devices`.

Default: Handle of the default device, thus the GPU with index *0*. If not available, this is an empty tuple.

'extract_feature_maps': **CL**

With this parameter value you can extract feature maps of the specified model layer for an inferred image. The selected layer must be part of the existing network. An overview of all existing layers of the model can be returned by the operator `get_dl_model_param` with the corresponding parameter *'summary'*.

Note, using this option modifies the network architecture: The network is truncated after a selected layer. This modification can not be reversed. If the original network architecture should be used again it must be read in again with the operator `read_dl_model`.

'freeze_backbone_level': **OD**

This parameter determines the backbone levels whose weights are kept (meaning not updated and thus frozen) during training. Thereby the given number signifies the highest level whose layers are frozen in the backbone. Setting *'freeze_backbone_level'* to *0*, for no level the weights are frozen and as a consequence the weights of

all layers are updated. It is recommended to set this in case the weights have been randomly initialized (e.g., after certain changes of the number of image channels) or the in case the backbone is not pretrained.

Default: *'freeze_backbone_level' = 2*

'gc_anomaly_networks': **GC-AD**

This parameter is used to select the subnetworks of the model. The following values can be set:

- *'local'*: The local subnetwork will be extracted.
- *'global'*: The global subnetwork will be extracted.

We refer to Deep Learning / Anomaly Detection and Global Context Anomaly Detection for more general information on the subnetworks and their properties.

Note, the original model contains both a *'local'* and a *'global'* subnetwork. Once the model architecture is reduced to a single subnetwork, the original network is truncated. This cannot be undone. If the original model architecture is to be used again, it must be read in again with `read_dl_model`.

Default: *'gc_anomaly_networks' = ['local', 'global']*

'gpu': **Any**

Identifier of the GPU where the training and inference operators (`train_dl_model_batch` and `apply_dl_model`) are executed. Per default, the first available GPU is used. `get_system` with *'cuda_devices'* can be used to retrieve a list of available GPUs. Pass the index in this list to *'gpu'*.

Note that the parameter *'gpu'* is only taken into account for *'runtime' = 'gpu'*. Therefore, it is preferable to set the GPU device, on which operators are run, using the parameter *'device'*. executed.

Default: *'gpu' = 0*

'ignore_class_ids': **SE**

With this parameter you can declare one or multiple classes as 'ignore' classes, see the chapter Deep Learning / Semantic Segmentation and Edge Extraction for further information. These classes are declared over their ID (integers).

Note, you can not set a class ID in *'ignore_class_ids'* and *'class_ids'* simultaneously.

'ignore_direction': **OD**

This parameter determines whether for the oriented bounding box also the direction of the object within the bounding box is considered or not. In case the direction within the bounding box is not to be considered you can set *'ignore_direction'* to *'true'*. In order to determine the bounding box unambiguously, in this case (but only in this case) the following conventions apply:

- $-\pi/2 <$ *'phi'* $\leq \pi/2$
- *'bbox_length1' > 'bbox_length2'*

This is consistent to `smallest_rectangle2`.

Note, this parameter only affects networks of *'instance_type' = 'rectangle2'*.

List of values: *'true'*, *'false'*

Default: *'ignore_direction' = 'false'*

'image_dimensions': **3D-GPD AD CL MLC OCR-D OCR-R GC-AD OD SE**

Tuple containing the input image dimensions *'image_width'*, *'image_height'*, and number of channels *'image_num_channels'*.

The respective default values and possible value ranges depend on the model and model type. Please see the individual dimension parameter description for more details.

'image_height', *'image_width'*: **3D-GPD AD CL MLC OCR-D OCR-R GC-AD OD SE**

Height and width of the input images, respectively, that the network will process.

This parameter can attain different values depending on the model type:

Models of *'type'='3d_gripping_point_detection'*:

The network architectures allow changes of the image height and width.
The default values are given by the network, see `read_dl_model`.

Models of *'type'='anomaly_detection'*:

The default values depend on the specific pretrained network, see `read_dl_model`. The network architectures allow changes of the image dimensions, which can be done using `set_dl_model_param`. Please also refer to `read_dl_model` for restrictions each of the delivered networks has on the input image size. Note that these parameters have to be set before training the model. Setting them on an already trained model would render this model useless. When trying to do so, an error is returned but the model itself is unchanged.

Models of *'type'='classification'*:
The default values depend on the specific pretrained classifier, see `read_dl_model`. The network architectures allow changes of the image dimensions, which can be done using `set_dl_model_param`. But for networks with at least one fully connected layer such a change makes a retraining necessary. Networks without fully connected layers are directly applicable to different image sizes. However, images with a size differing from the size with which the classifier has been trained are likely to show a reduced classification accuracy.

Models of *'type'='detection'*:
The network architectures allow changes of the image dimensions. But the image lengths are halved for every level, that is why the dimensions *'image_width'* and *'image_height'* need to be an integer multiple of 2^{level}. $level$ depends on the *'backbone'* and the parameter *'max_level'*, see `create_dl_model_detection` for further information.
Default: *'image_height'* = *640*, *'image_width'* = *640*

Models of *'type'='gc_anomaly_detection'*:
The network architecture allows changes of the image dimensions. Note that these parameters have to be set before training the model. Setting them on an already trained model would render this model useless.
Restriction: The *'image_width'* and the *'image_height'* must be greater than or equal to the value of the *'patch_size'* parameter.
Default: *'image_height'* = *256*, *'image_width'* = *256*

Models of *'type'='ocr_recognition'*:
The network architectures allow changes of the image width.
The default and minimal values are given by the network, see `read_dl_model`.

Models of *'type'='segmentation'*:
The network architectures allow changes of the image dimensions.
The default and minimal values are given by the network, see `read_dl_model`.

'image_num_channels': **3D-GPD AD CL MLC OCR-D OCR-R GC-AD OD SE**
Number of channels of the input images the network will process. The default value is given by the network, see `read_dl_model` and `create_dl_model_detection`.

For models of *'type'='anomaly_detection'* or *'type'='gc_anomaly_detection'*, only the values *1* and *3* are supported. In addition, this parameter should be set before the model is trained. For models of *'type'='anomaly_detection'*, setting *'image_num_channels'* on an already trained model would render this model useless. Therefore, an error is returned when trying to do so, but the model itself is unchanged.

Restriction: For models of *'type'='3d_gripping_point_detection'* the parameter *'image_num_channels'* cannot be set.

For other models, any number of input image channels is possible.

If number of channels is changed to a value >1, the weights of the first layers after the input image layer will be initialized with random values. Note, in this case more data for the retraining is needed. If the number of channels is changed to 1, the weights of the concerned layers are fused.

Models of *'type'='anomaly_detection'*:
Default: *'image_num_channels'* = *3*

Models of *'type'='detection'*:
Default: *'image_num_channels'* = *3*

'image_range_max', *'image_range_min'*: **3D-GPD AD CL MLC OCR-D OCR-R GC-AD OD SE**
Maximum and minimum gray value of the input images, respectively, the network will process.

The default values are given by the network, see `read_dl_model` and `create_dl_model_detection`.

'image_size': **3D-GPD AD CL MLC OCR-D OCR-R GC-AD OD SE**
Tuple containing the input image size *'image_width'*, *'image_height'*.

The respective default values and possible value ranges depend on the model and model type. Please see the individual dimension parameter description for more details.

'input_dimensions': **Any**
This parameter returns a dictionary containing all input dimensions of the network. Examples for such inputs: input image, `weight_image` (for models of *'type'='segmentation'*).

These dimensions are given in the dictionary as a tuple [`width`, `height`, `depth`]. In case this parameter is used to set the dimension, for every dimension a value of -1 may be set to keep the current value.

'instance_segmentation': **OD**

This parameter determines if the model is created for instance segmentation. If the parameter is set to *'true'* in `create_dl_model_detection`, the detection deep learning network is extended by additional layers for instance segmentation.

List of values: *'true'*, *'false'*

Default: *'instance_segmentation'* = *'false'*

'instance_type': **OD**

The parameter *'instance_type'* determines, which instance type is used for the object model. The current implementations differ regarding the allowed orientations of the bounding boxes. See the chapter Deep Learning / Object Detection and Instance Segmentation for more explanations to the different types and their bounding boxes.

List of values: *'rectangle1'*, *'rectangle2'*

Default: *'instance_type'* = *'rectangle1'*

'layer_names': **Any except 3D-GPD**

This parameter returns a tuple containing the name for every layer of the model. This name is the same human-readable identifier as is returned by `get_dl_model_param` with *'summary'*.

Note, for some networks distributed with HALCON, the network architecture is confidential. In this case `get_dl_model_param` returns an empty tuple with *'layer_names'*.

'learning_rate': **Any**

Value of the factor determining the gradient influence during training using `train_dl_model_batch`. Please refer to `train_dl_model_batch` for further details.

The default values depend on the model. Note that changing *'solver_type'* sets *'learning_rate'* back to its default value.

Models of *'type'*=*'anomaly_detection'*:

The parameter *'learning_rate'* has no effect.

Models of *'type'*=*'counting'*:

The parameter *'learning_rate'* has no effect.

'mask_head_weight': **OD**

The parameter *'mask_head_weight'* is a weighting factor for the calculation of the total loss. This means, when the losses of the individual network heads are summed up, the contribution from the mask prediction head is weighted by a factor *'mask_head_weight'*.

Restriction: Only applicable to models with *'instance_segmentation'*=*'true'*

Default: *'mask_head_weight'* = *1.0*

'max_level', *'min_level'*: **OD**

These parameters determine on which levels the additional networks are attached on the feature pyramid. We refer to the chapter Deep Learning / Object Detection and Instance Segmentation for further explanations to the feature pyramid and the attached networks.

From these (*'max_level'* - *'min_level'* + 1) networks all predictions with a minimum confidence value are kept as long they do not strongly overlap (see *'min_confidence'* and *'max_overlap'*).

The level declares how often the size of the feature map already has been scaled down. Thus, level 0 corresponds to the feature maps with size of the input image, level 1 to feature maps subscaled once, and so on. As a consequence, smaller objects are detected in the lower levels, whereas larger objects are detected in higher levels.

The value for *'min_level'* needs to be at least 2.

If *'max_level'* is larger than the number of levels the backbone can provide, the backbone is extended with additional (randomly initialized) convolutional layers in order to generate deeper levels. Further, *'max_level'* may have an influence on the minimal input image size.

Note, for small input image dimensions, high levels might not be meaningful, as the feature maps could already be too small to contain meaningful information.

A higher number of used levels might increase the runtime and memory-consumption, whereby especially lower levels carry weight.

Default: *'max_level'* = *6*, *'min_level'* = *2*

'max_num_detections': **OD**

This parameter determines the maximum number of detections (bounding boxes) per image proposed from the network.

Default: *'max_num_detections'* = *100*

'max_overlap': **OD**

The maximum allowed intersection over union (IoU) for two predicted bounding boxes of the same class. Or, vice-versa, when two bounding boxes are classified into the same class and have an IoU higher than *'max_overlap'*, the one with lower confidence value gets suppressed. We refer to the chapter Deep Learning / Object Detection and Instance Segmentation for further explanations to the IoU.

Default: *'max_overlap' = 0.5*

'max_overlap_class_agnostic': **OD**

The maximum allowed intersection over union (IoU) for two predicted bounding boxes independently of their predicted classes. Or, vice-versa, when two bounding boxes have an IoU higher than *'max_overlap_class_agnostic'*, the one with lower confidence value gets suppressed. As default, *'max_overlap_class_agnostic'* is set to 1.0, hence class agnostic bounding box suppression has no influence.

Default: *'max_overlap_class_agnostic' = 1.0*

'meta_data': **Any**

Dictionary with user defined meta data, whose entries can be set freely. The meta data may be used to store information such as the model author or a model version along with the model.

Restriction: Dictionary values are limited to strings.

'min_character_score': **OCR-D**

The parameter *'min_character_score'* specifies the lower threshold used for the character score map to estimate the dimensions of the characters. By adjusting the parameter, suggested instances can be split up or neighboring instances can be merged.

Value range: $\in [0, 1]$.

Default: *0.5*

'min_confidence': **MLC OD**

Models of *'type'='detection'*: This parameter determines the minimum confidence, when the image part within the bounding box is classified in order to keep the proposed bounding box. This means, when `apply_dl_model` is called, all output bounding boxes with a confidence value smaller than *'min_confidence'* are suppressed.

Models of *'type'='multi_label_classification'*: This parameter determines the minimum confidence level required for a class to be considered as detected. This means, classes with a confidence score below *'min_confidence'* are regarded as not detected, while classes with a confidence value equal to or exceeding *'min_confidence'* are deemed as detected.

Default: *'min_confidence' = 0.5*

'min_link_score': **OCR-D**

The parameter *'min_link_score'* defines the minimum link score required between two localized characters to recognize these characters as coherent word.

Value range: $\in [0, 1]$.

Default: *0.3*

'min_version': **Any**

The parameter *'min_version'* defines the minimum required HALCON version to use this model.

'min_word_area': **OCR-D**

The parameter *'min_word_area'* defines the minimum size that a localized word must have in order to be suggested. This parameter can be used to filter suggestions that are too small.

Value range: ≥ 0.

Default: *10*.

'min_word_score': **OCR-D**

The parameter *'min_word_score'* defines the minimum score a localized instance must contain to be suggested as valid word. With this parameter uncertain words can be filtered out.

Value range: $\in [0, 1]$.

Default: *0.7*

'momentum': **Any**

When updating the weights of the network, the hyperparameter *'momentum'* specifies to which extent previous updating vectors will be added to the current updating vector. Only applicable for *'solver_type' = 'sgd'*.

Please refer to train_dl_model_batch for further details.

The default value is given by the model.

Models of *'type'='anomaly_detection'*: The parameter *'momentum'* has no effect.

Models of *'type'='counting'*: The parameter *'momentum'* has no effect.

'num_classes': **OD SE**

Number of distinct classes that the model is able to distinguish for its predictions.

This parameter differs between the model types:

Models of *'type'='detection'*:

This parameter is set as NumClasses over create_dl_model_detection. *'class_ids'* and *'class_names'* always need to have *'num_classes'* entries.

Models of *'type'='segmentation'*:

A model of *'type'='segmentation'* does predict background and therefore in this case the 'background' class is included in *'num_classes'*. For these models, *'num_classes'* is determined implicitly by the length of *'class_ids'*.

'num_trainable_params': **Any**

Number of trainable parameters (weights and biases) of the model. This value is an indicator for the size of the model when it is serialized.

'ood_available': **CL**

This parameter specifies whether a classification model has been extended for Out-of-Distribution Detection. If the operator fit_dl_out_of_distribution has been called for the model, the value of *'ood_available'* is *'true'*. Otherwise it is *'false'*.

Default: *'false'*

'ood_threshold': **CL**

A threshold that determines when a sample is classified as Out-of-Distribution. After calling fit_dl_out_of_distribution for a classification model, apply_dl_model additionally returns an *'ood_score'* and an *'ood_result'* in the output dictionaries. If the value of *'ood_score'* is greater than or equal to *'ood_threshold'*, the value of *'ood_result'* is *'true'*. Otherwise it is *'false'*. *'ood_threshold'* is only available after fit_dl_out_of_distribution has been called. That operator calculates a value for *'ood_threshold'* based on the provided dataset.

Value range: ≥ 0.

'orientation': **OCR-D**

This parameter allows to set a predefined orientation angle for the word detection. To revert to default behavior using the internal orientation estimation, *'orientation'* is set to *'auto'*.

Value range: $(-\pi, \pi]$.

Default: *'auto'*

'optimize_for_inference': **3D-GPD CL MLC OCR-D OCR-R GC-AD OD SE Gen**

Defines whether the model is optimized and only applicable for inference.

The model remains executable on HALCON standard devices even after optimization (unlike optimize_dl_model_for_inference).

Setting this parameter to *'true'* frees model memory not needed for inference (e.g., memory of gradients). This can significantly reduce the amount of memory needed by the model. As a consequence, models with this characteristic have no gradients accessible (needed e.g., for training or calculations of heatmaps). Operators using values from freed memory (e.g., train_dl_model_batch) will automatically reset this parameter value to *'false'*.

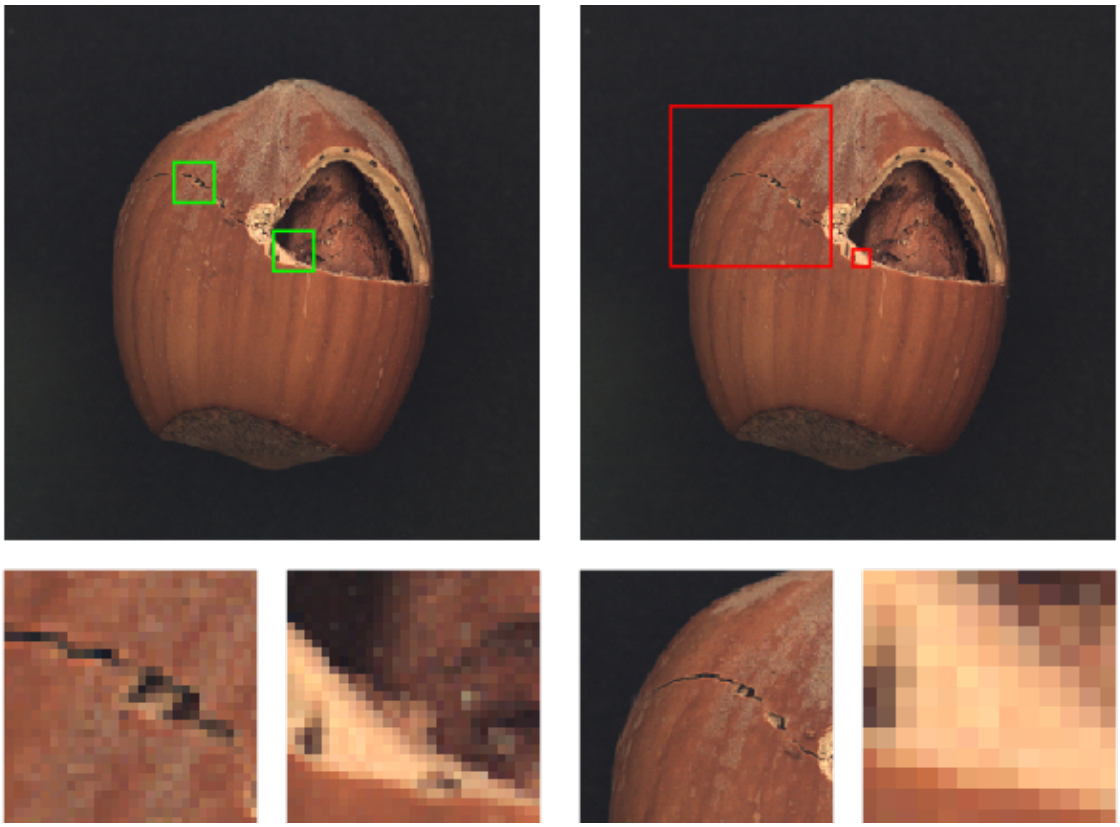
In case the value is reset to *'false'* (both, manually or automatically), memory needed by the model for training is reallocated. This implies, a following training behaves as if *'momentum'* is temporarily set to *0* (as possible updating vectors have to be accumulated again).

Default: *'false'*

Restriction: For models of *'type'='counting'* the parameter *'optimize_for_inference'* cannot be set to *'true'*.

'patch_size': **GC-AD**

This parameter determines the size of the patches analyzed by the *'local'* subnetwork. The patch size should be chosen such that patches containing defects will differ clearly from patches without defects. This should cover all kinds of anomalies that might occur during inference. The patch size does not need to cover the defects as a whole. Note that the image is not divided into separate patches, but *'patch_size'* solely determines the scale on which the image is gradually analyzed by the *'local'* subnetwork. If the image size is changed *'patch_size'* should be adjusted accordingly.



(1) (2)

(1) Examples of patches with a suitable size (green). (2) The example patches (red) are either too large or too small to work for all possible defect classes that could occur in the images.

Restriction: The parameter *'patch_size'* must be smaller than or equal to *'image_width'* and *'image_height'*.

Default: *'patch_size'* = *33*

'precision': **Any**

Defines the data type that is internally used for the calculation of a forward pass of a deep learning model.

Default: *'float32'*

'precision_is_converted': **Any**

Indicates whether the model was subjected to a conversion process after training done by `optimize_dl_model_for_inference`.

Default: *'false'*

'runtime': **Any**

Defines the device on which the deep learning operators will be executed.

Note that the parameter *'device'* should be preferred to set the devices on which the deep learning operators will be executed.

Default: *'runtime'* = *'gpu'*

'cpu':

The training and inference operator will be executed on CPU. Note, training is only supported for specific platform types, please see the HALCON "`Installation Guide`".
In case the GPU has been used before, CPU memory is initialized, and if necessary values stored on the GPU memory are moved to the CPU memory.
For parallelization: The runtime is highly dependent on the number of threads set. The use of all available threads does not necessarily create a faster performance. How many threads are currently set can be queried with the operator `get_system`.
The implemented CPU parallelization is dependent on the architecture:

- Intel or AMD architecture: OpenMP. By default all available threads of the OpenMP runtime environment are used. The number of threads used can be specified with the parameter *'tsp_thread_num'* of the operator `set_system`.
- Arm architectures: Global Thread Pool. The number of threads can be set with the global parameter *'thread_num'* of the operator `set_system`.

For both architectures mentioned above, it is not possible to specify a thread-specific number of threads (via the parameter *'tsp_thread_num'* of the operator `set_system`).

'gpu':
The GPU memory is initialized. The operators `apply_dl_model`, `train_dl_model_batch`, and `train_dl_model_anomaly_dataset` will be executed on the GPU. For the specific requirements please refer to the HALCON "`Installation Guide`".

'solver_type': **Any**
This value defines the optimization algorithm with the goal to minimize the value of the total loss function. For more information we refer to the documentation of `train_dl_model_batch`. The following values can be set:

- *'adam'*: Adaptive moment estimation
- *'sgd'*: Stochastic gradient descent

Note that changing *'solver_type'* sets *'learning_rate'* back to its default value.

Models of *'type'*=*'anomaly_detection'*: The parameter *'solver_type'* has no effect.

Models of *'type'*=*'counting'*: The parameter *'solver_type'* has no effect.

'sort_by_line': **OCR-D**
The words are sorted line-wise based on the orientation of the localized word instances. If the parameter *'sort_by_line'* is set to *'false'*, the results will not be sorted.

Default: *'true'*

'standard_deviation_factor': **AD**
The anomaly score is calculated internally as the mean of certain internal scores s plus lambda times their standard deviation.

$$S_{Image} = \mu(s) + \lambda\sigma(s)$$

Where s denotes a pixel value of the internal `anomaly_image`, $\mu(s)$ the mean value of s and $\sigma(s)$ the standard deviation of s. The parameter *'standard_deviation_factor'* sets the value λ and thus controls how important the standard deviation is in comparison to the mean.

Default: *'standard_deviation_factor' = 3.0*

'summary': **Any**
This parameter returns information on the layers of the model. More precisely, it returns a tuple with a string for every layer. The string is as follows: `ID; NAME; TYPE; OUTPUT_SHAPE; CONNECTED_NODES`

- `ID`: Index of the layer in the CNN graph.
- `NAME`: Human-readable identifier (optional).
- `TYPE`: Human-readable identifier representing the type of the layer (e.g., `input` or `convolution`).
- `OUTPUT_SHAPE`: Size of the output, given in the form (`Width`, `Height`, `Depth`, *'batch_size'*). This means, the layer has feature maps of size `Width` times `Height` and therefrom `Depth` many. Together they form an iconic object with a channel for every feature map. The parameter *'batch_size'* determines, how many objects are returned together.
- `CONNECTED_NODES`: Comma separated list with IDs of the layers using the output of the current layer as input

E.g., `'3; conv1; convolution; (112, 112, 64, 160); 4'`.

Note, for some networks distributed with HALCON, the network architecture is confidential. In this case `get_dl_model_param` returns an empty tuple with *'summary'*.

'tiling': **OCR-D**
The input image is automatically split into overlapping tile images of size *'image_size'*, which are processed separately by the model. This allows processing images that are much larger than the actual *'image_size'* without having to zoom the input image. **Default:** *'false'*

'tiling_overlap': **OCR-D**
This parameter defines how much neighboring tiles overlap when input images are split (see *'tiling'*). The overlap is given in pixels.

Value range: ≥ 0.

Default: *64*

'type': **Any**

This parameter returns the HALCON-specific model type. The following types are distinguished:

- *'3d_gripping_point_detection'*
- *'anomaly_detection'*
- *'classification'*
- *'counting'*
- *'detection'*
- *'gc_anomaly_detection'*
- *'segmentation'*
- *'ocr_recognition'*
- *'ocr_detection'*
- *'generic'* - for certain read in models or models created with the DL framework, see `set_dl_model_param`.

'weight_prior': **Any**

Regularization parameter $\alpha \geq 0.0$ used for the regularization of the loss function. For a detailed description of the regularization term we refer to `train_dl_model_batch`. Simply put: Regularization favors simpler models that are less likely to learn noise in the data and generalize better. In case the classifier overfits the data, it is strongly recommended to try different values for the parameter *'weight_prior'* to improve the generalization properties of the neural network. Choosing its value is a trade-off between the models ability to generalize, overfitting, and underfitting. If α is too small, the model might overfit, if its too large the model might loose its ability to fit the data, because all weights are effectively zero. For finding an ideal value for α, we recommend a cross-validation, i.e. to perform the training for a range of values and choose the value that results in the best validation error. For typical applications, we recommend testing the values for *'weight_prior'* on a logarithmic scale between $1.0, ..., 0.0001$. If the training takes a very long time, one might consider performing the hyperparameter optimization on a reduced amount of data.

Models of *'type'*=*'anomaly_detection'*: The parameter *'weight_prior'* has no effect.

Models of *'type'*=*'counting'*: The parameter *'weight_prior'* has no effect.

Default: *'weight_prior'* = *0.0*, with exception of the pretrained classifiers

- `pretrained_dl_classifier_resnet18`: *'weight_prior'* = *0.0001*
- `pretrained_dl_classifier_resnet50`: *'weight_prior'* = *0.0001*
- `pretrained_dl_classifier_alexnet`: *'weight_prior'* = *0.0005*

Parameters

▷ **`DLModelHandle`** (input_control) . . . . . dl_model ⇝ *handle*
Handle of the deep learning model.

▷ **`GenParamName`** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'batch_size'
List of values: `GenParamName` ∈ {'adam_beta1', 'adam_beta2', 'adam_epsilon', 'alphabet', 'alphabet_internal', 'alphabet_mapping', 'anchor_aspect_ratios', 'anchor_num_subscales', 'anchor_angles', 'anomaly_score_tolerance', 'backbone', 'backbone_docking_layers', 'batch_size', 'batch_size_multiplier', 'bbox_heads_weight', 'capacity', 'class_heads_weight', 'class_ids', 'class_ids_no_orientation', 'class_names', 'class_weights', 'complexity', 'device', 'extract_feature_maps', 'freeze_backbone_level', 'gc_anomaly_networks', 'gpu', 'ignore_class_ids', 'ignore_direction', 'image_dimensions', 'image_height', 'image_num_channels', 'image_range_max', 'image_range_min', 'image_size', 'image_width', 'input_dimensions', 'instance_segmentation', 'instance_type', 'layer_names', 'learning_rate', 'mask_head_weight', 'max_level', 'max_num_detections', 'max_overlap', 'max_overlap_class_agnostic', 'meta_data', 'min_character_score', 'min_confidence', 'min_level', 'min_link_score', 'min_word_area', 'min_word_score', 'momentum', 'num_classes', 'num_trainable_params', 'ood_available', 'ood_threshold', 'optimize_for_inference', 'orientation', 'sort_by_line', 'patch_size', 'precision', 'precision_is_converted', 'runtime', 'solver_type', 'standard_deviation_factor', 'summary', 'tiling', 'tiling_overlap', 'type', 'weight_prior', 'model_uid', 'release_version', 'min_version'}

▷ **`GenParamValue`** (output_control) . . . . . attribute.name(-array) ⇝ *integer* / string / real
Value of the generic parameter.

Result

If the parameters are valid, the operator `get_dl_model_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_dl_model`, `set_dl_model_param`

Possible Successors

`set_dl_model_param`, `apply_dl_model`, `train_dl_model_batch`, `train_dl_model_anomaly_dataset`

See also

`set_dl_model_param`

Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
3D Metrology, OCR/OCV, Matching, Deep Learning Enhanced, Deep Learning Professional

get_dl_pruning_param (: : DLPruningHandle, GenParamName : GenParamValue)

Get information from a pruning data handle.

`get_dl_pruning_param` returns the parameter and pruning values `GenParamValue` of `GenParamName` from the pruning data handle `DLPruningHandle`.

The values of following parameters `GenParamName` can be retrieved:

'mode': Specifies the pruning method See `create_dl_pruning` for further information.
Default: *'oracle'*

'percentage': Determines how much will be removed in percents. E.g., in case of *'mode'='oracle'* it specifies the relative amount of possibly removable kernels to be removed, whereby only removable kernels are considered.
Default: *10*

Additionally, for *'mode'='oracle'*, the following pruning values can be retrieved using `GenParamName`:

'prunable_conv_num': Number of prunable convolutional layers in the network. Whether a layer is prunable depends on the specifications of the layer itself as well as the network architecture.

'prunable_conv_layer_name': Names of the prunable convolutional layers in the network.

'prunable_kernel_num': Number of prunable convolution kernels in the network. It considers that a pruned convolution has to retain at least 1 convolution kernel.

'pruned_kernel_num': Number of pruned convolution kernels in the network after a call of `gen_dl_pruned_model`.

'pruned_percentage': Actual percentage of pruned convolution kernels in the network after a call of `gen_dl_pruned_model`: the ratio *'pruned_kernel_num'* versus *'prunable_kernel_num'*.

The following table gives an overview, which parameters and values can be set using `set_dl_pruning_param` and which ones can be retrieved using `get_dl_pruning_param`.

Parameters	set	get
'mode'	x	x
'percentage'	x	x
'prunable_conv_num'		x
'prunable_conv_layer_name'		x
'prunable_kernel_num'		x
'pruned_kernel_num'		x
'pruned_percentage'		x

Parameters

▷ **DLPruningHandle** (input_control) . . . . . dl_pruning ⇝ *handle*
Pruning data handle.

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'percentage'
List of values: GenParamName ∈ {'mode', 'percentage', 'prunable_conv_num', 'prunable_conv_layer_name', 'prunable_kernel_num', 'pruned_kernel_num', 'pruned_percentage'}

▷ **GenParamValue** (output_control) . . . . . attribute.name(-array) ⇝ *integer* / string / real
Value of the generic parameter.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

set_dl_pruning_param

Module

Deep Learning Professional

read_dl_model (: : FileName : DLModelHandle)

Read a deep learning model from a file.

The operator read_dl_model reads a deep learning model. Such models have to be in the HALCON format or in the ONNX format (see the reference below). Restrictions apply to the latter. As a result, the handle DLModelHandle is returned.

The model is loaded from the file FileName. This file is thereby searched in the directory $HALCONROOT/dl/ as well as in the currently used directory. The default HALCON file extension for deep learning networks is '.hdl'.

Please note that the values of runtime specific parameters are not written to file, see write_dl_model. As a consequence, when reading a model, these parameters are initialized with their default value, see get_dl_model_param.

Models that require a higher HALCON version (*'min_version'*) than the one currently in use cannot be read. Before writing a model the *'min_version'* can be checked with the operator get_dl_model_param.

For further explanations on deep learning models in HALCON, see the chapter Deep Learning / Model.

Reading in a Model Provided by HALCON

HALCON provides pretrained neural networks for classification and semantic segmentation. These neural networks are good starting points when training a custom network. They have been pretrained on a large image dataset. For anomaly detection, HALCON provides initial models.

Models for 3D Gripping Point Detection

The following network is provided for 3D Gripping Point Detection:

'pretrained_dl_3d_gripping_point.hdl'

The network expects up to 5 images of type `real`:

'image': intensity (gray value) image

'x': X-image (values need to increase from left to right)

'y': Y-image (values need to increase from top to bottom)

'z': Z-image (values need to increase from points close to the sensor to far points; this is for example the case if the data is given in the camera coordinate system)

'normals': 2D mappings

Additionally, the network requires certain image properties (for all input images mentioned above). The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values:

'image_width': 640

'image_height': 480

The network architecture allows changes concerning the image dimensions.

Models for Anomaly Detection

The following networks are provided for anomaly detection:

'initial_dl_anomaly_medium.hdl'

This neural network is designed to be memory and runtime efficient.

The network expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values:

'image_width': 480

'image_height': 480

'image_num_channels': 3

'image_range_min': -2

'image_range_max': 2

The network architecture allows changes concerning the image dimensions, but the sizes *'image_width'* and *'image_height'* have to be multiples of 32 pixels, resulting in a minimum of 32 pixels.

'initial_dl_anomaly_large.hdl'

This neural network is assumed to be better suited for more complex anomaly detection tasks. This comes at the cost of being more time and memory demanding.

The network expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values:

'image_width': 480

'image_height': 480

'image_num_channels': 3

'image_range_min': -2

'image_range_max': 2

The network architecture allows changes concerning the image dimensions, but the sizes *'image_width'* and *'image_height'* have to be multiples of 32 pixels, resulting in a minimum of 32 pixels.

Models for Global Context Anomaly Detection

The following networks are provided for Global Context Anomaly Detection:

'pretrained_dl_anomaly_global_context.hdl'

The network expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values:

'image_width': 256

'image_height': 256

'image_num_channels': 3

'image_range_min': -127.0

'image_range_max': 128.0

Models for Classification

The following pretrained neural networks are provided for classification and usable as backbones for detection:

'pretrained_dl_classifier_alexnet.hdl':

This neural network is designed for simple classification tasks. It is characterized by its convolution kernels in the first convolution layers, which are larger than those in other networks with comparable classification performance (e.g., *'pretrained_dl_classifier_compact.hdl'*). This may be beneficial for feature extraction.

This classifier expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224

'image_height': 224

'image_num_channels': 3

'image_range_min': -127.0

'image_range_max': 128.0

The network architecture allows changes concerning the image dimensions. *'image_width'* and *'image_height'* should not be less than 29 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Changing the image size will reinitialize the weights of the fully connected layers and therefore makes a retraining necessary.

Note that one can improve the runtime for this network by fusing the convolution and ReLU layers, see `set_dl_model_param` and the parameter *'fuse_conv_relu'*.

'pretrained_dl_classifier_compact.hdl':

This neural network is designed to be more memory and runtime efficient.

The classifier expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224

'image_height': 224

'image_num_channels': 3

'image_range_min': -127.0

'image_range_max': 128.0

This network does not contain any fully connected layer. The network architecture allows changes concerning the image dimensions. *'image_width'* and *'image_height'* should not be less than 15 pixels.

'pretrained_dl_classifier_enhanced.hdl':

This neural network has more hidden layers than *'pretrained_dl_classifier_compact.hdl'* and is therefore assumed to be better suited for more complex classification tasks. This comes at the cost of being more time and memory demanding.

The classifier expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224

'image_height': 224

'image_num_channels': 3

'image_range_min': -127.0

'image_range_max': 128.0

The network architecture allows changes concerning the image dimensions. *'image_width'* and *'image_height'* should not be less than 47 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Changing the image size will reinitialize the weights of the fully connected layers and therefore makes a retraining necessary.

'pretrained_dl_classifier_mobilenet_v2.hdl':

This classifier is a small and low-power model, for what reason it is more suitable for mobile and embedded vision applications.

The classifier expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224

'image_height': 224

'image_num_channels': 3

'image_range_min': -127.0

'image_range_max': 128.0

The network architecture allows changes concerning the image dimensions. *'image_width'* and *'image_height'* should not be less than 32 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly.
On the GPU, the network architecture can benefit greatly from special optimizations, without which the network can be significantly slower.

'pretrained_dl_classifier_resnet18.hdl':

As the neural network *'pretrained_dl_classifier_enhanced.hdl'*, this classifier is suited for more complex tasks. However, due to its special structure, it provides the advantage of making the training more stable and internally more robust. Compared to the neural network *'pretrained_dl_classifier_resnet50.hdl'* it is less complex and has faster inference times.
The classifier expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224

'image_height': 224

'image_num_channels': 3

'image_range_min': -127.0

'image_range_max': 128.0

The network architecture allows changes concerning the image dimensions. *'image_width'* and *'image_height'* should not be less than 32 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Despite the fully connected layer a change of the image size does not lead to a reinitialization of the weights.

'pretrained_dl_classifier_resnet50.hdl':

As the neural network *'pretrained_dl_classifier_enhanced.hdl'*, this classifier is suited for more complex tasks. However, due to its special structure, it provides the advantage of making the training more stable and internally more robust.
The classifier expects the images to be of the type `real`. Additionally, the network requires certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224

'image_height': 224

'image_num_channels': 3

'image_range_min': -127.0

'image_range_max': 128.0

The network architecture allows changes concerning the image dimensions. *'image_width'* and *'image_height'* should not be less than 32 pixels. There is no maximum image size, but large image sizes will increase the memory demand and the runtime significantly. Despite the fully connected layer a change of the image size does not lead to a reinitialization of the weights.

Models for Semantic Segmentation

The following pretrained neural networks are provided for semantic segmentation:

'pretrained_dl_edge_extractor.hdl':

This neural network is designed and pretrained for edge extraction. As a consequence this model is meant for two class problems with one class for edges and one for background.
This network expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the model has been trained:

'image_width': 512

'image_height': 512
'image_num_channels': 1
'image_range_min': -127.0
'image_range_max': 128.0
'num_classes': 2

The network architecture allows changes concerning the image dimensions, but the sizes *'image_width'* and *'image_height'* have to be multiples of 16 pixels, resulting in a minimum of 16 pixels.

'pretrained_dl_segmentation_compact.hdl':
This neural network is designed to handle segmentation tasks with detailed structures and uses only few memory and is runtime efficient.
The network architecture allows changes concerning the image dimensions, but requires a minimum *'image_width'* and *'image_height'* of 21 pixels.

'pretrained_dl_segmentation_enhanced.hdl':
This neural network has more hidden layers than *'pretrained_dl_segmentation_compact.hdl'* and is therefore better suited for segmentation tasks including more complex scenes.
The network architecture allows changes concerning the image dimensions, but requires a minimum *'image_width'* and *'image_height'* of 47 pixels.

Models for Deep OCR

The following pretrained neural networks are provided for Deep OCR:

'pretrained_deep_ocr_detection.hdl':
This neural network is the default pretrained detection component of a Deep OCR model, but can be retrained, too. It is designed to detect words in images.
This network expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the model has been trained:

'image_width': 1024
'image_height': 1024
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0

The network architecture allows changes concerning the image dimensions *'image_width'* and *'image_height'*.

'pretrained_deep_ocr_detection_compact.hdl':
This neural network is a more efficient pretrained network that can be used as detection component of a Deep OCR model. It is designed to detect words in images, and it can be retrained as well. This neural network is designed to be more memory and runtime efficient.
Regarding the input images and image dimensions, this network has the same requirements as the default model *'pretrained_deep_ocr_detection_compact.hdl'*.

'pretrained_deep_ocr_recognition.hdl':
This neural network is the default pretrained recognition component of a Deep OCR model, but can be retrained, too. It is designed to recognize words in images that are cropped to a single word.
This network expects the images to be of the type `real`. Additionally, the network is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the model has been trained:

'image_width': 120
'image_height': 32
'image_num_channels': 1
'image_range_min': -1.0
'image_range_max': 1.0

The network architecture allows changes concerning the image width *'image_width'*. The image height *'image_height'* cannot be changed. The parameter *'image_width'* is very important: its value can be decreased or increased to adapt to the expected lengths of words, e.g., due to the average width per character. A bigger *'image_width'* will consume more time and memory resources. The image width *'image_width'* may be changed after training.

Reading in a Model in the ONNX Format

You can read in an ONNX model, but there are some points to consider.

Restrictions

Reading in ONNX models with `read_dl_model`, some restrictions apply:

- Version 1.8.1 of the ONNX specification is supported. This means only operators until ONNX operator set version (OpSetVersion) 13 are supported. For operators with a higher OpSetVersion there is no guarantee that it can be supported. Further limitations are listed above.
- Only 32 bit floating point tensors are supported.
- Only models ending with a SoftMax layer are automatically recognized as classifiers. All other models are considered as generic model, thus models of *'type'* = *'generic'*. `set_dl_model_param` can be used to change the model type.
- The input graph nodes (images) must be of shape dimension 4: Number of images (=*'batch_size'*), *'num_channels'*, *'image_height'*, and *'image_width'*.

Automatic transformations

After reading an ONNX model with `read_dl_model`, some network transformations are executed automatically:

- Every non-global pooling layer with a resulting feature map of size 1x1 is converted to a global pooling layer. Doing so enables resizable input images. For more information about pooling layer and possible modes of operation, see the "`Solution Guide on Classification`".
- Layer pairs consisting of a convolution layer without activation and a directly connected activation layer with ReLU activation are fused. In order to so do, the output of the convolution layer is only used as input for the activation layer. As a result a convolution layer with activation mode ReLU is obtained. For more information about layers and possible modes of operation, see the "`Solution Guide on Classification`".

Supported operations

ONNX models with the following operations can be read by `read_dl_model`:

`'Add'`: No restrictions.

`'ArgMax'`: The following restrictions apply:

- attribute *'axis'*: The value must be *1*.
- attribute *'keepdims'*: The value must be *1*.
- attribute *'select_last_index'*: The value must be *0*.

`'AveragePool'`: The following restrictions apply:

- attribute *'count_include_pad'*: The value must be *0*.

`'BatchNormalization'`: No restrictions.

`'Clip'`: The following restrictions apply:

- attribute *'min'*: The value must be *0*.
- attribute *'max'*: The value must be greater than *0* and less than maximum float number.

`'Concat'`: No restrictions.

`'Constant'`: The following restrictions apply:

- attribute *'sparse_value'*: The attribute is not supported.
- attribute *'value'*: All entries in the tensor have to be identical.
- attribute *'value_floats'*: The attribute is not supported.
- attribute *'value_ints'*: The attribute is not supported.
- attribute *'value_string'*: The attribute is not supported.
- attribute *'value_strings'*: The attribute is not supported.

`'Conv'`: The following restrictions apply:

- attribute *'pads'*: Padding values greater than or equal to kernel size are not supported.

`'ConvTranspose'`: The following restrictions apply:

- attribute *'dilations'*: Only the value *'(1, 1)'* (no dilations) is supported.
- attribute *'group'*: Only the value *1* is supported (no grouped transposed convolution).
- attribute *'kernel_shape'*: Only symmetric kernel shapes are supported.

- attribute *'output_padding'*: See restrictions mentioned in `create_dl_layer_transposed_convolution`.
- attribute *'output_shape'*: The attribute is not supported.
- attribute *'pads'*: Padding values greater than or equal to kernel size are not supported.
- attribute *'strides'*: Only symmetric strides are supported.

'DepthToSpace': The following restrictions apply:

- attribute *'mode'*: The value must be *'CRD'*.

'Dropout': No restrictions.

'Gemm': The following restrictions apply:

- attribute *'alpha'*: The value must be *1*.
- attribute *'beta'*: The value must be *1*.
- attribute *'transA'*: The value must be *0*.

'GlobalAveragePool': No restrictions.

'GlobalMaxPool': The following restrictions apply:

- attribute *'dilations'*: The value must be *1*.

'LeakyRelu': No restrictions.

'LogSoftmax': The following restrictions apply:

- attribute *'axis'*: The value must be *1*.

'LRN': No restrictions. Hint: Attribute *'size'* has no effect.

'MaxPool': No restrictions.

'Mean': No restrictions.

'Mul': No restrictions.

'ReduceL2':

- attribute *'noop_with_empty_axes'*: The attribute is optional. The value must be *0*.
- attribute *'keepdims'*: The attribute is optional. The value must be *1*.
- attribute *'axes'*: The attribute is optional. If empty reduce all dimensions. In the new opset versions the attribute *'axes'* was moved to the inputs.

'ReduceMax': The following restrictions apply:

- attribute *'axes'*: The value must be *1*.
- attribute *'keepdims'*: The value must be *1*.

'ReduceSum':

- attribute *'noop_with_empty_axes'*: The attribute is optional. The value must be *0*.
- attribute *'keepdims'*: The attribute is optional. The value must be *1*.
- attribute *'axes'*: The attribute is optional. If empty reduce all dimensions. In the new opset versions the attribute *'axes'* was moved to the inputs.

'Relu': No restrictions.

'Resize': The following restrictions apply:

- attribute *'mode'*: Only the values *'linear'* or *'bilinear'* are supported.
- attribute *'coordinate_transformation_mode'*: Only the values *'pytorch_half_pixel'* and *'align_corners'* are supported.
- input tensor *'roi'*: If values are set they have no effect on the inference.
- The attributes *'cubic_coeff_a'*, *'exclude_outside'*, *'extrapolation_value'*, or *'nearest_mode'* have no effect.

'Reshape': The following restrictions apply:

- attribute *'allowzero'*: If the attribute is used its value must be *0*.

'Sigmoid': No restrictions.

'Softmax': The following restrictions apply:

- attribute *'axis'*: If the attribute is used its value must be *1*.

'Sub': No restrictions.

'Sum': No restrictions.

'Transpose': No restrictions.

Moreover the ONNX `'metadata_props'` field is supported. It is written to the model parameter *'meta_data'*.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
Filename
Default: 'pretrained_dl_classifier_compact.hdl'
List of values: FileName ∈ {'initial_dl_anomaly_large.hdl', 'initial_dl_anomaly_medium.hdl', 'pretrained_deep_ocr_detection.hdl', 'pretrained_deep_ocr_detection_compact.hdl', 'pretrained_deep_ocr_recognition.hdl', 'pretrained_dl_3d_gripping_point.hdl', 'pretrained_dl_classifier_alexnet.hdl', 'pretrained_dl_classifier_compact.hdl', 'pretrained_dl_classifier_enhanced.hdl', 'pretrained_dl_classifier_resnet18.hdl', 'pretrained_dl_classifier_resnet50.hdl', 'pretrained_dl_classifier_mobilenet_v2.hdl', 'pretrained_dl_anomaly_global_context.hdl', 'pretrained_dl_segmentation_compact.hdl', 'pretrained_dl_segmentation_enhanced.hdl', 'pretrained_dl_edge_extractor.hdl'}
File extension: .hdl, .onnx

▷ **DLModelHandle** (output_control) . . . . . dl_model ⇝ *handle*
Handle of the deep learning model.

Result

If the parameters are valid, the operator read_dl_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_dl_model_param, get_dl_model_param, apply_dl_model, train_dl_model_batch, train_dl_model_anomaly_dataset

Alternatives

create_dl_model_detection

References

Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
3D Metrology, OCR/OCV, Matching, Deep Learning Enhanced, Deep Learning Professional

serialize_dl_model (: : DLModelHandle : SerializedItemHandle)

Serialize a deep learning model.

serialize_dl_model serializes the deep learning model defined by the handle DLModelHandle. The serialized model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_dl_model. See fwrite_serialized_item for an introduction of the basic principle of serialization.

The operator acts the same as write_dl_model except that the output is a serialized item instead of a file. For a detailed description please refer to the documentation of write_dl_model.

For further explanations to deep learning models in HALCON, see the chapter Deep Learning / Model.

Parameters

▷ **DLModelHandle** (input_control) . . . . . dl_model ⇝ *handle*
Handle of the deep learning model.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_dl_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_dl_model_param (: : DLModelHandle, GenParamName, GenParamValue :)

Set the parameters of a deep learning model.

`set_dl_model_param` sets the parameters and hyperparameters `GenParamName` of the deep learning model `DLModelHandle` to the values `GenParamValue`.

The values `GenParamName` can attain, depend on the model type: There are parameters which can be set for any deep learning model while others can only be set for specific model types. A description of the parameters whose value you can only set but not retrieve is given below. For all other parameters the specific description is given in `get_dl_model_param`. In `get_dl_model_param` we also give an overview, for which type of model and using which operator a parameter can be set.

In the following we list the parameters `GenParamName` you can set using this operator, `set_dl_model_param`. Thereby, the following symbols denote the model type for which the parameter can be set and has a possible influence:

- 'Any': any method
- '3D-GPD': *'type'='3d_gripping_point_detection'*
- 'AD': *'type'='anomaly_detection'*
- 'CL': *'type'='classification'*
- 'MLC': *'type'='multi_label_classification'*
- 'DC': *'type'='counting'*
- 'OCR-D': *'type'='ocr_detection'*
- 'OCR-R': *'type'='ocr_recognition'*
- 'GC-AD': *'type'='gc_anomaly_detection'*

- 'OD': *'type'='detection'*
- 'SE': *'type'='segmentation'*
- 'Gen': *'type'='generic'*

'adam_beta1': **3D-GPD CL OCR-D OCR-R GC-AD OD SE Gen**
Moment for linear term in Adam solver. Only applicable if *'solver_type'* = *'adam'*.

'adam_beta2': **3D-GPD CL OCR-D OCR-R GC-AD OD SE Gen**
Moment for quadratic term in Adam solver. Only applicable if *'solver_type'* = *'adam'*.

'adam_epsilon': **3D-GPD CL OCR-D OCR-R GC-AD OD SE Gen**
Epsilon for numeric stability in Adam solver. Only applicable if *'solver_type'* = *'adam'*.

'alphabet': **OCR-R**

'alphabet_internal': **OCR-R**

'alphabet_mapping': **OCR-R**

'anomaly_score_tolerance': **GC-AD**

'backbone_docking_layers': **CL**
The docking layers can be specified for every classifier, also without using them as backbone. The specification is only considered for object detection backbones.

'batch_size': **Any**

'batch_size_multiplier': **3D-GPD CL MLC OCR-D OCR-R GC-AD OD SE Gen**

'batchnorm_momentum': **Any except DC**
Calling this option sets the momentum of all batch normalization layers within the network. The settable values are the same as described in `create_dl_layer_batch_normalization` for the parameter `Momentum`.
Note, if the network has no such layer, nothing is done and therewith the operation is regarded as successful.

'bbox_heads_weight', *'class_heads_weight'*: **OD**

'class_ids': **3D-GPD MLC OD SE**

'class_names': **CL MLC OD SE**

'class_weights': **CL**

'complexity': **AD**

'device': **Any**

'enable_resizing': **Any except DC**
Calling this option converts certain pooling layers within the network. More precisely, every non-global pooling layer with a resulting feature map of size 1x1 is converted into a global pooling layer. This means, a pooling layer performing e.g., average pooling is converted into one performing global average pooling. For more information about pooling layer and possible modes of operation, see the "`Solution Guide on Classification`".
Note, if this operation is performed, it can not be undone. Accordingly, you can only call it with the value *'true'*. Also, if the network has no such layer, nothing is done and therewith the operation is regarded as successful.

'extract_feature_maps': **CL**

'freeze_backbone_level': **OD**

'fuse_bn_relu': **Any except DC**
Calling this option, fuses layer pairs consisting of a batch normalization layer without activation and a directly connected activation layer with ReLU activation. In order to so do, the output of the batch normalization layer is only used as input for the activation layer. As a result a batch normalization layer with activation mode ReLU is obtained. For more information about layers and possible modes of operation, see the "`Solution Guide on Classification`".
Note, if this operation is performed, it can not be undone. Accordingly, you can only call it with the value *'true'*. Also, if the network has no such fusible layers, nothing is done and therewith the operation is regarded as successful.
Restriction: Leaky ReLU layers cannot be fused with batch normalization layers.

'fuse_conv_relu': **Any except DC**

Calling this option, fuses layer pairs consisting of a convolution layer without activation and a directly connected activation layer with ReLU activation. In order to so do, the output of the convolution layer is only used as input for the activation layer. As a result a convolution layer with activation mode ReLU is obtained. For more information about layers and possible modes of operation, see the "`Solution Guide on Classification`".

Note, if this operation is performed, it can not be undone. Accordingly, you can only call it with the value *'true'*. Also, if the network has no such fusible layers, nothing is done and therewith the operation is regarded as successful.

Restriction: Leaky ReLU layers cannot be fused with convolution layers.

'gc_anomaly_networks': **GC-AD**

'gpu': **Any**

'ignore_class_ids': **SE**

'image_dimensions': **3D-GPD AD CL MLC OCR-D OCR-R GC-AD SE**

'image_height', *'image_width'*: **3D-GPD AD CL MLC OCR-D OCR-R GC-AD SE**

'image_num_channels': **AD CL MLC OCR-D OCR-R GC-AD SE**

'image_range_max', *'image_range_min'*: **3D-GPD OCR-D OCR-R SE**

'image_size': **3D-GPD AD CL MLC OCR-D OCR-R GC-AD SE**

'input_dimensions': **AD CL MLC OCR-D OCR-R SE Gen**

'learning_rate': **3D-GPD CL MLC OCR-D OCR-R GC-AD OD SE Gen**

'mask_head_weight': **OD**

This parameter is only available for models with *'instance_segmentation'='true'*.

'max_num_detections': **OD**

'max_overlap': **OD**

'max_overlap_class_agnostic': **OD**

'meta_data': **Any**

'min_character_score': **OCR-D**

'min_confidence': **MLC OD**

'min_link_score': **OCR-D**

'min_word_area': **OCR-D**

'min_word_score': **OCR-D**

'momentum': **3D-GPD CL MLC OCR-D OCR-R GC-AD OD SE Gen**

Momentum for SGD solver.

Restriction: Only applicable for *'solver_type'* = *'sgd'*.

'ood_threshold': **CL**

'optimize_for_inference': **3D-GPD CL MLC OCR-D OCR-R GC-AD OD SE Gen**

'orientation': **OCR-D**

'patch_size': **GC-AD**

'runtime': **Any**

'runtime_init': **Any except DC**

If called with *'immediately'*, the GPU memory is initialized and the corresponding handle created. Otherwise this is done on demand, which may result in significantly larger execution times for the first call of `apply_dl_model` or `train_dl_model_batch`.

If the network architecture is changed subsequently, the GPU memory is reinitialized. This can happen e.g., for changes of *'batch_size'*, *'image_dimensions'* or *'input_dimensions'* with subsequent calls of `set_dl_model_param`.

Note, this parameter has no effect if:

- Running on CPUs, thus if *'runtime'* is set to *'cpu'*.
- Running with an AI^2-interface.

- The device has been set before using *'device'*.

'solver_type': **3D-GPD CL MLC OCR-D OCR-R GC-AD OD SE Gen**

'sort_by_line': **OCR-D**

'standard_deviation_factor': **AD**

'tiling': **OCR-D**

'tiling_overlap': **OCR-D**

'type': **Gen**

This parameter returns the HALCON-specific model type.

Models of *'generic'* fulfill all model functions. But several deep learning procedures rely a specific *'type'*. The value of *'type'* can be set from *'generic'* to the following values:

- *'classification'*
- *'segmentation'*

Setting a value for *'type'* to model it is checked if it has all layers necessary for inference and training. In case such layers are missing, they are added.

'weight_prior': **3D-GPD CL OCR-D OCR-R GC-AD OD SE Gen**

Attention

System requirements: To successfully set *'gpu'* parameters, cuDNN and cuBLAS are required, i.e., to set the parameter `GenParamName` *'runtime'* to *'gpu'*. For further details, please refer to the "`Installation Guide`", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

▷ **`DLModelHandle`** (input_control) . . . . . dl_model ⇝ *handle*
Handle of the deep learning model.

▷ **`GenParamName`** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'batch_size'
List of values: `GenParamName` ∈ {'adam_beta1', 'adam_beta2', 'adam_epsilon', 'alphabet', 'alphabet_internal', 'alphabet_mapping', 'anchor_aspect_ratios', 'anchor_num_subscales', 'anchor_angles', 'anomaly_score_tolerance', 'backbone', 'backbone_docking_layers', 'batch_size', 'batch_size_multiplier', 'batchnorm_momentum', 'bbox_heads_weight', 'capacity', 'class_heads_weight', 'class_ids', 'class_names', 'class_weights', 'complexity', 'device', 'enable_resizing', 'extract_feature_maps', 'freeze_backbone_level', 'fuse_bn_relu', 'fuse_conv_relu', 'gc_anomaly_networks', 'gpu', 'ignore_class_ids', 'ignore_direction', 'image_dimensions', 'image_height', 'image_num_channels', 'image_range_max', 'image_range_min', 'image_size', 'image_width', 'input_dimensions', 'instance_type', 'learning_rate', 'mask_head_weight', 'max_level', 'max_num_detections', 'max_overlap', 'max_overlap_class_agnostic', 'meta_data', 'min_character_score', 'min_confidence', 'min_level', 'min_link_score', 'min_word_area', 'min_word_score', 'momentum', 'num_classes', 'orientation', 'ood_threshold', 'optimize_for_inference', 'patch_size', 'runtime', 'runtime_init', 'solver_type', 'standard_deviation_factor', 'sort_by_line', 'summary', 'tiling', 'tiling_overlap', 'type', 'weight_prior'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value(-array) ⇝ *integer* / string / real
Value of the generic parameter.
Default: 1
Suggested values: `GenParamValue` ∈ {1, 2, 3, 50, [80,60], 80, 60, 0.001, -127, 128, 'adam', 'cpu', 'gpu', 'immediately', 'sgd'}

Result

If the parameters are valid, the operator `set_dl_model_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_dl_pruning_param (: : DLPruningHandle, GenParamName, GenParamValue :)

Set parameter in a pruning data handle.

set_dl_pruning_param sets the parameter GenParamName in the pruning handle DLPruningHandle to the value GenParamValue.

An overview as well as a description of the settable parameters is given in get_dl_model_param.

Parameters

▷ **DLPruningHandle** (input_control) . . . . . dl_pruning ⇝ *handle*
Pruning data handle.

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'percentage'
List of values: GenParamName ∈ {'mode', 'percentage'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / string / integer
Value of the generic parameter.
Default: 10
Suggested values: GenParamValue ∈ {'oracle', 10, 20, 30, 40, 50}

Result

If the parameters are valid, the operator set_dl_pruning_param returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Deep Learning Professional

train_dl_model_batch (: : DLModelHandle, DLSampleBatch : DLTrainResult)

Train a deep learning model.

The operator train_dl_model_batch performs a training step of the deep learning model contained in DLModelHandle. The current loss values are returned in the dictionary DLTrainResult.

For DLModelHandle all model types but *'anomaly_detection'* and *'counting'* are valid. See train_dl_model_anomaly_dataset for the training of anomaly detection models.

A training step means here to perform a single update of the weights, based on the batch images given in DLSampleBatch. The optimization algorithms which can be used are explained further in the subsection "Further Information on the Algorithms" below. For more information on how to train a network, please see the subchapter "The Network and the Training Process" in Deep Learning.

To successfully train the model, its applicable hyperparameters need to be set and the training data handed over according to the model requirements. For information to the hyperparameters, see the chapter of the corresponding model and the general chapter Deep Learning.

The training data consists of images and corresponding information. This operator expects one batch of training data, handed over in the tuple of dictionaries DLSampleBatch. Such a DLSample dictionary is created out of DLDataset for every image sample, e.g., by the procedure gen_dl_samples. See the chapter Deep Learning / Model for further information to the used dictionaries and their keys.

The number of images in a DLSampleBatch tuple needs to be a multiple of the *'batch_size'*. In particular on GPU the parameter *'batch_size'* is limited by the amount of available memory. In order to process more images in one training step, the model parameter *'batch_size_multiplier'* can be set to a value greater than 1. The number of DLSample dictionaries being passed to the training operator needs to be equal to *'batch_size'* times *'batch_size_multiplier'*. Note that a training step calculated for a batch and a *'batch_size_multiplier'* greater 1 is an approximation of a training step calculated for the same batch but with a *'batch_size_multiplier'* equal to 1 and an accordingly greater *'batch_size'*. As an example, the loss calculated with a *'batch_size'* of 4 and a *'batch_size_multiplier'* of 2 is usually not equal to the loss calculated with a *'batch_size'* of 8 and a *'batch_size_multiplier'* of 1, although the same number of DLSample dictionaries is used for training in both cases. However, the approximation generally delivers comparably good results, so it can be utilized if you wish to train with a larger number of images than your GPU allows. In some rare cases the approximation with a *'batch_size'* of 1 and an accordingly large *'batch_size_multiplier'* does not show the expected performance. Set the *'batch_size'* to a value greater than 1 can help to solve this issue.

In the output dictionary DLTrainResult you get the current value of the total loss as the value for the key total_loss as well as the values for all other losses included in your model.

For models of *'type'* = *'detection'* such losses are e.g., the losses for the heads of every selected level, namely the 'Huber Loss' for the bounding box regression heads and the 'Focal Loss' for the classification heads (see also Deep Learning / Object Detection and Instance Segmentation as well as *'max_level'* and *'min_level'* in get_dl_model_param).

Further Information on the Algorithms

During training, an optimization algorithm is applied with the goal to minimize the value of the total loss function. The latter one is determined based on the prediction of the neural network for the current batch of images.

In HALCON we have two optimization algorithms available so far, the SGD (stochastic gradient descent) and Adam (adaptive moment estimation).

SGD: The SGD updates the layers' weights of the previous iteration $t-1$, w_{t-1}, to the new values w_t at iteration t as follows:

$$\begin{aligned} v_t &= \mu v_{t-1} - \lambda \nabla_w L \\ w_t &= w_{t-1} + v_t. \end{aligned}$$

Here, λ is the learning rate, μ the momentum, L the total loss, and $\nabla_w L$ the gradient of the total loss with respect to the weights. The variable v_t is used to include the influence of the momentum μ.

Adam: Like the SGD, Adam updates the layer's weights of the previous iteration but comes with an adaptive moment estimation to automatically estimate a scaling for the learning rate. In this way it is determined how fast the solver moves towards a minimum. The estimated moments are the first two moments of the weights' gradients which are the mean and the uncentered variance. To estimate the moments Adam uses exponentially moving averages m_t and v_t, computed on the gradient evaluated on a mini-batch. This results in the following formula:

$$\begin{aligned} m_t &= \beta_1 m_{t-1} + (1-\beta_1) g_t \\ v_t &= \beta_2 v_{t-1} + (1-\beta_2) g_t^2. \end{aligned}$$

g is the weight's gradient on the current mini-batch, β_1 is the moment for the linear term, and β_2 is the moment for the quadratic term of the Adam solver. Furthermore, Adam has so-called bias correctors $\hat{m}_t$ and $\hat{v}_t$. These values are computed as follows:

$$\begin{aligned} \hat{m}_t &= \frac{m_t}{1-\beta_1^t} \\ \hat{v}_t &= \frac{v_t}{1-\beta_2^t}. \end{aligned}$$

As a last step the moving averages are used to scale the learning rates individually for each parameter. To perform the weights update this results with w_t as the model weights, and λ as the learning rate in the following formula.

$$w_t = w_{t-1} - \lambda \frac{\hat{m}_t}{\sqrt{\hat{v}_t} + \epsilon}.$$

Here ϵ is the parameter to ensure numeric stability. For a more detailed description we refer to the referenced paper.

The different models may have several losses implemented, which are summed up. To this sum the regularization term $E_\alpha(w)$ is added, which generally penalizes large weights, and together they form the total loss. The different types of losses are:

`Huber Loss` (model of *'type'='detection'*): The 'Huber Loss' is also known as 'Smooth L1 Loss'. The total 'Huber Loss' is the sum of the contributions from all bounding box variables of all found instances in the batch. For a single bounding box variable this contribution defined as follows:

$$L_{Huber}(x) = \begin{cases} 0.5x^2/\beta & \text{if } |x| < \beta \\ |x| - 0.5\beta & \text{else} \end{cases}.$$

Thereby, x denotes a bounding box variable and β a parameter fixed to a value of 0.11.

We refer to `create_dl_layer_loss_huber` for more information.

`Focal Loss` (model of *'type'='detection'*): The total 'Focal Loss' is the sum of the contributions from all found instance in the batch. For a single sample, this contribution is defined as follows:

$$L_{focal}(p) = -\sum_{c=0}^{C-1} \alpha_t^c \left(1 - p_t^c\right)^\gamma \log\left(p_t^c\right),$$

where γ is a parameter fixed to a value of 2. α^c stands for the class specific weight ('class_weights') of the c-th class and p_t, α_t are defined as

$$p_t := \begin{cases} p & \text{if } y = 1 \\ 1-p & \text{else} \end{cases}, \quad \text{and} \quad \alpha_t := \begin{cases} \alpha & \text{if } y = 1 \\ 1-\alpha & \text{else} \end{cases}.$$

Here, $p = (p^0, \ldots, p^{C-1})$ is a tuple of the model's estimated probabilities for each of the C-many classes, and y_c is a one-hot encoded target vector that encodes the class of the annotation.

We refer to `create_dl_layer_loss_focal` for more information.

`Multinomial Logistic Loss` (model of *'type'= 'classification', 'segmentation'*): The 'Multinomial Logistic Loss' is also known as 'Cross Entropy Loss'. It is defined as follows:

$$L_{mn}\big(f(x,w)\big) \quad = \quad -\frac{1}{N}\sum_{n=0}^{N-1}\alpha(y_n)\langle y_n, \log\big(f(x_n,w)\big)\rangle$$

Here, $f(x,w)$ is the predicted result which depends on the network weights w and the input batch x. y_n is a one-hot encoded target vector that encodes the label of the n-th image x_n of the batch x containing N-many images, and $\log(f(x_n,w))$ shall be understood to be a vector such that $\log$ is applied on each component of $f(x_n,w)$. The value $\alpha(y_n)$ is a class specific weight for the class given by y_n. This weight corresponds to the value set by 'class_weights' and is normalized by the sum over the weights for all classes in addition.

We refer to `create_dl_layer_loss_cross_entropy` for more information.

The regularization term $E_\alpha(w)$ is a weighted l^2-norm involving all K weights except for biases. Its influence can be controlled through α. Latter one is the hyperparameter *'weight_prior'*, which can be set with `set_dl_model_param`.

$$E_\alpha(w) = \frac{\alpha}{2}\sum_{k=0}^{K-1}|w_k|^2$$

Here the index k runs over all weights of the network, except for the biases which are not regularized. The regularization term $E_\alpha(w)$ generally penalizes large weights, thus pushing the weights towards zero, which effectively reduces the complexity of the model.

Attention

The operator `train_dl_model_batch` internally calls functions that might not be deterministic. Therefore, results from multiple calls of `train_dl_model_batch` can slightly differ, although the same input values have been used. Setting *'cudnn_deterministic'* of `set_system` may influence this behavior.

System requirements: Implementation on CPU is limited to specific platform types. To run this operator on GPU by setting *'runtime'* to *'gpu'* (see `get_dl_model_param`), cuDNN and cuBLAS are required. Please refer to the "`Installation Guide`", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods", for the specific system requirements.

Parameters

- ▷ **`DLModelHandle`** (input_control) . . . . . dl_model ⇝ *handle*
  Deep learning model handle.
- ▷ **`DLSampleBatch`** (input_control) . . . . . dict-array ⇝ *handle*
  Tuple of Dictionaries with input images and corresponding information.
- ▷ **`DLTrainResult`** (output_control) . . . . . dict ⇝ *handle*
  Dictionary with the train result data.

Result

If the parameters are valid, the operator `train_dl_model_batch` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

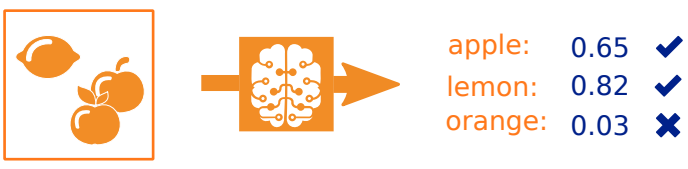
9.5 Multi-Label Classification

This chapter explains how to use multi-label classification based on deep learning, both for the training and inference phases.

Multi-label classification based on deep learning is a method, in which an image gets assigned multiple confidence values. These confidence values indicate how likely the image belongs to each of the different classes. Thus, multi-label classification means to assign multiple specific classes to an image. This is illustrated with the following schema.



A possible multi-label classification example, in which the network has three classes. The input image gets confidence values assigned for each of the three classes: 'apple' 0.65, 'lemon' 0.82, and 'orange' 0.03. The top predictions tell us, the image has the classes 'apple' and 'lemon'.

In order to do your specific task, thus to classify your data into the different classes, the classifier has to be trained accordingly. In HALCON, we use a technique called transfer learning (see also the chapter Deep Learning). Hence, we provide pretrained networks, representing classifiers which have been trained on huge amounts of labeled image data. These classifiers have been trained and tested to perform well on industrial image classification tasks. One of these classifiers, already trained for general multi-label classifications, is now retrained for your specific task. To do this, the classifier must know, which classes have to be distinguished and what examples of these classes look like. This is represented by your dataset, i.e., your images with the corresponding ground truth labels. More information on the data requirements can be found in the section "Data".

In HALCON, multi-label classification with deep learning is implemented within the more general deep learning model. For more information to the latter one, see the chapter Deep Learning / Model. For the specific system requirements in order to apply deep learning, please refer to the HALCON "Installation Guide".

The following sections are introductions to the general workflow needed for multi-label classification, information related to the involved data and parameters, and explanations to the evaluation measures.

General Workflow

In this paragraph, we describe the general workflow for a multi-label classification task based on deep learning. It is subdivided into the five parts creation of the model, preprocessing of the data, training of the model, evaluation of the trained model, and inference on new images. Thereby we assume, your dataset is already labeled, see also the section "Data" below. Have a look at the HDevelop example `dl_multi_label_classification_workflow.hdev` for an application.

Create a Multi-Label Classification Model This part is about how to create a multi-label classification model. The model is created based on a backbone model. The creation can be done with the procedure

- `create_dl_model_multi_label_classification`.

Thereby, a model `DLModelHandle` is created, where the backbone serves as feature extractor, to which the necessary layers for the training are added. Generally it is possible to use any deep learning model as a backbone, but, depending on the complexity, we recommend one of the classification models. For further information about the backbone and which one to use, see the procedure documentation of `create_dl_model_multi_label_classification`.

`create_dl_model_multi_label_classification` uses a docking layer, to attach the necessary layers for multi-label classification to the backbone classifier. The pretrained classifiers provided by HALCON have already specified docking layers. But when you use a self-provided classifier as backbone, you have to specify it yourself.

After the model has been created it can be saved using `write_dl_model` and subsequently read using `read_dl_model`.

Preprocess the data This part is about how to preprocess your data. The single steps are also shown in the HDevelop example `dl_multi_label_classification_workflow.hdev`.

1. The information what is to be found on an image of your training dataset needs to be transferred. This is done by the procedure
   - `read_dl_dataset_multi_label_classification`.

   Thereby a dictionary `DLDataset` is created, which serves as a database and stores all necessary information about your data. For more information about the data and the way it is transferred, see the section "Data" below and the chapter Deep Learning / Model.
2. Split the dataset represented by the dictionary `DLDataset`. This can be done using the procedure
   - `split_dl_dataset`.

   The resulting split will be saved under the key `split` in each sample entry of `DLDataset`.
3. Now you can preprocess your dataset. For this, you can use the procedure

- preprocess_dl_dataset.

In case of custom preprocessing, this procedure offers guidance on the implementation.

To use this procedure, specify the preprocessing parameters as e.g., the image size. Store all the parameters with their values in a dictionary DLPreprocessParam, wherefore you can use the procedure

- create_dl_preprocess_param.

We recommend to save this dictionary DLPreprocessParam in order to have access to the preprocessing parameter values later during the inference phase.

Training of the model This part is about how to train a multi-label classifier. The single steps are also shown in the HDevelop example dl_multi_label_classification_workflow.hdev.

1. Set the training parameters and store them in the dictionary TrainParam. These parameters include:
   - the hyperparameters, for an overview see the chapter Deep Learning.
   - parameters for possible data augmentation (optional).
   - parameters for the evaluation during training.
   - parameters for the visualization of training results.
   - parameters for serialization.

   This can be done using the procedure
   - create_dl_train_param.
2. Train the model. This can be done using the procedure
   - train_dl_model.

   The procedure expects:
   - the model handle DLModelHandle
   - the dictionary with the data information DLDataset
   - the dictionary with the training parameter TrainParam
   - the information, over how many epochs the training shall run.

   In case the procedure train_dl_model is used, the total loss as well as optional evaluation measures are visualized.

Evaluation of the trained model In this part we evaluate the trained classifier. The single steps are also shown in the HDevelop example dl_multi_label_classification_workflow.hdev.

1. The evaluation can conveniently be done using the procedure
   - evaluate_dl_model.
2. The dictionary EvaluationResult holds the asked evaluation measures. You can visualize your evaluation results using the procedure
   - dev_display_multi_label_classification_evaluation.

Inference on new images This part covers the application of a deep-learning-based multi-label classification model. The single steps are also shown in the HDevelop example dl_multi_label_classification_workflow.hdev.

1. Set the parameters as e.g., *'batch_size'* using the operator
   - set_dl_model_param.
2. Generate a data dictionary DLSample for each image. This can be done using the procedure
   - gen_dl_samples_from_images.
3. Preprocess the images as done for the training. We recommend to do this using the procedure
   - preprocess_dl_samples.

   When you saved the dictionary DLPreprocessParam during the preprocessing step, you can directly use it as input to specify all parameter values.
4. Apply the model using the operator

- apply_dl_model.

5. Retrieve the results from the dictionary *'DLResultBatch'*.

Data

We distinguish between data used for training and data for inference. Latter one consists of bare images. But for the former one you already know to which classes the images belong and provide this information over the corresponding labels.

As a basic concept, the model handles data over dictionaries, meaning it receives the input data over a dictionary DLSample and returns a dictionary DLResult and DLTrainResult, respectively. More information on the data handling can be found in the chapter Deep Learning / Model.

Data for training and evaluation The dataset consists of images and corresponding information. They have to be provided in a way the model can process them. Concerning the image requirements, find more information in the section "Images" below.

The training data is used to train and evaluate a network for your specific task. With the aid of this data the network can learn which classes are to be distinguished, how such examples look like, and how to find them. For each image the class of every object in the image is provided as label. There are various ways to store and retrieve this information. How the data has to be formatted in HALCON for a DL model is explained in the chapter Deep Learning / Model. In short, a dictionary DLDataset serves as a database for the information needed by the training and evaluation procedures.

If you have already a labeled multi-label classification dataset, you can use the procedure read_dl_dataset_multi_label_classification. It formats the data and creates a dictionary DLDataset. This procedure can also be used to create a DLDataset for multi-label classification from object detection, segmentation or classification data.

For training a multi-label classifier, we use a technique called transfer learning (see the chapter Deep Learning). For this, you need less resources, but still a suitable set of data. While in general the network should be more reliable when trained on a larger dataset, the amount of data needed for training also depends on the complexity of the task. You also want enough training data to split it into three subsets, used for training, validation, and testing the network. These subsets are preferably independent and identically distributed, see the section "Data" in the chapter Deep Learning.

Images Regardless of the application, the network poses requirements on the images regarding e.g., the image dimensions. The specific values depend on the backbone-network itself and can be queried with get_dl_model_param. In order to fulfill these requirements, you may have to preprocess your images. Standard preprocessing is implemented in preprocess_dl_dataset and in preprocess_dl_samples for a single sample, respectively. In case of custom preprocessing these procedures offer guidance on the implementation.

Network output The network output depends on the task:

training As output, the operator train_dl_model_batch will return a dictionary DLTrainResult with the current value of the total loss as well as values for all other losses included in your model.

inference and evaluation As output, the operator apply_dl_model will return a dictionary DLResult for every image. For multi-label classification, this dictionary will include a tuple for every image, with the confidence values for every class to be distinguished in descending order and a second tuple with the corresponding class IDs. Further information on the output dictionary can be found in the chapter Deep Learning / Model.

Interpreting the Multi-Label Classification Results

When we classify an image, we obtain a set of confidence values, telling us the affinity of the image to every class. It is also possible to compute the following values.

Precision, Recall, and F-Score In multi-label classification whole images are classified. To check how well the trained network is performing, precision and recall are computed.

The precision is the proportion of all correct predicted positives to all predicted positives (true and false ones). Thus, it is a measure of how many positive predictions really belong to the selected class.

$$\text{precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

The recall, also called the "true positive rate", is the proportion of all correct predicted positives to all real positives. Thus, it is a measure of how many samples belonging to the selected class were predicted correctly as positives.

$$\text{recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

A classifier with high recall but low precision finds most members of positives (thus members of the class), but at the cost of also classifying many negatives as member of the class. A classifier with high precision but low recall is just the opposite, classifying only few samples as positives, but most of these predictions are correct. An ideal classifier with high precision and high recall will classify many samples as positive with a high accuracy.

To represent this with a single number, we compute the F1-score, the harmonic mean of precision and recall. Thus, it is a measure of the classifier's accuracy.

$$\text{F1-score} = 2 * \frac{\text{precision} * \text{recall}}{\text{precision} + \text{recall}}$$

Mean Average Precision Mean average precision (mAP), and average precision (AP) of a class for a threshold.

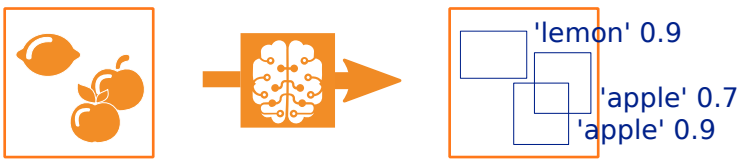
The AP value is an average of maximum precision at different recall values. In simple words it tells us, if the classes predicted for the images are generally correct predictions or not. Thereby we pay more attention to the predictions with high confidence values. The higher the value, the better.

You can obtain the specific AP values, the averages over the classes, the averages over the thresholds, and the average over both, the classes and the thresholds. The latter one is the mAP, a measure to tell us how well images are classified.

9.6 Object Detection and Instance Segmentation

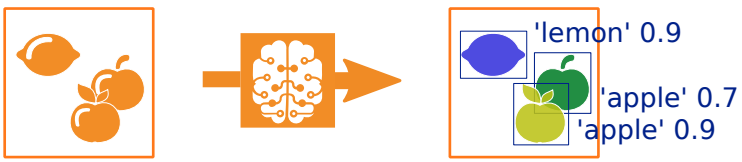
This chapter explains how to use object detection based on deep learning.

With **object detection** we want to find the different instances in an image and assign them to a class. The instances can partially overlap and still be distinguished as distinct. This is illustrated in the following schema.



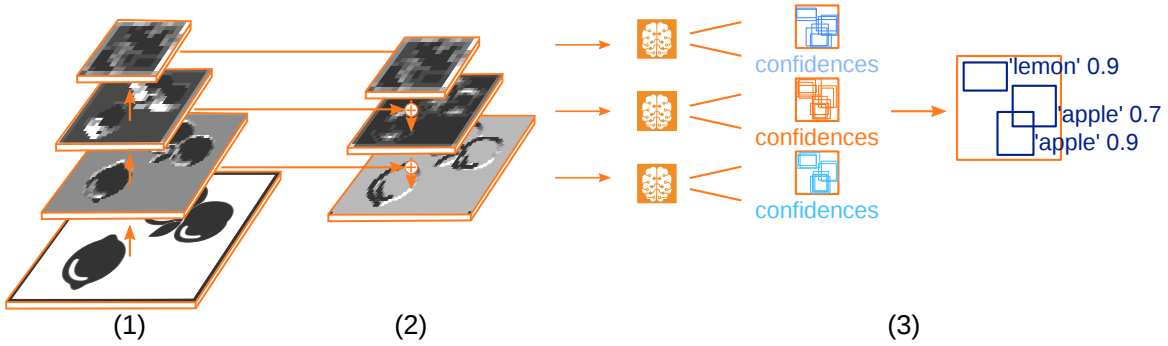
A possible example for object detection: Within the input image three instances are found and assigned to a class.

Instance segmentation is a special case of object detection, where the model also predicts an instance mask marking the specific region of the instance within the image. This is illustrated in the following schema. In general the explanations to object detection also apply to instance segmentation. Possible differences are brought up in the specific sections.



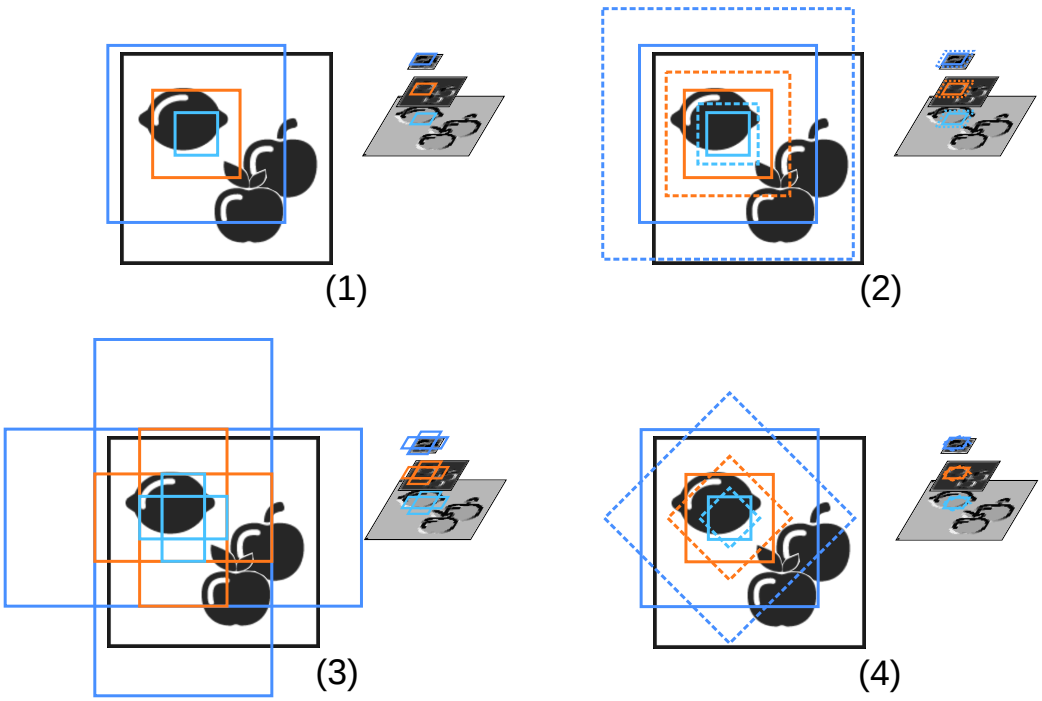
A possible example for instance segmentation: Within the input image three instances are found. Each instances is assigned to a class and obtains a mask marking its particular region.

Object detection leads to two different tasks: Finding the instances and classifying them. In order to do so, we use a combined network consisting of three main parts. The first part, called backbone, consists of a pretrained classification network. Its task is to generate various feature maps, so the classifying layer is removed. These feature maps encode different kinds of information at different scales, depending how deep they are in the network. See also the chapter Deep Learning. Thereby, feature maps with the same width and height are said to belong to the same level. In the second part, backbone layers of different levels are combined. More precisely, backbone levels of different levels are specified as docking layers. Their feature maps are combined. As a result we obtain feature maps containing information of lower and higher levels. These are the feature maps we will use in the third part. This second part is also called feature pyramid and together with the first part it constitutes the feature pyramid network. The third part consists of additional networks, called heads, for every selected level. They get the corresponding feature maps as input and learn how to localize and classify, respectively, potential objects. Additionally this third part includes the reduction of overlapping predicted bounding boxes. An overview of the three parts is shown in the following figure.



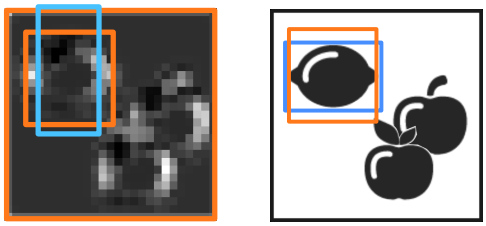
A schematic overview of the mentioned three parts: (1) The backbone. (2) Backbone feature maps are combined and new feature maps generated. (3) Additional networks, called heads, which learn how to localize and classify, respectively, potential objects. Overlapping bounding boxes are suppressed.

Let us have a look what happens in this third part. In object detection, the location in the image of an instance is given by a rectangular bounding box. Hence, the first task is to find a suiting bounding box for every single instance. To do so, the network generates reference bounding boxes and learns, how to modify them to fit the instances best possible. These reference bounding boxes are called anchors. The better these anchors represent the shape of the different ground truth bounding boxes, the easier the network can learn them. For this purpose the network generates a set of anchors on every anchor point, thus on every pixel of the used feature maps of the feature pyramid. Such a set consists of anchors of all combinations of shapes, sizes, and for instance type *'rectangle2'* (see below) also orientations. The shape of those boxes is affected by the parameter *'anchor_aspect_ratios'* the size by the parameter *'anchor_num_subscales'*, and the orientation by the parameter *'anchor_angles'*, see the illustration below and `get_dl_model_param`. If the parameters generate multiple identical anchors, the network internally ignores those duplicates.



Schema for anchors in the feature map (right) and in the input image (left). (1) Anchors are created on the feature maps of different levels, e.g., the ones drawn (in light blue, orange, and dark blue). (2) Anchors of different sizes are created setting *'anchor_num_subscales'*. (3) Anchors of different shapes are created setting *'anchor_aspect_ratios'*. (4) Anchors of different orientations are created setting *'anchor_angles'* (only for instance type *'rectangle2'*).

The network predicts offsets how to modify the anchors in order to obtain bounding boxes fitting the potential instances better. The network learns this with its bounding box heads, which compare the anchors generated for their level with the corresponding ground truth bounding boxes, thus the information where in the image the single instances are. An illustration is shown in the figure below.



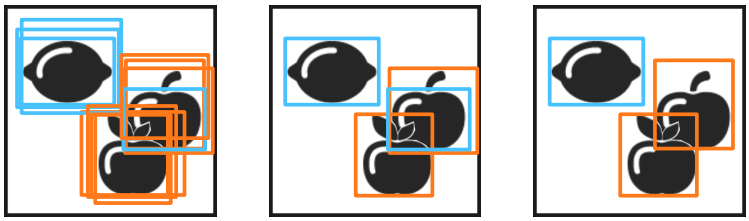
Bounding box comparisons, illustrated for instance type *'rectangle1'*. (1) The network modifies the anchor (light blue) in order to predict a better fitting bounding box (orange). (2) During training, the predicted bounding box (orange) gets compared with the most overlapping ground truth bounding box (blue) so the network can learn the necessary modifications.

As mentioned before, feature maps of different levels are used. Depending on the size your instances have in comparison to the total image it is beneficial to include early feature maps (where the feature map is not very compressed and therefore small features are still visible) and deeper feature maps (where the feature map is very compressed and only large features are visible) or not. This can be controlled by the parameters *'min_level'* and *'max_level'*, which determine the levels of the feature pyramid.

With these bounding boxes we have the localization of a potential instance, but the instance is not classified yet. Hence, the second task consists of classifying the content of the image part within the bounding boxes. This is done by the class heads. For more information about classification in general, see the chapter Deep Learning / Classification and the "`Solution Guide on Classification`".

Most probably the network will find several promising bounding boxes for a single object. The reduction of overlapping predicted bounding boxes is done by non-maximum suppression, set over the parameters *'max_overlap'*

and *'max_overlap_class_agnostic'* when creating the model or using `set_dl_model_param` afterwards. An illustration is given in the figure below.

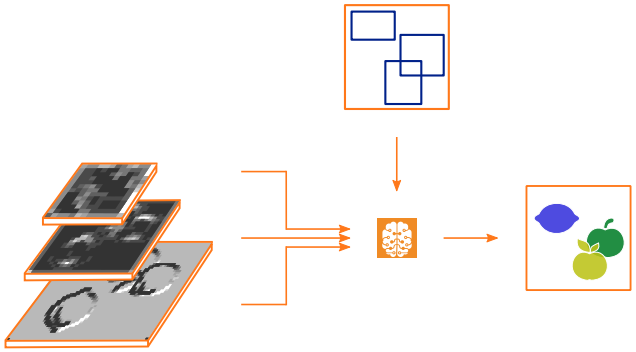


(1) (2) (3)

Suppression of significant overlapping bounding boxes, illustrated for instance type *'rectangle1'*. (1) The network finds several promising instances for the class apple (orange) and lemon (blue). (2) The suppression of overlapping instances assigned to the same class is set by *'max_overlap'*. Overlapping instances of different classes are not suppressed. (3) Using the parameter *'max_overlap_class_agnostic'*, also strongly overlapping instances of different classes get suppressed.

As output you get bounding boxes proposing possible localizations of objects and confidence values, expressing the affinity of this image part to one of the classes.

In case of instance segmentation a further part follows. An additional head obtains as input those parts of the feature maps that correspond to the predicted bounding boxes. Thereout it predicts a (class-agnostic) binary mask image. This mask marks the region within the image belonging to the predicted instance. A schematic overview is given below.



A schematic overview of the mask prediction. The illustration uses the parts shown in the overview of the three parts of an object detection network shown above.

In HALCON, object detection with deep learning is implemented within the more general deep learning model. For more information to the latter one, see the chapter Deep Learning / Model. Two different instance types of object detection models are implemented, differing in the orientation of the bounding boxes:

instance type *'rectangle1'* The rectangular bounding boxes are axis-aligned.

instance type *'rectangle2'* The rectangular bounding boxes have an arbitrary orientation.

For the specific system requirements in order to apply deep learning, please refer to the HALCON "`Installation Guide`".

The following sections are introductions to the general workflow needed for object detection, information related to the involved data and parameters, and explanations to the evaluation measures.

General Workflow

In this paragraph, we describe the general workflow for an object detection task based on deep learning. It is subdivided into the four parts creating the model and preprocessing of the data, training of the model, evaluation of the trained model, and inference on new images. Thereby we assume, your dataset is already labeled, see also the section "Data" below. Have a look at the HDevelop example series `detect_pills_deep_learning` for an application. The example `dl_instance_segmentation_workflow.hdev` shows the complete workflow for an instance segmentation application.

Creation of the model and dataset preprocessing This part covers the creation of a DL object detection model and the adaptation the data for this model. The single steps are also shown in the HDevelop example `detect_pills_deep_learning_1_prepare.hdev`.

1. Create a model using the operator
   - `create_dl_model_detection`.

   Thereby you will have to specify at least the backbone and the number of classes to be distinguished. For instance segmentation the parameter *'instance_segmentation'* has to be set to create an according model.

   Further parameters can be set over the dictionary `DLModelDetectionParam`. Their values should be well chosen for the specific task, not least to possibly reduce memory consumption and runtime. See the operator documentation for more information.

   Anchor parameters suiting your dataset can be estimated using the procedure
   - `determine_dl_model_detection_param`.

   In case the dataset is not representing all orientations the network will face during training (e.g., due to augmentation), the suggested values need to be adapted accordingly.

   Note, after creation of the model, its underlying network architecture is fixed to the specified input values. As a result the operator returns a handle *'DLModelHandle'*.

   Alternatively you can also use
   - `read_dl_model`.

   to read in a model you have already saved with `write_dl_model`.
2. The information what is to be found on which image of your training dataset needs to be read in. This can be done reading the data out of
   - a `DLDataset` dictionary using `read_dict`, or
   - a file in the COCO data format using the procedure `read_dl_dataset_from_coco`, whereby a dictionary `DLDataset` is created.

   The dictionary `DLDataset` serves as a database storing all necessary information about your data. For more information about the data and the way it is transferred, see the section "Data" below and the chapter Deep Learning / Model.
3. Split the dataset represented by the dictionary `DLDataset`. This can be done using the procedure
   - `split_dl_dataset`.

   The resulting split will be saved over the key `split` in each sample entry of `DLDataset`.
4. The network imposes requirements on the images, as e.g., the image width and height. You can retrieve every single value using the operator
   - `get_dl_model_param`.

   or you can retrieve all necessary parameter using the procedure
   - `create_dl_preprocess_param_from_model`.

   Note, for classes declared by *'class_ids_no_orientation'* the bounding boxes need to be treated specially during preprocessing. As a consequence, these classes should be set at this point latest.

   Now you can preprocess your dataset. For this, you can use the procedure
   - `preprocess_dl_dataset`.

   This procedure also offers guidance on how to implement a customized preprocessing procedure. We recommend to preprocess and store all images used for the training before starting the training, since this speeds up the training significantly.

   To visualize the preprocessed data, the procedure
   - `dev_display_dl_data`

   is available.

Training of the model This part covers the training of a DL object detection model. The single steps are also shown in the HDevelop example `detect_pills_deep_learning_2_train.hdev`.

1. Set the training parameters and store them in the dictionary `TrainParam`. These parameters include:
   - the hyperparameters, for an overview see the section "Model Parameters and Hyperparameters" below and the chapter Deep Learning.
   - parameters for possible data augmentation
2. Train the model. This can be done using the procedure
   - `train_dl_model`.

   The procedure expects:
   - the model handle `DLModelHandle`
   - the dictionary with the data information `DLDataset`
   - the dictionary with the training parameters `TrainParam`
   - the information, over how many epochs the training shall run.

   During the training you should see how the total loss minimizes.

Evaluation of the trained model In this part we evaluate the object detection model. The single steps are also shown in the HDevelop example `detect_pills_deep_learning_3_evaluate.hdev`.

1. Set the model parameters which may influence the evaluation.
2. The evaluation can conveniently be done using the procedure
   - `evaluate_dl_model`.

   This procedure expects a dictionary `GenParamEval` with the evaluation parameters. Set the parameter `detailed_evaluation` to *'true'* to get the data necessary for the visualization.
3. You can visualize your evaluation results using the procedure
   - `dev_display_detection_detailed_evaluation`.

Inference on new images This part covers the application of a DL object detection model. The single steps are also shown in the HDevelop example `detect_pills_deep_learning_4_infer.hdev`.

1. Request the requirements the network imposes on the images using the operator
   - `get_dl_model_param`

   or the procedure
   - `create_dl_preprocess_param_from_model`.
2. Set the model parameter described in the section "Model Parameters and Hyperparameters" below, using the operator
   - `set_dl_model_param`.

   The *'batch_size'* can be generally set independently from the number of images to be inferred. See `apply_dl_model` for details on how to set this parameter for greater efficiency.
3. Generate a data dictionary `DLSample` for each image. This can be done using the procedure
   - `gen_dl_samples_from_images`.
4. Every image has to be preprocessed as done for the training. For this, you can use the procedure
   - `preprocess_dl_samples`.
5. Apply the model using the operator
   - `apply_dl_model`.
6. Retrieve the results from the dictionary *'DLResultBatch'*.

Data

We distinguish between data used for training and evaluation, consisting of images with their information about the instances, and data for inference, which are bare images. For the first ones, you provide the information defining for each instance to which class it belongs and where it is in the image (via its bounding box). For instance segmentation the pixel-precise region of the objects is needed (provided via the masks).

As a basic concept, the model handles data over dictionaries, meaning it receives the input data over a dictionary `DLSample` and returns a dictionary `DLResult` and `DLTrainResult`, respectively. More information on the data handling can be found in the chapter Deep Learning / Model.

Data for training and evaluation The dataset consists of images and corresponding information. They have to be provided in a way the model can process them. Concerning the image requirements, find more information in the section "Images" below.

The training data is used to train and evaluate a network for your specific task. With the aid of this data the network can learn which classes are to be distinguished, how such examples look like, and how to find them. The necessary information is provided by telling for each object in every image to which class this object belongs to and where it is located. This is done by providing a class label and an enclosing bounding box for every object. In case of instance segmentation additionally a mask is needed for every instance. There are different ways possible, how to store and retrieve this information. How the data has to be formatted in HALCON for a DL model is explained in the chapter Deep Learning / Model. In short, a dictionary `DLDataset` serves as a database for the information needed by the training and evaluation procedures. You can label your data and directly create the dictionary `DLDataset` in the respective format using the MVTec Deep Learning Tool, available from the MVTec website. If you have your data already labeled in the standard COCO format, you can use the procedure `read_dl_dataset_from_coco` (for *'instance_type'* = *'rectangle1'* only). It formats the data and creates a dictionary `DLDataset`. For further information on the needed part of the COCO data format, please refer to the documentation of the procedure.

You also want enough training data to split it into three subsets, used for training, validation and testing the network. These subsets are preferably independent and identically distributed, see the section "Data" in the chapter Deep Learning.

Note, that in object detection the network has to learn how to find possible locations and sizes of the instances. That is why also the later important instance locations and sizes need to appear representatively in your training dataset.

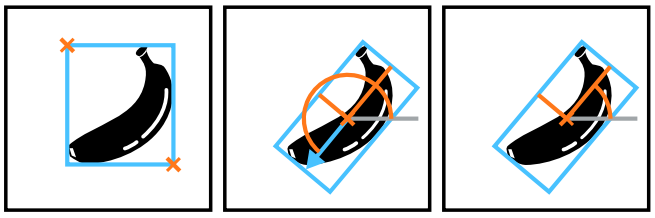
Images Regardless of the application, the network poses requirements on the images regarding e.g., the image dimensions. The specific values depend on the network itself and can be queried with `get_dl_model_param`. In order to fulfill these requirements, you may have to preprocess your images. Standard preprocessing of the entire dataset and therewith also the images is implemented in `preprocess_dl_dataset` and in `preprocess_dl_samples` for a single sample, respectively. This procedure also offers guidance on how to implement a customized preprocessing procedure.

Bounding boxes Depending on the instance type of object detection model, the bounding boxes are parametrized differently:

instance type *'rectangle1'* The bounding boxes are defined over the coordinates of upper left corner (*'bbox_row1'*, *'bbox_col1'*) and the lower right corner (*'bbox_row2'*, *'bbox_col2'*). This is consistent with `gen_rectangle1`.

instance type *'rectangle2'* The bounding boxes are defined over the coordinates of their center (*'bbox_row'*, *'bbox_col'*), the orientation *'bbox_phi'* and the half edge lengths *'bbox_length1'* and *'bbox_length2'*. The orientation is given in arc measure and indicates the angle between the horizontal axis and *'bbox_length1'* (mathematically positive). This is consistent with `gen_rectangle2`.

If in case of *'rectangle2'* you are interested in the oriented bounding box, but without considering the direction of the object within the bounding box, the parameter *'ignore_direction'* can be set to *'true'*. This is illustrated in the figure below.



(1) (2) (3)

Bounding box formats of the different object detection instance types: (1) Instance type *'rectangle1'*. (2) Instance type *'rectangle2'*, where the bounding box is oriented towards the banana end. (3) Instance type *'rectangle2'*, where the oriented bounding box is of interest without considering the direction of the banana within the bounding box.

Mask Instance segmentation requires, in addition to a tight bounding box, a mask for every object to be learned. Such a mask is given as a region. Note, these regions are given with respect to the image.

The masks for a single image are given as an object tuple of regions, see the illustration below. The order of the masks corresponds to the order of the bounding box annotations.

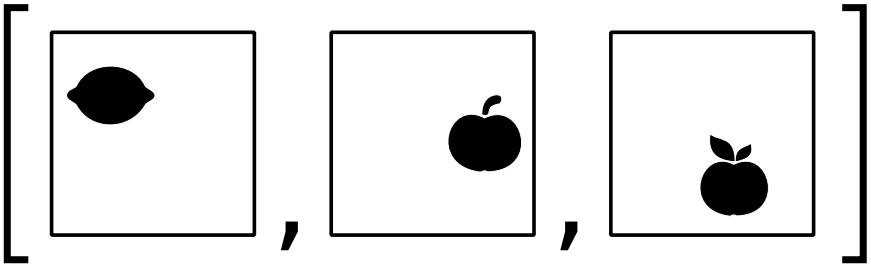


Illustration of the masks of an image: The tupel contains for every object to be learned an independent region.

Network output The network output depends on the task:

training As output, the operator `train_dl_model_batch` will return a dictionary `DLTrainResult` with the current value of the total loss as well as values for all other losses included in your model.

inference and evaluation As output, the operator `apply_dl_model` will return a dictionary `DLResult` for every image. For object detection, this dictionary will include for every detected instance its bounding box and confidence value of the assigned class as well as its mask in case of instance segmentation. Thereby several instances may be detected for the same object in the image, see the explanation to the non-maximum suppression above. The resulting bounding boxes are parametrized according to the instance type (specified over *'instance_type'*) and given in pixel centered sub-pixel accurate coordinates. For more information to the coordinate system, see the chapter Transformations / 2D Transformations. Further information on the output dictionary can be found in the chapter Deep Learning / Model.

Model Parameters and Hyperparameters

Next to the general DL hyperparameters explained in Deep Learning, there are further hyperparameters relevant for object detection:

- *'bbox_heads_weight'*
- *'class_heads_weight'*
- *'mask_head_weight'* (in case of instance segmentation)

These hyperparameters are explained in more detail in `get_dl_model_param` and set using `create_dl_model_detection`.

For an object detection model, there are two different types of model parameters:

- Parameter defining your architecture. They can not be changed anymore once your model is created. These parameters are all set using the operator `create_dl_model_detection` when creating your model.
- Parameter influencing your predictions and as a consequence the evaluation results. Those only relevant for object detection are
  - *'max_num_detections'*
  - *'max_overlap'*
  - *'max_overlap_class_agnostic'*
  - *'min_confidence'*

  They are explained in more detail in `get_dl_model_param`. To set them you can use `create_dl_model_detection` when creating your model or `set_dl_model_param` afterwards.

Evaluation measures for the Results from Object Detection

For object detection, the following evaluation measures are supported in HALCON. Note that for computing such a measure for an image, the related ground truth information is needed.

- Mean average precision, `mAP` and average precision (AP) of a class for an IoU threshold, `ap_iou_classname`

  The AP value is an average of maximum precision at different recall values. In simple words it tells us, if the objects predicted for this class are generally correct detections or not. Thereby we pay more attention to the predictions with high confidence values. The higher the value, the better.

  To count a prediction as a hit, we want both correct, its top-1 classification and its localization. The measure, telling us the correctness of the localization is the intersection over union, IoU: an instance is localized correctly if the IoU is higher than the demanded threshold. The IoU is explained in more detail below. For this reason, the AP value depends on the class and on the IoU threshold.

  You can obtain the specific AP values, the averages over the classes, the averages over the IoU thresholds, and the average over both, the classes and the IoU thresholds. The latter one is the mean average precision, mAP, a measure to tell us how well instances are found and classified.

- True Positives, False Positives, False Negatives

  The concept of true positive, false positives, and false negatives is explained in Deep Learning. It applies for object detection with the exception that there are different kinds of false positives, as e.g.:

  - An instance got classified wrongly.
  - An instance was found where there is only background.
  - An instance was localized badly, meaning the IoU between the instance and its ground truth is lower than the evaluation IoU threshold.
  - There is a duplicate, thus at least two instances overlap mainly with the same ground truth bounding box, but they overlap not more than *'max_overlap'* with each other, so none of them got suppressed.

  Note, these values are only available from the detailed evaluation. This means, in `evaluate_dl_model` the parameter `detailed_evaluation` has to be set to *'true'*.

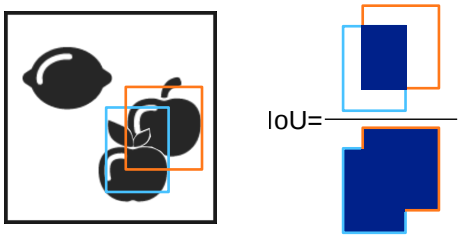
- Score of Angle Precision (SoAP)

  The SoAP value is a score for the precision of the inferred orientation angles. This score is determined by the angle differences between the inferred instances (I) and the corresponding ground truth annotations (GT):

  $\text{SoAP} = 1.0 - \frac{1}{\pi}\frac{1}{k} \cdot \sum_k \left|\varphi_k^{\text{I}} - \varphi_k^{\text{GT}}\right|,$

  where the index k runs over all inferred instances. This score only applies for detection models of *'instance_type' 'rectangle2'*.

Before mentioned measures use the intersection over union (IoU). The IoU is a measure for the accuracy of an object detection. For a proposed bounding box it compares the ratio between area of intersection and the area of overlap with the ground truth bounding box. A visual example is shown in the following schema.



(1) (2)

Visual example of the IoU, illustrated for instance type *'rectangle1'*. (1) The input image with the ground truth bounding box (orange) and the predicted bounding box (light blue). (2) The IoU is the ratio between the area intersection and the area overlap.

In case of instance segmentation the IoU is calculated (by default) based on the masks. It is possible to change the default and use the bounding boxes instead.

```
create_dl_model_detection ( : : Backbone, NumClasses,
    DLModelDetectionParam : DLModelHandle )
```

Create a deep learning network for object detection or instance segmentation.

With the operator `create_dl_model_detection` a deep learning network for object detection or instance segmentation is created. See the chapter Deep Learning / Object Detection and Instance Segmentation for further information on object detection and instance segmentation based on deep learning. The handle of this network is returned in `DLModelHandle`.

You can specify your model and its architecture over the parameters listed below. To successfully create a detection model, you need to specify its backbone and the number of classes the model shall be able to distinguish. The first information is handed over through the parameter `Backbone` which is explained below in the section "Possible Backbones". The second information is given through the parameter `NumClasses`. Note, this parameter fixes the number of classes the network will distinguish and therewith also the number of entries in *'class_ids'* and *'class_names'*.

The values of all other applicable parameters can be specified using the dictionary `DLModelDetectionParam`. Such a parameter is e.g., the *'instance_type'*, determining which kind of bounding boxes the model handles. To create a deep learning network for instance segmentation the parameter *'instance_segmentation'* has to be set to *'true'*. The full list of parameters that can be set is given below in the section "Settable Parameters". Some parameters are only available for instance segmentation. In case a parameter is not specified, the default value is taken to create the model. Note, parameters influencing the network architecture will not be changeable anymore once the network has been created. All the other parameters can still be set or changed using the operator `set_dl_model_param`. An overview, how parameters can be set is given in `get_dl_model_param`, where also a description of the specific parameters is provided. After creating the object detection model, the *'type'* will automatically be set to *'detection'*.

Possible Backbones

The parameter `Backbone` determines the backbone your network will use. See the chapter Deep Learning / Object Detection and Instance Segmentation for more information to the backbone. In short, the backbone consists of a pretrained classifier, from which only the layers necessary to generate the feature maps are kept. Hence, there are no fully connected layers anymore in the network. This implies that you read in a classifier as feature extractor for the subsequent detection network. For this you can read in a classifier in the HALCON format or a model in the ONNX format, see `read_dl_model` for more information.

`create_dl_model_detection` attaches the feature pyramid on different levels of the backbone. More precisely, the backbone has for different levels a layer specified as docking layer. When creating a detection model, the feature pyramid is attached on the corresponding docking layer. The pretrained classifiers provided by HALCON have already specified docking layers. But when you use a self-provided classifier as backbone, you have to specify them yourself. You can set `backbone_docking_layers` as part of the classifier using the operator `set_dl_model_param` or the backbone as such using this operator.

The docking layers are from different levels and therefore the feature maps used in the feature pyramid are of different size. More precisely, in the feature pyramid the feature map lengths are halved with every level. By implication, the input image lengths need to be halved for every level. This means, the network architectures allow changes concerning the image dimensions, but the dimensions *'image_width'* and *'image_height'* need to be an integer multiple of 2^{level}. Here, $level$ is the highest level up to which the feature pyramid is built. This value depends on the attached networks as well as on the docking layers. For the provided classifiers the list below mentions, up to which levels the feature pyramid is built using default settings.

HALCON provides the following pretrained classifiers you can read in as backbone:

'pretrained_dl_classifier_alexnet.hdl':

This neural network is designed for simple classification tasks. It is characterized by its convolution kernels in the first convolution layers, which are larger than in other networks with comparable classification performance (e.g., *'pretrained_dl_classifier_compact.hdl'*). This may be beneficial for feature extraction.

This backbone expects the images to be of the type `real`. Additionally, the backbone is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0

The default feature pyramid built on this backbone goes up to level 4.

'pretrained_dl_classifier_compact.hdl':
This neural network is designed to be memory and runtime efficient.

This backbone expects the images to be of the type `real`. Additionally, the backbone is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0

The default feature pyramid built on this backbone goes up to level 4.

'pretrained_dl_classifier_enhanced.hdl':
This neural network has more hidden layers than *'pretrained_dl_classifier_compact.hdl'* and is therefore assumed to be better suited for more complex tasks. But this comes at the cost of being more time and memory demanding.

This backbone expects the images to be of the type `real`. Additionally, the backbone is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0

The default feature pyramid built on this backbone goes up to level 5.

'pretrained_dl_classifier_mobilenet_v2.hdl':
This classifier is a small and low-power model, and hence it is more suitable for mobile and embedded vision applications.

This backbone expects the images to be of the type `real`. Additionally, the backbone is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0

The default feature pyramid built on this backbone goes up to level 4.

'pretrained_dl_classifier_resnet18.hdl':
As the network *'pretrained_dl_classifier_enhanced.hdl'*, this network is suited for more complex tasks. But its structure differs, bringing the advantage of making the training more stable and being internally more robust. Compared to the neural network *'pretrained_dl_classifier_resnet50.hdl'* it is less complex and has faster inference times.

This backbone expects the images to be of the type `real`. Additionally, the backbone is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224

'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0

The default feature pyramid built on this backbone goes up to level 5.

***'pretrained_dl_classifier_resnet50.hdl'*:**

As the network *'pretrained_dl_classifier_enhanced.hdl'*, this network is suited for more complex tasks. But its structure differs, bringing the advantage of making the training more stable and being internally more robust.

This backbone expects the images to be of the type `real`. Additionally, the backbone is designed for certain image properties. The corresponding values can be retrieved with `get_dl_model_param`. Here we list the default values with which the classifier has been trained:

'image_width': 224
'image_height': 224
'image_num_channels': 3
'image_range_min': -127.0
'image_range_max': 128.0

The default feature pyramid built on this backbone goes up to level 5.

Settable Parameters

Parameters you can set for your model when creating it using `create_dl_model_detection` (see `get_dl_model_param` for explanations):

- *'anchor_angles'*
- *'anchor_aspect_ratios'* (legacy: *'aspect_ratios'*)
- *'anchor_num_subscales'* (legacy: *'num_subscales'*)
- *'backbone_docking_layers'*
- *'bbox_heads_weight'*, *'class_heads_weight'*
- *'capacity'*
- *'class_ids'*
- *'class_ids_no_orientation'*

Attention

To successfully set *'gpu'* parameters, cuDNN and cuBLAS are required, i.e., to set the parameter `GenParamName` *'runtime'* to *'gpu'*. For further details, please refer to the "`Installation Guide`", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

▷ **Backbone** (input_control) . . . . . filename.read ⇝ *string*
Deep learning classifier, used as backbone network.
Default: 'pretrained_dl_classifier_compact.hdl'
List of values: Backbone ∈ {'pretrained_dl_classifier_alexnet.hdl', 'pretrained_dl_classifier_compact.hdl', 'pretrained_dl_classifier_enhanced.hdl', 'pretrained_dl_classifier_mobilenet_v2.hdl', 'pretrained_dl_classifier_resnet18.hdl', 'pretrained_dl_classifier_resnet50.hdl'}
File extension: .hdl

▷ **NumClasses** (input_control) . . . . . integer ⇝ *integer*
Number of classes.
Default: 3

▷ **DLModelDetectionParam** (input_control) . . . . . dict ⇝ *handle*
Parameters for the object detection model.
Default: []

▷ **DLModelHandle** (output_control) . . . . . dl_model ⇝ *handle*
Deep learning model for object detection.

Result

If the parameters are valid, the operator create_dl_model_detection returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_dl_model_param, get_dl_model_param, apply_dl_model, train_dl_model_batch

Alternatives

read_dl_model

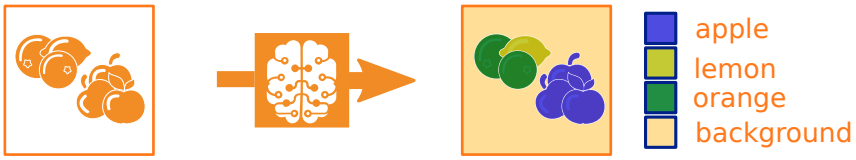
Module

Deep Learning Professional

9.7 Semantic Segmentation and Edge Extraction

This chapter explains how to use semantic segmentation based on deep learning, both for the training and inference phases.

With **semantic segmentation** we assign each pixel of the input image to a class using a deep learning (DL) network.

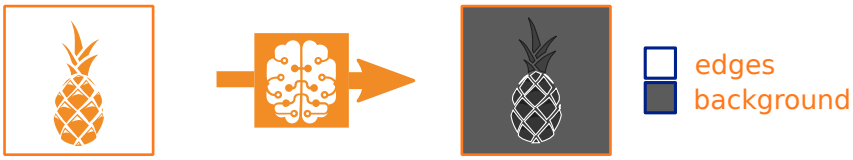


A possible example for semantic segmentation: Every pixel of the input image is assigned to a class, but neither the three different instances of the class 'apple' nor the two different instances of the class 'orange' are distinguished objects.

The result of semantic segmentation is an output image, in which the pixel value signifies the assigned class of the corresponding pixel in the input image. Thus, in HALCON the output image is of the same size as the input

image. For general DL networks the deeper feature maps, representing more complex features, are usually smaller than the input image (see the section “The Network and the Training Process” in Deep Learning). To obtain an output of the same size as the input, HALCON uses segmentation networks with two components: an encoder and a decoder. The encoder determines features of the input image as done, e.g., for deep-learning-based classification. As this information is ’encoded’ in a compressed format, the decoder is needed to reconstruct the information to the desired outcome, which, in this case, is the assignment of each pixel to a class. Note that, as pixels are classified, overlapping instances of the same class are not distinguished as distinct.

Edge extraction is a special case of semantic segmentation, where the model is trained to distinguish two classes: ’edge’ and ’background’. For more information, see “Solution Guide I - Basics”.



A possible example for edge extraction: A special case of semantic segmentation, where every pixel of the input image is assigned to one of the two classes: ’edge’ and ’background’.

Semantic segmentation with deep learning is implemented within the more general deep learning model of HALCON. For more information to the latter one, see the chapter Deep Learning / Model. For the specific system requirements in order to apply deep learning, please refer to the HALCON “Installation Guide”.

The following sections are introductions to the general workflow needed for semantic segmentation, information related to the involved data and parameters, and explanations to the evaluation measures.

General Workflow

In this paragraph, we describe the general workflow for a semantic segmentation task based on deep learning. It is subdivided into the four parts preprocessing of the data, training of the model, evaluation of the trained model, and inference on new images. Thereby we assume, your dataset is already labeled, see also the section “Data” below. Have a look at the HDevelop example series `segment_pill_defects_deep_learning` for an application. The example `segment_edges_deep_learning_with_retraining` shows the complete workflow for an edge extraction application.

Preprocess the data This part is about how to preprocess your data. The single steps are also shown in the HDevelop example `segment_pill_defects_deep_learning_1_preprocess.hdev`.

1. The information what is to be found in which image of your training dataset needs to be transferred. This is done by the procedure
   - `read_dl_dataset_segmentation`.

   Thereby a dictionary `DLDataset` is created, which serves as a database and stores all necessary information about your data. For more information about the data and the way it is transferred, see the section “Data” below and the chapter Deep Learning / Model.
2. Split the dataset represented by the dictionary `DLDataset`. This can be done using the procedure
   - `split_dl_dataset`.

   The resulting split will be saved over the key `split` in each sample entry of `DLDataset`.
3. Now you can preprocess your dataset. For this, you can use the procedure
   - `preprocess_dl_dataset`.

   This procedure also offers guidance on how to implement a customized preprocessing procedure.

   To use this procedure, specify the preprocessing parameters as e.g., the image size. For this latter one you should select the smallest possible image size at which the regions to segment are still well recognizable. Store all the parameter with their values in a dictionary `DLPreprocessParam`, wherefore you can use the procedure
   - `create_dl_preprocess_param`.

We recommend to save this dictionary `DLPreprocessParam` in order to have access to the preprocessing parameter values later during the inference phase.
During the preprocessing of your dataset also the images `weight_image` will be generated for the training dataset by `preprocess_dl_dataset`. They assign each class the weight ('class weights') its pixels get during training (see the section "Model Parameters and Hyperparameters" below).

Training of the model This part is about how to train a DL semantic segmentation model. The single steps are also shown in the HDevelop example `segment_pill_defects_deep_learning_2_train.hdev`.

1. A network has to be read using the operator
   - `read_dl_model`.
2. The model parameters need to be set via the operator
   - `set_dl_model_param`.

   Such parameters are e.g., *'image_dimensions'* and *'class_ids'*, see the documentation of `get_dl_model_param`.
   You can always retrieve the current parameter values using the operator
   - `get_dl_model_param`.
3. Set the training parameters and store them in the dictionary `TrainParam`. These parameters include:
   - the hyperparameters, for an overview see the section "Model Parameters and Hyperparameters" below and the chapter Deep Learning.
   - parameters for possible data augmentation (optional).
   - parameters for the evaluation during training.
   - parameters for the visualization of training results.
   - parameters for serialization.

   This can be done using the procedure
   - `create_dl_train_param`.
4. Train the model. This can be done using the procedure
   - `train_dl_model`.

   The procedure expects:
   - the model handle `DLModelHandle`
   - the dictionary with the data information `DLDataset`
   - the dictionary with the training parameter `TrainParam`
   - the information, over how many epochs the training shall run.

   In case the procedure `train_dl_model` is used, the total loss as well as optional evaluation measures are visualized.

Evaluation of the trained model In this part we evaluate the semantic segmentation model. The single steps are also shown in the HDevelop example `segment_pill_defects_deep_learning_3_evaluate.hdev`.

1. Set the model parameters which may influence the evaluation, as e.g., *'batch_size'*, using the operator
   - `set_dl_model_param`.
2. The evaluation can conveniently be done using the procedure
   - `evaluate_dl_model`.
3. The dictionary `EvaluationResult` holds the asked evaluation measures. You can visualize your evaluation results using the procedure
   - `dev_display_segmentation_evaluation`.

Inference on new images This part covers the application of a DL semantic segmentation model. The single steps are also shown in the HDevelop example `segment_pill_defects_deep_learning_4_infer.hdev`.

1. Set the parameters as e.g., *'batch_size'* using the operator
   - set_dl_model_param.
2. Generate a data dictionary DLSample for each image. This can be done using the procedure
   - gen_dl_samples_from_images.
3. Preprocess the image as done for the training. We recommend to do this using the procedure
   - preprocess_dl_samples.

   When you saved the dictionary DLPreprocessParam during the preprocessing step, you can directly use it as input to specify all parameter values.
4. Apply the model using the operator
   - apply_dl_model.
5. Retrieve the results from the dictionary *'DLResultBatch'*. The regions of the particular classes can be selected using e.g., the operator threshold on the segmentation image.

Data

We distinguish between data used for training and evaluation, and data for inference. The latter ones consist of bare images. The first ones consist of images with their information and ground truth annotations. You provide this information defining for each pixel, to which class it belongs (over the segmentation_image, see below for further explanations).

As basic concept, the model handles data over dictionaries, meaning it receives the input data over a dictionary DLSample and returns a dictionary DLResult and DLTrainResult, respectively. More information on the data handling can be found in the chapter Deep Learning / Model.

Data for training and evaluation The training data is used to train a network for your specific task. The dataset consists of images and corresponding information. They have to be provided in a way the model can process them. Concerning the image requirements, find more information in the section "Images" below. The information about the images and their ground truth annotations is provided over the dictionary DLDataset and for every sample the respective segmentation_image, defining the class for every pixel.

Classes The different classes are the sets or categories differentiated by the network. They are set in the dictionary DLDataset and are passed to the model via the operator set_dl_model_param.

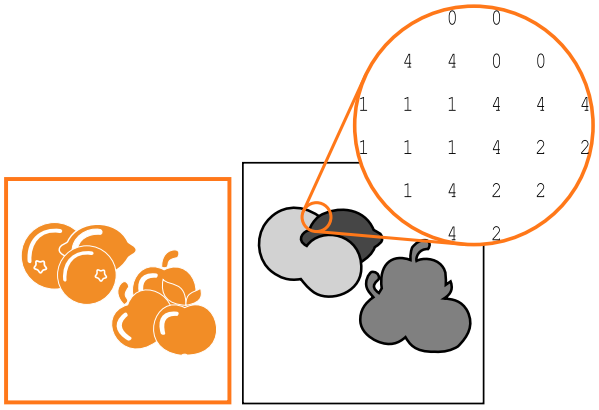
In **semantic segmentation**, we call your attention to two special cases: the class 'background' and classes declared as 'ignore':

- 'background' class: The networks treats the background class like any other class. It is also not necessary to have a background class. But if you have different classes in your dataset you are not interested in although they have to be learned by the network, you can set them all as 'background'. As a result, the class background will be more diverse. See the procedure preprocess_dl_samples for more information.
- 'ignore' classes: There is the possibility to declare one or multiple classes as 'ignore'. Pixels assigned to a 'ignore' class are ignored by the loss as well as for all measures and evaluations. Please see the section "The Network and the Training Process" in the chapter Deep Learning for more information about the loss. The network does not classify any pixel into a class declared as 'ignore'. Also, the pixels labeled to belong to such a class will be classified by the network like every other pixel into a non-'ignore' class. In the example given in the image below, this means the network will classify also the pixels of the class 'border', but it will not classify any pixel into the class 'border'. You can declare a class as 'ignore' using the parameter *'ignore_class_ids'* of set_dl_model_param.

In **edge extraction** only two classes are distinguished: 'edge' and 'background'. The class 'edge' is labeled just like a normal class. Thus, only one class is labeled and this class is called 'edge'.

DLDataset This dictionary serves as a database, this means, it stores all information about your data necessary for the network as, e.g., the names and paths to the images, the classes, ... Please see the documentation of Deep Learning / Model for the general concept and key entries. Keys only applicable for semantic segmentation concern the segmentation_image (see the entry below). Over the keys segmentation_dir and segmentation_file_name you provide the information how they are named and where they are saved.

segmentation_image In order that the network can learn, how the member of different classes look like, you tell for each pixel of every image in the training dataset to which class it belongs. This is done by storing for every pixel of the input image the class encoded as pixel value in the corresponding `segmentation_image`. These annotations are the ground truth annotations.



(1) (2)

Schema of `segmentation_image`. For visibility, gray values are used to represent numbers. (1) Input image. (2) The corresponding `segmentation_image` providing the class annotations, 0: background (white), 1: orange, 2: lemon, 3: apple, and 4: border (black) as a separate class so we can declare it as 'ignore'.

You need enough training data to split it into three subsets, one used for training, one for validation and one for testing the network. These subsets are preferably independent and identically distributed (see the section "Data" in the chapter Deep Learning. For the splitting you can use the procedure `split_dl_data_set`.

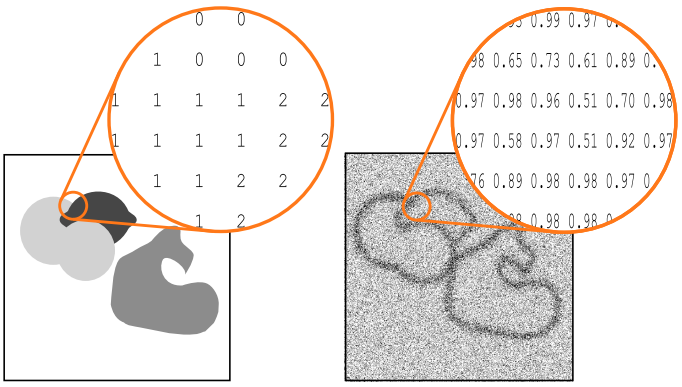
Images Regardless of the application, the network poses requirements on the images regarding the image dimensions, the gray value range, and the type. The specific values depend on the network itself, see the documentation of `read_dl_model` for the specific values of different networks. For a loaded network they can be queried with `get_dl_model_param`. In order to fulfill these requirements, you may have to preprocess your images. Standard preprocessing of an entire sample and therewith also the image is implemented in `preprocess_dl_samples`. This procedure also offers guidance on how to implement a customized preprocessing procedure.

Network output The network output depends on the task:

training As output, the operator will return a dictionary `DLTrainResult` with the current value of the total loss as well as values for all other losses included in your model.

inference and evaluation As output, the network will return a dictionary `DLResult` for every sample. For semantic segmentation, this dictionary will include for each input image the handles of the two following images:

- `segmentation_image`: An image where each pixel has a value corresponding to the class its corresponding pixel has been assigned to (see the illustration below).
- `segmentation_confidence`: An image, where each pixel has the confidence value out of the classification of the according pixel in the input image (see the illustration below).



(1) (2)

A schema over different data images. For visibility, gray values are used to represent numbers. (1) `segmentation_image`: also the pixels of classes declared as 'ignore' (see the figure above) get classified. (2) `segmentation_confidence`.

Model Parameters and Hyperparameters

Next to the general DL hyperparameters explained in Deep Learning, there is a further hyperparameter relevant for semantic segmentation:

- 'class weights', see the explanations below.

For a semantic segmentation model, the model parameters as well as the hyperparameters (with the exception of 'class weights') are set using `set_dl_model_param`. The model parameters are explained in more detail in `get_dl_model_param`.

Note, due to large memory usage, typically only small batch sizes are possible for training. As a consequence, training is rather slow and we advice to use a momentum higher than e.g., for classification. The HDevelop example `segment_pill_defects_deep_learning_2_train.hdev` provides good initial parameter values for the training of a segmentation network in HALCON.

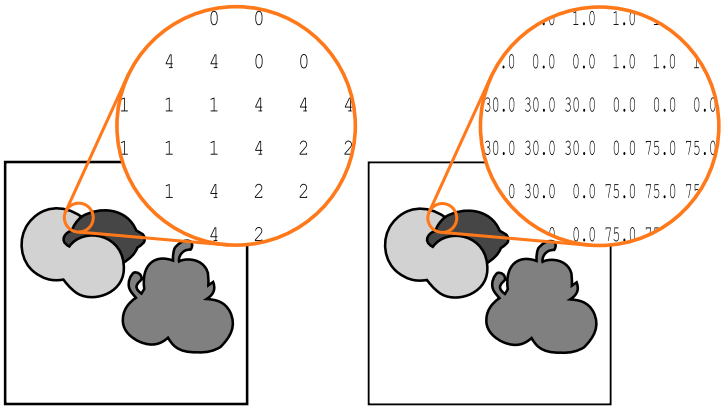
'class weights' With the hyperparameter 'class weights' you can assign each class the weight its pixels get during training. Giving the unique classes a different weight, it is possible to force the network to learn the classes with different importance. This is useful in cases where a class dominates the images, as e.g., defect detection, where the defects take up only a small fraction within an image. In such a case a network classifying every pixel as background (thus, 'not defect') would achieve generally good loss results. Assigning different weights to the distinct classes helps to re-balance the distribution. In short, you can focus the loss to train especially on those pixels you determine to be important.

The network obtains these weights over `weight_image`, an image which is created for every training sample. In `weight_image`, every pixel value corresponds to the weight the corresponding pixel of the input image gets during training. You can create these images with the help of the following two procedures:

- `calculate_dl_segmentation_class_weights` helps you to create the class weights. The procedure uses the concept of inverse class frequency weights.
- `gen_dl_segmentation_weight_images` uses the class weights and generates the `weight_image`.

This step has to be done before the training. Usually it is done during the preprocessing and it is part of the procedure `preprocess_dl_dataset`. Note, this hyperparameter is referred as `class_weights` or `ClassWeights` within procedures. An illustration, how such an image with different weights looks like, is shown in the figure below.

Note, giving a specific part of the image the weight 0.0, these pixels do not contribute to the loss (see the section "The network and its training" in Deep Learning for more information about the loss).



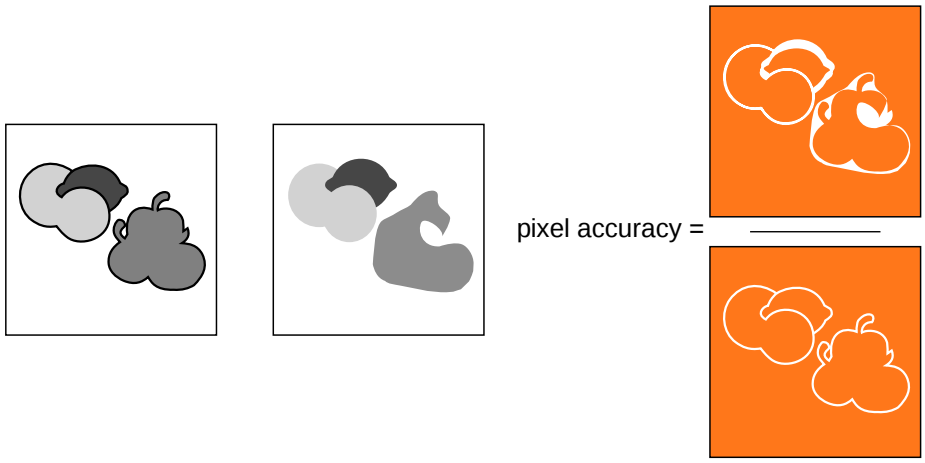
(1) (2)

Schema for `weight_image`. For visibility, gray values are used to represent numbers. (1) The `segmentation_image` defining the classes for every pixel within the image, 0: background (white), 1: orange, 2: lemon, 3: apple, and 4: border (black), declared as 'ignore'. (2) The corresponding `weight_image` providing class weights, background: 1.0, orange: 30.0, lemon: 75.0. Pixels of classes declared as 'ignore', here the class border, will be ignored and get the weight 0.0.

Evaluation measures for the Data from Semantic Segmentation

For semantic segmentation, the following evaluation measures are supported in HALCON. Note that for computing such a measure for an image, the related ground truth information is needed. All the measure values explained below for a single image (e.g., `mean_iou`) can also be calculated for an arbitrary number of images. For this, imagine a single, large image formed by the ensemble of the output images, for which the measure is computed. Note, all pixels of a class declared as 'ignore' are ignored for the computation of the measures.

`pixel_accuracy` The pixel accuracy is simply the ratio of all pixels that have been predicted with the correct class-label to the total number of pixels.



(1) (2) (3)

Visual example of the `pixel_accuracy`: (1) The `segmentation_image` defining the ground truth class for each pixel (see the section "Data" above). Pixels of a class declared as 'ignore' are drawn in black. (2) The output image, also the pixels of classes declared as 'ignore' get classified. (3) The pixel accuracy is the ratio between the total orange areas. Note, pixels labeled as part of a class declared as 'ignore' are ignored.

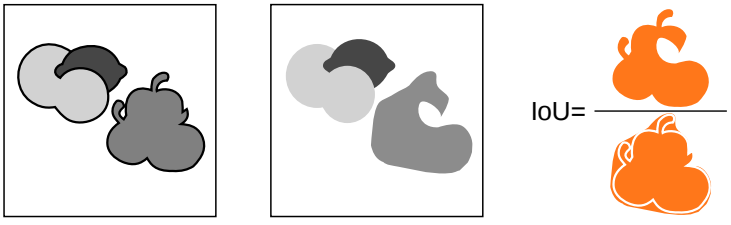
`class_pixel_accuracy` The per-class pixel accuracy considers only pixels of a single class. It is defined as the ratio between the correctly predicted pixels and the total number of pixels labeled with this class.

In case a class does not occur it gets a `class_pixel_accuracy` value of *-1* and does not contribute to the average value, `mean_accuracy`.

`mean_accuracy` The mean accuracy is defined as the averaged per-class pixel accuracy, `class_pixel_accuracy`, of all occurring classes.

`class_iou` The per-class intersection over union (IoU) gives for a specific class the ratio of correctly predicted pixels to the union of annotated and predicted pixels. Visually this is the ratio between the intersection and the union of the areas, see the image below.

In case a class does not occur it gets a `class_iou` value of *-1* and does not contribute to the `mean_iou`.



(1) (2) (3)

Visual example of the per-class IoU, `class_iou`, here for the class apple only. (1) The `segmentation_image` defining the ground truth class for each pixel (see the section “Data”). Pixels of a class declared as 'ignore' are drawn in black. (2) The output image, also the pixels of classes declared as 'ignore' get classified. (3) The intersection over union is the ratio between the intersection and the union of the areas of pixels denoted as apple. Note, pixels labeled as part of a class declared as 'ignore' are ignored.

`mean_iou` The mean IoU is defined as the averaged per-class intersection over union, `class_iou`, of all occurring classes. Note that every occurring class has the same impact on this measure, independent of the number of pixels they contain.

`frequency_weighted_iou` As for the mean IoU, the per-class IoU is calculated first. But the contribution of each occurring class to this measure is weighted by the ratio of pixels that belong to that class. Note that classes with many pixels can dominate this measure.

`pixel_confusion_matrix` The concept of a confusion matrix is explained in the section “Supervising the training” within the chapter Deep Learning. It applies for semantic segmentation, where the instances are single pixels.

Chapter 10

Develop

dev_clear_obj (Objects : : :)

Delete an iconic object from the HALCON database.

dev_clear_obj deletes iconic objects, which are no longer needed, from the HALCON database.

Attention

Never use clear_obj to clear objects in HDevelop. The operator dev_clear_obj has to be used instead.

Parameters

▷ **Objects** (input_object) ..... object(-array) ⇝ *object*
Objects to be deleted.

Result

dev_clear_obj returns always 2 (H_MSG_TRUE).

See also

clear_obj, dev_set_check, reset_obj_db

Module

Foundation

dev_clear_window (: : :)

Clear the contents of the active graphics window.

dev_clear_window clears the contents of the active graphics window including the history of the displayed iconic objects. The output parameters that have been set for this window via the context menu, the visualization parameters dialog, or the appropriate operators (e.g., with dev_set_color, dev_set_draw, etc.) remain unmodified.

The operator is equivalent to pressing the Clear button of the active graphics window.

A graphics window can be activated by calling dev_set_window or by pressing the Activate button in the tool bar of the selected graphics window.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Example

```
read_image (Image, 'fabrik')
regiongrowing (Image, Regions, 3, 3, 6, 100)
```

```
Number := |Regions|
dev_update_window ('off')
for i := 1 to Number by 1
  select_obj (Regions, RegionSelected, i)
  dev_clear_window ()
  dev_display (RegionSelected)
  * stop ()
endfor
```

Result

dev_clear_window returns always 2 (H_MSG_TRUE).

Possible Predecessors

dev_set_window, dev_open_window, dev_display

Possible Successors

dev_display

See also

clear_window

Module

Foundation

dev_close_inspect_ctrl (: : Variable :)

Close inspect window(s) of one or more control variables.

dev_close_inspect_ctrl is the counterpart operator to dev_inspect_ctrl. It closes the variable inspect window or windows corresponding to the variables specified in Variable. The parameter Variable can contain an expression (e.g., tuple) with several variable names. First, the operator dev_close_inspect_ctrl tries to find an inspect window with an exact match of the listed variables. If it is found, it will be closed. If no exact match is found, the operator tries to remove for every listed variable one column from the first matching inspect window. By removing the last column of an inspect window the window is closed.

As an alternative, the inspect windows can be closed by pressing the Close-button in the title bar.

Attention

This operator only works for single floating inspect windows, i.e., inspect windows that are neither docked nor tabbed.

This operator is not supported for code export.

Parameters

▷ **Variable** (input_control) ..... real(-array) ⇝ *real* / integer / string
Name of the variable which inspect window has to be closed.

Example

```
Var := 1
dev_inspect_ctrl (Var)
Var := [1,2,3,9,5,6,7,8]
Var[3] := 4
stop ()
dev_close_inspect_ctrl (Var)
```

Result

dev_close_inspect_ctrl returns always 2 (H_MSG_TRUE).

Possible Predecessors

dev_inspect_ctrl

Module

Foundation

dev_close_tool (: : ToolId :)

Close the specified floating tool window.

dev_close_tool closes the tool with the ToolId. Instead of using the ToolId, given during opening the tool, you can use the name that has to be used in dev_open_tool. In that case a arbitrary tool, which fits the parameter ToolId, is used.

Attention

This operator only works for single floating tools, i.e., tools that are neither docked nor tabbed.

This operator is not supported for code export.

Parameters

▷ **ToolId** (input_control) . . . . . dev_tool ⇝ *string*
Tool identifier.

Example

```
dev_open_tool ('matching_assistant', 0, 0, 'default','default', ToolId)
dev_close_tool (ToolId)
```

Result

If the values of the specified parameters are correct, dev_open_tool returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

dev_set_tool_geometry, dev_open_tool

Possible Successors

dev_open_tool

See also

dev_show_tool

Module

Foundation

dev_close_window (: : :)

Close the active floating graphics window.

dev_close_window closes the active floating graphics window.

The operator is equivalent to pressing the Close button in the title bar of the active window or selecting the appropriate menu entry from the Visualization menu.

A graphics window can be activated by calling dev_set_window or by pressing the Activate button in the tool bar of the selected graphics window.

Attention

This operator only works for single floating graphics windows, i.e., graphics windows that are neither docked nor tabbed.

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Example

```
* close all windows
for i := 1 to 10 by 1
  dev_close_window ()
endfor
```

```
read_image (For5, 'for5')
get_image_size (For5, Width, Height)
dev_open_window (0, 0, Width, Height, 'black', WindowHandle)
dev_display (For5)
```

Result

`dev_close_window` returns always 2 (`H_MSG_TRUE`).

Possible Predecessors

`dev_set_window`, `dev_open_window`

Possible Successors

`dev_open_window`, `dev_get_window`

See also

`close_window`

Module

Foundation

dev_disp_text (: : String, CoordSystem, Row, Column, Color, GenParamName, GenParamValue :)

Display text in the current graphics window.

`dev_disp_text` displays text in the current graphics window at the position (`Row`,`Column`).

If only a single position is defined, one text line is displayed for each element of `String`. Also, *'\n'* will be interpreted as a newline character, i.e., a line break is performed.

If multiple positions are defined, only a single string or one string for each position is allowed in `String`. In this case, line breaks have to be forced with *'\n'*.

Newlines (*'\n'*) at the end of `String` are ignored.

The position of the text may be specified in window coordinates (`CoordSystem` = *'window'*) or in image coordinates (`CoordSystem` = *'image'*), which is useful when using zoomed images.

In addition to supplying (`Row`,`Column`) coordinates, it is also possible to pass predefined values to `Row` and `Column` to display the text at a fixed position in the window (only if `CoordSystem` = *'window'*).:

'top', *'left'*	*'top'*, *'center'*	*'top'*, *'right'*
'center', *'left'*	*'center'*, *'center'*	*'center'*, *'right'*
'bottom', *'left'*	*'bottom'*, *'center'*	*'bottom'*, *'right'*

The parameter `Color` also accepts tuples of values. In that case, the specified colors are used cyclically for every new text position or for every new line of text if a single position is used.

Generic Parameters

`dev_disp_text` may display the `String` within a box (default). This behavior and the look of the box are defined with the generic parameters in `GenParamName` and `GenParamValue`.

'box' If *'box'* is set to *'true'*, the text is written within a box. The look of the box and its optional shadow can be configured with the generic parameters below.

List of values: *'true'* and *'false'*

Default: *'true'*

'box_color' Sets the color of the box.

List of values: a string containing the color name (e.g., *'white'*, *'red'*, or *'#aa00bba0'*)

Default: *'#fce9d4'* (which is a light orange)

'shadow' If *'shadow'* is set to *'true'*, an additional shadow is displayed beneath the box (if *'box'* is *'true'*).

List of values: *'true'* and *'false'*

Default: *'true'* if *'box_color'* is set to a color without alpha value, *'false'* otherwise

'shadow_color' Sets the color of the shadow if *'shadow'* is *'true'*.

List of values: a string containing the color name (e.g., *'black'*, *'red'*, or *'#aa00bba0'*)

Default: *'#f28d26'* (which is a darker orange) if *'box_color'* is not set, *'white'* otherwise

'border_radius' Controls the roundness of the box's corners. For sharp corners set it to *0*, for smoother corners to higher values.

List of values: positive real numbers or *0*

Default: 2

'box_padding' Controls to which amount in pixels the box is extended around the text.

List of values: positive real number

Default: 0

'shadow_sigma' Controls to which amount the shadow beneath the box is blurred. Set it to *0* for a sharp shadow.

List of values: positive real number or *0*

Default: 1.5

'shadow_dx' and 'shadow_dy' Controls the offset of the shadow in column (*'shadow_dx'*) and row (*'shadow_dy'*) direction in pixels.

List of values: any real number

Default: 2

'backdrop_blur_sigma' Controls to which amount the background of the box is blurred. s only an effect if *'box'* is *'true'* and *'box_color'* is not opaque (i.e. alpha is not 255). It is recommended to use *'backdrop_blur_sigma'* with *'shadow'* set to *'false'*.

List of values: positive real number or *0*

Default: 0

'rotate_phi' Angle in degrees to rotate the displayed text.

List of values: any real number

Default: 0

'rotate_col' Column coordinate of the rotation center if *'rotate_phi'* is different to zero. Choose either a column coordinate by setting a real number or determine the rotation center on the left edge (*'text_left'*), the right edge (*'text_right'*), or in the center (*'text_center'*) of the text box.

List of values: any real number or *'text_left'*, *'text_center'*, *'text_right'*

Default: *'text_center'*

'rotate_row' Row coordinate of the rotation center if *'rotate_phi'* is different to zero. Choose either a row coordinate by setting a real number or determine the rotation center on the top edge (*'text_top'*), the bottom edge (*'text_bottom'*), or in the center (*'text_center'*) of the text box.

List of values: any real number or *'text_top'*, *'text_center'*, *'text_bottom'*

Default: *'text_center'*

'border_color' Sets the color of the border of the text box.

List of values: a string containing the color name (e.g., *'black'*, *'red'*, or *'#aa00bba0'*)

Default: *'#ffffff'*

'border_width' Controls the width of the text box border.

List of values: positive real numbers or *0*

Default: 0

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

- ▷ **String** (input_control) . . . . . string(-array) ⇝ *string*
  A tuple of strings containing the text message to be displayed. Each value of the tuple will be displayed in a single line.
  Default: 'hello'
- ▷ **CoordSystem** (input_control) . . . . . string ⇝ *string*
  If set to 'window', the text position is given with respect to the window coordinate system. If set to 'image', image coordinates are used (this may be useful in zoomed images).
  Default: 'window'
  List of values: `CoordSystem` ∈ {'window', 'image'}
- ▷ **Row** (input_control) . . . . . point.y(-array) ⇝ *integer* / real / string
  The vertical text alignment or the row coordinate of the desired text position.
  Default: 12
  List of values: `Row` ∈ {12, 'bottom', 'center', 'top'}
- ▷ **Column** (input_control) . . . . . point.x(-array) ⇝ *integer* / real / string
  The horizontal text alignment or the column coordinate of the desired text position.
  Default: 12
  List of values: `Column` ∈ {12, 'center', 'left', 'right'}
- ▷ **Color** (input_control) . . . . . string(-array) ⇝ *string*
  A tuple of strings defining the colors of the texts.
  Default: 'black'
  List of values: `Color` ∈ {'black', 'blue', 'yellow', 'red', 'green', 'cyan', 'magenta', 'forest green', 'lime green', 'coral', 'slate blue'}
- ▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
  Generic parameter names.
  Default: []
  List of values: `GenParamName` ∈ {'backdrop_blur_sigma', 'box', 'shadow', 'box_color', 'shadow_color', 'border_radius', 'box_padding', 'shadow_sigma', 'shadow_dx', 'shadow_dy', 'rotate_phi', 'rotate_col', 'rotate_row', 'border_color', 'border_width'}
- ▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
  Generic parameter values.
  Default: []
  List of values: `GenParamValue` ∈ {'true', 'false', 'white', 'red', 'forest green', 'black', 'blue', 5.0}

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
dev_disp_text ('Display some text in a box', 'window', 12, 12, \
               'black', [], [])
```

Result

If the values of the specified parameters are correct, `dev_disp_text` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

`dev_open_window`, `set_font`, `get_string_extents`

Alternatives

`disp_text`, `write_string`

See also

`get_string_extents`, `set_font`

Module

Foundation

dev_display (Object : : :)

Displays image objects in the current graphics window.

dev_display displays an iconic object (image, region, or XLD) in the active graphics window. This is equivalent to a double click on an icon variable inside the variable window.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **Object** (input_object) . . . . . object(-array) ⇝ *object*
Image objects to be displayed.

Example

```
read_image (Image, 'fabrik')
regiongrowing (Image, Regions, 3, 3, 6, 100)
dev_clear_window ()
dev_display (Image)
dev_set_colored (12)
dev_set_draw ('margin')
dev_display (Regions)
```

Result

If the values of the specified parameters are correct, dev_display returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Alternatives

disp_obj, disp_image, disp_region, disp_xld

See also

dev_set_color, dev_set_colored, dev_set_draw, dev_set_line_width

Module

Foundation

dev_error_var (: : ErrorVar, Mode :)

Define or undefine an error variable.

dev_error_var defines an error variable, i.e., a variable which contains the result state of the last operator call. ErrorVar will be 2 (H_MSG_TRUE) if no error had occurred. The parameter Mode specifies whether the error variable should be used (*1*) or not (*0*). If an error variable is active it will be updated each time an operator execution is finished. Thus a value is only valid until the next call of an operator. The value can be saved by assigning it to another variable (see example) or by calling dev_error_var(ErrorVar,0).

Parameters

▷ **ErrorVar** (input_control) . . . . . integer ⇝ *integer*
Name of the variable which shall contain the error status.
Default: 'ErrorVar'

▷ **Mode** (input_control) . . . . . integer ⇝ *integer*
Switch the error variable on or off.
Default: 1
List of values: Mode ∈ {0, 1}

Example

```
dev_close_window ()
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
dev_error_var (Error, 1)
dev_set_check ('~give_error')
```

```
FileName := 'wrong_name'
read_image (Image, FileName)
ReadError := Error
if (ReadError != H_MSG_TRUE)
  write_string (WindowHandle, 'wrong file name: '+FileName)
endif
```

Result

If the values of the specified parameters are correct, dev_error_var returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

dev_set_check

Possible Successors

dev_set_check, if, elseif, else, assign

See also

dev_set_check, set_check

Module

Foundation

dev_get_exception_data (: : Exception, Name : Value)

Access the elements of an exception tuple.

The operator dev_get_exception_data enables to access specific items of an exception tuple that was caught by the operator catch. Except the error code that is always passed as the first element of the exception tuple all other data of the exception tuple has to be accessed exclusively via the operator dev_get_exception_data. This is due to the fact that the order and the extent of the provided data may change in future versions and may vary for the different code exports.

If an operator error occurred within HDevelop or HDevEngine, the caught exception tuple contains the data items listed below. This tuple has to be passed to the parameter Exception. The name of the requested data slot has to be passed to the parameter Name. The requested data is returned in the parameter Value. By passing a tuple of slot names to Name it is possible to request several exception data items in a single call of dev_get_exception_data. In that case a corresponding data tuple is returned in Value. For requested items that are not available an empty string ('') is returned.

Note that the operator dev_get_exception_data is meant to be used within HDevelop or HDevEngine. Some information is not available when the operator is exported.

Supported data slots:

'error_code': HALCON or user defined error code. A list of HALCON error codes (codes < 10000) can be found in the appendix of the "Extension Package Programmer's Manual".

'add_error_code': Additional HDevelop specific error code. These error codes specify whether an error was caught within the HALCON operator (code = 21000) or outside the operator, e.g., during the evaluation and assignment of the parameter expressions. In the latter case the error code specifies the error type more precisely. The relevant error codes are listed in the "HDevelop User's Guide".

'error_message': HALCON error message.

'add_error_message': Additional error message that describes the HDevelop specific error more precisely.

'program_line': Number of the program line, where the error occurred.

'operator': Name of the operator that threw the exception (if the exception was thrown in a protected procedure, '--protected--' is returned instead of the operator name).

'call_stack_depth': Depth of the call stack (if the error occurred in 'main' a depth of 1 is returned).

'procedure': Name of the procedure where the error occurred.

'user_data': User defined exception tuple. If an operator exception was caught and rethrown, this is the tuple that was appended to the caught exception tuple in the call of `throw`. In case of a completely user defined exception all tuple items except the first element containing the error code ($\geq$ 30000) are returned. If no user data was passed with the exception tuple, an empty tuple is returned. Note, that the user data tuple cannot be requested together with any other exception data in one `dev_get_exception_data` call.

Parameters

▷ **`Exception`** (input_control) . . . . . exception-array ⇝ *integer* / string
Tuple containing the exception data or user defined error codes.

▷ **`Name`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name(s) of the requested exception data.
Default: 'error_code'
List of values: `Name` ∈ {'error_code', 'add_error_code', 'error_message', 'add_error_message', 'operator', 'procedure', 'program_line', 'call_stack_depth', 'user_data'}

▷ **`Value`** (output_control) . . . . . attribute.value-array ⇝ *integer* / string
Requested exception data.

Result

If the values of the specified parameters are correct, `dev_get_exception_data` (as operator) returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

`catch`

`try`, `catch`, `endtry`, `throw`, `dev_set_check`

Module

Foundation

`dev_get_preferences ( : : PreferenceNames : PreferenceValues )`

Query HDevelop preferences within a program.

`dev_get_preferences` allows to query selected preferences of HDevelop within a program. Until now, the following preferences are supported:

'graphics_window_context_menu': Returns whether a right click into the graphics window opens a context menu or not. By default the context menu is enabled.

'graphics_window_mouse_wheel': Returns whether the mouse wheel can be used to zoom the contents of the graphics window or not. By default the moue wheel is enabled.

'graphics_window_tool_tip': Returns whether pressing the Ctrl key over the graphics window shows a tool tip with the current pixel position and the gray values under the mouse cursor or not. By default the tool tip is enabled.

'suppress_handled_exceptions_dlg': Returns whether the error dialog is suppressed that is by default opened for exceptions that are thrown during program execution and that are enclosed by a `try-catch` block and can therefore be handled by an exception handler. This option is persistently stored in the HDevelop.ini file and can be configured via the Preferences dialog / General Options / Experienced User.

Attention

This operator is not supported for code export.

Parameters

▷ **`PreferenceNames`** (input_control) . . . . . attribute.name-array ⇝ *string*
Selection of the preferences.
Default: 'graphics_window_context_menu'
List of values: `PreferenceNames` ∈ {'graphics_window_context_menu', 'graphics_window_mouse_wheel', 'graphics_window_tool_tip', 'suppress_handled_exception_dlg'}

▷ **`PreferenceValues`** (output_control) . . . . . attribute.value-array ⇝ *string*
Values of the selected preferences.

See also

dev_set_preferences

Module

Foundation

dev_get_system (: : SystemQueries : SystemInformations)

Query the HDevelop system within a program.

The operator dev_get_system returns information concerning the HDevelop system parameters.

Read-Only Parameters

The following system parameters can be queried:

'call_stack': Returns the call stack, that is the procedure names and lines of the calls. See also "Thread View / Call Stack" in the HDevelop User's Guide.

Attention: This option only works when executing without JIT compilation.

'engine_environment': Returns *'HDevelop'* if it is called within HDevelop, else *'HDevEngine'*.

'jit_enabled': Returns *'true'* if the JIT Compiler is enabled, *'false'* otherwise. Not all procedures can be JIT compiled.

Attention

This operator is not supported for code export.

Parameters

▷ **SystemQueries** (input_control) ..... attribute.name-array ⇝ *string*
Desired system parameters.
Default: 'engine_environment'
List of values: SystemQueries ∈ {'call_stack', 'engine_environment', 'jit_enabled'}

▷ **SystemInformations** (output_control) ..... attribute.value-array ⇝ *string*
Current value of the system parameters.

Module

Foundation

dev_get_window (: : : WindowHandle)

Return the handle of the active graphics window.

dev_get_window returns the window handle of the active graphics window. If currently no graphics window is open, the return value is *-1*.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **WindowHandle** (output_control) ..... window ⇝ *handle*
Window handle.

Example

```
read_image (Image,'mreut')
threshold (Image, Region, 100, 200)
dev_open_window (1, 1, 200, 200, 'black', WindowID1)
dev_open_window (1, 220, 200, 200, 'black', WindowID2)
```

```
dev_get_window (CurrentWindowID)
dev_set_window (WindowID1)
dev_set_color ('blue')
dev_display (Image)
dev_display (Region)
dev_set_window(CurrentWindowID)
```

Result

If the values of the specified parameters are correct, `dev_get_window` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

`dev_close_window`

Possible Successors

`dev_set_window`

Module

Foundation

dev_inspect_ctrl (: : Variable :)

Open a window to inspect one or more control variables.

`dev_inspect_ctrl` opens an inspection window to display the contents of one or more control variables.

The standard inspection window displays the variable values with some optional statistics in a table. The window title is generated from the given parameter names. For some semantic types a special representation exists, e.g., functions are displayed as function plot by default. For more information, see the chapter "`Inspecting Variables`" in the "`HDevelop User's Guide`".

You can pass a tuple of variables in `Variable` to open an inspection window for multiple variables. It is also possible to override the default inspection mode by including a string literal as the first element of the tuple:

'tuple': Show the values in the default inspection window even if the semantic type of the variable has a special representation.

'plot': Plot the values of numeric variables against their tuple index.

'plot_xy': Plot the values of numeric variables as X-Y pairs. The number of variables must be even, with each pair of variables having the same length.

Note that no expressions are evaluated inside the call of `dev_inspect_ctrl`, but only the contained parameter names are parsed. Therefore, operations like, e.g., accessing a specific tuple range or arithmetic tuple operations need to be done beforehand.

Normally, the window contents will be updated whenever the variables change. However, the update behavior can be influenced by the operator `dev_update_var` and the `Update Variable` preference.

The window can be closed by pressing the `Close` button or by calling `dev_close_inspect_ctrl`.

Attention

This operator is not supported for code export.

Parameters

▷ **Variable** (input_control) ..... integer(-array) ⇝ *integer* / real / string
Name of the variable to be checked.

Example

```
read_image (Image, 'fabrik')
regiongrowing (Image, Regions, 3, 3, 6, 100)
area_center (Regions, Area, Row, Column)
dev_inspect_ctrl (Area)
dev_inspect_ctrl (['plot_xy', Row, Column])
```

Result

If the values of the specified parameters are correct, `dev_inspect_ctrl` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

See also

`dev_update_var`

Module

Foundation

dev_open_dialog (: : DialogName :)

Open a modal HDevelop dialog.

`dev_open_dialog` opens a modal HDevelop dialog type `DialogName`. `DialogName` contains the name of the dialog which should be opened.

The following dialogs, are supported:

DialogName	Dialog
'about_dialog'	About dialog
'duplicate_procedure_dialog'	Duplicate Procedure dialog
'export_dialog'	Export dialog
'open_graphics_windows_dialog'	Open Graphics Window dialog
'insert_visualization_code_dialog'	Insert Visualization Code dialog
'read_image_dialog'	Read Image dialog
'print_dialog'	Print dialog
'properties_dialog'	Properties dialog
'save_window_dialog'	Save Graphic Window dialog

Attention

This operator is not supported for code export.

Parameters

▷ **DialogName** (input_control) . . . . . string ⇝ *string*
Name of the dialog to be opened.

Example

```
dev_open_dialog ('print_dialog')
```

Result

If the values of the specified parameters are correct, `dev_open_tool` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Module

Foundation

dev_open_file_dialog (: : Filter, Mode, Path : Selection)

Opens a file selection dialog.

`dev_open_file_dialog` opens a file selection dialog for reading one file (`Mode` = *'read'*), reading one or more files (`Mode` = *'read_multi'*), writing (`Mode` = *'write'*) a file or choosing (`Mode` = *'dir'*) a directory. If `Mode` is set to *'default'* and `Filter` is set to an HALCON operator the type is set to the value the operator would use.

The `Filter` can be used to select the types of the files which shall be selected for reading or writing. The `Filter` can be set to an HALCON operator, for example `read_image`, which should read or write the selected file. In

that case, the filter is set appropriate to the files used by the HALCON operator. To select images of type JPEG and TIFF the filter could be set to *'Images (*.jpg *.tif *.tiff)'* or *'JPEG Files (*.jpg);;TIFF-Files (*.tif *.tiff)'*. In the first case, by selecting the entry 'Images' all supported images files are displayed together. In the second case it is possible to choose between JPEG Files or TIFF Files. The Filter is not case sensitive, therefore the same results are supplied by *'JPEG Files (*.jpg)'* and *'JPEG Files (*.JPG)'*. The *'All Files (*)'* is always added. To combine more than one filter you have to separate them by *';;'*.

Examples:

The filter *'Images (*.jpg *.tiff *.tif)'* lists all files with the extensions jpg, tiff and tif.

The filter *'JPEG Files (*.jpg)'* lists all files with the extension jpg.

Combination of 3 filters: *'Images (*.jpg *.tiff *.tif);;JPEG Files (*.jpg);;TIFF Files (*.tiff *.tif)'*

The `Path` can be used to set the working directory. If `Path` is set to *'default'* the working directory is set to the last one used for this type of `Mode`.

After a successful execution the `Selection` contains the selected files or file.

Attention

This operator is not supported for code export.

Parameters

- ▷ **`Filter`** (input_control) . . . . . string ⇝ *string*
  Type of file or files to select.
- ▷ **`Mode`** (input_control) . . . . . string ⇝ *string*
  Mode of the file selection dialog.
  Default: 'default'
  List of values: `Mode` ∈ {'default', 'read', 'read_multi', 'write', 'dir'}
- ▷ **`Path`** (input_control) . . . . . string ⇝ *string*
  Working directory.
  Default: 'default'
- ▷ **`Selection`** (output_control) . . . . . string(-array) ⇝ *string*
  Selected file names.
  Default: 'default'

Example

```
dev_open_file_dialog ('read_image', 'default','c:/',Selection)
read_image(ToolId, Selection)
```

Result

If the values of the specified parameters are correct, `dev_open_file_dialog` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Alternatives

`dev_open_dialog`

Module

Foundation

`dev_open_tool` (: : `ToolName`, `Row`, `Column`, `Width`, `Height`, `GenParamName`, `GenParamValue` : `ToolId`)

Open a HDevelop tool, a non-modal dialog, or assistant.

`dev_open_tool` opens a HDevelop tool, a non-modal dialog, or assistant. The parameter `ToolName` contains the name of the tool to be opened. This operator returns the `ToolId` of the newly created tool, which can be used by operators like `dev_set_tool_geometry`, `dev_show_tool`, `dev_close_tool` to address a specific tool. The opened tool automatically becomes active.

The tool is closed by pressing the `Close` button of the window frame, or by calling `dev_close_tool`.

The parameters GenParamName and GenParamValue are optional. For certain ToolName they can be used to specify which page is displayed and more, see below. If they are set to *[]* the tool opens with default settings.

Following the supported tools are listed, whereby they are sorted thematically.

Concerning the **Main Windows** supported values for ToolName:

- *'graphics_window'*: Graphics Window
- *'operator_window'*: Operator Window
- *'program_window'*: Program Window
- *'variable_window'*: Variable Window

Concerning the **Assistants** supported ToolName:

- *'calibration_assistant'*: Camera Calibration Assistant
  Supported values for GenParamName:
  - *'page'*: Page to be displayed. Supported values for GenParamValue:
    - *'setup'*: Setup
    - *'calibration'*: Calibration
    - *'result'*: Results
    - *'code_generation'*: Code Generation

    Example: `dev_open_tool('calibration_assistant', ..., 'page', 'result', ...)` opens the calibration assistant and shows the tab card `Results`.
- *'image_acquisition_assistant'*: Image Acquisition Assistant
  Supported values for GenParamName:
  - *'page'*: Page to be displayed. Supported values for GenParamValue:
    - *'source'*: Source
    - *'connection'*: Connection
    - *'parameters'*: Parameters
    - *'code_generation'*: Code Generation

    Example: `dev_open_tool('image_acquisition', ...,'page', 'source', ...)` opens the image acquisition assistant and shows the tab card `Source`.
- *'matching_assistant'*: Matching Assistant
  Supported values for GenParamName:
  - *'page'*: Page to be displayed. Supported values for GenParamValue:
    - *'model_creation'*: Model Creation
    - *'model_parameter'*: Model Parameter
    - *'model_use'*: Model Use
    - *'inspect'*: Inspect
    - *'code_generation'* & Code Generation

    Example: `dev_open_tool('matching_assistant', ...,'page', 'inspect', ...)` opens the matching assistant and shows the tab card `Inspect`.
- *'measure1d_assistant'*: Measure Assistant
  Supported values for GenParamName:
  - *'page'*: Page to be displayed. Supported values for GenParamValue:
    - *'input'*: Input
    - *'edges'*: Edges
    - *'fuzzy'*: Fuzzy
    - *'result'*: Results
    - *'code_generation'*& Code Generation

    Example: `dev_open_tool('measure1d_assistant', ..., 'page', 'edges', ...)` opens the measure assistant and shows the tab card `Edges`.
- *'ocr_assistant'*: OCR Assistant

Concerning the **Tools** supported values for `ToolName`:

- *'call_stack'*: Call Stack
- *'canvas'*: Canvas Window
- *'feature_histogram'*: Feature Histogram
- *'feature_inspection'*: Feature Inspection
- *'gray_histogram'*: Gray Histogram
- *'line_profile'*: Line Profile
- *'zoom_window'*: Zoom Window
- *'ocr_training_file_browser'*: OCR Training File Browser

Concerning the **Dialogs** supported values for `ToolName`:

- *'browse_examples_dialog'*: Browse Examples Dialog
- *'create_procedure_dialog'*: Create Procedure Dialog
- *'edit_procedure_interface_dialog'*: Edit Procedure Interface Dialog
- *'find_replace_dialog'*: Find Replace Dialog
- *'output_console'*: Output Console
- *'quick_navigation'*: Quick Navigation
  Supported values for `GenParamName`:
  - *'page'*: Page to be displayed. Supported values for `GenParamValue`:
    - *'invalid_lines'*: Invalid Lines
    - *'find_results'*: Find Results
    - *'breakpoints'*: Breakpoints
    - *'bookmarks'*: Bookmarks

    Example: `dev_open_tool('quick_navigation', ..., 'page', 'breakpoints', ...)` opens the quick navigation window and shows the tab card `Breakpoints`.
- *'breakpoints_dialog'*: Quick Navigation / Breakpoints
- *'bookmarks_dialog'*: Quick Navigation / Bookmarks
- *'invalid_lines_dialog'*: Quick Navigation / Invalid Lines
- *'visualization_parameters_dialog'*: Visualization Parameters Dialog
- *'help'*: Help Browser
  Supported values for `GenParamName`:
  - *'page'*: Page to be displayed. Supported values for `GenParamValue`:
    - *'contents'*: Contents
    - *'operator'*: Operator
    - *'search'*: Search
    - *'index'*: Index
    - *'bookmarks'*: Bookmarks

    Example: `dev_open_tool('help', ..., 'page', 'search', ...)` opens the help tool and selects the tab card `Search`.
  - *'operator'*: Operator whose HTML page should be displayed.
    Supported values for `GenParamValue`: Operator names (written in snake case).
    Example: `dev_open_tool('help', ...,['page','operator'], ['search','read_image'], ...)` opens the help tool, selects the tab card `Search` and displays the description of the operator `read_image`.
  - *'manual'*: Manual whose HTML page should be displayed.
    Supported values for `GenParamValue`: Manual names (including their path, both written in snake case).
    Example: `dev_open_tool('help', 'default', 'default', 'default', 'default', 'manual', 'hdevelop_users_guide/hdevelop_users_guide_0000', ToolId)` opens the manual "`HDevelop User's Guide`".

- *'preferences'*: Preferences Dialog
  Supported values for GenParamName:
  - *'page'*: Page to be displayed. Supported values for GenParamValue are listed in groups of menu items.
    For the menu User Interface supported values for GenParamValue:
    * *'user_interface/program_window'*: Program Window
    * *'user_interface/fonts'*: Fonts
    * *'user_interface/language'*: Language
    * *'user_interface/themes'*: Themes

    For the menu Procedures supported values for GenParamValue:
    * *'procedures/directories'*: Directories
    * *'procedures/external_procedures'*: External Procedures
    * *'procedures/manage_procedure_libraries'*: Manage Procedure Libraries
    * *'procedures/manage_passwords'*: Manage Passwords
    * *'procedures/procedure_use'*: Procedure Use
    * *'procedures/unresolved_procedure_calls'*: Unresolved Procedure Calls

    For the menu General Options supported values for GenParamValue:
    * *'general_options/general_options'*: General Options
    * *'general_options/experienced_user'*: Experienced User

    For the menu Visualization Settings, supported values for GenParamValue:
    * *'visualization_settings/pen'*: Pen
    * *'visualization_settings/lut'*: LUT
    * *'visualization_settings/paint'*: Paint

    For the menu Runtime Settings supported values for GenParamValue:
    * *'runtime_settings/runtime_settings'*: Runtime Settings
    * *'runtime_settings/override_operator_behavior'*: Override Operator Behavior

    For the menu Telemetry Settings supported values for GenParamValue:
    * *'telemetry_settings'*: Telemetry Settings

    Example: `dev_open_tool('preferences', ..., 'page', 'user_interface/language', ...)` shows the page language from the group User Interface.
- *'halcon_news'*: HALCON News website - an empty ToolId is returned because this simply opens the news page.

The parameters Row and Column can be used to open the tool at a specific position. Note that the offset values specified under Edit ▷ Preferences ▷ General Options ▷ General Options ▷ Window open offset are added to the row and the column index, respectively. For more information, see the chapter "Menu Edit" in the "HDevelop User's Guide". In order to apply the standard behavior, that is in general opening the tool at the last position, *'default'* can be passed.

The parameters Width and Height can be used to open the tool with a specific size. In order to apply the standard behavior, that is in general opening the tool with the last size, *'default'* can be passed. If Width and Height are less than the minimum size of the tool the minimum size is used.

Attention

This operator is not supported for code export.

Parameters

▷ **ToolName** (input_control) . . . . . string ⇝ *string*
Name of the tool to be opened and additional parameters.
List of values: ToolName ∈ {'graphics_window', 'operator_window', 'program_window', 'variable_window', 'calibration_assistant', 'image_acquisition_assistant', 'matching_assistant', 'measure1d_assistant', 'ocr_assistant', 'call_stack', 'canvas', 'feature_histogram', 'feature_inspection', 'gray_histogram', 'line_profile', 'zoom_window', 'ocr_training_file_browser', 'browse_examples_dialog', 'create_procedure_dialog', 'edit_procedure_interface_dialog', 'find_replace_dialog', 'output_console', 'quick_navigation', 'breakpoints_dialog', 'bookmarks_dialog', 'invalid_lines_dialog', 'visualization_parameters_dialog', 'help', 'preferences', 'halcon_news'}

▷ **Row** (input_control) . . . . . rectangle.origin.y ⇝ *integer* / string
Row index of upper left corner.
Default: 'default'
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) . . . . . rectangle.origin.x ⇝ *integer* / string
Column index of upper left corner.
Default: 'default'
Minimum increment: 1
Recommended increment: 1

▷ **Width** (input_control) . . . . . rectangle.extent.x ⇝ *integer* / string
Width of the tool.
Default: 'default'
Minimum increment: 1
Recommended increment: 1
Restriction: Width > 0

▷ **Height** (input_control) . . . . . rectangle.extent.y ⇝ *integer* / string
Height of the tool.
Default: 'default'
Minimum increment: 1
Recommended increment: 1
Restriction: Height > 0

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters.
Default: []

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string*
Values of the generic parameters.
Default: []

▷ **ToolId** (output_control) . . . . . dev_tool ⇝ *string*
Tool identifier.

Example

```
dev_open_tool ('zoom_window',0, 0, Width, Height, [], [], ToolId)
dev_close_tool (ToolId)
```

Result

If the values of the specified parameters are correct, `dev_open_tool` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Possible Successors

`dev_set_tool_geometry`, `dev_show_tool`, `dev_close_tool`

Module

Foundation

dev_open_window (: : Row, Column, Width, Height, Background : WindowHandle)

Open a new graphics window.

`dev_open_window` opens a new graphics window, which can be used to display iconic objects like images, regions, and lines as well as to perform textual output. This window automatically becomes active, which means that all output (`dev_display` and automatic display of operator results) is redirected to this window. This is shown by the lucent lamp on the `Active` button.

Each graphics window is identified by its `WindowHandle`. This logical number is displayed in the title bar of the graphics window and is required as input parameter for some operators like `disp_image`, `disp_region`, `draw_circle`, `get_mbutton`, `write_string`, and `set_rgb`.

The graphics window is closed by pressing the Close button of the window frame, via the Visualization menu, or by calling dev_close_window.

Graphics Window Position

By default, the graphics window opens within the canvas window. If this is not desired, select Restore Default Layout use ▷ Docked Graphics Window from the Window menu in HDevelop. See also "Canvas Window" in the "HDevelop User's Guide".

The parameters Row and Column are used to pass the position of the window. Its reference point (0, 0) on the canvas is visualized by a cross.

For floating windows, the reference point is by default the upper left corner of the HDevelop main window. You can change this reference point, so that, for example, the graphics window position aligns with the upper left corner of the screen. To do so, open the HDevelop preferences and choose the desired Origin of coordinates under General options.

Moreover, you can adapt the window position via the setting Window open offset. These offset values are added to the row and the column index, respectively. See also "Menu Window open offset" in the "HDevelop User's Guide".

Graphics Window Visualization

The background of the created graphics window is set to the color specified in Background. This parameter is not available for the operator open_window. There, the same behavior can be achieved by calling set_window_attr(::'background_color',Background:) in advance.

As a default, the visible image part in the graphics window (viewport) is set in a way that images are displayed without clipping and fitted completely into the window. The image part is adapted to the window's size according to this rule for the first image that is displayed after a program reset or the loading of a new program or if the current image has a different image size than the image that was displayed before. The size of the window is not adapted automatically, hence, if the aspect ratio of the image differs from that of the window, the image is distorted to fit into the window. This can be changed via the Window Size menu.

The visible image part can be changed interactively by spinning the mouse wheel, using the Move or Zoom mode, via the Image Size menu, with the help of the Zoom tab card on the Visualization Parameters dialog, or with the operator dev_set_part.

The display parameters of the graphics window can be specified via its context menu, the Visualization menu, the Visualization Parameters dialog, or the appropriate HDevelop operators like dev_set_color, dev_set_line_width, dev_set_draw. Depending on the Apply Immediately preference, the parameter changes are applied to the lastly displayed object or apply from now on for all following objects. In contrast to the standard HALCON window operators, the new settings are also used for all new graphics windows.

Graphics Window History

Each graphics window manages a history that contains the

- objects and
- display parameters

that have been displayed or changed since the most recent clear action or display of a full image. This history is used if a redraw of the window is triggered, e.g., after a change of the window's size, in order to reconstruct the complete window contents. Other iconic output that was displayed using HALCON operators like disp_image or disp_region, text (write_string), or geometric objects (disp_line, disp_circle, etc.) are **not** part of the history, and can therefore **not** be redrawn. Only the object classes image, region, and XLD that are displayed with the HDevelop operator dev_display or by HDevelop actions like double clicking on an icon are part of the history.

Pressing the Clear button clears the graphics window contents and the history of the window. This can also be achieved by using the operator dev_clear_window. This will not affect the current display parameters.

Further Information

Additional information about the underlying HALCON window can be found at open_window. For more information about the graphics window, please have a look at the "HDevelop User's Guide".

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics

operators into the different programming languages, in the "HDevelop User's Guide", see the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **Row** (input_control) . . . . . rectangle.origin.y ⇝ *integer*
Row index of upper left corner.
Default: 0
Value range: 0 ≤ Row
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) . . . . . rectangle.origin.x ⇝ *integer*
Column index of upper left corner.
Default: 0
Value range: 0 ≤ Column
Minimum increment: 1
Recommended increment: 1

▷ **Width** (input_control) . . . . . rectangle.extent.x ⇝ *integer*
Width of the window.
Default: 512
Minimum increment: 1
Recommended increment: 1
Restriction: Width > 0 || Width == -1

▷ **Height** (input_control) . . . . . rectangle.extent.y ⇝ *integer*
Height of the window.
Default: 512
Minimum increment: 1
Recommended increment: 1
Restriction: Height > 0 || Height == -1

▷ **Background** (input_control) . . . . . integer ⇝ *integer* / string
Color of the background of the new window.
Default: 'black'

▷ **WindowHandle** (output_control) . . . . . window ⇝ *handle*
Window handle.

Example

```
dev_close_window ()
read_image (For5, 'for5')
get_image_size (For5, Width, Height)
dev_open_window (0, 0, Width, Height, 'black', WindowHandle)
dev_display (For5)
dev_set_lut ('rainbow')
dev_display (For5)
stop ()
dev_set_lut ('default')
dev_display (For5)
stop ()
dev_set_part (100, 100, 300, 300)
dev_display (For5)
```

Result

If the values of the specified parameters are correct, dev_open_window returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_display, dev_set_lut, dev_set_color, dev_set_draw, dev_set_part

Alternatives

open_window

query_color

Module

Foundation

dev_set_check (: : Mode :)

Specify the error handling in HDevelop.

dev_set_check specifies how HDevelop has to react in case of an error, i.e., if the return state of an operator is not 2 (H_MSG_TRUE).

If Mode has the value *'give_error'*—which is the system default—an erroneous operator call will throw an exception, that can be caught within the HDevelop program by the catch statement. However, if there is no surrounding try-catch block in the HDevelop program and the program is executed within HDevelop, the program execution stops at the erroneous operator and an error message box is opened to display the error text. In addition, the appropriate operator call is entered into the *Operator Window*, so that the user can easily edit and possibly correct the parameters of the erroneous operator call. If the procedure was called from HDevEngine and the exception is not caught within the HDevelop program, an HDevEngineException object is thrown and the procedure is left.

If Mode is set to *'~give_error'*, the error will be ignored and the program continues with the next operator. dev_set_check('~give_error') is intended to be used in connection with dev_error_var, which allows to check the result state that is returned by the operator calls.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **Mode** (input_control) ..... string ⇝ *string*
Mode of error handling.
Default: 'give_error'

Example

```
dev_close_window ()
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
dev_error_var (Error, 1)
dev_set_check ('~give_error')
FileName := 'wrong_name'
read_image (Image, FileName)
ReadError := Error
if (ReadError != H_MSG_TRUE)
  write_string (WindowHandle, 'wrong file name: '+FileName)
endif
* Now the program will stop with an exception
dev_set_check ('give_error')
read_image (Image, FileName)
```

Result

If the values of the specified parameters are correct, dev_set_check returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_error_var

set_check, try, catch, endtry

Module

Foundation

dev_set_color (: : ColorName :)

Set one or more output colors.

dev_set_color defines the color(s) that are used to display regions, XLDs, and other geometrical objects in the graphics windows. The available colors can be queried with the operator query_color. In addition, the ColorName may be specified as hexadecimal RGB triplet or RGBA quadruplet in the form *'#rrggbb'* and *'#rrggbbaa'*. 'rr', 'gg', 'bb', and 'aa' are hexadecimal numbers between '00' and 'ff', respectively. 'aa' denotes the alpha value of a color and can be used to display transparent regions.

For more information see the description of the operator set_color. However, in contrast to that operator the color setting is also used for all new graphics windows that are opened afterwards.

These color settings remain valid until dev_set_color or dev_set_colored is called or until the color settings are modified interactively.

Color name	75% alpha	50% alpha	25% alpha
'black'	'#000000c0'	'#00000080'	'#00000040'
'white'	'#ffffffc0'	'#ffffff80'	'#ffffff40'
'red'	'#ff0000c0'	'#ff000080'	'#ff000040'
'green'	'#00ff00c0'	'#00ff0080'	'#00ff0040'
'blue'	'#0000ffc0'	'#0000ff80'	'#0000ff40'
'dim gray'	'#696969c0'	'#69696980'	'#69696940'
'gray'	'#bebebec0'	'#bebebe80'	'#bebebe40'
'light gray'	'#d3d3d3c0'	'#d3d3d380'	'#d3d3d340'
'cyan'	'#00ffffc0'	'#00ffff80'	'#00ffff40'
'magenta'	'#ff00ffc0'	'#ff00ff80'	'#ff00ff40'
'yellow'	'#ffff00c0'	'#ffff0080'	'#ffff0040'
'medium slate blue'	'#7b68eec0'	'#7b68ee80'	'#7b68ee40'
'coral'	'#ff7f50c0'	'#ff7f5080'	'#ff7f5040'
'slate blue'	'#6a5acdc0'	'#6a5acd80'	'#6a5acd40'
'spring green'	'#00ff7fc0'	'#00ff7f80'	'#00ff7f40'
'orange red'	'#ff4500c0'	'#ff450080'	'#ff450040'
'dark olive green'	'#556b2fc0'	'#556b2f80'	'#556b2f40'
'pink'	'#ffc0cbc0'	'#ffc0cb80'	'#ffc0cb40'
'cadet blue'	'#5f9ea0c0'	'#5f9ea080'	'#5f9ea040'
'goldenrod'	'#daa520c0'	'#daa52080'	'#daa52040'
'orange'	'#ffa500c0'	'#ffa50080'	'#ffa50040'
'gold'	'#ffd700c0'	'#ffd70080'	'#ffd70040'
'forest green'	'#228b22c0'	'#228b2280'	'#228b2240'
'cornflower blue'	'#6495edc0'	'#6495ed80'	'#6495ed40'
'navy'	'#000080c0'	'#00008080'	'#00008040'
'turquoise'	'#40e0d0c0'	'#40e0d080'	'#40e0d040'
'dark slate blue'	'#483d8bc0'	'#483d8b80'	'#483d8b40'

'indian red'	'#cd5c5cc0'	'#cd5c5c80'	'#cd5c5c40'
'violet red'	'#d02090c0'	'#d0209080'	'#d0209040'
'light steel blue'	'#b0c4dec0'	'#b0c4de80'	'#b0c4de40'
'medium blue'	'#0000cdc0'	'#0000cd80'	'#0000cd40'
'khaki'	'#f0e68cc0'	'#f0e68c80'	'#f0e68c40'
'violet'	'#ee82eec0'	'#ee82ee80'	'#ee82ee40'
'firebrick'	'#b22222c0'	'#b2222280'	'#b2222240'
'midnight blue'	'#191970c0'	'#19197080'	'#19197040'

Examples of possible color strings

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **ColorName** (input_control) ..... string(-array) ⇝ *string*
Output color names.
Default: 'white'
Suggested values: ColorName ∈ {'white', 'black', 'gray', 'red', 'green', 'blue', '#003075', '#e53019', '#ffb529'}

Example

```
read_image(Image,'mreut')
dev_set_draw('fill')
dev_set_color('red')
threshold(Image,Region,180,255)
dev_set_color('green')
threshold(Image,Region,0,179)
```

Result

If the values of the specified parameters are correct, dev_set_color returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

Module

Foundation

dev_set_colored (: : NumColors :)

Set multiple output colors.

dev_set_colored allows to display tuples of regions, XLDs, and other geometrical objects in the graphics windows in different colors using a set of NumColors predefined colors. Valid values for NumColors can be queried with the operator query_colored.

For more information see the description of the operator set_colored. However, in contrast to that operator the color setting is also used for all new graphics windows that are opened afterwards.

These color settings remain valid until dev_set_color or dev_set_colored is called or until the color setting are modified interactively.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **NumColors** (input_control) . . . . . integer ⇝ *integer*
Number of output colors.
Default: 6
List of values: NumColors ∈ {3, 6, 12}

Example

```
read_image(Image,'monkey')
threshold(Image,Region,128,255)
dev_set_colored(6)
connection(Region,Regions)
```

Result

If the values of the specified parameters are correct, dev_set_colored returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

dev_set_draw, dev_set_line_width, set_colored

Module

Foundation

dev_set_contour_style (: : Style :)

Define the contour display fill style.

dev_set_contour_style defines the fill style of contour displays. The following values are supported for Style:

- *'stroke'*: Only the line of the contour gets displayed.
- *'fill'*: The area enclosed by the contour is filled.
- *'stroke_and_fill'*: The line of the contour gets displayed and the enclosed area filled. especially makes a difference for larger line widths, see set_line_width.

For all styles the current drawing color is used.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **Style** (input_control) . . . . . string ⇝ *string*
Fill style for contour display.
Default: 'stroke'
List of values: Style ∈ {'stroke', 'fill', 'stroke_and_fill'}

Result

If the values of the specified parameters are correct, dev_set_contour_style returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_display

See also

set_contour_style

Module

Foundation

dev_set_draw (: : DrawMode :)

Define the region fill mode.

dev_set_draw defines the fill mode for regions. If DrawMode is set to *'fill'*, regions are displayed filled, if set to *'margin'*, only contours are displayed. In the *'margin'* mode, the appearance of the contours can be affected by dev_set_line_width and set_line_style.

For more information see the description of the operator set_draw. However, in contrast to that operator the draw mode is also used for all new graphics windows that are opened afterwards.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **DrawMode** (input_control) ..... string ⇝ *string*
Fill mode for region output.
Default: 'fill'
List of values: DrawMode ∈ {'fill', 'margin'}

Example

```
read_image(Image,'monkey')
threshold(Image,Region,128,255)
dev_clear_window ()
dev_set_color('red')
dev_set_draw('fill')
dev_display(Region)
dev_set_color('white')
dev_set_draw('margin')
dev_display(Region)
```

Result

If the values of the specified parameters are correct, dev_set_draw returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_set_line_width, dev_display

See also

set_draw

Module

Foundation

dev_set_line_width (: : LineWidth :)

Define the line width for region contour output.

dev_set_line_width defines the line width (in pixel) that is used to display region contours (in *'margin'* mode), XLDs, and other geometric output (e.g., disp_region, disp_line, etc.).

For more information see the description of the operator set_line_width. However, in contrast to that operator the new line width is also used for all new graphics windows that are opened afterwards.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **LineWidth** (input_control) ..... integer ⇝ *integer*
Line width for region output in contour mode.
Default: 1
Restriction: LineWidth >= 1

Example

```
read_image(Image,'monkey')
threshold(Image,Region,128,255)
dev_set_draw('margin')
dev_set_line_width(5)
dev_clear_window ()
dev_display(Region)
```

Result

If the values of the specified parameters are correct, dev_set_line_width returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_display

See also

set_line_width, query_line_width

Module

Foundation

dev_set_lut (: : LutName :)

Set "look-up-table" (lut).

dev_set_lut sets the look-up-table of the active graphics window. A look-up-table defines the transformation of a "gray value" from an one-channel-image into a gray value or color on the screen. query_lut lists the names of all look-up-tables.

For more information see the description of the operator set_lut. However, in contrast to that operator the new look-up-table is also used for all new graphics windows that are opened afterwards.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **LutName** (input_control) ..... filename.read(-array) ⇝ *string* / real / integer
Name of look-up-table, values of look-up-table (RGB) or file name.
Default: 'default'
Suggested values: LutName ∈ {'default', 'linear', 'inverse', 'sqr', 'inv_sqr', 'cube', 'inv_cube', 'sqrt', 'inv_sqrt', 'cubic_root', 'inv_cubic_root', 'color1', 'color2', 'color3', 'color4', 'three', 'six', 'twelve',

'twenty_four', 'rainbow', 'temperature', 'cyclic_gray', 'cyclic_temperature', 'hsi', 'change1', 'change2', 'change3', 'jet', 'inverse_jet', 'batlow', 'inverse_batlow'}
File extension: .lut

Example

```
read_image(Image,'mreut')
dev_set_lut('inverse')
* For true color only:
dev_display(Image)
```

Result

If the values of the specified parameters are correct, dev_set_lut returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_display

See also

set_lut

Module

Foundation

dev_set_paint (: : Mode :)

Define the gray value output mode.

dev_set_paint defines the output mode that is used for displaying image objects in the graphics window.

For a detailed description of all possible options see set_paint. However, in contrast to that operator the display mode is also used for all new graphics windows that are opened afterwards.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **Mode** (input_control) . . . . . string-array ⇝ *string* / integer
Grayvalue output name. Additional parameters possible.
Default: 'default'
Suggested values: Mode ∈ {'default', '3d_plot'}

Example

```
read_image(Image,'fabrik')
dev_set_paint('3d_plot')
dev_display(Image)
```

Result

If the values of the specified parameters are correct, dev_set_paint returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Module

Foundation

dev_set_part (: : Row1, Column1, Row2, Column2 :)

Modify the displayed image part.

dev_set_part is used to set the part of the image that is displayed in the graphics window. The parameters Row1 and Column1 specify the upper left corner, Row2 and Column2 the lower right corner of the image part to display.

For more information see the description of the operator set_part. In addition, if Row1 is larger than Row2 or Column1 larger than Column2, the zooming in the particular dimension will be reset to show the complete height and/or width of the image. Please note that this is not possible with the operator set_part outside HDevelop.

In addition, note that the part is automatically reset, if a new program is loaded, a program reset is performed, or a new image with a different image size is displayed.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **Row1** (input_control) ..... rectangle.origin.y ⇝ *integer*
Row of the upper left corner of the chosen image part.
Default: 0

▷ **Column1** (input_control) ..... rectangle.origin.x ⇝ *integer*
Column of the upper left corner of the chosen image part.
Default: 0

▷ **Row2** (input_control) ..... rectangle.corner.y ⇝ *integer*
Row of the lower right corner of the chosen image part.
Default: 128

▷ **Column2** (input_control) ..... rectangle.corner.x ⇝ *integer*
Column of the lower right corner of the chosen image part.
Default: 128

Example

```
read_image (Image, 'fabrik')
for i := 1 to 240 by 10
  dev_set_part (i, i, 511-i, 511-i)
  dev_display (Image)
endfor
dev_set_part (1, 1, -1, -1)
dev_display (Image)
```

Result

If the values of the specified parameters are correct, dev_set_part returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_display

set_part

Module

Foundation

dev_set_preferences (: : PreferenceNames, PreferenceValues :)

Set HDevelop preferences within a program.

dev_set_preferences allows to set selected preferences of HDevelop within a program. The following preferences are supported:

'graphics_window_context_menu': Controls whether a right click into the graphics window opens a context menu or not. By default the context menu is enabled. Disabling the context menu may be sensible if the right mouse button is used for controlling some kind of navigation in the graphics window, e.g., for moving or zooming 3D objects.

List of values: *'false'*, *'true'*.

Default: *'true'*.

'graphics_window_mouse_wheel': Controls whether the mouse wheel can be used to zoom the contents of the graphics window or not. By default the mouse wheel is enabled. Disabling the mouse wheel may be sensible if 3D objects are displayed and if the zooming into the objects is realized interactively with the help of 3D display operators.

List of values: *'false'*, *'true'*.

Default: *'true'*.

'graphics_window_tool_tip': Controls whether pressing the Ctrl key over the graphics window shows a tool tip with the current pixel position and the gray values under the mouse cursor or not. By default the tool tip is enabled. Disabling the tool tip may be sensible if the state of the Ctrl key shall be evaluated for program based user interactions, e.g., for manipulating the view on 3D objects.

List of values: *'false'*, *'true'*.

Default: *'true'*.

'suppress_handled_exceptions_dlg': Controls whether the error dialog should be suppressed that is by default opened for exceptions that are thrown during program execution and that are enclosed by a try-catch block and can therefore be handled by an exception handler. This option is persistently stored into the HDevelop.ini file and can also be configured via the Preferences dialog / General Options / Experienced User. If an exception is thrown by a program line that is not enclosed by a try-catch block, an error message dialog is always opened.

List of values: *'false'*, *'true'*.

Default: *'false'* (Any changes are persistently saved).

Attention

This operator is not supported for code export.

Parameters

▷ **PreferenceNames** (input_control) . . . . . attribute.name-array ⇝ *string*
Selection of the preferences.
Default: 'graphics_window_context_menu'
List of values: PreferenceNames ∈ {'graphics_window_context_menu', 'graphics_window_mouse_wheel', 'graphics_window_tool_tip', 'suppress_handled_exception_dlg'}

▷ **PreferenceValues** (input_control) . . . . . attribute.value-array ⇝ *string*
New values for the selected preferences.
Default: 'false'
List of values: PreferenceValues ∈ {'true', 'false'}

See also

dev_get_preferences

Module

Foundation

dev_set_shape (: : Shape :)

Define the region output shape.

dev_set_shape defines the shape that is used for displaying regions. The available shapes can be queried with query_shape.

These shapes are supported:

'original': The shape is displayed unchanged. Nevertheless modifications via parameters like dev_set_line_width can take place. This is also true for all other modes.

'outer_circle': Each region is displayed by the smallest surrounding circle. (See smallest_circle.)

'inner_circle': Each region is displayed by the largest included circle. (See inner_circle.)

'ellipse': Each region is displayed by an ellipse with the same moments and orientation (See elliptic_axis.)

'rectangle1': Each region is displayed by the smallest surrounding rectangle parallel to the coordinate axes. (See smallest_rectangle1.)

'rectangle2': Each region is displayed by the smallest surrounding rectangle. (See smallest_rectangle2.)

'convex': Each region is displayed by its convex hull (See shape_trans.)

'icon': Each region is displayed by the icon set with set_icon in the center of gravity.

For more information see the description of the operator set_shape. However, in contrast to that operator the selected shape is also used for all new graphics windows that are opened afterwards.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **Shape** (input_control) ..... string ⇝ *string*
Region output mode.
Default: 'original'
List of values: Shape ∈ {'original', 'convex', 'outer_circle', 'inner_circle', 'rectangle1', 'rectangle2', 'ellipse', 'icon'}

Example

```
read_image(Image,'monkey')
threshold(Image,Region,128,255)
connection(Region,Regions)
dev_set_shape('rectangle1')
dev_set_draw('margin')
dev_set_line_width(5)
dev_clear_window()
dev_display(Regions)
```

Result

If the values of the specified parameters are correct, dev_set_shape returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_display, dev_set_color

See also

set_shape, dev_set_line_width

Module

Foundation

dev_set_system (: : SystemParameter, Value :)

Change HDevelop system parameter within a program.

The operator dev_set_system sets HDevelop system parameters.

Available options for SystemParameter:

'jit_enabled': Determines whether the JIT Compiler is enabled (*'true'*) or not (*'false'*).
Note, not all procedures can be JIT compiled.
List of values: *'true'*, *'false'*
Default: *'false'*

'all': Reset all system parameters to their default value. To do so, set `Value` to *'default'*.
List of values: *'default'*

Attention

This operator is not supported for code export.

Parameters

▷ **`SystemParameter`** (input_control) . . . . . attribute.name ⇝ *string*
Name of the system parameter to be changed.
Default: 'jit_enabled'
List of values: `SystemParameter` ∈ {'jit_enabled', 'all'}

▷ **`Value`** (input_control) . . . . . attribute.value ⇝ *integer* / string
New value of the system parameter.
Default: 'false'
List of values: `Value` ∈ {'false', 'true', 'default'}

Module

Foundation

`dev_set_tool_geometry` `( : : ToolId, Row, Column, Width, Height : )`

Sets the position and size of the specified tool.

`dev_set_tool_geometry` sets the position and dimension of the tool with the id `ToolId`.

Instead of using the `ToolId`, given during opening the tool, you can use the name that has to be used in `dev_open_tool`. In that case a arbitrary tool, which fits the parameter `ToolId`, is used.

The parameters `Row` and `Column` can be used to modify the position of the tool. Note that the offset values specified under `Edit ▷ Preferences ▷ General Options ▷ General Options ▷ Window open offset` are added to the row and the column index, respectively. For more information, see the chapter "Menu `Edit`" in the "`HDevelop User's Guide`". In order to unmodify the position *'default'* can be passed.

The parameters `Width` and `Height` can be used to modify the size of the tools. In order to unmodify the size *'default'* can be passed. If `Width` and `Height` are less than the minimum size of the tool the minimum size is used.

Attention

This operator is not supported for code export.

Parameters

▷ **`ToolId`** (input_control) . . . . . dev_tool ⇝ *string*
Tool identifier.

▷ **`Row`** (input_control) . . . . . rectangle.origin.y ⇝ *integer* / string
Row index of upper left corner.
Default: 'default'
Minimum increment: 1
Recommended increment: 1

▷ **`Column`** (input_control) . . . . . rectangle.origin.x ⇝ *integer* / string
Column index of upper left corner.
Default: 'default'
Minimum increment: 1
Recommended increment: 1

▷ **Width** (input_control) . . . . . rectangle.extent.x ⇝ *integer* / string
Width of the tool.
Default: 'default'
Minimum increment: 1
Recommended increment: 1
Restriction: Width > 0

▷ **Height** (input_control) . . . . . rectangle.extent.y ⇝ *integer*
Height of the tool.
Default: 'default'
Minimum increment: 1
Recommended increment: 1
Restriction: Height > 0

Example

```
dev_open_tool ('zoom_window', 0, 0, Width, 'default', ToolId)
dev_close_tool (ToolId)
```

Result

If the values of the specified parameters are correct, dev_open_tool returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

Module

Foundation

dev_set_window (: : WindowHandle :)

Activate a graphics window.

dev_set_window activates the graphics window with the passed window handle. This is equivalent to pressing the Active button in the tool bar of the graphics window.

Attention

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "HDevelop User's Guide" the chapter Code Export ▷ General Aspects of Code Generation ▷ Graphics Windows.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

Example

```
dev_open_window (1, 1, 200, 200, 'black', WindowID1)
dev_open_window (1, 220, 200, 200, 'black', WindowID2)
read_image(Image,'monkey')
dev_set_window(WindowID1)
dev_display(Image)
dev_set_window(WindowID2)
dev_display(Image)
```

Result

If the values of the specified parameters are correct, `dev_set_window` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Possible Predecessors

`dev_open_window`

Possible Successors

`dev_display`

Module

Foundation

dev_set_window_extents (: : Row, Column, Width, Height :)

Change position and size of the active floating graphics window.

`dev_set_window_extents` changes the position and/or the size of the currently active floating graphics window.

The parameters `Row` and `Column` specify the new position (upper left corner) of the window. Note that the offset values specified under `Edit` ▷ `Preferences` ▷ `General Options` ▷ `General Options` ▷ `Window open offset` are added to the row and the column index, respectively. For more information, see the chapter "Menu `Edit`" in the "`HDevelop User's Guide`". Negative coordinates of the position are ignored, i.e., in this direction the window will not be moved.

The parameters `Width` and `Height` specify the new size of the window. This is the size of the inner part that actually displays the iconic objects. If one of the two values is negative, this dimension will remain unchanged.

Attention

This operator only works for single floating graphics windows, i.e., graphics windows that are neither docked nor tabbed.

Never use `set_window_extents` to change the size and position of an HDevelop graphics window. The operator `dev_set_window_extents` has to be used instead.

Using the code export feature of HDevelop, the code that is generated for this operator may have a different behavior than the related HALCON operator. For a detailed description of the code export of HDevelop graphics operators into the different programming languages see in the "`HDevelop User's Guide`" the chapter `Code Export` ▷ `General Aspects of Code Generation` ▷ `Graphics Windows`.

Parameters

▷ **Row** (input_control) . . . . . rectangle.origin.y ⇝ *integer*
Row index of upper left corner.
Default: 0
Minimum increment: 1
Recommended increment: 1
Restriction: Row >= 0 || Row == -1

▷ **Column** (input_control) . . . . . rectangle.origin.x ⇝ *integer*
Column index of upper left corner.
Default: 0
Minimum increment: 1
Recommended increment: 1
Restriction: Column >= 0 || Column == -1

▷ **Width** (input_control) . . . . . rectangle.extent.x ⇝ *integer*
Width of the window.
Default: 256
Minimum increment: 1
Recommended increment: 1
Restriction: Width > 0 || Width == -1

▷ **Height** (input_control) ..... rectangle.extent.y ⇝ *integer*
Height of the window.
Default: 256
Minimum increment: 1
Recommended increment: 1
Restriction: Height > 0 || Height == -1

Example

```
dev_close_window ()
read_image (For5, 'for5')
get_image_size (For5, Width, Height)
dev_open_window (0, 0, Width, Height, 'black', WindowHandle)
dev_display (For5)
stop ()
dev_set_window_extents (-1,-1,Width/2,Height/2)
dev_display (For5)
stop ()
dev_set_window_extents (200,200,-1,-1)
```

Result

If the values of the specified parameters are correct, `dev_set_window_extents` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Possible Successors

`dev_display`, `dev_set_lut`, `dev_set_color`, `dev_set_draw`, `dev_set_part`

`set_window_extents`

Module

Foundation

dev_show_tool (: : ToolId, Action :)

Shows the specified tool.

`dev_show_tool` executes the action `Action` on the tool `ToolId`

Instead of using the `ToolId`, given during opening the tool, you can use the name that has to be used in `dev_open_tool`. In that case an arbitrary tool, which fits the parameter `ToolId`, is used.

`Action`

'show': Activates the tool.

'normal': Shows the tool, brings it to the front and activates it.

'minimize': Minimizes the tool.

'maximize': Maximizes the tool.

'hide': Hides the tool.

Attention

This operator is not supported for code export.

Parameters

▷ **ToolId** (input_control) ..... dev_tool ⇝ *string*
Tool identifier.

▷ **Action** (input_control) ..... string ⇝ *string*
Action to execute.

Example

```
dev_open_tool ('matching_assistant', 0, 0, 'default','default', ToolId)
dev_show_tool (ToolId, 'minimize')
```

Result

If the values of the specified parameters are correct, dev_show_tool returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Module

Foundation

dev_update_pc (: : DisplayMode :)

Switches the update of the PC during program execution on or off.

dev_update_pc specifies the behavior of the PC during program execution. If DisplayMode is set to *'on'*, which is the default, within the selected procedure the PC is always displayed left to the currently executed operator. In addition the program text is scrolled—if necessary—so that the current operator is visible.

If the mode is *'off'* the PC is not visible during program execution and the program text will not be scrolled automatically. When the program stops the PC becomes visible again and the listing is scrolled to the current PC position.

For measuring the execution time of a sequence of operators all update options should be switched off in order to reduce the influence of the runtime of GUI updates in HDevelop. For this the operators dev_update_pc, dev_update_time, dev_update_var, and dev_update_window or the procedures dev_update_on and dev_update_off can be used.

This option can also be controlled via the Preferences dialog: Edit ▷ Preferences ▷ Runtime Settings ▷ Update Program Counter.

Attention

This operator is not supported for code export.

Parameters

▷ **DisplayMode** (input_control) . . . . . string ⇝ *string*
Mode for runtime behavior.
Default: 'off'
List of values: DisplayMode ∈ {'on', 'off'}

Result

If the values of the specified parameters are correct, dev_update_pc returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

See also

dev_update_time, dev_update_window, dev_update_var

Module

Foundation

dev_update_time (: : DisplayMode :)

Switch time measurement for operators on or off.

dev_update_time controls whether the execution time of an operator is displayed.

For measuring the execution time of a sequence of operators all `update` options should be switched off in order to reduce the influence of the runtime of GUI updates in HDevelop. For this the operators `dev_update_pc`, `dev_update_time`, `dev_update_var`, and `dev_update_window` or the procedures `dev_update_on` and `dev_update_off` can be used.

This option can also be controlled via the `Preferences` dialog: `Edit` ▷ `Preferences` ▷ `Runtime Settings` ▷ `Show Processing Time`.

Attention

This operator is not supported for code export.

Parameters

▷ **`DisplayMode`** (input_control) . . . . . string ⇝ *string*
Mode for graphic output.
Default: 'off'
List of values: `DisplayMode` ∈ {'on', 'off'}

Result

If the values of the specified parameters are correct, `dev_update_time` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

See also

`dev_update_pc`, `dev_update_window`, `dev_update_var`

Module

Foundation

`dev_update_var ( : : DisplayMode : )`

Switches the update of the variable window during program execution on or off.

`dev_update_var` specifies the behavior of the variable window during program execution. If `DisplayMode` is set to *'on'*, which is the default, the contents of the variable window (iconic and control variables) is updated each time a variable is modified by the program.

If the mode is *'off'* the values of the control variables and the icons of the iconic variables are not updated before the execution stops.

For measuring the execution time of a sequence of operators all `update` options should be switched off in order to reduce the influence of the runtime of GUI updates in HDevelop. For this the operators `dev_update_pc`, `dev_update_time`, `dev_update_var`, and `dev_update_window` or the procedures `dev_update_on` and `dev_update_off` can be used.

This option can also be controlled via the `Preferences` dialog: `Edit` ▷ `Preferences` ▷ `Runtime Settings` ▷ `Update Variables`.

Attention

This operator is not supported for code export.

Parameters

▷ **`DisplayMode`** (input_control) . . . . . string ⇝ *string*
Mode for graphic output.
Default: 'off'
List of values: `DisplayMode` ∈ {'on', 'off'}

Result

If the values of the specified parameters are correct, `dev_update_var` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

See also

`dev_update_pc`, `dev_update_window`, `dev_update_time`

Module

Foundation

dev_update_window (: : DisplayMode :)

Switches the automatic output of iconic output objects into the graphics window during program execution on or off.

dev_update_window specifies whether all iconic objects that are returned by an operator call have to be displayed in the active graphics window (DisplayMode = *'on'*—default) or not (DisplayMode = *'off'*).

This option has no influence on the object output in single step mode. After the execution of a single operator the iconic output objects are always displayed in the active graphics window.

This option should be set to *'off'*, if only selected objects should to be displayed in the graphics window. In this case the objects should be displayed by dev_display.

For measuring the execution time of a sequence of operators all update options should be switched off in order to reduce the influence of the runtime of GUI updates in HDevelop. For this the operators dev_update_pc, dev_update_time, dev_update_var, and dev_update_window or the procedures dev_update_on and dev_update_off can be used.

This option can also be controlled via the Preferences dialog: Edit ▷ Preferences ▷ Runtime Settings ▷ Update Window.

Attention

This operator is not supported for code export.

Parameters

▷ **DisplayMode** (input_control) . . . . . string ⇝ *string*
Mode for graphic output.
Default: 'off'
List of values: DisplayMode ∈ {'on', 'off'}

Result

If the values of the specified parameters are correct, dev_update_window returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Possible Successors

dev_display

Chapter 11

File

11.1 Access

close_file (: : FileHandle :)

Closing a text file.

The operator close_file closes a file which was opened via the operator open_file.

Parameters

▷ **FileHandle** (input_control) ..... file(-array) ⇝ *handle*
File handle.

Example

```
open_file ('standard', 'output', FileHandle)
* ....
close_file(FileHandle)
```

Result

If the file handle is correct close_file returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_file

See also

open_file

Module

Foundation

fnew_line (: : FileHandle :)

Write a line break and clear the output buffer.

The operator fnew_line writes a line break into the output file defined by the handle FileHandle. The input file must have been opened with open_file in text format. The call of fnew_line also empties possibly retained data from the output buffer into the file (see fwrite_string and set_system(::'flush_file', <boolean-value>:)).

Which characters are written as line break depends on the operating system: under Windows the sequence '$\backslash r \backslash n$' (carriage return + line feed) is used as the standard line break, under Linux just '$\backslash n$' (line feed).

Parameters

▷ **FileHandle** (input_control) ..... file ⇝ *handle*
File handle.

Example

```
fwrite_string(FileHandle,'Good Morning')
fnew_line(FileHandle)
```

Result

If an output file is open and it can be written to the file, the operator `fnew_line` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`fwrite_string`

See also

`fwrite_string`

Module

Foundation

fread_bytes (: : FileHandle, NumberOfBytes : ReadData, IsEOF)

Read bytes from a binary file.

The operator `fread_bytes` reads bytes from the input file defined by `FileHandle`. The input file must have been opened with `open_file` in binary format.

The number of bytes to be read, greater than *0*, is specified as `NumberOfBytes`.

The bytes that are read are returned in `ReadData`. `IsEOF` is set to *1* if end of file is reached while reading the bytes from the input binary file. Otherwise, it is set to *0*.

When the number of bytes to be read is larger than the number of bytes in the input binary file, the operator `fread_bytes` returns all bytes read till the end of the file in `ReadData` and parameter `IsEOF` is set to *1*.

If no byte can be read because the end of the file is reached, `ReadData` is empty and `IsEOF` is set to *1*.

Parameters

▷ **FileHandle** (input_control) ..... file ⇝ *handle*
File handle.

▷ **NumberOfBytes** (input_control) ..... integer ⇝ *integer*
Number of bytes to be read.

▷ **ReadData** (output_control) ..... integer-array ⇝ *integer*
Bytes read from the input binary file.

▷ **IsEOF** (output_control) ..... integer ⇝ *integer*
Indicates if end of file is reached while reading the file.

Example

```
* Read a binary file 5 bytes at a time till EOF is reached.
open_file(Filename,'input_binary',FileHandle)
repeat
  fread_bytes(FileHandle, 5, BytesRead, IsEOF)
until (IsEOF)
close_file (FileHandle)
```

Result

If an input file is open in binary mode and no file read error occurs,the operator `fread_bytes` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`open_file`

Possible Successors

`close_file`

Alternatives

`fread_char`

See also

`open_file`, `close_file`, `fwrite_bytes`

Module

Foundation

fread_char (: : FileHandle : Char)

Read one character from a text file.

The operator `fread_char` reads a character from the input file defined by `FileHandle`. The input file must have been opened with `open_file` in text format.

The read character or the control character sequence 'eof' is returned in parameter `Char`. The operator `fread_char` respects the encoding of the characters, unless the file was opened with the option *'ignore_encoding'* (see `open_file`). Thus, when opened with the correct encoding the operator `fread_char` returns multi-byte characters at once. If necessary, the character is transcoded into the current encoding of the HALCON library (see `set_system(::'filename_encoding',<encoding>:)`).

When the file was opened with encoding mode *'ignore_encoding'*, `Char` always returns one byte without any interpretation or transcoding. This is useful for reading a file with special control bytes in a kind of raw mode. If no character can be read because the end of the file is reached, `fread_char` returns the control character sequence *'eof'* in `Char`.

The operator `fread_char` emits a low-level error message, when the next byte or byte sequence does not represent a valid code point in the specified encoding. Despite of the low-level error message, the operator will not fail and `Char` will contain the next byte. Furthermore, the operator also emits a low-level error message, when the read character cannot be transcoded without loss of information into the current encoding of the HALCON library. This can only happen when the file is UTF-8 encoded and the current encoding of the HALCON library is *'locale'* (see `set_system(::'filename_encoding','locale':)`).

Parameters

▷ **FileHandle** (input_control) ..... file ⇝ *handle*
File handle.

▷ **Char** (output_control) ..... string ⇝ *string*
Read character, which can be multi-byte or the control string *'eof'*.

Example

```
* Read a text file character by character.
open_file (FileName, 'input', FileHandle)
repeat
    fread_char (FileHandle, Char)
until (Char == 'eof')
close_file (FileHandle)
```

Result

If an input file is open, the operator `fread_char` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised. Encoding errors have no influence on the result state.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_file`

Possible Successors

`close_file`

Alternatives

`fread_string`, `read_string`, `fread_line`

See also

`open_file`, `close_file`, `fread_string`, `fread_line`

Module

Foundation

fread_line (: : FileHandle : OutLine, IsEOF)

Read a character line from a text file.

The operator `fread_line` reads a whole line (including the line break character) from the input file defined by the handle `FileHandle`. The input file must have been opened with `open_file` in text format.

The read line is returned in parameter `OutLine`. It starts at the current file position and ends at the end of the file or with the first line break character found. A subsequent read operation on the file would start after the line break, i.e., at the beginning of the next line. If needed, the output string is transcoded into the current encoding of the HALCON library (the default is UTF-8).

The range of control characters that are handled as line break depends on the file encoding, which can be specified when the file is opened with `open_file`. The standard line break characters are *'\n'* (line feed), *'\r'* (carriage return), and *'\f'* (form feed). These characters are accepted on all encodings or when the encoding has to be ignored. The line break sequence *'\r\n'* (carriage return + line feed), which is the default line break under Windows, is handled (on all systems) as one line break and returned as *'\n'* in the output string. In UTF-8 encoded files, the following Unicode control code points will also terminate the read line: *U+0085* (next line), *U+2028* (line separator), and *U+2029* (paragraph separator).

If the end of the file is reached before any character was written to the output string, the parameter `IsEOF` returns the value *1*, otherwise *0*.

The operator fread_line emits a low-level error message, when it encounters bytes that do not represent a valid code point in the specified encoding. Despite of the low-level error message, the operator will not fail and OutLine will contain potentially invalid bytes (invalid within the specified encoding). Furthermore, the operator also emits a low-level error message, when the output string cannot be transcoded without loss of information into the current encoding of the HALCON library. For a correctly encoded string this can only happen when the file is UTF-8 encoded and the current encoding of the HALCON library is *'locale'* (see set_system('filename_encoding','locale')).

Parameters

- ▷ **FileHandle** (input_control) ..... file ⇝ *handle*
  File handle.
- ▷ **OutLine** (output_control) ..... string ⇝ *string*
  Read line.
- ▷ **IsEOF** (output_control) ..... integer ⇝ *integer*
  Reached end of file before any character was read.

Example

```
do {
  fread_line(FileHandle,&Line,&IsEOF);
} while(IsEOF==0);
```

Result

If the file is open and a suitable line is read, fread_line returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised. Encoding errors have no influence on the result state.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

open_file, close_file, fread_char, fread_string

Module

Foundation

fread_string (: : FileHandle : OutString, IsEOF)

Read a string from a text file.

The operator fread_string reads a string from the input file defined by the handle FileHandle. The input file must have been opened with open_file in text format.

A string begins with the first character that is not a separator, i.e., that is no white space or line break: all other characters, mainly letters, numbers, and all other printable characters, but also all other control characters that are no separators are added to the output string. The string ends at the first separator character after one or more accepted characters, or when the end of the file was reached. The terminating separator character is not added to the output string, but the file position indicator remains after it. Thus, a subsequent read operation on the file would start after the terminating separator character. The read character sequence is returned in parameter OutString. If needed, the output string is transcoded into the current encoding of the HALCON library (the default is UTF-8).

The range of characters that are handled as separator depends on the file encoding, which can be specified when the file is opened. The character ' ' (space) and the standard ASCII whitespace control characters '\t' (tab), '\f' (form feed), '\n' (line feed), '\r' (carriage return), and '\v' (vertical tab) are all accepted as separator on all locales or when the encoding has to be ignored. Other encodings may provide additional separator characters, e.g., Latin-1 defines *'0xA0'* (no-break space) or Shift-JIS (as many other Asian encodings) defines *'0x8140'* (ideographic space) as valid separator. UTF-8 handles these characters also as a separator just as all other code points which in the Unicode standard are defined as white spaces in the categories space separators *Zs*, line separators *Zl*, and paragraph separators *Zp*.

If the end of the file is reached before any character was written to the output string, `IsEOF` returns the value *1*, otherwise *0*.

The operator `fread_string` emits a low-level error message, when it encounters bytes that do not represent a valid code point in the specified encoding. Despite of the low-level error message, the operator will not fail and `OutString` will contain potentially invalid bytes (invalid within the specified encoding). Furthermore, the operator also emits a low-level error message, when the output string cannot be transcoded without loss of information into the current encoding of the HALCON library. For a correctly encoded string this can only happen when the file is UTF-8 encoded and the current encoding of the HALCON library is *'locale'* (see `set_system(::'filename_encoding','locale':)`).

Parameters

- ▷ **`FileHandle`** (input_control) ..... file ⇝ *handle*
  File handle.
- ▷ **`OutString`** (output_control) ..... string ⇝ *string*
  Read character sequence.
- ▷ **`IsEOF`** (output_control) ..... integer ⇝ *integer*
  Reached end of file before any character was added to the output string.

Example

```
fwrite_string(FileHandle,'Please enter text and return: ..')
fread_string(FileHandle,String,IsEOF)
fwrite_string(FileHandle,['here it is again: ',String])
fnew_line(FileHandle)
```

Result

If a file is open and a suitable string is read, `fread_string` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised. Encoding errors have no influence on the result state.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`fwrite_bytes ( : : FileHandle, DataToWrite : NumberOfBytesWritten )`

Write bytes to a binary file.

The operator fwrite_bytes writes bytes to the output file defined by FileHandle. The output file must have been opened with open_file in binary format.

The data to be written to the file is specified as DataToWrite.

The number of bytes that are written to the file is returned in NumberOfBytesWritten.

Parameters

▷ **FileHandle** (input_control) ..... file ⇝ *handle*
File handle.

▷ **DataToWrite** (input_control) ..... integer-array ⇝ *integer*
Data to be written to the file.

▷ **NumberOfBytesWritten** (output_control) ..... integer ⇝ *integer*
Number of bytes written to the output binary file.

Example

```
* Write a binary file byte by byte.
open_file (Filename, 'append_binary', FileHandle)
fwrite_bytes(FileHandle, [0x97, 99, 102], BytesWritten)
close_file (FileHandle)
```

Result

If an output file is open in binary mode and no file write error occurs, the operator fwrite_bytes returns 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

fwrite_string (: : FileHandle, String :)

Write strings and numbers into a text file.

The operator fwrite_string writes one or more strings or numbers to the output file defined by the handle FileHandle. The output file must have been opened with open_file in text format.

Strings and numbers that are to be written into the file are passed via the input parameter String to the operator fwrite_string. The parameter String accepts also tuples where strings and numbers are mixed. All elements of the tuple are written consecutively into the file without blanks or other separators in between. Numbers are converted into a string before they are written.

The operator fwrite_string emits a low-level error message, when the string cannot be transcoded without loss of information into the specified file encoding. This can only happen when the file encoding is *'locale_encoding'* and the current encoding of the HALCON library is *'utf8'* (see set_system(::'filename_encoding','utf8':)).

The call set_system(::'flush_file', <boolean-value>:) determines whether the output characters are immediately written to the file or not. If the value *'flush_file'* is set to *'false'*, the characters (especially in case of screen output) show up only after the operator fnew_line is called.

Parameters

▷ **FileHandle** (input_control) ..... file ⇝ *handle*
File handle.

▷ **String** (input_control) ..... string(-array) ⇝ *string* / integer / real
Values to be written into the file.
Default: 'hallo'

Example

```
fwrite_string(FileHandle,['text with numbers:',5,' and ',1.0])
* results in the following output:
* 'text with numbers:5 and 1.00000'
```

Result

If the writing procedure was carried out successfully, the operator fwrite_string returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised. Encoding errors have no influence on the result state.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

open_file (: : FileName, FileType : FileHandle)

Open a file in text or binary format.

open_file opens a file in text format or in binary format. The name of the file is defined by the parameter FileName. The operator open_file returns a handle to the file in the output parameter FileHandle. The parameter FileType determines the type of the file. For text files this parameter can also be used to specify the encoding used for strings in that file, where besides UTF-8 only the local-8-bit encoding is supported.

The following settings for FileType are supported:

'input': An already existing input file is opened for reading in text format.

'output': A new output file is opened for writing in text format.

'append': An already existing output file is opened for writing at the end of the file in text format.

'input_binary': An already existing input file is opened for reading in binary format.

'output_binary': A new output file is opened for writing in binary format.

'append_binary': An already existing output file is opened for writing at the end of the file in binary format.

For text files the tuple passed to `FileType` can be extended by one of the following encoding settings:

'utf8_encoding': Strings in the file are encoded in UTF-8. This is the default, so for UTF-8 encoded files and all files which use only pure 7-bit US-ASCII characters this value can be omitted.

'locale_encoding': Strings in the file are encoded in the local-8-bit encoding which depends on the system's current locale setting. Valid encodings are defined, e.g., under Windows by the code pages 1252 (a Microsoft dialect of Latin-1) or 932 (Shift-JIS) or on Linux by the locales en_US.utf8, de_DE.iso885915, or ja_JP.sjis.

'ignore_encoding': The encoding of the strings that are read from the file or written into it is not handled. In that mode multi-byte characters are neither processed nor interpreted, the operator `fread_char` returns always one byte, and separator characters that depend on a specific locale are not handled in `fread_line` and `fread_string`. Furthermore, the strings are not transcoded into or from the current encoding of the HALCON library.

Note: Strings are still transcoded in the HALCON C/C++ interface, when the encoding of the HALCON C/C++ interface differs from the encoding of the HALCON library. For HDevelop scripts, the encoding is always set to UTF-8. To avoid transcoding of strings to HDevelop, the encoding of the HALCON library should be set to UTF-8.

For the standard terminal input and output streams, the file names *'standard'* (*'input'* and *'output'*) and *'error'* (only *'output'*) are reserved.

Parameters

▷ **`FileName`** (input_control) ..... filename ⇝ *string*
Name of file to be opened.
Default: 'standard'
Suggested values: `FileName` ∈ {'standard', 'error', '/tmp/dat.dat'}

▷ **`FileType`** (input_control) ..... string(-array) ⇝ *string*
Type of file access and optional the string encoding.
Default: 'output'
List of values: `FileType` ∈ {'input', 'output', 'append', 'input_binary', 'output_binary', 'append_binary', 'utf8_encoding', 'locale_encoding', 'ignore_encoding'}

▷ **`FileHandle`** (output_control) ..... file ⇝ *handle*
File handle.

Example

```
* Creating an output text file with the name '/tmp/log.txt' and writing
* of a string:
   open_file('/tmp/log.txt','output',FileHandle)
   fwrite_string(FileHandle,'these are the first and last lines')
   fnew_line(FileHandle)
   close_file(FileHandle)
```

Result

If the parameters are valid, the operator `open_file` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

close_file

Module

Foundation

11.2 Images

deserialize_image (: Image : SerializedItemHandle :)

Deserialize a serialized image object.

deserialize_image deserializes an image object, that was serialized by serialize_image (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized image object is defined by the parameter SerializedItemHandle. The deserialized image is stored in the image object defined by the parameter Image.

Parameters

▷ **Image** (output_object) ..... image(-array) ⇝ *object :* byte / direction / cyclic / int1 / complex / int2 / uint2 / vector_field / int4 / int8 / real
Image object.

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator deserialize_image returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

serialize_image

Module

Foundation

image_to_memory_block (Image : : Format, FillColor : MemoryBlockHandle)

Write an image to a memory block in various graphic formats.

The operator image_to_memory_block saves the input image Image to the memory block MemoryBlockHandle in the format Format. If the domain (region) cannot be saved in the specified Format (this is the case for 'jpeg'), all pixels outside the region receive the color defined by FillColor. For gray value images a value between *0* (black) and *255* (white) must be passed. For RGB color images the RGB values can be passed directly as a hexadecimal value: e.g., *0xffff00* for a yellow background (red=255, green=255, blue=0).

The following formats can be set in Format:

'jpeg': JPEG format (lossy compression), file extension *.jpg This format can only store images with one channel (gray value image) or three channels (RGB image).

Only images with the pixel type byte are supported for this file format.

Together with the format string the quality value determining the compression rate can be provided. Large values (maximum 100) create a large memory block with high image quality. Small values significantly decrease the image quality and the size of the memory block.

Possible values: 'jpeg', 'jpeg 30', 'jpeg 60'.

Attention: Images stored for being processed later should not be stored in this format due to the loss of information during compression.

'png': PNG format (lossless compression), file extension *.png This format can only store images with one channel (gray value image) or three channels (RGB image). The maximal supported image size (width x height) for PNG is $2^{31} - 1$, also in HALCON XL.

Images of type byte and uint2 can be stored in PNG format.

Together with the format string, a compression level between 0 and 9 can be specified, where 0 corresponds to no compression and 9 to the best possible compression. Alternatively, the compression can be selected by using string constants.

Possible values: 'png', 'png 7', 'png none', 'png best', 'png fastest'.

If an image with a reduced domain is written, the region is stored as the alpha channel, where the points within the domain are stored as the maximum gray value of the image type and the points outside the domain are stored as the gray value 0. If an image with a full domain is written, no alpha channel is stored.

Parameters

▷ **`Image`** (input_object) ..... (multichannel-)image ⇝ *object :* byte / direction / cyclic / int1 / complex / int2 / uint2 / vector_field / int4 / int8 / real

Input image.

▷ **`Format`** (input_control) ..... string ⇝ *string*

Graphic format.
Default: 'jpeg'
Suggested values: `Format` ∈ {'jpeg', 'png'}

▷ **`FillColor`** (input_control) ..... number ⇝ *integer* / real

Gray value for pixels not belonging to the image domain (region).
Default: 0
Suggested values: `FillColor` ∈ {-1, 0, 255, 65280, 16711680}

▷ **`MemoryBlockHandle`** (output_control) ..... memory_block ⇝ *handle*

Memory block handle.

Result

If the parameter values are correct the operator `image_to_memory_block` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`get_memory_block_ptr`, `write_memory_block`, `serialize_tuple`

See also

`memory_block_to_image`

Module

Foundation

memory_block_to_image (: Image : MemoryBlockHandle :)

Read an image from a memory block with different file formats.

The operator memory_block_to_image reads image data from the indicated memory block MemoryBlockHandle and generates the image Image.

The formats JPEG and PNG can be read. The file formats are recognized by the internal structure of the memory block. In case of colored images an image with three color channels is created, the red channel being stored in the first, the green channel in the second and the blue channel in the third component (channel number).

For the PNG image format binary alpha channels are interpreted as domains. Otherwise, the domain of the generated image object (all pixels of the matrix) is chosen maximal.

Attention

If CMYK or YCCK JPEG memory blocks are read, HALCON assumes that these follow the Adobe Photoshop convention that the CMYK channels are stored inverted, i.e., 0 represents 100% ink coverage, rather than 0% ink as one would expect. The images are converted to RGB images using this convention. If the JPEG memory block does not follow this convention, but stores the CMYK channels in the usual fashion, invert_image must be called after reading the image.

If PNG images that contain an alpha channel are read, the alpha channel is returned as the second or fourth channel of the output image, unless the alpha channel contains exactly two different gray values, in which case a one or three channel image with a reduced domain is returned, in which the points in the domain correspond to the points with the higher gray value in the alpha channel.

Parameters

▷ **Image** (output_object) ..... image ⇝ *object :* byte / direction / cyclic / int1 / complex / int2 / uint2 / vector_field / int4 / int8 / real
Read image.

▷ **MemoryBlockHandle** (input_control) ..... memory_block ⇝ *handle*
Memory block handle.

Result

If the parameters are correct the operator memory_block_to_image returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_memory_block, deserialize_tuple

Possible Successors

disp_image, threshold, regiongrowing, count_channels, decompose3, class_ndim_norm, gauss_filter, fill_interlace, zoom_image_size, zoom_image_factor, crop_part, write_image, rgb1_to_gray

See also

image_to_memory_block

Module

Foundation

read_image (: Image : FileName :)

Read an image with different file formats.

The operator read_image reads the indicated image files from the background storage and generates the image. One or more file names can be passed in FileName. If more than one file name is passed, an image object tuple with the corresponding number of image objects is returned.

HALCON formats (HOBJ and IMA)

For images in the HALCON Iconic Object format (HOBJ), multiple images saved in one file are returned as a tuple of images. If regions or XLDs are contained within the file, an exception is raised. See write_object for more information about the HOBJ format.

All images files written by the operator write_image (format 'ima') have the extension '.ima'. A description file can be available for every image in IMA format (same file name with extension '.exp'). The type of the pixel data (byte, int4, real) can also be taken from the description file. If the description file is not available, the type byte is used by default as well as a default data size ('height' x 'width') that can be queried via get_system. If the data size of the '.ima' file and the default data size are not equal, an exception is raised.

Other formats

Besides the HALCON formats, TIFF, GIF, BMP, JPEG, JPEG-2000, JPEG-XR, PNG, PCX, SUN-Raster, PGM, PPM, PBM, and XWD files can also be read. The gray values of PBM images are set at the values 0 and 255. The file formats are either recognized by the extension (if indicated) or because of the internal structure of the files. If the extension is indicated the image can be found faster. If no extension is indicated, files with an extension are preferred to files without extension. In case of PGM, PPM, and PBM the corresponding extension (e.g., 'pgm') or the general value 'pnm' can be used. In case of TIFF 'tiff' and 'tif' are accepted. In case of JPEG-XR 'jxr', 'wdp', 'wmp', and 'hdp' are accepted. In case of JPEG-2000 only 'jp2' is accepted. In case of colored images an image with three color channels is created, the red channel being stored in the first, the green channel in the second and the blue channel in the third component (channel number).

For the image formats TIFF, PNG, JPEG-XR, and JPEG-2000, binary alpha channels are interpreted as domains. For TIFF files, additionally binary SubIFDs with PhotometricInterpretation = TransparencyMask are interpreted as domains. Otherwise, the domain of the generated image object (= all pixels of the matrix) is chosen maximal.

For TIFF images, multipage TIFF files are returned as image object tuples. SubIFDs in a TIFF file are only read if their dimensions are equal to the dimensions of the main image.

Images of type 'int8' can be read on 64 bit systems only. Furthermore, only the IMA and the TIFF format support this image type.

Image files are searched in the current directory and in the image directory of HALCON (determined by the environment variable). The image directory of HALCON is preset at '.' and '/usr/local/halcon/images' in a Unix-like environment and can be set via the operator set_system. More than one image directory can be indicated. This is done by separating the individual directories by a colon.

Furthermore, the search path can be set via the environment variable HALCONIMAGES (same structure as 'image_dir'). Example:

```
setenv HALCONIMAGES "/usr/images:/usr/local/halcon/images"
```

HALCON also searches images in the subdirectory 'images' (Images for the program examples). The environment variable HALCONROOT is used for the HALCON directory.

Attention

If CMYK or YCCK JPEG/JPEG-XR files are read, HALCON assumes that these files follow the Adobe Photoshop convention that the CMYK channels are stored inverted, i.e., 0 represents 100% ink coverage, rather than 0% ink as one would expect. The images are converted to RGB images using this convention. If the JPEG file does not follow this convention, but stores the CMYK channels in the usual fashion, invert_image must be called after reading the image.

If PNG images that contain an alpha channel are read, the alpha channel is returned as the second or fourth channel of the output image, unless the alpha channel contains exactly two different gray values, in which case a one or three channel image with a reduced domain is returned, in which the points in the domain correspond to the points with the higher gray value in the alpha channel.

Parameters

▷ **Image** (output_object) ..... image(-array) ⇝ *object :* byte / direction / cyclic / int1 / complex / int2 / uint2 / vector_field / int4 / int8 / real

Read image.

▷ **FileName** (input_control) . . . . . filename.read(-array) ⇝ *string*
Name of the image to be read.
Default: 'printer_chip/printer_chip_01'
Suggested values: FileName ∈ {'fabrik', 'fuse', 'mreut', 'multiple_dies_01', 'particle', 'patras', 'printer_chip/printer_chip_01', 'rings_and_nuts', 'tooth_rim'}
File extension: .hobj, .ima, .tif, .tiff, .gif, .bmp, .jpg, .jpeg, .jp2, .jxr, .png, .pcx, .ras, .xwd, .pbm, .pnm, .pgm, .ppm

Example

```
* Reading an image:
  read_image(Image,'mreut')

* Reading 3 images into an image array:
  read_image(Images,['ic0','ic1','ic2'])

* Setting of search path for images on '/mnt/images' and '/home/images':
  set_system('image_dir','/mnt/images:/home/images')
```

Result

If the parameters are correct the operator read_image returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

disp_image, threshold, regiongrowing, count_channels, decompose3, class_ndim_norm, gauss_filter, fill_interlace, zoom_image_size, zoom_image_factor, crop_part, write_image, rgb1_to_gray

Alternatives

read_sequence

See also

set_system, write_image

Module

Foundation

read_image_metadata (: : Format, TagName, FileName : TagValue)

Read metadata from image files.

The operator read_image_metadata reads the metadata of the file FileName and returns the information in TagValue. With TagName you specify, for which single tag or tuple of tags you want to retrieve the information. The parameter Format specifies, in which format the metadata is encoded.

This operators supports for Format the TIFF metadata formats *'tiff'* and *'bigtiff'*. The file extension .tif is expected.

The following tags are readable:

TagName	TagValue **data type**
'tiff_aperture_value'	double
'tiff_copyright'	string
'tiff_date_time'	string
'tiff_exposure_time'	double
'tiff_image_description'	string
'tiff_light_source'	integer
'tiff_make'	string
'tiff_software'	string

Note, the operator returns an error in case the tag specified by TagName has no value set.

You can retrieve all readable tags with the string *'tiff_tags_supported_for_reading'* for TagName as well as retrieve all writable tags with the string *'tiff_tags_supported_for_writing'*. Each of both strings can be used only as single value for TagName.

Parameters

▷ **Format** (input_control) . . . . . string ⇝ *string*
Graphic format.
Default: 'tiff'
Suggested values: Format ∈ {'tiff', 'bigtiff'}

▷ **TagName** (input_control) . . . . . tuple ⇝ *string*
Name of the tag to be written in the image file.
Default: 'tiff_image_description'
Suggested values: TagName ∈ {'tiff_image_description', 'tiff_make', 'tiff_software', 'tiff_date_time', 'tiff_copyright', 'tiff_exposure_time', 'tiff_aperture_value', 'tiff_light_source', 'tiff_tags_supported_for_reading', 'tiff_tags_supported_for_writing'}

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
Name of image file.
File extension: .tif, .tiff

▷ **TagValue** (output_control) . . . . . tuple ⇝ *string* / integer / real
Output tag value read from the image file.

Result

If TagValue can be correctly read for the specified input parameters the operator read_image_metadata returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. In this case, an extended error information, as e.g., the causative tag, may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

write_image_metadata

Possible Successors

read_image

Module

Foundation

read_sequence (: Image : HeaderSize, SourceWidth, SourceHeight, StartRow, StartColumn, DestWidth, DestHeight, PixelType, BitOrder, ByteOrder, Pad, Index, FileName :)

Read images.

The operator read_sequence reads unformatted image data, from a file and returns a "suitable" image. The image data must be filled consecutively pixel by pixel and line by line.

Any file headers (with the length HeaderSize bytes) are skipped. The parameters SourceWidth and SourceHeight indicate the size of the filled image. DestWidth and DestHeight indicate the size of the image. In the simplest case these parameters are the same. However, areas can also be read. The upper left corner of the required image area can be determined via StartRow and StartColumn.

The pixel types *'bit'*, *'byte'*, *'short'* (16 bits, unsigned), *'signed_short'* (16 bits, signed), *'long'* (32 bits, signed), *'swapped_long'* (32 bits, with swapped segments), and *'real'* (32 bit floating point numbers) are supported. Furthermore, the operator read_sequence enables the extraction of components of a RBG image, if a triple of three bytes (in the sequence "red", "green", "blue") was filed in the image file. For the red component the pixel type *'r_byte'* must be chosen, and correspondingly for the green and blue components *'g_byte'* or *'b_byte'*, respectively.

'MSBFirst' (most significant bit first) or the inversion thereof (*'LSBFirst'*) can be chosen for the bit order (BitOrder). The byte orders (ByteOrder) *'MSBFirst'* (most significant byte first) or *'LSBFirst'*, respectively, are processed analogously. Finally an alignment (Pad) can be set at the end of the line: *'byte'*, *'short'* or *'long'*. If a whole image sequence is stored in the file a single image (beginning at Index 1) can be chosen via the parameter Index.

Image files are searched in the current directory (determined by the environment variable) and in the image directory of HALCON. The image directory of HALCON is preset at '.' and '/usr/local/halcon/images' in a Unix-like environment and can be set via the operator set_system. More than one image directory can be indicated. This is done by separating the individual directories by a colon.

Furthermore the search path can be set via the environment variable HALCONIMAGES (same structure as *'image_dir'*). Example:

```
setenv HALCONIMAGES "/usr/images:/usr/local/halcon/images"
```

HALCON also searches images in the subdirectory 'images' (Images for the program examples). The environment variable HALCONROOT is used for the HALCON directory.

Attention

If files of pixel type *'real'* are read and the byte order is chosen incorrectly (i.e., differently from the byte order in which the data is stored in the file) program error and even crashes because of floating point exceptions may result.

Parameters

▷ **Image** (output_object) . . . . . image ⇝ *object :* byte / int2 / uint2 / int4
Image read.

▷ **HeaderSize** (input_control) . . . . . integer ⇝ *integer*
Number of bytes for file header.
Default: 0
Value range: 0 ≤ HeaderSize

▷ **SourceWidth** (input_control) . . . . . extent.x ⇝ *integer*
Number of image columns of the filed image.
Default: 512
Value range: 1 ≤ SourceWidth

▷ **SourceHeight** (input_control) . . . . . extent.y ⇝ *integer*
Number of image lines of the filed image.
Default: 512
Value range: 1 ≤ SourceHeight

▷ **StartRow** (input_control) . . . . . point.y ⇝ *integer*
Starting point of image area (line).
Default: 0
Value range: 0 ≤ StartRow
Restriction: StartRow < SourceHeight

▷ **StartColumn** (input_control) . . . . . point.x ⇝ *integer*
Starting point of image area (column).
Default: 0
Value range: 0 ≤ StartColumn
Restriction: StartColumn < SourceWidth

▷ **DestWidth** (input_control) . . . . . extent.x ⇝ *integer*
Number of image columns of output image.
Default: 512
Value range: 1 ≤ DestWidth
Restriction: DestWidth <= SourceWidth

▷ **DestHeight** (input_control) . . . . . extent.y ⇝ *integer*
Number of image lines of output image.
Default: 512
Value range: 1 ≤ DestHeight
Restriction: DestHeight <= SourceHeight

▷ **PixelType** (input_control) . . . . . string ⇝ *string*
Type of pixel values.
Default: 'byte'
List of values: `PixelType` ∈ {'bit', 'byte', 'r_byte', 'g_byte', 'b_byte', 'short', 'signed_short', 'long', 'swapped_long', 'real'}

▷ **BitOrder** (input_control) . . . . . string ⇝ *string*
Sequence of bits within one byte.
Default: 'MSBFirst'
List of values: `BitOrder` ∈ {'MSBFirst', 'LSBFirst'}

▷ **ByteOrder** (input_control) . . . . . string ⇝ *string*
Sequence of bytes within one 'short' unit.
Default: 'MSBFirst'
List of values: `ByteOrder` ∈ {'MSBFirst', 'LSBFirst'}

▷ **Pad** (input_control) . . . . . string ⇝ *string*
Data units within one image line (alignment).
Default: 'byte'
List of values: `Pad` ∈ {'byte', 'short', 'long'}

▷ **Index** (input_control) . . . . . integer ⇝ *integer*
Number of images in the file.
Default: 1
Value range: 1 ≤ Index (lin)

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
Name of input file.

Result

If the parameter values are correct the operator `read_sequence` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`disp_image`, `count_channels`, `decompose3`, `write_image`, `rgb1_to_gray`

Alternatives

`read_image`

See also

`read_image`

Module

Foundation

serialize_image (Image : : : SerializedItemHandle)

Serialize an image object.

serialize_image serializes an image object (see fwrite_serialized_item for an introduction of the basic principle of serialization). The image object is defined by the parameter Image. The serialized image object is returned by the handle SerializedItemHandle and can be deserialized by deserialize_image.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / complex / int2 / uint2 / vector_field / int4 / int8 / real

Image object.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*

Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_image returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_image

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_image

Module

Foundation

write_image (Image : : Format, FillColor, FileName :)

Write images in graphic formats.

The operator write_image saves the input image Image in the file FileName in the format Format. If the domain (region) cannot be saved in the specified Format (this is the case for 'bmp', 'jpeg', and 'ima'), all pixels outside the region receive the color defined by FillColor. For gray value images a value between 0 (black) and 255 (white) must be passed. For RGB color images the RGB values can be passed directly as a hexadecimal value: e.g., 0xffff00 for a yellow background (red=255, green=255, blue=0).

The following formats are currently supported:

'tiff', 'bigtiff': TIFF format, file extension *.tif

All HALCON pixel types are supported. Image object tuples with up to 65535 image objects and up to 65535 channels can be written. Image objects with channels of mixed pixel types can be written.

Compression is possible with

'deflate [num]':	Adobe deflate compression (lossless)
'jpeg [num]':	JPEG (lossy)
'lzw'	LZW (lossless)
'packbits'	PackBits (lossless)

Here, *'[num]'* denotes an optional specification of a compression parameter. For *'deflate'*, a number between *0* (no compression) and *9* (maximum compression) can be specified. For *'jpeg'*, a number between *0* and *100* can be specified. The semantics are identical to the semantics of 'jpeg' described below. *'jpeg'* can only be used for images of type byte and int1 with up to four channels.

The domain (region) of each image object can be saved in compressed form via *'mask'* (default setting) or as an additional alpha channel via *'alpha'*. The domain is only stored if it does not comprise the full image. *'jpeg'* and

'alpha' cannot be used together because owing to the lossy compression of JPEG the domain of the image cannot be reconstructed correctly. The different options can be accumulated by appending them separated by a space character.

Examples:

'tiff deflate 9':	Adobe deflate compression, the domain is stored as a mask image if necessary
'tiff jpeg 90':	JPEG compression with high quality, the domain is stored as a mask image if necessary
'tiff lzw alpha':	LZW compression, the domain is stored as an alpha channel if necessary
'tiff' or *'tiff none'*:	no compression, the domain is stored as a mask image if necessary

Attention: Note that *'bigtiff'* denotes TIFF files that can be larger than 4 GB, while *'tiff'* denotes TIFF files that are limited to 4 GB. The file size depends on the image size and the selected compression. Therefore, *'bigtiff'* should be selected if there is a possibility that the compressed file will grow to more than 4 GB.

'bmp': Windows-BMP format, file extension *.bmp

Restriction:

- This format can only store images with one channel (gray value image) or three channels (RGB image).
- Only images with the pixel type byte are supported for this file format.

'jpeg': JPEG format (lossy compression), file extension *.jpg

Together with the format string the quality value determining the compression rate can be provided, e.g., 'jpeg 30'.

Restriction:

- This format can only store images with one channel (gray value image) or three channels (RGB image).
- Only images with the pixel type byte are supported for this file format.

Attention: Images stored for being processed later should not be stored in this format due to the loss of information during compression.

'jp2': JPEG-2000 format (lossless and lossy compression), file extension *.jp2

Together with the format string the quality value determining the compression rate can be provided (e.g., *'jp2 40'*). This value corresponds to the ratio of the size of the compressed image and the size of the uncompressed image (in percent). Since lossless JPEG-2000 compression already reduces the file size significantly, only smaller values (typically smaller than 50) influence the file size. If no value is provided for the compression (and only then), the image is compressed without loss.

The image can contain an arbitrary number of channels. Possible types are byte, cyclic, direction, int1, uint2, int2, and int4. In the case of int4 it is only possible to store images with less or equal to 24 bits precision (otherwise an exception is raised). If an image with a reduced domain is written, the region is stored as 1-bit alpha channel.

Restriction: The maximal supported image size (width x height) for JPEG-2000 is $2^{31} - 1$ also in HALCON-XL.

Attention: Note that the JPEG-2000 encoding of an image requires a lot of memory. For large images, it is therefore recommended to use a different format (e.g., *'tiff'*).

'jpegxr': JPEG-XR format (lossless and lossy compression), file extension *.jxr

Together with the format string the quality value determining the compression rate can be provided, e.g., *'jpegxr 30'* (use *'jpegxr 100'* or *'jpegxr'* for lossless encoding). Image object tuples with an arbitrary number of image objects can be written. In the case of int4 and real images, the numeric range is compressed to 24 bit accuracy. Note that this may induce loss regardless of the quality setting. If an image with a reduced domain is written, the region is stored without loss as 1-bit alpha channel. Complex images, vector fields and regular images with two gray value channels are padded with an empty third channel to be compliant with the standard.

Restriction:

- This format cannot be written in parallel.

- Images can have up to 8 channels.
- All HALCON pixel types except int8 are supported.

Attention: Note that you need to have write permission in your current working directory in order to save an image in JPEG-XR format, regardless of the target directory.

'png': PNG format (lossless compression), file extension *.png

Together with the format string, a compression level between 0 and 9 can be specified, where 0 corresponds to no compression and 9 to the best possible compression. Alternatively, the compression can be selected with the following strings: *'best'*, *'fastest'*, and *'none'*. Hence, examples for correct parameters are *'png'*, *'png 7'*, and *'png none'*.

Images of type byte and uint2 can be stored in PNG files. If an image with a reduced domain is written, the region is stored as the alpha channel, where the points within the domain are stored as the maximum gray value of the image type and the points outside the domain are stored as the gray value 0. If an image with a full domain is written, no alpha channel is stored.

Restriction:

- This format can only store images with one channel (gray value image) or three channels (RGB image).
- The maximal supported image size (width x height) for PNG is $2^{31} - 1$ also in HALCON-XL.

'hobj': HALCON Iconic Object (HOBJ), file extension *.hobj

All types of HALCON images are supported. See `write_object` for more information about the HOBJ format.

'ima': HALCON format, file extension *.ima and *.exp

This file format is now legacy and the HOBJ format should be used instead. The data is written in binary form line by line (without header or carriage return). The size of the image and the pixel type are stored in the description file "`FileName`.exp". All HALCON pixel types except *'complex'* and *'vector_field'* can be written.

Restriction: This format can only store images with one channel (gray value image).

Parameters

▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / complex / int2 / uint2 / vector_field / int4 / int8 / real

Input images.

▷ **`Format`** (input_control) ..... string ⇝ *string*

Graphic format.
Default: 'tiff'
Suggested values: `Format` ∈ {'tiff', 'tiff mask', 'tiff alpha', 'tiff deflate 9', 'tiff deflate 9 alpha', 'tiff jpeg 90', 'tiff lzw', 'tiff lzw alpha ', 'tiff packbits', 'bigtiff', 'bigtiff mask', 'bigtiff alpha', 'bigtiff deflate 9', 'bigtiff deflate 9 alpha', 'bigtiff jpeg 90', 'bigtiff lzw', 'bigtiff lzw alpha ', 'bigtiff packbits', 'bmp', 'jpeg', 'jpeg 100', 'jpeg 80', 'jpeg 60', 'jpeg 40', 'jpeg 20', 'jp2', 'jp2 50', 'jp2 40', 'jp2 30', 'jp2 20', 'jpegxr', 'jpegxr 50', 'jpegxr 40', 'jpegxr 30', 'jpegxr 20', 'png', 'png best', 'png fastest', 'png none', 'ima', 'hobj'}

▷ **`FillColor`** (input_control) ..... number ⇝ *integer* / real

Fill gray value for pixels not belonging to the image domain (region).
Default: 0
Suggested values: `FillColor` ∈ {-1, 0, 255, 65280, 16711680}

▷ **`FileName`** (input_control) ..... filename.write(-array) ⇝ *string*

Name of image file.
File extension: `.hobj`, `.ima`, `.tif`, `.tiff`, `.bmp`, `.jpg`, `.jpeg`, `.jp2`, `.jxr`, `.png`

Result

If the parameter values are correct the operator `write_image` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Predecessors

read_image

Module

Foundation

write_image_metadata (: : Format, TagName, TagValue, FileName :)

Write metadata of image files.

The operator write_image_metadata saves the information in TagValue with the tag TagName into the file FileName. In doing so, TagValue and TagName can be single values or tuples of values. The parameter Format specifies, in which format the metadata is to be written.

This operators supports for Format the TIFF metadata formats *'tiff'* and *'bigtiff'*. A file extension .tif is expected.

A list of the supported tag names for TagName and the according data types for TagValue is given in read_image_metadata.

Parameters

▷ **Format** (input_control) . . . . . string ⇝ *string*
Graphic format.
Default: 'tiff'
Suggested values: Format ∈ {'tiff', 'bigtiff'}

▷ **TagName** (input_control) . . . . . tuple ⇝ *string*
Name of the tag to be written in the image file.
Default: 'tiff_image_description'
Suggested values: TagName ∈ {'tiff_image_description', 'tiff_make', 'tiff_software', 'tiff_date_time', 'tiff_copyright', 'tiff_exposure_time', 'tiff_aperture_value', 'tiff_light_source'}

▷ **TagValue** (input_control) . . . . . tuple ⇝ *string* / integer / real
Value of the tag to be written in the image file.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of image file.
File extension: .tif, .tiff

Result

If TagValue can be correctly written for the specified parameters the operator write_image_metadata returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. In this case, an extended error information, as e.g., the causative tag, may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

11.3 Misc

copy_file (: : SourceFile, DestinationFile :)

Copy a file to a new location.

copy_file copies SourceFile to DestinationFile. Existing files are silently overwritten. The file attributes of SourceFile are kept.

Parameters

▷ **SourceFile** (input_control) ..... filename.read ⇝ *string*
File to be copied.

▷ **DestinationFile** (input_control) ..... filename.write ⇝ *string*
Target location.

Result

copy_file returns the value 2 (H_MSG_TRUE) if the file could be copied. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

delete_file (: : FileName :)

Delete a file.

delete_file deletes the file given by FileName.

Parameters

▷ **FileName** (input_control) ..... filename ⇝ *string*
File to be deleted.

Result

delete_file returns the value 2 (H_MSG_TRUE) if the file exists and could be deleted. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

file_exists (: : FileName : FileExists)

Check whether file exists.

The operator file_exists checks whether the indicated file already exists. If this is the case, the parameter FileExists is set to TRUE, otherwise to FALSE.

Parameters

▷ **FileName** (input_control) . . . . . filename ⇝ *string*
Name of file to be checked.
Default: '/bin/cc'

▷ **FileExists** (output_control) . . . . . integer ⇝ *integer*
Boolean number.

Result

If the parameters are correct the operator `file_exists` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`open_file`

Alternatives

`open_file`

Module

Foundation

get_current_dir (: : : DirName)

Get the current working directory.

`get_current_dir` returns the current working directory in `DirName`.

Parameters

▷ **DirName** (output_control) . . . . . filename.dir ⇝ *string*
Name of current working directory.

Result

`get_current_dir` returns the value `2` (`H_MSG_TRUE`) if the current working directory could be determined. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

list_files (: : Directory, Options : Files)

List all files in a directory.

`list_files` returns all files in the directory given by `Directory` in the parameters `Files`. The current directory can be specified with '' or '.'. The parameter `Options` can be used to specify different processing options by passing a tuple of values.

If `Options` contains *'files'* only the files present in `Directory` are returned. If *'directories'* is passed, only the directories present in `Directory` are returned. On Unix-like systems *'symlinks'* may be passed to list symbolic

links. Directories are marked by a trailing '\' (Windows) or a trailing '/' (Unix-like systems). If files as well as directories should be returned, *['files','directories']* must be passed. If none of *'files'*, *'directories'* or *'symlinks'* is passed, `list_files` returns an empty tuple.

By passing *'recursive'*, it can be specified that the directory tree should be searched recursively by examining all sub-directories. On Unix-like systems, *'follow_links'* can be used to specify that symbolic links to files or directories should be followed. In the default setting, symbolic links are not dereferenced, and hence are not searched if they point to directories, and not returned if they point to files. The option *'follow_links'* can not be used in conjunction with the option *'symlinks'*.

For the recursive search, a maximum search depth can be specified with *'max_depth <d>'* , where *'<d>'* is a number that specifies the maximum depth. Hence, *'max_depth 2'* specifies that `Directory` and all immediate sub-directories should be searched. If symbolic links should be followed it might happen that the search does not terminate if the symbolic links lead to a cycle in the directory structure. Because of this, at most 1000000 files (and directories) are returned in `Files`. By specifying a different number with *'max_files <d>'*, this value can be modified.

Parameters

▷ **`Directory`** (input_control) . . . . . filename.dir ⇝ *string*
Name of directory to be listed.

▷ **`Options`** (input_control) . . . . . string(-array) ⇝ *string*
Processing options.
Default: 'files'
Suggested values: `Options` ∈ {'files', 'directories', 'symlinks', 'recursive', 'follow_links', 'max_depth 5', 'max_files 1000'}

▷ **`Files`** (output_control) . . . . . string-array ⇝ *string*
Found files (and directories).

Result

`list_files` returns the value `2` (`H_MSG_TRUE`) if the directory exists and could be read. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`tuple_regexp_select`

Module

Foundation

`make_dir` (: : DirName :)

Make a directory.

`make_dir` creates the directory given by `DirName`.

Parameters

▷ **`DirName`** (input_control) . . . . . filename.dir ⇝ *string*
Name of directory to be created.

Result

`make_dir` returns the value `2` (`H_MSG_TRUE`) if the directory could be created. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

read_world_file (: : FileName : WorldTransformation)

Read the geo coding from an ARC/INFO world file.

read_world_file reads a geocoding from an ARC/INFO world file with the file name FileName and returns it as a homogeneous 2D transformation matrix in WorldTransformation. To find the file FileName, all directories contained in the HALCON system variable *'image_dir'* (usually this is the content of the environment variable HALCONIMAGES) are searched (see read_image). This transformation matrix can be used to transform XLD contours to the world coordinate system before writing them with write_contour_xld_arc_info. If the matrix WorldTransformation is inverted by calling hom_mat2d_invert, the resulting matrix can be used to transform contours that have been read with read_contour_xld_arc_info to the image coordinate system.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the ARC/INFO world file.

▷ **WorldTransformation** (output_control) ..... hom_mat2d ⇝ *real*
Transformation matrix from image to world coordinates.

Result

If the parameters are correct and the world file could be read, the operator read_world_file returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

hom_mat2d_invert, affine_trans_contour_xld, affine_trans_polygon_xld

See also

write_contour_xld_arc_info, read_contour_xld_arc_info, write_polygon_xld_arc_info, read_polygon_xld_arc_info

Module

Foundation

remove_dir (: : DirName :)

Delete an empty directory.

remove_dir deletes the empty directory given by DirName.

Parameters

▷ **DirName** (input_control) ..... filename.dir ⇝ *string*
Name of directory to be deleted.

Result

remove_dir returns the value 2 (H_MSG_TRUE) if the directory could be deleted. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_current_dir (: : DirName :)

Set the current working directory.

set_current_dir sets the current working directory to the directory DirName.

Parameters

▷ **DirName** (input_control) ..... filename.dir ⇝ *string*
Name of current working directory to be set.

Result

set_current_dir returns the value 2 (H_MSG_TRUE) if the current working directory could be set. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

11.4 Object

deserialize_object (: Object : SerializedItemHandle :)

Deserialize a serialized iconic object.

deserialize_object deserializes an iconic object, that was serialized by serialize_object (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized iconic object is defined by the parameter SerializedItemHandle. The deserialized iconic object is stored in the iconic object defined by the parameter Object.

Parameters

▷ **Object** (output_object) ..... object(-array) ⇝ *object*
Iconic object.

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator deserialize_object returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_object

See also

serialize_object

Module

Foundation

read_object (: Object : FileName :)

Read an iconic object.

read_object reads an iconic object from the file FileName. The file must be written in the HALCON Iconic Object format (HOBJ), which is supported by the operators write_object, write_image, and write_region. See write_object for more information about the HOBJ format.

Parameters

▷ **Object** (output_object) ..... object(-array) ⇝ *object*
Iconic object.

▷ **FileName** (input_control) ..... filename ⇝ *string*
Name of file.
File extension: .hobj

Result

If the parameters are valid, the operator read_object returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

write_image, write_object

See also

write_object, write_image, read_image

Module

Foundation

serialize_object (Object : : : SerializedItemHandle)

Serialize an iconic object.

serialize_object serializes an iconic object (see fwrite_serialized_item for an introduction of the basic principle of serialization). The iconic object is a tuple of image objects, region objects, or XLD objects, and is defined by the parameter Object. The serialized iconic object is returned by the handle SerializedItemHandle and can be deserialized by deserialize_object.

Parameters

▷ **Object** (input_object) ..... object(-array) ⇝ *object*
Iconic object.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_object returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_object

See also

deserialize_object

Module

Foundation

write_object (Object : : FileName :)

Write an iconic object.

write_object writes the iconic Object to the file FileName. The iconic object is a (possibly mixed) tuple of images, regions, or XLDs. If no extension is specified in FileName, the extension '.hobj' will be appended. The iconic data is written in the HALCON Iconic Object format described below.

HALCON Iconic Object (HOBJ): HOBJ is a binary file format, which provides the functionality to write and read all kinds of iconic HALCON objects (images, regions, and XLDs). Since data is written with neither compression nor conversion, writing this file format is faster than other supported file formats in most circumstances. Hence, if an application needs to read and write all kinds of iconic HALCON objects as fast as possible and no compression is required, this format should be used. The default file extension for this file format is '.hobj'. For images, all HALCON pixel types can be written. Multi-channel images are supported. The channels can have mixed pixel types but must have the same width and height. The domain of an image and it's creation date are stored in the file as well. An object tuple is written into a single file.

Parameters

▷ **Object** (input_object) ..... object(-array) ⇝ *object*
Iconic object.

▷ **FileName** (input_control) ..... filename ⇝ *string*
Name of file.
File extension: .hobj

Result

If the parameters are valid, the operator write_object returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

read_object, read_image

See also

read_object, write_image, read_image, write_region, read_region

Module

Foundation

11.5 Region

deserialize_region (: Region : SerializedItemHandle :)

Deserialize a serialized region.

deserialize_region deserializes a region, that was serialized by serialize_region (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized region is defined by the parameter SerializedItemHandle. The deserialized region is stored in the region defined by the parameter Region.

Parameters

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Region.

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator deserialize_region returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_image, fread_serialized_item, receive_serialized_item, serialize_region

Possible Successors

reduce_domain, disp_region

See also

serialize_region

Module

Foundation

read_region (: Region : FileName :)

Read binary images or HALCON regions.

The operator read_region reads regions from a binary file.

The following formats are currently supported:

HALCON Iconic Object (HOBJ): File format for iconic HALCON objects. The HOBJ file must contain *only* regions to be readable by read_region. If other objects (e.g., images or XLDs) are stored in the file, an exception is raised. In this case read_object can be used to read the corresponding HOBJ file. The HOBJ format is the default file format for regions. Therefore, the extension '.hobj' does not have to be specified when reading or writing the file. See write_object for more information about the HOBJ format.

HALCON regions: File format for HALCON regions. This file format supports multiple regions in a single file. The file extension is '.reg'. This format is now legacy and the HOBJ format should be used instead.

Tiff: Binary Tiff images with extension '.tiff' or '.tif'. A tiff image can contain any number of regions. The color white is used as foreground.

PNG: Binary PNG images with extension '.png'. The result is always *one* region. The color white is used as foreground.

BMP: Binary Windows bitmap images with extension '.bmp'. The result is always *one* region. The color white is used as foreground.

A search path (`'image_dir'`) can be defined analogous to the operator `read_image`.

Attention

The clipping based on the current image format is set via the operator `set_system('clip_region',<'true'/'false'>)`. Consequently, if no image of sufficient size has been created before the call to `read_region`, `set_system('clip_region','false')` should be called before calling `read_region` to ensure that the region is not being clipped.

Parameters

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Read region.

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the region to be read.
File extension: `.hobj`, `.reg`, `.tif`, `.tiff`, `.png`, `.bmp`

Example

```
* Reading of regions and giving them gray values.
  read_image(Img,'ima_test')
  read_region(Regs,'reg_test')
  reduce_domain(Img,Regs,Res)
```

Result

If the parameter values are correct the operator `read_region` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_image`

Possible Successors

`reduce_domain`, `disp_region`

See also

`write_region`, `read_image`, `write_object`

Module

Foundation

serialize_region (Region : : : SerializedItemHandle)

Serialize a region.

`serialize_region` serializes a region (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The region is defined by the parameter `Region`. The serialized region is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_region`.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_region` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_image, read_region, threshold, regiongrowing

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_region

See also

deserialize_region

Module

Foundation

write_region (Region : : FileName :)

Write regions to a file.

The operator write_region writes the regions in Region into a binary file. The regions can be written in the HALCON Iconic Object format (HOBJ), as TIFF files or as HALCON region files. The format is selected via the file name extension of FileName. If no extension is specified or if the file extension is '.hobj', the regions are stored in the HOBJ format. If no extension is specified in FileName, the extension '.hobj' will be appended. See write_object for more information about the HOBJ format. If the extension '.tif' or '.tiff' is specified, the regions are stored as TIFF files. If the extension '.reg' is specified, the regions are stored as a HALCON region file. The HALCON region file format is now legacy and the file format HOBJ should be used instead unless the files must be readable with HALCON versions older than 12.0. Iconic object tuples with an arbitrary number of regions can be written. The output data can be read via the operator read_region.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region of the images which are returned.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Name of region file.
Default: 'region.hobj'
File extension: .hobj, .reg, .tif, .tiff

Example

```
regiongrowing(Img,Segments,3,3,5,10)
write_region(Segments,'result1')
```

Result

If the parameter values are correct the operator write_region returns the value 2 (H_MSG_TRUE). Otherwise an exception handling is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_image, read_region, read_object, threshold, regiongrowing

read_region

Module

Foundation

11.6 Tuple

deserialize_handle (: : SerializedItem : Handle)

Deserialize a serialized item.

deserialize_handle deserializes the content of SerializedItem and returns the deserialized item in Handle (see fwrite_serialized_item for an introduction of the basic principle of serialization).

The serialized item must have been created by serialize_handle, or by the type specific serialization operators, such as serialize_matrix or serialize_shape_model.

Parameters

▷ **SerializedItem** (input_control) ..... serialized_item ⇝ *handle*
Handle containing the serialized item to be deserialized.

▷ **Handle** (output_control) ..... handle ⇝ *handle*
Handle containing the deserialized item.

Example

```
create_matrix (3, 3, 0, MatrixID)
serialize_handle (MatrixID, SerializedMatrix)
deserialize_handle (SerializedMatrix, MatrixID2)
```

Result

If the parameters are valid, the operator deserialize_handle returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

serialize_handle, fread_serialized_item, receive_serialized_item

Module

Foundation

deserialize_tuple (: : SerializedItemHandle : Tuple)

Deserialize a serialized tuple.

deserialize_tuple deserializes the data of a tuple, that was serialized by serialize_tuple (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized data of the tuple is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created tuple with the handle Tuple.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **Tuple** (output_control) ..... tuple(-array) ⇝ *real* / integer / string / handle
Tuple.

Result

If the parameters are valid, the operator deserialize_tuple returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_tuple

Module

Foundation

read_tuple (: : FileName : Tuple)

Read a tuple from a file.

The operator read_tuple reads the contents of FileName and converts it into Tuple. The default HALCON file extension for the tuple is 'tup'. The file has to be generated by write_tuple.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the file to be read.
File extension: .tup

▷ **Tuple** (output_control) ..... tuple(-array) ⇝ *real* / integer / string
Tuple with any kind of data.

Result

If the parameters are correct the operator read_tuple returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

fwrite_string

See also

write_tuple, write_image, write_region, open_file

Module

Foundation

serialize_handle (: : Handle : SerializedItem)

Serialize the content of a handle.

serialize_handle serializes the content of Handle and returns the serialized item in SerializedItem (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized item can later be deserialized with deserialize_handle.

Note that not all handle types support serialization. To check if a handle can be serializes, use tuple_is_serializable or tuple_is_serializable_elem. Handles that have already been cleared cannot be serialized.

Also note that the serialized item created by this operator is compatible with the type specific deserialization operators, such as deserialize_matrix or deserialize_shape_model.

Parameters

▷ **Handle** (input_control) . . . . . handle ⇝ *handle*
Handle that should be serialized.

▷ **SerializedItem** (output_control) . . . . . serialized_item ⇝ *handle*
Handle containing the serialized item.

Example

```
create_matrix (3, 3, 0, MatrixID)
serialize_handle (MatrixID, SerializedMatrix)
deserialize_handle (SerializedMatrix, MatrixID2)
```

Result

If the parameters are valid, the operator `serialize_handle` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`tuple_is_serializable`, `tuple_is_serializable_elem`

Possible Successors

`deserialize_handle`, `fwrite_serialized_item`, `send_serialized_item`

Module

Foundation

serialize_tuple (: : Tuple : SerializedItemHandle)

Serialize a tuple.

`serialize_tuple` serializes the data of a tuple (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_tuple` is converted to a serialized item. The tuple is defined by the handle `Tuple`. The serialized data of a tuple is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_tuple`.

Note that not all handle types can be serialized. If `Tuple` contains a handle that can not be serialized or that has been freed already, an exception is raised. The operators `tuple_is_serializable` and `tuple_is_serializable_elem` can be used to find out if a tuple or its elements can be serialized.

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string / handle
Tuple.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_tuple` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_tuple

Module

Foundation

tuple_is_serializable (: : Tuple : IsSerializable)

Test if a tuple is serializable.

tuple_is_serializable checks if Tuple can be serialized with serialize_tuple. If yes, *1* is returned in IsSerializable. Otherwise, *0* is returned.

A tuple can be serialized if it contains only integers, strings, reals, and serializable handles. Handles that are already freed cannot be serialized. To check all elements of a tuple individually, use tuple_is_serializable_elem.

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *handle* / integer / real / string
Tuple to check for serializability.

▷ **IsSerializable** (output_control) . . . . . number ⇝ *integer*
Boolean value indicating if the input can be serialized.

Result

If the parameters are valid, the operator tuple_is_serializable returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

serialize_tuple, write_tuple

Alternatives

tuple_is_serializable_elem

See also

tuple_is_serializable_elem, serialize_tuple, serialize_handle, deserialize_tuple, deserialize_handle, write_tuple

Module

Foundation

tuple_is_serializable_elem (: : Tuple : IsSerializableElem)

Test if the elements of a tuple are serializable.

tuple_is_serializable checks if the elements of Tuple can be serialized with serialize_tuple. The output IsSerializableElem has the same length as the input Tuple and contains at each position either *0* if the corresponding entry in Tuple cannot be serialized, or *1* if it can.

A tuple element can be serialized if it is an integer, a string, a real value or a serializable handle. Handles that are already freed cannot be serialized. To check the complete tuple for serializability, use tuple_is_serializable.

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *handle* / integer / real / string
Tuple to check for serializability.

▷ **IsSerializableElem** (output_control) . . . . . number(-array) ⇝ *integer*
Boolean value indicating if the input elements can be serialized.

Example

```
* Serialize all serializable elements of a tuple
tuple_is_serializable_elem (Tuple, IsSerializableElem)
if (sum(IsSerializableElem[=]0)>0)
  Tuple[find(IsSerializableElem,0)] := HNULL
endif
serialize_tuple (Tuple, SerializedItem)
```

Result

If the parameters are valid, the operator `tuple_is_serializable` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`serialize_tuple`, `write_tuple`

Alternatives

`tuple_is_serializable`

See also

`tuple_is_serializable`, `serialize_tuple`, `serialize_handle`, `deserialize_tuple`, `deserialize_handle`, `write_tuple`

Module

Foundation

`write_tuple ( : : Tuple, FileName : )`

Write a tuple to a file.

The operator `write_tuple` writes the contents of `Tuple` to a file. The data is written in an ASCII format. Therefore, the file can be exchanged between different architectures (see also Tuple / String Operations). The default HALCON file extension for the tuple is 'tup'.

Exception: Handles

Note that `write_tuple` does not support handles, since binary data is not supported by the underlying ASCII format. Any handle contained in `Tuple` is replaced by the integer *0*. To write a tuple that contains handles, use `serialize_tuple` and `fwrite_serialized_item`.

Parameters

▷ **`Tuple`** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Tuple with any kind of data.

▷ **`FileName`** (input_control) . . . . . filename.write ⇝ *string*
Name of the file to be written.
File extension: `.tup`

Result

If the parameters are correct the operator `write_tuple` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Alternatives

fwrite_string

read_tuple, write_image, write_region, open_file

Module

Foundation

11.7 XLD

deserialize_xld (: XLD : SerializedItemHandle :)

Deserialize a serialized XLD object.

deserialize_xld deserializes an XLD object, that was serialized by serialize_xld (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized XLD object is defined by the parameter SerializedItemHandle. The deserialized XLD object is stored in the XLD object defined by the parameter XLD.

Parameters

- ▷ **XLD** (output_object) ..... xld(-array) ⇝ *object*
  XLD object.
- ▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
  Handle of the serialized item.

Result

If the parameters are valid, the operator deserialize_xld returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

See also

serialize_xld

Module

Foundation

read_contour_xld_arc_info (: Contours : FileName :)

Read XLD contours to a file in ARC/INFO generate format.

read_contour_xld_arc_info reads the lines stored in ARC/INFO generate format in the file FileName, and returns them as XLD contours in Contours. To find the file FileName, all directories contained in the HALCON system variable *'image_dir'* (usually this is the content of the environment variable HALCONIMAGES) are searched (see read_image). The returned contours are in world coordinates. They can be transformed to the image coordinate system with the operator affine_trans_contour_xld. The necessary transformation matrix can be generated by using read_world_file to read the transformation matrix from image to world coordinates, and inverting this matrix by calling hom_mat2d_invert.

Parameters

▷ **Contours** (output_object) ..... xld_cont(-array) ⇝ *object*
Read XLD contours.

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the ARC/INFO file.

Example

```
* Read the transformation and invert it
read_world_file ('image.tfw', WorldTransformation)
hom_mat2d_invert (WorldTransformation, ImageTransformation)
* Read the image
read_image (Image, 'image.tif')
* Read the line data
read_contour_xld_arc_info (LinesWorld, 'lines.gen')
* Transform the line data to image coordinates
affine_trans_contour_xld (LinesWorld, Lines, ImageTransformation)
```

Result

If the parameters are correct and the file could be read, the operator `read_contour_xld_arc_info` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`hom_mat2d_invert`, `affine_trans_contour_xld`

See also

`read_world_file`, `write_contour_xld_arc_info`, `read_polygon_xld_arc_info`

Module

Foundation

read_contour_xld_dxf (: Contours : FileName, GenParamName, GenParamValue : DxfStatus)

Read XLD contours from a DXF file.

`read_contour_xld_dxf` reads the contents of the DXF file `FileName` (DXF version AC1009, AutoCAD Release 12) and converts them to the XLD contours `Contours`. If no absolute path is given in `FileName` the DXF file is searched in the current directory of the HALCON process.

The output parameter `DxfStatus` contains information about the number of contours that were read and, if necessary, warnings that parts of the DXF file could not be interpreted.

The operator `read_contour_xld_dxf` supports the following DXF entities:

- POLYLINE
  - 2D curves made up of line segments
  - Closed 2D curves made up of line segments
- LWPOLYLINE
- LINE
- POINT
- CIRCLE

- ARC
- ELLIPSE
- SPLINE
- BLOCK
- INSERT

The x and y coordinates of the DXF entities are stored in the column and row coordinates, respectively, of the XLD contours `Contours`. The z coordinates of the DXF entities are ignored.

If the file has been created with the operator `write_contour_xld_dxf`, all attributes and global attributes that were originally defined for the XLD contours are read. This means that `read_contour_xld_dxf` supports all the extended data written by the operator `write_contour_xld_dxf`. The reading of these attributes can be switched off by setting the generic parameter *'read_attributes'* to *'false'*. Generic parameters are set by specifying the parameter name(s) in `GenParamName` and the corresponding value(s) in `GenParamValue`.

DXF entities of the type CIRCLE, ARC, ELLIPSE, and SPLINE are approximated by XLD contours. The accuracy of this approximation can be controlled with the two generic parameters *'min_num_points'* and *'max_approx_error'*. The parameter *'min_num_points'* defines the minimum number of sampling points that are used for the approximation. Note that the parameter *'min_num_points'* always refers to the full circle or ellipse, respectively, even for ARCs or elliptical arcs, i.e., if *'min_num_points'* is set to *50* and a DXF entity of the type ARC is read that represents a semi-circle, this semi-circle is approximated by at least 25 sampling points. The parameter *'max_approx_error'* defines the maximum deviation of the XLD contour from the ideal circle or ellipse, respectively (unit: pixel). For the determination of the accuracy of the approximation both criteria are evaluated. Then, the criterion that leads to the more accurate approximation is used.

Internally, the following default values are used for the generic parameters:

- *'read_attributes' = 'true'*
- *'min_num_points' = 20*
- *'max_approx_error' = 0.25*

To achieve a more accurate approximation, either the value for *'min_num_points'* must be increased or the value for *'max_approx_error'* must be decreased.

Parameters

▷ **`Contours`** (output_object) ..... xld_cont(-array) ⇝ *object*
Read XLD contours.

▷ **`FileName`** (input_control) ..... filename.read ⇝ *string*
Name of the DXF file.
File extension: `.dxf`

▷ **`GenParamName`** (input_control) ..... attribute.name(-array) ⇝ *string*
Names of the generic parameters that can be adjusted for the DXF input.
Default: []
List of values: `GenParamName` ∈ {'read_attributes', 'min_num_points', 'max_approx_error'}

▷ **`GenParamValue`** (input_control) ..... attribute.value(-array) ⇝ *real* / integer / string
Values of the generic parameters that can be adjusted for the DXF input.
Default: []
Suggested values: `GenParamValue` ∈ {'true', 'false', 0.1, 0.25, 0.5, 1, 2, 5, 10, 20}

▷ **`DxfStatus`** (output_control) ..... string(-array) ⇝ *string*
Status information.

Result

If the parameters are correct and the file could be read the operator `read_contour_xld_dxf` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Foundation

read_polygon_xld_arc_info (: Polygons : FileName :)

Read XLD polygons from a file in ARC/INFO generate format.

read_polygon_xld_arc_info reads the lines stored in ARC/INFO generate format in the file FileName, and returns them as XLD polygons in Polygons. To find the file FileName, all directories contained in the HALCON system variable *'image_dir'* (usually this is the content of the environment variable HALCONIMAGES) are searched (see read_image). The returned polygons are in world coordinates. They can be transformed to the image coordinate system with the operator affine_trans_polygon_xld. The necessary transformation matrix can be generated by using read_world_file to read the transformation matrix from image to world coordinates, and inverting this matrix by calling hom_mat2d_invert.

Parameters

▷ **Polygons** (output_object) ..... xld_poly(-array) ⇝ *object*
Read XLD polygons.

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the ARC/INFO file.

Example

```
* Read the transformation and invert it
read_world_file ('image.tfw', WorldTransformation)
hom_mat2d_invert (WorldTransformation, ImageTransformation)
* Read the image
read_image (Image, 'image.tif')
* Read the line data
read_polygon_xld_arc_info (LinesWorld, 'lines.gen')
* Transform the line data to image coordinates
affine_trans_polygon_xld (LinesWorld, Lines, ImageTransformation)
```

Result

If the parameters are correct and the file could be read, the operator read_polygon_xld_arc_info returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

hom_mat2d_invert, affine_trans_polygon_xld

read_world_file, write_polygon_xld_arc_info, read_contour_xld_arc_info

Module

Foundation

read_polygon_xld_dxf (: Polygons : FileName, GenParamName, GenParamValue : DxfStatus)

Read XLD polygons from a DXF file.

read_polygon_xld_dxf reads the contents of the DXF file FileName (DXF version AC1009, AutoCAD Release 12) and converts them to the XLD polygons Polygons. If no absolute path is given in FileName the DXF file is searched in the current directory of the HALCON process.

The output parameter DxfStatus contains information about the number of polygons that were read and, if necessary, warnings that parts of the DXF file could not be interpreted.

The operator read_polygon_xld_dxf supports the following DXF entities:

- POLYLINE
  - 2D curves made up of line segments
  - Closed 2D curves made up of line segments
- LWPOLYLINE
- LINE
- POINT
- CIRCLE
- ARC
- ELLIPSE
- SPLINE
- BLOCK
- INSERT

The x and y coordinates of the DXF entities are stored in the column and row coordinates, respectively, of the XLD polygons Polygons. The z coordinates of the DXF entities are ignored.

DXF entities of the type CIRCLE, ARC, ELLIPSE, and SPLINE are approximated by XLD polygons. The accuracy of this approximation can be controlled with the two generic parameters *'min_num_points'* and *'max_approx_error'* (for SPLINE only *'max_approx_error'*). Generic parameters are set by specifying the parameter name(s) in GenParamName and the corresponding value(s) in GenParamValue. The parameter *'min_num_points'* defines the minimum number of sampling points that are used for the approximation. Note that the parameter *'min_num_points'* always refers to the full circle or ellipse, respectively, even for ARCs or elliptical arcs, i.e., if *'min_num_points'* is set to *50* and a DXF entity of the type ARC is read that represents a semi-circle, this semi-circle is approximated by at least 25 sampling points. The parameter *'max_approx_error'* defines the maximum deviation of the XLD polygon from the ideal circle or ellipse, respectively (unit: pixel). For the determination of the accuracy of the approximation both criteria are evaluated. Then, the criterion that leads to the more accurate approximation is used.

Internally, the following default values are used for the generic parameters:

- *'min_num_points'* = 20
- *'max_approx_error'* = 0.25

To achieve a more accurate approximation, either the value for *'min_num_points'* must be increased or the value for *'max_approx_error'* must be decreased.

Note that reading a DXF file with read_polygon_xld_dxf results in exactly the same geometric information as reading the file with read_contour_xld_dxf. However, the resulting data structure is different.

Parameters

▷ **Polygons** (output_object) ..... xld_poly(-array) ⇝ *object*
Read XLD polygons.

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the DXF file.
File extension: .dxf

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that can be adjusted for the DXF input.
Default: []
List of values: GenParamName ∈ {'min_num_points', 'max_approx_error'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string
Values of the generic parameters that can be adjusted for the DXF input.
Default: []
Suggested values: GenParamValue ∈ {0.1, 0.25, 0.5, 1, 2, 5, 10, 20}

▷ **DxfStatus** (output_control) . . . . . string(-array) ⇝ *string*
Status information.

Result

If the parameters are correct and the file could be read the operator read_polygon_xld_dxf returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

serialize_xld (XLD : : : SerializedItemHandle)

Serialize an XLD object.

serialize_xld serializes an XLD object (see fwrite_serialized_item for an introduction of the basic principle of serialization). The XLD object is defined by the parameter XLD. The serialized XLD object is returned by the handle SerializedItemHandle and can be deserialized by deserialize_xld.

Parameters

▷ **XLD** (input_object) . . . . . xld(-array) ⇝ *object*
XLD object.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_xld returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_contour_xld_arc_info (Contours : : FileName :)

Write XLD contours to a file in ARC/INFO generate format.

write_contour_xld_arc_info writes the XLD contours Contours to an ARC/INFO generate format file with name FileName. If no absolute path is given in FileName, the output file is created in the current directory of the HALCON process. The contours must have been transformed to the world coordinate system with affine_trans_contour_xld beforehand. The necessary transformation can be read from an ARC/INFO world file with read_world_file.

Parameters

- ▷ **Contours** (input_object) ..... xld_cont(-array) ⇝ *object*
  XLD contours to be written.
- ▷ **FileName** (input_control) ..... filename.write ⇝ *string*
  Name of the ARC/INFO file.

Example

```
* Read transformation and image
read_world_file ('image.tfw', WorldTransformation)
read_image (Image, 'image.tif')
* Segment image
* ...
* Write result
affine_trans_contour_xld (Contours, ContoursWorld, WorldTransformation)
write_contour_xld_arc_info (ContoursWorld, 'result.gen')
```

Result

If the parameters are correct and the file could be written, the operator write_contour_xld_arc_info returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_contour_xld_dxf (Contours : : FileName :)

Write XLD contours to a file in DXF format.

write_contour_xld_dxf writes the XLD contours Contours to the file FileName in DXF format. If no absolute path is given in FileName the output file is created in the current directory of the HALCON process.

Besides the geometry of the Contours, all attributes and global attributes that are defined for the Contours are written to the file.

write_contour_xld_dxf writes the file according to the DXF version AC1009 (AutoCAD Release 12). Each contour is stored as a POLYLINE. The attribute values are stored as extended data of each VERTEX of the POLYLINE. The global attribute values are stored as extended data of the POLYLINE. All attribute names are also stored as extended data of the POLYLINE.

The operator read_contour_xld_dxf can be used to read the XLD contours together with their attributes.

Other applications that are able to read DXF files only import the contour geometry, but they ignore the attribute information.

Description of the format of the extended data

Each block of extended data starts with the following DXF group:

1001 HALCON

The attributes are written in the following format as extended data of each VERTEX:

DXF	Explanation
1000	Meaning
contour attributes	
1002	Beginning of the value list
{	
1070	Number of attributes (here: 3)
3	
1040	Value of the first attribute
5.00434303	
1040	Value of the second attribute
126.8638916	
1040	Value of the third attribute
4.99164152	
1002	End of the value list
}	

The global attributes are written in the following format as extended data of each POLYLINE:

DXF	Explanation
1000	Meaning
global contour attributes	
1002	Beginning of the value list
{	
1070	Number of global attributes (here: 5)
5	
1040	Value of the first global attribute
0.77951831	
1040	Value of the second global attribute
0.62637949	
1040	Value of the third global attribute
103.94314575	
1040	Value of the fourth global attribute
0.21434096	
1040	Value of the fifth global attribute
0.21921949	
1002	End of the value list
}	

The names of the attributes are written in the following format as extended data of each POLYLINE:

DXF	Explanation
1000	Meaning
names of contour attributes	
1002	Beginning of the value list
{	
1070	Number of attribute names (here: 3)
3	
1000	Name of the first attribute
angle	
1000	Name of the second attribute
response	
1000	Name of the third attribute
edge_direction	
1002	End of the value list
}	

The names of the global attributes are written in the following format as extended data of each POLYLINE:

DXF	Explanation
1000	Meaning
names of global contour attributes	
1002	Beginning of the value list
{	
1070	Number of global attribute names (here: 5)
5	
1000	Name of the first global attribute
regr_norm_row	
1000	Name of the second global attribute
regr_norm_col	
1000	Name of the third global attribute
regr_dist	
1000	Name of the fourth global attribute
regr_mean_dist	
1000	Name of the fifth global attribute
regr_dev_dist	
1002	End of the value list
}	

Parameters

▷ **Contours** (input_object) . . . . . xld_cont(-array) ⇝ *object*
XLD contours to be written.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of the DXF file.
File extension: `.dxf`

Result

If the parameters are correct and the file could be written the operator `write_contour_xld_dxf` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

write_polygon_xld_arc_info (Polygons : : FileName :)

Write XLD polygons to a file in ARC/INFO generate format.

write_polygon_xld_arc_info writes the XLD polygons Polygons to an ARC/INFO generate format file with name FileName. If no absolute path is given in FileName, the output file is created in the current directory of the HALCON process. The polygons must have been transformed to the world coordinate system with affine_trans_polygon_xld beforehand. The necessary transformation can be read from an ARC/INFO world file with read_world_file.

Attention

The XLD contours that are possibly referenced by Polygons are not stored in the ARC/INFO file, since this is not possible with the ARC/INFO generate file format. Therefore, when the polygons are read again using read_polygon_xld_arc_info, this information is lost, and no references to contours are generated for the polygons. Hence, operators that access the contours associated with a polygon, e.g., split_contours_xld will not work correctly.

Parameters

▷ **Polygons** (input_object) ..... xld_poly(-array) ⇝ *object*
XLD polygons to be written.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Name of the ARC/INFO file.

Example

```
* Read transformation and image
read_world_file ('image.tfw', WorldTransformation)
read_image (Image, 'image.tif')
* Segment image
* ...
* Write result
affine_trans_polygon_xld (Polygons, PolygonsWorld, WorldTransformation)
write_polygon_xld_arc_info (PolygonsWorld, 'result.gen')
```

Result

If the parameters are correct and the file could be written, the operator write_polygon_xld_arc_info returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_polygon_xld_dxf (Polygons : : FileName :)

Write XLD polygons to a file in DXF format.

write_polygon_xld_dxf writes the XLD polygons Polygons to the file FileName in DXF format. If no absolute path is given in FileName the output file is created in the current directory of the HALCON process.

write_polygon_xld_dxf writes the file according to the DXF version AC1009 (AutoCAD Release 12). Each polygon is stored as a POLYLINE.

The operator read_polygon_xld_dxf can be used to read the XLD polygon.

Attention

The XLD contours that are possibly referenced by Polygons are not stored in the DXF file. Therefore, when the polygons are read again using read_polygon_xld_dxf, this information is lost, and no references to contours are generated for the polygons. Hence, operators that access the contours associated with a polygon, e.g., split_contours_xld will not work correctly.

Parameters

▷ **Polygons** (input_object) ..... xld_poly(-array) ⇝ *object*
XLD polygons to be written.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Name of the DXF file.
File extension: .dxf

Result

If the parameters are correct and the file could be written the operator write_polygon_xld_dxf returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

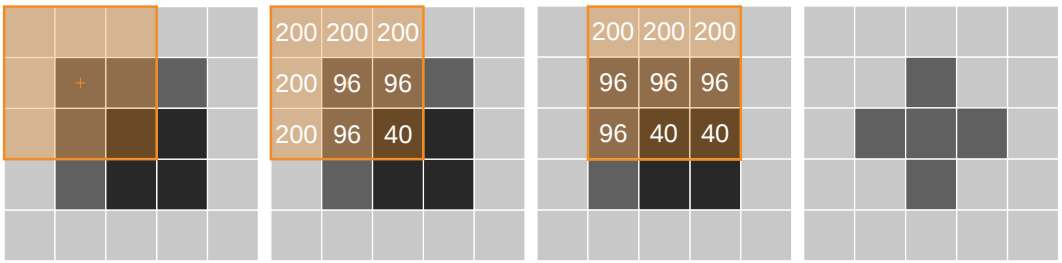
Chapter 12

Filters

Filters are an important part of nearly every machine vision application. They can, for instance, be used to smooth images (e.g., `mean_image`), extract sub-pixel precise edges (e.g., `edges_sub_pix`) or process the frequency domain of images (e.g., `fft_image`).

Usually, filter operations are applied using filter masks, which are moved across the input image pixelwise. For each pixel a new value is calculated based on its neighborhood. The neighborhood is determined by shape and size of the filter mask (see the scheme below).



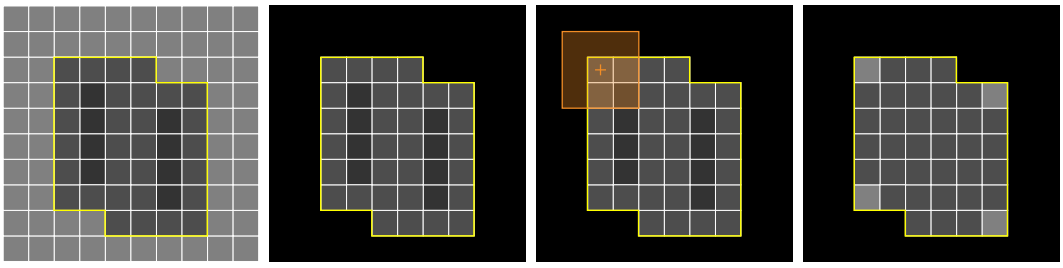
(1) (2) (3) (4)

(1) Image with a filter mask of size 3x3 pixels (orange). (2) For the computation of the new pixel value of the pixel located at the center point of the mask all the pixel values within the mask are taken into account. (3) The mask is moved across the image pixel by pixel. (4) In this case a median filter (see `median_rect`) is used for the computation of the resulting image.

You can tell from the working principle of filter masks, the treatment of pixels along the image or domain border requires special attention, as part of the filter mask exceeds the domain. In the following sections some consequential issues will be discussed.

Applying Filter Masks on Reduced Image Domains

If a filter that is using a mask is applied on an image with a reduced domain, the result along the domain boundary might be surprising because gray values lying outside the boundary are used as input for the filter process (see scheme below).



(1) (2) (3) (4)

(1) Image with a region (yellow) to which the image domain shall be reduced to. (2) The image domain is reduced to the chosen region using reduce_domain. (3) For the computation of a new value for the pixel in the center of the mask all the pixel values within the mask are taken into account. For pixels along the domain border this also includes pixels from outside the domain. (4) Result image after the application of a median filter (see median_rect).

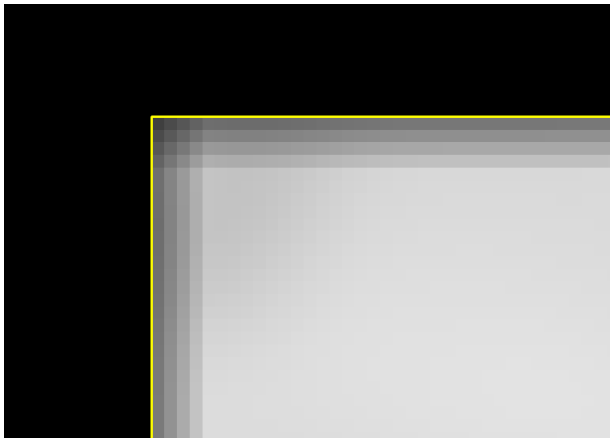
To understand this, the definition of domains in this context must be considered: For a filter, a domain defines for which input pixels output pixels must be calculated. But pixels outside the domain (which lie within the image matrix) might be used for processing nevertheless.

Problems Caused by Gray Values Outside of the Input Image Domain

Another point to notice is the handling of pixels outside the input image domain. The parameter *'init_new_image'* of set_system determines how those pixels are treated. If the pixels are initialized with 0, consecutive runs will yield identical results. Otherwise, those pixels remain undefined. While this enhances the program runtime, undefined pixels can differ from system to system, for example if parallelization is activated or not. It is merely guaranteed that the values are consistent if the program is executed repeatedly on systems with the same configuration. In certain cases, these 'undefined' pixels might lead to problems. Expanding the resulting image to the full domain with full_domain will lead to artifacts appearing outside of the former image domain.

Problems Caused when Applying Filters Consecutively

When two or more filters are applied consecutively on the same domain, the undefined or unexpected values (as described in the paragraphs above) have a higher impact on the result image. This is because with every following filter the error increases, starting from the border to the middle. In the following, four strategies for solving those problems are presented.



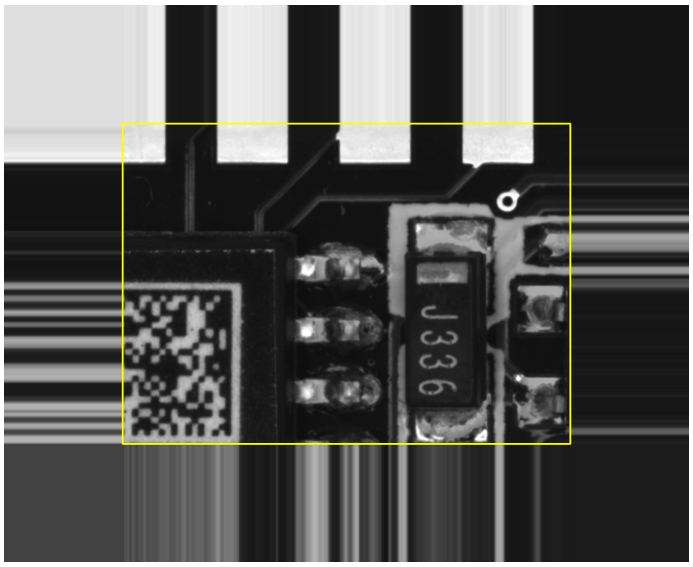
Artifacts at the domain border after applying two consecutive filters.

1. Errors caused by undefined pixels can easily be prevented by, e.g., choosing a dilated domain (see Morphology / Region) according to the filter mask. If multiple filters are applied consecutively, the image domain can be dilated in advance, considering the filter sizes to be used. For instance, when using a cascade of rectangular filters of arbitrary dimensions, the width and length dimension dim_d of the dilation mask can be calculated considering the individual filter mask dimensions dim_i and the number of filter operations n:

   $dim_d = (\sum_{i=1}^{n} dim_i) - (n-1)$.

   After the filters were applied, the image domain can be reduced to its original size (e.g., with reduce_domain).

2. Another option is to set the domain exactly to the size of the interesting part within the image and then calling the operator expand_domain_gray before applying a filter. This operator copies the pixels inside of the border to the outside of the border and therefore avoids errors caused by pixels that are undefined outside of the domain. Subsequently, the domain can again be reduced to its original size. This process should be repeated for every following filter operation. Note, however, that this option increases the runtime significantly.



The result of expand_domain_gray looks as if the boundary is copied multiple times and added at the outside.

3. If runtime is not an issue, the operator full_domain can be called before applying the first filter to the image. That way, the whole image is defined as domain and undefined pixels are avoided completely.

4. Another possibility of getting an image without undefined pixels is by calling the operator crop_domain before applying a filter. The operator crop_domain crops the image to the size of the domain, which means that the domain then covers a complete smaller image. Note, however, that for the cropped image the coordinate system has changed in relation to the original image, which will influence all following applications depending on the image coordinate system (e.g., calculating the center of gravity).

12.1 Arithmetic

abs_diff_image (Image1, Image2 : ImageAbsDiff : Mult :)

Calculate the absolute difference of two images.

abs_diff_image calculates the absolute difference between two images. The gray values g' of the output image ImageAbsDiff are calculated from the gray values $(g1, g2)$ of the input images (Image1 and Image2) as follows:

$$g' = |(g1 - g2)| * \texttt{Mult}$$

If an overflow or an underflow occurs the resulting values are clipped.

Several images can be processed in one call. In this case, both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

Please note that the runtime of the operator depends on the value of Mult. For Mult = 1, a special optimization is used. Since values of Mult different from 1 cannot yield additional information, Mult = 1 should be used in applications. All other values of Mult should only be used for visualization purposes. Additionally, for byte, int1, int2, and uint2 images special optimizations are implemented for Mult = 1 that use SIMD technology. The actual application of these special optimizations is controlled by the system parameter *'mmx_enable'* (see set_system). If *'mmx_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations are performed using SIMD technology.

abs_diff_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, and real images. However, since for OpenCL 1.0 only single precision floating point is supported for all devices, and not all rounding modes are supported, the OpenCL implementation can produce slightly different results from the scalar or SIMD implementations.

Attention

Note that the acceleration gained by SIMD technology is highest on large, compact input regions. However, in rare cases, the execution of `abs_diff_image` might take significantly longer with SIMD technology than without, depending on the input region and the capabilities of the hardware. In these cases, the use of SIMD technology can be avoided by `set_system(::'mmx_enable','false':)`.

Parameters

▷ **`Image1`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real

Input image 1.

▷ **`Image2`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real

Input image 2.

▷ **`ImageAbsDiff`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real

Absolute value of the difference of the input images.

▷ **`Mult`** (input_control) ..... number ⇝ *real* / integer

Scale factor.
Default: 1.0
Suggested values: `Mult` ∈ {1.0, 2.0, 3.0, 4.0}
Restriction: Mult > 0

Result

The operator `abs_diff_image` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)`. If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

`threshold`

Alternatives

`sub_image`

See also

`add_image`, `scale_image`, `dyn_threshold`

Module

Foundation

`abs_image` (Image : ImageAbs : :)

Calculate the absolute value (modulus) of an image.

The operator `abs_image` calculates the absolute gray values of images of any type and stores the result in `ImageAbs`. The power spectrum of complex images is calculated as a `real` image. For a `Image` of type 'int1', `ImageAbs` is of type `byte`. For `Image` of other signed types the type of the input image is used for `ImageAbs`. The behavior in case of overflows or underflows is undefined. The operator `abs_image` generates a logical copy of unsigned images.

`abs_image` can be executed on an OpenCL device for `int1`, `int2`, `int4`, `real`, and `complex` images. However, since for OpenCL 1.0 only single precision floating point is supported for all devices, and not all rounding

modes are supported, the OpenCL implementation can produce slightly different results from the scalar or SIMD implementations.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* int1 / int2 / int4 / int8 / real / complex
  Image(s) for which the absolute gray values are to be calculated.
- ▷ **ImageAbs** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / int4 / int8 / real
  Result image(s).

Example

```
convert_image_type (Image, ImageInt2, 'int2')
texture_laws (ImageInt2, ImageTexture, 'el', 2, 5)
abs_image (ImageTexture, ImageTexture)
```

Result

The operator `abs_image` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)`

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

See also

`convert_image_type`, `power_byte`

Module

Foundation

acos_image (Image : ArccosImage : :)

Calculate the arccosine of an image.

`acos_image` calculates the arccosine of an input image `Image` and stores the result in the image `ArccosImage`. The angles in `ArccosImage` are represented in radians. If `Image` contains gray values outside the valid domain $[-1, 1]$ of the arccosine function, the corresponding gray values in `ArccosImage` are set to 0.

Attention

`acos_image` can be executed on OpenCL devices.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
  Input image.
- ▷ **ArccosImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
  Output image.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

asin_image, atan_image, atan2_image, tan_image, sin_image, cos_image

Module

Foundation

add_image (Image1, Image2 : ImageResult : Mult, Add :)

Add two images.

The operator add_image adds two images. The gray values $(g1, g2)$ of the input images (Image1 and Image2) are transformed as follows:

$$g' := (g1 + g2) * \texttt{Mult} + \texttt{Add}$$

If an overflow or an underflow occurs the values are clipped. Note that this is not the case with cyclic and direction images. The resulting image is stored in ImageResult.

It is possible to add byte images with int2, uint2 or int4 images and to add int4 to int2 or uint2 images. In this case the result will be of type int2 or int4 respectively.

Several images can be processed in one call. In this case both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

Please note that the runtime of the operator varies with different control parameters. For frequently used combinations special optimizations are used. Additionally, for byte, int2, uint2, and int4 images special optimizations are implemented that use SIMD technology. The actual application of these special optimizations is controlled by the system parameter *'mmx_enable'* (see set_system). If *'mmx_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations are performed using SIMD technology.

add_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, real, direction, cyclic, and complex images. However, since for OpenCL 1.0 only single precision floating point is supported for all devices, and not all rounding modes are supported, the OpenCL implementation can produce slightly different results from the scalar or SIMD implementations.

Attention

Note that the acceleration gained by SIMD technology is highest on large, compact input regions. However, in rare cases, the execution of add_image might take significantly longer with SIMD technology than without, depending on the input region and the capabilities of the hardware. In these cases, the use of SIMD technology can be avoided by set_system(::'mmx_enable','false':).

Parameters

▷ **Image1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Image(s) 1.

▷ **Image2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Image(s) 2.

▷ **ImageResult** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Result image(s) by the addition.

▷ **Mult** (input_control) ..... number ⇝ *real* / integer

Factor for gray value adaption.
Default: 0.5
Suggested values: Mult ∈ {0.2, 0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 5.0}
Value range: -255.0 ≤ Mult ≤ 255.0
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Add** (input_control) . . . . . number ⇝ *real* / integer
Value for gray value range adaption.
Default: 0
Suggested values: Add ∈ {0, 64, 128, 255, 512}
Value range: -512.0 ≤ Add ≤ 512.0
Minimum increment: 0.01
Recommended increment: 1.0

Example

```
read_image(Image1,'fabrik')
dev_display (Image1)
read_image(Image2,'monkey')
dev_display (Image2)
add_image(Image1,Image2,Result,0.5,10.0)
dev_display (Result)
```

Result

The operator add_image returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:) If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

sub_image, mult_image

See also

sub_image, mult_image

Module

Foundation

asin_image (Image : ArcsinImage : :)

Calculate the arcsine of an image.

asin_image calculates the arcsine of an input image Image and stores the result in the image ArcsinImage. The angles in ArcsinImage are represented in radians. If Image contains gray values outside the valid domain $[-1, 1]$ of the arcsine function, the corresponding gray values in ArcsinImage are set to 0.

Attention

asin_image can be executed on OpenCL devices.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Input image.

▷ **ArcsinImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Output image.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

acos_image, atan_image, atan2_image, tan_image, sin_image, cos_image

Module

Foundation

atan2_image (ImageY, ImageX : ArctanImage : :)

Calculate the arctangent of two images.

atan2_image calculates the arctangent ImageY/ImageX of the input images ImageY and ImageX, using the signs of the gray values of the two images to determine the quadrant of the result, and stores the result in the image ArctanImage. The angles in ArctanImage are represented in radians.

Attention

atan2_image can be executed on an OpenCL device for int1, int2, int4, and real images. Note that the results of the OpenCL code may vary from the results produced by the CPU.

Parameters

▷ **ImageY** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* int1 / int2 / int4 / int8 / real
Input image 1.

▷ **ImageX** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* int1 / int2 / int4 / int8 / real
Input image 2.

▷ **ArctanImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Output image.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

atan_image

See also

acos_image, asin_image, tan_image, sin_image, cos_image

Module

Foundation

atan_image (Image : ArctanImage : :)

Calculate the arctangent of an image.

atan_image calculates the arctangent of an input image Image and stores the result in the image ArctanImage. The angles in ArctanImage are represented in radians.

Attention

`atan_image` can be executed on OpenCL devices.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Input image.

▷ **ArctanImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Output image.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

`atan2_image`

See also

Module

Foundation

cos_image (Image : CosImage : :)

Calculate the cosine of an image.

`cos_image` calculates the cosine of an input image `Image` and stores the result in the image `CosImage` of type real. If `Image` is of type direction or cyclic, the angles in `Image` are converted to radians internally. If `Image` is of type real, the angles in `Image` are assumed to be represented in radians. For direction images, the value of 255 will result in a value of 0 in the output image.

Attention

`cos_image` can be executed on OpenCL devices.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* direction / cyclic / real
Input image.

▷ **CosImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Output image.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

div_image (Image1, Image2 : ImageResult : Mult, Add :)

Divide two images.

The operator div_image divides two images. The gray values $(g1, g2)$ of the input images (Image1) are transformed as follows:

$$g' := g1/g2 * \texttt{Mult} + \texttt{Add}$$

If an overflow or an underflow occurs the values are clipped. For a division by zero the result is set to zero.

Several images can be processed in one call. In this case both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

div_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, real and complex images. However, since for OpenCL 1.0 only single precision floating point is supported for all devices, and not all rounding modes are supported, the OpenCL implementation can produce slightly different results from the scalar implementation.

Parameters

▷ **Image1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / complex

Image(s) 1.

▷ **Image2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / complex

Image(s) 2.

▷ **ImageResult** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / complex

Result image(s) by the division.

▷ **Mult** (input_control) ..... number ⇝ *real* / integer

Factor for gray range adaption.
Default: 255
Suggested values: Mult ∈ {0.1, 0.2, 0.5, 1.0, 2.0, 3.0, 10, 100, 500, 1000}
Value range: -1000 ≤ Mult ≤ 1000
Minimum increment: 0.001
Recommended increment: 1

▷ **Add** (input_control) ..... number ⇝ *real* / integer

Value for gray range adaption.
Default: 0
Suggested values: Add ∈ {0.0, 128.0, 256.0, 1025}
Value range: -1000 ≤ Add ≤ 1000
Minimum increment: 0.01
Recommended increment: 1.0

Example

```
read_image(Image1,'fabrik')
dev_display (Image1)
read_image(Image2,'monkey')
dev_display (Image2)
div_image (Image1, Image2, Result, 200, 10)
dev_display (Result)
```

Result

The operator div_image returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:) If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

add_image, sub_image, mult_image

See also

add_image, sub_image, mult_image

Module

Foundation

exp_image (Image : ExpImage : Base :)

Calculate the exponentiation of an image.

exp_image calculates the exponentiation to the base Base of an input image Image and stores the result in the image ExpImage. If Image contains gray values that would overflow the range of ExpImage, e.g., > 88.722839 for Base $= 'e'$, the corresponding gray values in ExpImage are set to the largest value representable in ExpImage (i.e., 3.4028235×10^{38}).

Attention

exp_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, and real images. Note that the results of the OpenCL code may vary from the results produced by the CPU.

Parameters

▷ **Image** (input_object) . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / uint2 / int2 / int4 / int8 / real
Input image.

▷ **ExpImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Output image.

▷ **Base** (input_control) . . . . . number ⇝ *string* / integer / real
Base of the exponentiation.
Default: 'e'
Suggested values: Base ∈ {'e', 2, 10}

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

See also

pow_image, log_image

Module

Foundation

gamma_image (Image : GammaImage : Gamma, Offset, Threshold, MaxGray, Encode :)

Perform a gamma encoding or decoding of an image.

gamma_image performs a general gamma encoding or decoding of the input image Image and returns the resulting image in GammaImage. A generalized gamma encoding can be described as follows:

$$G' = \begin{cases} m\left((1+o)(G/m)^{\gamma} - o\right), & t < G/m \leq 1 \\ sG, & 0 \leq G/m \leq t \end{cases}$$

Here, G' is the gamma-encoded gray value, G is the linear gray value, $\gamma =$ Gamma, $o =$ Offset, $m =$ MaxGray, $t =$ Threshold, and s is a factor that is computed from Gamma, Offset, Threshold, and MaxGray in such a way that the linear and exponential parts of the transformation are continuous.

Analogously, a generalized gamma decoding can be described as follows:

$$G = \begin{cases} m\left(\frac{G'/m+o}{1+o}\right)^{1/\gamma}, & t' < G'/m \leq 1 \\ G'/s, & 0 \leq G'/m \leq t' \end{cases}$$

where the variables have identical meanings as for the gamma encoding and $t' = st$.

For example, the gamma encoding or decoding required by the sRGB standard can be obtained by setting Gamma $= 1.0/2.4$, Offset $= 0.055$, and Threshold $= 0.0031308$. Similarly, the gamma encoding or decoding required by the HDTV video standard can be obtained by setting Gamma $= 0.45$, Offset $= 0.099$, and Threshold $= 0.018$. In any case, MaxGray should be set as appropriate for the image type of Image (e.g., 255.0 for byte images).

Attention

gamma_image can be executed on an OpenCL device for byte, uint2 and real images. As the operation is performed in single precision floating point instead of double precision as on the CPU, the result of the OpenCL implementation can vary slightly from that of the CPU implementation.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **GammaImage** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Output image.

▷ **Gamma** (input_control) ..... real ⇝ *real*
Gamma coefficient of the exponential part of the transformation.
Default: 0.416666666667
Suggested values: Gamma ∈ {0.416666666667, 0.45}

▷ **Offset** (input_control) ..... real ⇝ *real*
Offset of the exponential part of the transformation.
Default: 0.055
Suggested values: Offset ∈ {0.055, 0.099}

▷ **Threshold** (input_control) ..... real ⇝ *real*
Gray value for which the transformation switches from linear to exponential.
Default: 0.0031308
Suggested values: Threshold ∈ {0.0031308, 0.018}

▷ **MaxGray** (input_control) ..... number ⇝ *real* / integer
Maximum gray value of the input image type.
Default: 255.0
Suggested values: MaxGray ∈ {1.0, 255.0, 511.0, 1023.0, 4095.0, 16383.0, 65535.0}

▷ **Encode** (input_control) ..... string ⇝ *string*
If *'true'*, perform a gamma encoding, otherwise a gamma decoding.
Default: 'true'
List of values: Encode ∈ {'true', 'false'}

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

invert_image (Image : ImageInvert : :)

Invert an image.

The operator invert_image inverts the gray values of an image. For images of the byte and cyclic type the result is calculated as:

$$g' = 255 - g$$

Images of the 'direction' type are transformed by

$$g' = (g + 90) \text{ modulo } 180$$

In the case of signed types the values are negated. The resulting image has the same pixel type as the input image.

Several images can be processed in one call. An output image is generated for every input image.

invert_image can be executed on an OpenCL device for byte, direction, cyclic, int1, int2, uint2, int4, and real images.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

Input image(s).

▷ **ImageInvert** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

Image(s) with inverted gray values.

Example

```
read_image(Orig,'fabrik')
invert_image(Orig,Invert)
dev_display(Invert)
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

scale_image, add_image, sub_image

Module

Foundation

log_image (Image : LogImage : Base :)

Calculate the logarithm of an image.

log_image calculates the logarithm to the base Base of an input image Image and stores the result in the image LogImage. If Image contains gray values outside the valid domain of the logarithm function, i.e., ≤ 0, the corresponding gray values in LogImage are set to 0.

Attention

log_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, and real images. Note that the results of the OpenCL code may vary from the results produced by the CPU.

Parameters

▷ **Image** (input_object) . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / uint2 / int2 / int4 / int8 / real
Input image.

▷ **LogImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Output image.

▷ **Base** (input_control) . . . . . number ⇝ *string* / integer / real
Base of the logarithm.
Default: 'e'
Suggested values: Base ∈ {'e', 2, 10}

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

pow_image, exp_image

Module

Foundation

max_image (Image1, Image2 : ImageMax : :)

Calculate the maximum of two images pixel by pixel.

max_image calculates the maximum of the images Image1 and Image2 (pixel by pixel). The result is stored in the image ImageMax. The resulting image has the same pixel type as the input image. If several (pairs of) images

are processed in one call, every i-th image from Image1 is compared to the i-th image from Image2. Thus the number of images in both input parameters must be the same. An output image is generated for every input pair.

max_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, real, direction, and cyclic images.

Attention

The two input images must be of the same type and size.

Parameters

▷ **Image1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic

Image(s) 1.

▷ **Image2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic

Image(s) 2.

▷ **ImageMax** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic

Result image(s) by the maximization.

Example

```
read_image(Image1,'monkey')
read_image(Image2,'fabrik')
max_image(Image1,Image2,Max)
dev_display (Max)
```

Result

If the parameter values are correct the operator max_image returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:). If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

See also

min_image

Module

Foundation

min_image (Image1, Image2 : ImageMin : :)

Calculate the minimum of two images pixel by pixel.

The operator min_image determines the minimum (pixel by pixel) of the images Image1 and Image2. The result is stored in the image ImageMin. The resulting image has the same pixel type as the input image. If several (pairs of) images are processed in one call, every i-th image from Image1 is compared to the i-th image from Image2. Thus the number of images in both input parameters must be the same. An output image is generated for every input pair.

min_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, real, direction, and cyclic images.

Parameters

▷ **Image1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic

Image(s) 1.

▷ **Image2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic

Image(s) 2.

▷ **ImageMin** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic

Result image(s) by the minimization.

Result

If the parameter values are correct the operator `min_image` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)` If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

`gray_erosion`

mult_image (Image1, Image2 : ImageResult : Mult, Add :)

Multiply two images.

`mult_image` multiplies two images. The gray values $(g1, g2)$ of the input images (`Image1`) are transformed as follows:

$$g' := g1 * g2 * \texttt{Mult} + \texttt{Add}$$

If an overflow or an underflow occurs the values are clipped. Note that this is not the case with cyclic and direction images.

Several images can be processed in one call. In this case both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

`mult_image` can be executed on an OpenCL device for byte, int1, int2, uint2, int4, real, direction, cyclic, and complex images. However, since for OpenCL 1.0 only single precision floating point is supported for all devices, and not all rounding modes are supported, the OpenCL implementation can produce slightly different results from the scalar implementation.

Parameters

▷ **Image1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Image(s) 1.

▷ **Image2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Image(s) 2.

▷ **ImageResult** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Result image(s) by the product.

▷ **Mult** (input_control) ..... number ⇝ *real* / integer

Factor for gray range adaption.
Default: 0.005
Suggested values: `Mult` ∈ {0.001, 0.01, 0.5, 1.0, 2.0, 3.0, 5.0, 10.0}
Value range: -255.0 ≤ `Mult` ≤ 255.0
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Add** (input_control) ..... number ⇝ *real* / integer

Value for gray range adaption.
Default: 0
Suggested values: `Add` ∈ {0.0, 128.0, 256.0}
Value range: -512.0 ≤ `Add` ≤ 512.0
Minimum increment: 0.01
Recommended increment: 1.0

Example

```
read_image(Image1,'fabrik')
dev_display (Image1)
read_image(Image2,'monkey')
dev_display (Image2)
mult_image (Image1, Image2, Result, 0.01, 10)
dev_display (Result)
```

Result

The operator `mult_image` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)` If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

Module

Foundation

pow_image (Image : PowImage : Exponent :)

Raise an image to a power.

pow_image raises the gray values of the input image Image to the power Exponent and stores the result in the image PowImage. If Image contains gray values that would overflow the range of PowImage, e.g., > 7131.55017 for Exponent $= 10$, the corresponding gray values in PowImage are set to the largest value representable in PowImage (i.e., 3.4028235×10^{38}). If Image contains gray values that cannot be raised to the power Exponent, i.e., if the gray values are negative and Exponent is not an integer, the corresponding gray values in PowImage are set to 0.

Attention

pow_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, and real images. Note that the results of the OpenCL code may vary from the results produced by the CPU.

Parameters

- ▷ **Image** (input_object) .... (multichannel-)image(-array) ⇝ *object :* byte / int1 / uint2 / int2 / int4 / int8 / real
  Input image.
- ▷ **PowImage** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* real
  Output image.
- ▷ **Exponent** (input_control) ..... number ⇝ *real* / integer
  Power to which the gray values are raised.
  Default: 2
  Suggested values: Exponent ∈ {0.25, 0.5, 2, 3, 4}

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

gamma_image

See also

sqrt_image, exp_image, log_image

Module

Foundation

scale_image (Image : ImageScaled : Mult, Add :)

Scale the gray values of an image.

The operator scale_image scales the input images (Image) by the following transformation:

$$g' := g * \texttt{Mult} + \texttt{Add}$$

If an overflow or an underflow occurs the values are clipped. Note that this is not the case with cyclic and direction images.

This operator can be applied, e.g., to map the gray values of an image, i.e., the interval [GMin,GMax], to the maximum range [0:255]. For this, the parameters are chosen as follows:

$$\texttt{Mult} = \frac{255}{\text{GMax} - \text{GMin}} \qquad \texttt{Add} = -\texttt{Mult} * \text{GMin}$$

The values for GMin and GMax can be determined, e.g., with the operator `min_max_gray`.

Please note that the runtime of the operator varies with different control parameters. For frequently used combinations special optimizations are used. Additionally, special optimizations are implemented that use fixed point arithmetic (for int2 and uint2 images), and further optimizations that use SIMD technology (for byte, int2, and uint2 images). The actual application of these special optimizations is controlled by the system parameters *'int_zooming'* and *'mmx_enable'* (see `set_system`). If *'int_zooming'* is set to *'true'*, the internal calculation is performed using fixed point arithmetic, leading to much shorter execution times. However, the accuracy of the transformed gray values is slightly lower in this mode. The difference to the more accurate calculation (using *'int_zooming'* = *'false'*) is typically less than two gray levels. If *'mmx_enable'* is set to *'true'*(and the SIMD instruction set is available), the internal calculations are performed using fixed point arithmetic and SIMD technology. In this case the setting of *'int_zooming'* is ignored.

`scale_image` can be executed on an OpenCL device for byte, int1, int2, uint2, int4, real, direction, cyclic, and complex images. However, since for OpenCL 1.0 only single precision floating point is supported for all devices, and not all rounding modes are supported, the OpenCL implementation can produce slightly different results from the scalar or SIMD implementations.

Attention

Note that the acceleration gained by SIMD technology is highest on large, compact input regions. However, in rare cases, the execution of `scale_image` might take significantly longer with SIMD technology than without, depending on the input region and the capabilities of the hardware. In these cases, the use of SIMD technology can be avoided by `set_system(::'mmx_enable','false':)`.

Parameters

▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Image(s) whose gray values are to be scaled.

▷ **`ImageScaled`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Result image(s) by the scale.

▷ **`Mult`** (input_control) ..... number ⇝ *real* / integer

Scale factor.
Default: 0.01
Suggested values: `Mult` ∈ {0.001, 0.003, 0.005, 0.008, 0.01, 0.02, 0.03, 0.05, 0.08, 0.1, 0.5, 1.0}
Minimum increment: 0.001
Recommended increment: 0.1

▷ **`Add`** (input_control) ..... number ⇝ *real* / integer

Offset.
Default: 0
Suggested values: `Add` ∈ {0, 10, 50, 100, 200, 500}
Minimum increment: 0.01
Recommended increment: 1.0

Example

```
* Complement of the gray values:
scale_image(Image,Invert,-1.0,255.0)
```

Result

The operator `scale_image` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)` Otherwise an exception treatment is carried out.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

min_max_gray

Module

Foundation

sin_image (Image : SinImage : :)

Calculate the sine of an image.

sin_image calculates the sine of an input image Image and stores the result in the image SinImage of type real. If Image is of type direction or cyclic, the angles in Image are converted to radians internally. If Image is of type real, the angles in Image are assumed to be represented in radians. For direction images, the value of 255 will result in a value of 0 in the output image.

Attention

sin_image can be executed on OpenCL devices.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* direction / cyclic / real
Input image.

▷ **SinImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
Output image.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

sqrt_image (Image : SqrtImage : :)

Calculate the square root of an image.

sqrt_image calculates the square root of an input image Image and stores the result in the image SqrtImage of the same pixel type. In case the picture Image is of a signed pixel type, negative pixel values will be mapped to zero in SqrtImage.

sqrt_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, and real images.

Parameters

▷ **Image** (input_object) . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real
Input image

▷ **SqrtImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real
Output image

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

pow_image

Module

Foundation

sub_image (ImageMinuend, ImageSubtrahend : ImageSub : Mult, Add :)

Subtract two images.

The operator sub_image subtracts two images. The gray values $(g1, g2)$ of the input images (ImageMinuend and ImageSubtrahend) are transformed as follows:

$$g' := (g1 - g2) * \texttt{Mult} + \texttt{Add}$$

If an overflow or an underflow occurs the values are clipped. Note that this is not the case with cyclic and direction images.

Several images can be processed in one call. In this case both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

Please note that the runtime of the operator varies with different control parameters. For frequently used combinations special optimizations are used. Additionally, for byte, int2, and uint2 images special optimizations are implemented that use SIMD technology. The actual application of these special optimizations is controlled by the system parameter *'mmx_enable'* (see set_system). If *'mmx_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations are performed using SIMD technology.

sub_image can be executed on an OpenCL device for byte, int1, int2, uint2, int4, real, direction, cyclic, and complex images. However, since for OpenCL 1.0 only single precision floating point is supported for all devices, and not all rounding modes are supported, the OpenCL implementation can produce slightly different results from the scalar or SIMD implementations.

Attention

Note that the acceleration gained by SIMD technology is highest on large, compact input regions. However, in rare cases, the execution of sub_image might take significantly longer with SIMD technology than without, depending on the input region and the capabilities of the hardware. In these cases, the use of SIMD technology can be avoided by set_system(::'mmx_enable','false':).

Parameters

▷ **ImageMinuend** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Minuend(s).

▷ **ImageSubtrahend** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Subtrahend(s).

▷ **ImageSub** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / int8 / real / direction / cyclic / complex

Result image(s) by the subtraction.

▷ **Mult** (input_control) . . . . . number ⇝ *real* / integer

Correction factor.
Default: 1.0
Suggested values: Mult ∈ {0.0, 1.0, 2.0, 3.0, 4.0}
Value range: -255.0 ≤ Mult ≤ 255.0
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Add** (input_control) . . . . . number ⇝ *real* / integer

Correction value.
Default: 128.0
Suggested values: Add ∈ {0.0, 128.0, 256.0}
Value range: -512.0 ≤ Add ≤ 512.0
Minimum increment: 0.01
Recommended increment: 1.0

Example

```
read_image(Image1,'fabrik')
dev_display (Image1)
read_image(Image2,'monkey')
dev_display (Image2)
sub_image (Image1, Image2, Result, 1, 100)
dev_display (Result)
```

Result

The operator sub_image returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:) If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

dual_threshold

Alternatives

mult_image, add_image

add_image, mult_image, dyn_threshold, check_difference

Module

Foundation

tan_image (Image : TanImage : :)

Calculate the tangent of an image.

tan_image calculates the tangent of an input image Image and stores the result in the image TanImage of type real. If Image is of type direction or cyclic, the angles in Image are converted to radians internally. If Image is of type real, the angles in Image are assumed to be represented in radians. For direction images, the value of 255 will result in a value of 0 in the output image.

Attention

tan_image can be executed on OpenCL devices.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* direction / cyclic / real
  Input image.
- ▷ **TanImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* real
  Output image.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

12.2 Bit

bit_and (Image1, Image2 : ImageAnd : :)

Bit-by-bit AND of all pixels of the input images.

The operator bit_and calculates the "and" of all pixels of the input images bit by bit. The semantics of the "and" operation corresponds to that of C for the respective types (signed char, unsigned char, short, unsigned short, int/long). The images must have the same size and pixel type. The pixels within the definition range of the image in the first parameter are processed.

Several images can be processed in one call. In this case both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

Parameters

- ▷ **Image1** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4
  Input image(s) 1.
- ▷ **Image2** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4
  Input image(s) 2.
- ▷ **ImageAnd** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4
  Result image(s) by AND-operation.

Example

```
read_image(Image1,'fabrik')
dev_display (Image1)
read_image(Image2,'monkey')
dev_display (Image2)
bit_and(Image1,Image2,ImageBitAnd)
dev_display (ImageBitAnd)
```

Result

If the images are correct (type and number) the operator `bit_and` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)` If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

`bit_mask`, `add_image`, `max_image`

See also

`bit_mask`, `add_image`, `max_image`

Module

Foundation

`bit_lshift` (Image : ImageLShift : Shift :)

Left shift of all pixels of the image.

The operator `bit_lshift` calculates a "left shift" of all pixels of the input image bit by bit. The semantics of the "left shift" operation corresponds to that of C ("«") for the respective types (signed char, unsigned char, short, unsigned short, int/long). If an overflow occurs the result is limited to the maximum value of the respective pixel type. Only the pixels within the definition range of the image are processed.

Several images can be processed in one call. An output image is generated for every input image.

Parameters

▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4
Input image(s).

▷ **`ImageLShift`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4
Result image(s) by shift operation.

▷ **`Shift`** (input_control) ..... integer ⇝ *integer*
Shift value.
Default: 3
Suggested values: `Shift` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, 30, 31}
Minimum increment: 1
Recommended increment: 1

Example

```
read_image(&ByteImage,"fabrik");
convert_image_type(ByteImage,&Int2Image,"int2");
bit_lshift(Int2Image,&FullInt2Image,8);
```

Result

If the images are correct (type) and if `Shift` has a valid value the operator `bit_lshift` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)` If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

bit_mask (Image : ImageMask : BitMask :)

Logical "AND" of each pixel using a bit mask.

The operator `bit_mask` carries out an "and" operation of each pixel with a fixed mask. The semantics of the "and" operation corresponds to that of C for the respective types (signed char, unsigned char, unsigned short, short, int/long). Only the pixels within the definition range of the image are processed.

Several images can be processed in one call. An output image is generated for every input image.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Input image(s).

▷ **ImageMask** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Result image(s) by combination with mask.

▷ **BitMask** (input_control) ..... integer ⇝ *integer*

Bit field
Default: 128
Suggested values: `BitMask` ∈ {1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096}

Result

If the images are correct (type) the operator `bit_mask` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)` If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

bit_not (Image : ImageNot : :)

Complement all bits of the pixels.

The operator bit_not calculates the "complement" of all pixels of the input image bit by bit. The semantics of the "complement" operation corresponds to that of C ("~") for the respective types (signed char, unsigned char, short, unsigned short, int/long). Only the pixels within the definition range of the image are processed.

Several images can be processed in one call. An output image is generated for every input image.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Input image(s).

▷ **ImageNot** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Result image(s) by complement operation.

Example

```
read_image(Image,'monkey')
dev_display(Image)
bit_not(Image,ImageBitNot)
dev_display(ImageBitNot)
```

Result

If the images are correct (type) the operator bit_not returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:) If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

bit_or (Image1, Image2 : ImageOr : :)

Bit-by-bit OR of all pixels of the input images.

The operator bit_or calculates the "or" of all pixels of the input images bit by bit. The semantics of the "or"operation corresponds to that of C for the respective types (signed char, unsigned char, short, unsigned short, int/long). The images must have the same size and pixel type. The pixels within the definition range of the image in the first parameter are processed.

Several images can be processed in one call. In this case both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

Parameters

▷ **Image1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Input image(s) 1.

▷ **Image2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Input image(s) 2.

▷ **ImageOr** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Result image(s) by OR-operation.

Example

```
read_image(Image1,'fabrik')
dev_display (Image1)
read_image(Image2,'monkey')
dev_display (Image2)
bit_or(Image1,Image2,ImageBitOr)
dev_display (ImageBitOr)
```

Result

If the images are correct (type and number) the operator bit_or returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:) If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

bit_and, add_image

bit_rshift (Image : ImageRShift : Shift :)

Right shift of all pixels of the image.

The operator bit_rshift calculates a “right shift” of all pixels of the input image bit by bit. The semantics of the “right shift” operation corresponds to that of C (“»”) for the respective types (signed char, unsigned char, short, unsigned short, int/long). Only the pixels within the definition range of the image are processed.

Several images can be processed in one call. An output image is generated for every input image.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Input image(s).

▷ **ImageRShift** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Result image(s) by shift operation.

▷ **Shift** (input_control) . . . . . integer ⇝ *integer*

shift value
Default: 3
Suggested values: Shift ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, 30, 31}
Minimum increment: 1
Recommended increment: 1

Example

```
bit_rshift(Int2Image,&ReducedInt2Image,8);
convert_image_type(ReducedInt2Image,&ByteImage,"byte");
```

Result

If the images are correct (type) and Shift has a valid value the operator bit_rshift returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:) If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

scale_image

bit_lshift

Module

Foundation

bit_slice (Image : ImageSlice : Bit :)

Extract a bit from the pixels.

The operator bit_slice extracts a bit level from the input image. The semantics of the “and” operation corresponds to that of C for the respective types (signed char, unsigned char, short, unsigned short, int/long). Only the pixels within the definition range of the image are processed.

Several images can be processed in one call. An output image is generated for every input image.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4
Input image(s).

▷ **ImageSlice** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4
Result image(s) by extraction.

▷ **Bit** (input_control) ..... integer ⇝ *integer*
Bit to be selected.
Default: 8
Suggested values: `Bit` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, 30, 32}
Minimum increment: 1
Recommended increment: 1

Example

```
read_image(Image,'fabrik')
for I:= 1 to 8 by 1
    bit_slice (Image, ImageSlice, I)
    threshold (ImageSlice, Region, 1, 255)
    dev_display (Region)
endfor
```

Result

If the images are correct (type) and `Bit` has a valid value, the operator `bit_slice` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system(::'no_object_result',<Result>:)` If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

bit_xor (Image1, Image2 : ImageXor : :)

Bit-by-bit XOR of all pixels of the input images.

The operator `bit_xor` calculates the "xor" of all pixels of the input images bit by bit. The semantics of the "xor" operation corresponds to that of C for the respective types (signed char, unsigned char, short, unsigned short, int/long). The images must have the same size and pixel type. The pixels within the definition range of the image in the first parameter are processed.

Several images can be processed in one call. In this case both input parameters contain the same number of images which are then processed in pairs. An output image is generated for every pair.

Parameters

▷ **Image1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Input image(s) 1.

▷ **Image2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Input image(s) 2.

▷ **ImageXor** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4

Result image(s) by XOR-operation.

Example

```
read_image(Image1,'fabrik')
dev_display (Image1)
read_image(Image2,'monkey')
dev_display (Image2)
bit_xor(Image1,Image2,ImageBitXor)
dev_display (ImageBitXor)
```

Result

If the parameter values are correct the operator `bit_xor` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) can be determined by the operator `set_system(::'no_object_result',<Result>:)` If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

12.3 Color

apply_color_trans_lut (Image1, Image2, Image3 : ImageResult1, ImageResult2, ImageResult3 : ColorTransLUTHandle :)

Color space transformation using pre-generated look-up-table.

`apply_color_trans_lut` transforms an 3-channel image from the RGB color space to further color spaces and vice versa using a pre-generated look-up-table. The three channels of the image are passed as three separate images on input and output.

For further information about the color space transformations see operators `trans_from_rgb` and `trans_to_rgb`

Parameters

- ▷ **Image1** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Input image (channel 1).
- ▷ **Image2** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Input image (channel 2).
- ▷ **Image3** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Input image (channel 3).
- ▷ **ImageResult1** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Color-transformed output image (channel 1).
- ▷ **ImageResult2** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Color-transformed output image (channel 2).
- ▷ **ImageResult3** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Color-transformed output image (channel 3).
- ▷ **ColorTransLUTHandle** (input_control) ..... color_trans_lut ⇝ *handle*
  Handle of the look-up-table for the color space transformation.

Result

The operator `apply_color_trans_lut` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct and the input images could be successfully transformed. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

cfa_to_rgb (CFAImage : RGBImage : CFAType, Interpolation :)

Convert a single-channel color filter array image into an RGB image.

`cfa_to_rgb` converts a single-channel color filter array image `CFAImage` into an RGB image `RGBImage`. Color filter array images are typically generated by single-chip CCD cameras. The conversion from color filter array image to RGB image is typically done on the camera itself or is performed by the device driver of the frame grabber that is used to grab the image. In some cases, however, the device driver simply passes the color filter array image through unchanged. In this case, the corresponding HALCON frame grabber interface typically converts the image into an RGB image. Hence, the operator `cfa_to_rgb` is normally used if the images are not being grabbed using the HALCON frame grabber interface (`grab_image` or `grab_image_async`), but are grabbed using function calls from the frame grabber SDK, and are passed to HALCON using `gen_image1` or `gen_image1_extern`.

In single-chip CCD cameras, a color filter array in front of the sensor provides (subsampled) color information. The most frequently used filter is the so-called Bayer filter. The color filter array has the following layout in this case:

G	B	G	B	G	B	⋯
R	G	R	G	R	G	⋯
G	B	G	B	G	B	⋯
R	G	R	G	R	G	⋯
⋮	⋮	⋮	⋮	⋮	⋮	⋱

Each gray value of the input image `CFAImage` corresponds to the brightness of the pixel behind the corresponding color filter. Hence, in the above layout, the pixel (0,0) corresponds to a green color value, while the pixel (0,1) corresponds to a blue color value. The layout of the Bayer filter is completely determined by the first two elements of the first row of the image, and can be chosen with the parameter `CFAType`. In particular, this enables the correct conversion of color filter array images that have been cropped out of a larger image (e.g., using `crop_part` or `crop_rectangle1`).

The algorithm that is used to interpolate the RGB values is determined by the parameter `Interpolation`. For `Interpolation` = *'bilinear'*, a bilinear interpolation is performed. While this algorithm is very fast, it typically leads to "zipper-like" artifacts and color artifacts at strong edges. For `Interpolation` = *'bilinear_dir'*, a modified version of the bilinear interpolation is performed that may lead to fewer zipper-like artifacts, especially at horizontal or vertical edges in the image. The results may still exhibit color artifacts at strong edges, however. The runtime of this algorithm is only slightly longer than that of bilinear interpolation. For `Interpolation` = *'bilinear_enhanced'*, an enhanced version of the bilinear interpolation is performed that produces fewer zipper-like artifacts and color artifacts than the other two bilinear algorithms in most cases. The runtime of this algorithm is significantly longer than that of the other two algorithms.

If *'mmx_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations for `byte` images are performed using SIMD technology for `Interpolation` = *'bilinear'* and `Interpolation` = *'bilinear_dir'*.

For `Interpolation` = *'bilinear'* and `Interpolation` = *'bilinear_dir'*, `cfa_to_rgb` can be executed on OpenCL devices. The width of the input image should be a multiple of four for `byte` images, or two for `uint2` images, as the operation will be much slower otherwise.

Parameters

▷ **`CFAImage`** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2
Input image.

▷ **`RGBImage`** (output_object) ..... multichannel-image(-array) ⇝ *object :* byte / uint2
Output image.

▷ **`CFAType`** (input_control) ..... string ⇝ *string*
Color filter array type.
Default: 'bayer_gb'
List of values: `CFAType` ∈ {'bayer_gb', 'bayer_gr', 'bayer_bg', 'bayer_rg'}

▷ **`Interpolation`** (input_control) ..... string ⇝ *string*
Interpolation type.
Default: 'bilinear'
List of values: `Interpolation` ∈ {'bilinear', 'bilinear_dir', 'bilinear_enhanced'}

Result

`cfa_to_rgb` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system(::'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

Module

Foundation

clear_color_trans_lut (: : ColorTransLUTHandle :)

Release the look-up-table needed for color space transformation.

The operator clear_color_trans_lut frees the memory of the look-up-table created by create_color_trans_lut. After calling clear_color_trans_lut the handle ColorTransLUTHandle becomes invalid.

Parameters

▷ **ColorTransLUTHandle** (input_control) ..... color_trans_lut ⇝ *handle*
Handle of the look-up-table handle for the color space transformation.

Result

The operator clear_all_color_trans_luts returns the value 2 (H_MSG_TRUE) if the look-up-table was successfully released. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_color_trans_lut, apply_color_trans_lut

Module

Foundation

create_color_trans_lut (: : ColorSpace, TransDirection, NumBits : ColorTransLUTHandle)

Creates the look-up-table for transformation of an image from the RGB color space to an arbitrary color space.

The operator create_color_trans_lut returns a look-up table (LUT) for color space transformation of a 8 bit RGB image to a different color space and vice versa. That means, this operator is only valid for three channel images, where each channel has pixels of type byte. If the input images have different domains, only the intersection of the three input images is used for the transformation.

The parameter ColorSpace identifies the initial or the target color space transformation and the direction of the transformation is set by TransDirection. ColorTransLUTHandle contains the handle of the created look-up-table.

Using a LUT significantly speeds up the process of transformation a RGB image to another color space and vice versa with exception of the *'yiq'*, *'yuv'*, *'argyb'*, *'ciexyz'*, and *'i1i2i3'* color spaces. Be aware that the LUT already needs 48MB of memory space.

For further information about the possible color space transformations see the description of the operators trans_from_rgb and trans_to_rgb.

Parameters

▷ **ColorSpace** (input_control) . . . . . string ⇝ *string*
Color space of the output image.
Default: 'hsv'
List of values: ColorSpace ∈ {'yiq', 'yuv', 'argyb', 'ciexyz', 'ciexyz4', 'cielab', 'cielchab', 'cieluv', 'cielchuv', 'hls', 'hsi', 'hsv', 'ciexyz3', 'ciexyz4', 'hls', 'ihs', 'i1i2i3', 'lms'}

▷ **TransDirection** (input_control) . . . . . string ⇝ *string*
Direction of color space transformation.
Default: 'from_rgb'
List of values: TransDirection ∈ {'from_rgb', 'to_rgb'}

▷ **NumBits** (input_control) . . . . . integer ⇝ *integer*
Number of bits of the input image.
Default: 8
List of values: NumBits ∈ {8}

▷ **ColorTransLUTHandle** (output_control) . . . . . color_trans_lut ⇝ *handle*
Handle of the look-up-table for color space transformation.

Result

The operator create_color_trans_lut returns the value 2 (H_MSG_TRUE) if the given parameters are correct and the look-up-table is generated. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

gen_principal_comp_trans (MultichannelImage : : : Trans, TransInv, Mean, Cov, InfoPerComp)

Compute the transformation matrix of the principal component analysis of multichannel images.

gen_principal_comp_trans computes the transformation matrix of a principal components analysis of multichannel images. This is useful for images obtained, e.g., with the thematic mapper of the Landsat satellite. Because the spectral bands are highly correlated, it is desirable to transform them to uncorrelated images. This can be used to save storage, since the bands containing little information can be discarded, and with respect to a later classification step.

The operator gen_principal_comp_trans takes one or more multichannel images MultichannelImage and computes the transformation matrix Trans for the principal components analysis, as well as its inverse TransInv. All input images must have the same number of channels. The principal components analysis is performed based on the collection of data of all images. Hence, gen_principal_comp_trans facilitates using the statistics of multiple images.

If n is the number of channels, Trans and TransInv are matrices of dimension $n \times (n+1)$, which describe an affine transformation of the multichannel gray values. They can be used to transform a multichannel image with linear_trans_color. For information purposes, the mean gray value of the channels and the $n \times n$ covariance matrix of the channels are returned in Mean and Cov, respectively. The parameter InfoPerComp contains the relative information content of each output channel.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **MultichannelImage** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Multichannel input image.

▷ **Trans** (output_control) ..... real-array ⇝ *real*
Transformation matrix for the computation of the PCA.

▷ **TransInv** (output_control) ..... real-array ⇝ *real*
Transformation matrix for the computation of the inverse PCA.

▷ **Mean** (output_control) ..... real-array ⇝ *real*
Mean gray value of the channels.

▷ **Cov** (output_control) ..... real-array ⇝ *real*
Covariance matrix of the channels.

▷ **InfoPerComp** (output_control) ..... real-array ⇝ *real*
Information content of the transformed channels.

Result

The operator `gen_principal_comp_trans` returns the value 2 (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`linear_trans_color`

Alternatives

`principal_comp`

Module

Foundation

linear_trans_color (Image : ImageTrans : TransMat :)

Compute an affine transformation of the color values of a multichannel image.

`linear_trans_color` performs an affine transformation of the color values of the multichannel image `Image` and returns the result in `ImageTrans`. The affine transformation of the color values is described by the transformation matrix `TransMat`. If n is the number of channels in `Image` and m is the number of channels in `ImageTrans`, `TransMat` is a homogeneous $m \times (n+1)$ matrix that is stored row by row. Homogeneous means that the left $m \times n$ submatrix of `TransMat` describes a linear transformation of the color values, while the last column of `TransMat` describes a constant offset of the color values. The transformation matrix is typically computed with `gen_principal_comp_trans`. In particular, it is possible to project an image onto the first m principal components by selecting the first $m \times (n+1)$ values of the transformation returned by `gen_principal_comp_trans`. The transformation can, however, also be specified directly. For example, a transformation from RGB to YIQ, which is described by the following transformation

$$\begin{pmatrix} Y \\ I \\ Q \end{pmatrix} = \begin{pmatrix} 0.299 & 0.587 & 0.114 \\ 0.599 & -0.276 & -0.324 \\ 0.214 & -0.522 & 0.309 \end{pmatrix} \begin{pmatrix} R \\ G \\ B \end{pmatrix} + \begin{pmatrix} 0 \\ 127.5 \\ 127.5 \end{pmatrix}$$

can be achieved by setting `TransMat` to

$$[0.299, 0.587, 0.114, 0.0, 0.599, -0.276, -0.324, 127.5, 0.214, -0.522, 0.309, 127.5]$$

Here, it should be noted that the above transformation is unnormalized, i.e., the resulting color values can lie outside the range $[0, 255]$. The transformation *'yiq'* in `trans_from_rgb` additionally scales the rows of the matrix (except for the constant offset) appropriately.

To avoid a loss of information, `linear_trans_color` returns an image of type real. If a different image type is desired, the image can be transformed with `convert_image_type`.

Attention

`linear_trans_color` can be executed on OpenCL devices if the image `Image` consists of nine channels or less and is transformed to an image of three channels or less. Since the calculations are done in single precision floating point, the results may differ from those calculated by the CPU.

Parameters

▷ **Image** (input_object) ..... multichannel-image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Multichannel input image.

▷ **ImageTrans** (output_object) ..... multichannel-image(-array) ⇝ *object :* real
Multichannel output image.

▷ **TransMat** (input_control) ..... real-array ⇝ *real*
Transformation matrix for the color values.

Result

The operator `linear_trans_color` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

Possible Successors

`convert_image_type`

Alternatives

`principal_comp`, `trans_from_rgb`, `trans_to_rgb`

Module

Foundation

principal_comp (MultichannelImage : PCAImage : : InfoPerComp)

Compute the principal components of multichannel images.

`principal_comp` does a principal components analysis of multichannel images. This is useful for images obtained, e.g., with the thematic mapper of the Landsat satellite. Because the spectral bands are highly correlated, it is desirable to transform them to uncorrelated images. This can be used to save storage, since the bands containing little information can be discarded, and with respect to a later classification step.

The operator `principal_comp` takes a (multichannel) image `MultichannelImage` and transforms it to the output image `PCAImage`, which contains the same number of channels, using the principal components analysis. The parameter `InfoPerComp` contains the relative information content of each output channel.

Attention

`principal_comp` can be executed on OpenCL devices if image consists of eight channels or less. Since the calculations are done in single precision floating point, the results may differ from those calculated by the CPU.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`MultichannelImage`** (input_object) ..... (multichannel-)image ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Multichannel input image.

▷ **`PCAImage`** (output_object) ..... multichannel-image ⇝ *object :* real
Multichannel output image.

▷ **`InfoPerComp`** (output_control) ..... real-array ⇝ *real*
Information content of each output channel.

Result

The operator `principal_comp` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`rgb1_to_gray` (RGBImage : GrayImage : :)

Transform an RGB image into a gray scale image.

`rgb1_to_gray` transforms an RGB image into a gray scale image. The three channels of the RGB image are passed as the first three channels of the input image. The image is transformed according to the following formula:

$k = 0.299r + 0.587g + 0.114b$.

If one of the input images in `RGBImage` is a single-channel image its reference will be simply copied to the output `GrayImage`.

Parameters

▷ **`RGBImage`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Three-channel RBG image.

▷ **`GrayImage`** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte / int2 / uint2 / real
Gray scale image.

Example

```
* Transformation from rgb to gray
read_image(Image,'patras')
dev_display(Image)
rgb1_to_gray(Image,GrayImage)
dev_display(GrayImage)
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

decompose3

Alternatives

rgb1_to_gray, trans_from_rgb

Module

Foundation

trans_from_rgb (ImageRed, ImageGreen, ImageBlue : ImageResult1, ImageResult2, ImageResult3 : ColorSpace :)

Transform an image from the RGB color space to an arbitrary color space.

trans_from_rgb transforms an image from the RGB color space to an arbitrary color space (ColorSpace). The three channels of the image are passed as three separate images on input and output.

The operator trans_from_rgb supports the image types byte, uint2, int4, and real. In the case of real images, all values should lay within 0 and 1. If not, the results of the transformation may not be reasonable.

Certain scalings are performed accordingly to the image type:

- Considering byte and uint2 images, the domain of color space values is generally mapped to the full domain of [0..255] or [0..65535], respectively. Because of this, the origin of signed values (e.g., CIELab) may not be at the center of the domain.
- Hue values are represented by angles of $[0..2\pi[$ and are coded for the particular image types differently:
  - byte-images map the angle domain to $[0..255]$.
  - uint2/int4-images are coded in minutes of arc $[0..21600[$, except for the transformations *'cielchab'* and *'cielchuv'* for int4-images, where they are coded in seconds of arc $[0..1296000[$.
  - real-images are coded in radians $[0..2\pi[$, except for the transformations *'cielchab'* and *'cielchuv'*, where the standards ISO 11664-4:2008 and ISO 11664-5:2009 require the hue to be specified in degrees.
- Saturation values are represented by percentages of $[0..100]$ and are coded differently for the particular image type:
  - byte-images map the saturation values to $[0..255]$.
  - uint2/int4 map the saturation values to $[0..10000]$.
  - real-images map the saturation values to $[0..1]$.

Supported are the transformations listed below. Note, all domains are based on RGB values scaled to [0; 1]. To obtain the domain of a certain image type, they must be scaled accordingly with the value range. Due to different precision the values obtained using the given equations may slightly differ from the values returned by the operator.

This conceptually is a transformation from RGB to CIE XYZ (see *'ciexyz'* above) followed by a transformation from CIE XYZ to LMS.

Value range:
$L \in [0;0.949280]$, $M \in [0;1.035401]$, $S \in [0;1.087132]$

Attention

As the calculations are made with a different numerical precision, the OpenCL implementation of the cielab transformation for images of type `int4` is slightly less accurate than the pure C version.

Parameters

- ▷ **ImageRed** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Input image (red channel).
- ▷ **ImageGreen** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Input image (green channel).
- ▷ **ImageBlue** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Input image (blue channel).
- ▷ **ImageResult1** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Color-transformed output image (channel 1).
- ▷ **ImageResult2** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Color-transformed output image (channel 1).
- ▷ **ImageResult3** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Color-transformed output image (channel 1).
- ▷ **ColorSpace** (input_control) . . . . . string ⇝ *string*
  Color space of the output image.
  Default: 'hsv'
  List of values: `ColorSpace` ∈ {'cielab', 'cielchab', 'cieluv', 'cielchuv', 'hsv', 'hsi', 'yiq', 'yuv', 'argyb', 'ciexyz', 'ciexyz2', 'ciexyz3', 'ciexyz4', 'hls', 'ihs', 'i1i2i3', 'lms'}

Example

```
* Transformation from rgb to hsv and conversely
read_image(Image,'patras')
dev_display(Image)
decompose3(Image, Image1, Image2, Image3)
trans_from_rgb(Image1,Image2,Image3,ImageH,ImageS,ImageV,'hsv')
trans_to_rgb(ImageH,ImageS,ImageV,ImageR,ImageG,ImageB,'hsv')
compose3(ImageR,ImageG,ImageB,Multichannel)
dev_display(Multichannel)
```

Result

`trans_from_rgb` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result', <Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

Possible Predecessors

`decompose3`

Possible Successors

`compose3`

Alternatives

Module

Foundation

trans_to_rgb (ImageInput1, ImageInput2, ImageInput3 : ImageRed, ImageGreen, ImageBlue : ColorSpace :)

Transform an image from an arbitrary color space to the RGB color space.

`trans_to_rgb` transforms an image from an arbitrary color space (`ColorSpace`) to the RGB color space. The three channels of the image are passed as three separate images on input and output.

The operator `trans_to_rgb` supports the image types `byte`, `uint2`, `int4`, and `real`. The domain of the input images must match the domain provided by a corresponding transformation with `trans_from_rgb`. If not, the results of the transformation may not be reasonable.

This includes some scalings in the case of certain image types and transformations:

- Considering `byte` and `uint2` images, the domain of color space values is expected to be spread to the full domain of [0..255] or [0..65535], respectively. This includes a shift in the case of signed values, such that the origin of signed values (e.g., CIELab) may not be at the center of the domain.

- Hue values are represented by angles of $[0..2\pi[$ and are coded for the particular image types differently:
  - `byte`-images map the angle domain on $[0..255]$.
  - `uint2`/`int4`-images are coded in minutes of arc $[0..21600[$, except for the transformations *'cielchab'* and *'cielchuv'* for `int4`-images, where they are coded in seconds of arc $[0..1296000[$.
  - `real`-images are coded in radians $[0..2\pi[$, except for the transformations *'cielchab'* and *'cielchuv'*, where the standards ISO 11664-4:2008 and ISO 11664-5:2009 require the hue to be specified in degrees.
- Saturation values are represented by percentages of $[0..100]$ and are coded for the particular image type differently:
  - `byte`-images map the saturation values to $[0..255]$.
  - `uint2`/`int4`-images map the saturation values to $[0..10000]$.
  - `real`-images map the saturation values to $[0..1]$.

Supported are the transformations listed below. Note, all domains are based on RGB values scaled to [0; 1]. To obtain the domain of a certain image type, they must be scaled accordingly with the value range. Due to different precision the values obtained using the given equations may slightly differ from the values returned by the operator.

'yiq'

$$\begin{pmatrix} R \\ G \\ B \end{pmatrix} = \begin{pmatrix} 1.0 & 0.946882217 & 0.623556582 \\ 1.0 & -0.267024956 & -0.649523352 \\ 1.0 & -1.108545035 & 1.709006928 \end{pmatrix} \begin{pmatrix} Y \\ I \\ Q \end{pmatrix}$$

Value range:
$Y \in [0;1]$, $I \in [-0.59947; 0.59947]$, $Q \in [-0.52243; 0.52243]$

'yuv'

$$\begin{aligned} R &= Y + \tfrac{1.0}{0.877} V \\ G &= Y - \tfrac{0.114}{0.493*0.587} U - \tfrac{0.299}{0.877*0.587} V \\ B &= Y + \tfrac{1.0}{0.493} U \end{aligned}$$

Note, this implies that Y, U, and V are not independent of each other.

Value range:

Attention

As the calculations are made with a different numerical precision, the OpenCL implementation of the cielab transformation for images of type `int4` is slightly less accurate than the pure C version.

Parameters

- ▷ **ImageInput1** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Input image (channel 1).
- ▷ **ImageInput2** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Input image (channel 2).
- ▷ **ImageInput3** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Input image (channel 3).
- ▷ **ImageRed** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Red channel.
- ▷ **ImageGreen** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Green channel.
- ▷ **ImageBlue** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
  Blue channel.
- ▷ **ColorSpace** (input_control) . . . . . string ⇝ *string*
  Color space of the input image.
  Default: 'hsv'
  List of values: `ColorSpace` ∈ {'hsi', 'yiq', 'yuv', 'argyb', 'ciexyz', 'ciexyz4', 'cielab', 'cielchab', 'cieluv', 'cielchuv', 'hls', 'hsv', 'lms'}

Example

```
* Transformation from rgb to hsv and conversely
read_image(Image,'patras')
dev_display(Image)
decompose3(Image, Image1, Image2, Image3)
trans_from_rgb(Image1,Image2,Image3,ImageH,ImageS,ImageV,'hsv')
trans_to_rgb(ImageH,ImageS,ImageV,ImageR,ImageG,ImageB,'hsv')
compose3(ImageR,ImageG,ImageB,Multichannel)
dev_display(Multichannel)
```

Result

`trans_to_rgb` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system(::'no_object_result', <Result>:)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

Possible Predecessors

`decompose3`

Possible Successors

`compose3`, `disp_color`

Alternatives

`linear_trans_color`

Foundation

12.4 Edges

close_edges (Edges, EdgeImage : RegionResult : MinAmplitude :)

Close edge gaps using the edge amplitude image.

close_edges closes gaps in the output of an edge detector, and thus tries to produce complete object contours. This is done by examining the neighbors of each edge point to determine the point with maximum amplitude (i.e., maximum gradient), and adding the point to the edge if its amplitude is larger than the minimum amplitude passed in MinAmplitude. This operator expects as input the edges (Edges) and amplitude image (EdgeImage) returned by typical edge operators, such as edges_image or sobel_amp. close_edges does not take into account the edge directions that may be returned by an edge operator. Thus, in areas where the gradient is almost constant the edges may become rather "wiggly."

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Edges** (input_object) . . . . . region(-array) ⇝ *object*
  Region containing one pixel thick edges.
- ▷ **EdgeImage** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2 / int4
  Edge amplitude (gradient) image.
- ▷ **RegionResult** (output_object) . . . . . region(-array) ⇝ *object*
  Region containing closed edges.
- ▷ **MinAmplitude** (input_control) . . . . . integer ⇝ *integer*
  Minimum edge amplitude.
  Default: 16
  Suggested values: MinAmplitude ∈ {5, 8, 10, 12, 16, 20, 25, 30, 40, 50}
  Value range: 1 ≤ MinAmplitude
  Minimum increment: 1
  Recommended increment: 1

Example

```
sobel_amp(Image,&EdgeAmp,"sum_abs",5);
threshold(EdgeAmp,&EdgeRegion,40.0,255.0);
skeleton(EdgeRegion,&ThinEdge);
close_edges(ThinEdge,EdgeAmp,&CloseEdges,15);
skeleton(CloseEdges,&ThinCloseEdges);
```

Result

close_edges returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

edges_image, sobel_amp, threshold, skeleton

Possible Successors

skeleton

Alternatives

close_edges_length, dilation1, closing

gray_skeleton

Module

Foundation

close_edges_length (Edges, Gradient : ClosedEdges : MinAmplitude, MaxGapLength :)

Close edge gaps using the edge amplitude image.

close_edges_length closes gaps in the output of an edge detector, and thus tries to produce complete object contours. This operator expects as input the edges (Edges) and amplitude image (Gradient) returned by typical edge operators, such as edges_image or sobel_amp.

Contours are closed in two steps: First, one pixel wide gaps in the input contours are closed, and isolated points are eliminated. After this, open contours are extended by up to MaxGapLength points by adding edge points until either the contour is closed or no more significant edge points can be found. A gradient is regarded as significant if it is larger than MinAmplitude. The neighboring points examined as possible new edge points are the point in the direction of the contour and its two adjacent points in an 8-neighborhood. For each of these points, the sum of its gradient and the maximum gradient of that points three possible neighbors is calculated (*look ahead* of length 1). The point with the maximum sum is then chosen as the new edge point.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Edges** (input_object) ..... region(-array) ⇝ *object*
Region containing one pixel thick edges.

▷ **Gradient** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
Edge amplitude (gradient) image.

▷ **ClosedEdges** (output_object) ..... region(-array) ⇝ *object*
Region containing closed edges.

▷ **MinAmplitude** (input_control) ..... integer ⇝ *integer*
Minimum edge amplitude.
Default: 16
Suggested values: MinAmplitude ∈ {5, 8, 10, 12, 16, 20, 25, 30, 40, 50}
Value range: 0 ≤ MinAmplitude ≤ 255
Minimum increment: 1
Recommended increment: 1

▷ **MaxGapLength** (input_control) ..... integer ⇝ *integer*
Maximal number of points by which edges are extended.
Default: 3
Suggested values: MaxGapLength ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 20, 30, 40, 50, 70, 100}
Value range: 1 ≤ MaxGapLength ≤ 127
Minimum increment: 1
Recommended increment: 1

Example

```
sobel_amp(Image,&EdgeAmp,"sum_abs",5);
threshold(EdgeAmp,&EdgeRegion,40.0,255.0);
skeleton(EdgeRegion,&ThinEdge);
close_edges_length(ThinEdge,EdgeAmp,&CloseEdges,15,3);
```

Result

close_edges_length returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

edges_image, sobel_amp, threshold, skeleton

Alternatives

close_edges, dilation1, closing

derivate_gauss (Image : DerivGauss : Sigma, Component :)

Convolve an image with derivatives of the Gaussian.

derivate_gauss convolves an image with the derivatives of a Gaussian and calculates various features derived therefrom. Sigma is the parameter of the Gaussian (i.e., the amount of smoothing). If one value is passed in Sigma the amount of smoothing in the column and row direction is identical. If two values are passed in Sigma the first value specifies the amount of smoothing in the column direction, while the second value specifies the amount of smoothing in the row direction. The possible values for Component are:

'none': Smoothing only.

'x': First derivative along x.

$$g'(x,y) = \frac{\partial g(x,y)}{\partial x}$$

'y': First derivative along y.

$$g'(x,y) = \frac{\partial g(x,y)}{\partial y}$$

'gradient': Absolute value of the gradient.

$$g'(x,y) = \sqrt{\frac{\partial g(x,y)^2}{\partial x}\frac{\partial g(x,y)^2}{\partial y}}$$

'gradient_dir': Gradient direction in radians.

$$\phi = \text{atan2}(\frac{\partial g(x,y)}{\partial y}, \frac{\partial g(x,y)}{\partial x})$$

'xx': Second derivative along x.

$$g'(x,y) = \frac{\partial^2 g(x,y)}{\partial x^2}$$

'yy': Second derivative along y.

$$g'(x,y) = \frac{\partial^2 g(x,y)}{\partial y^2}$$

'xy': Second derivative along x and y.

$$g'(x,y) = \frac{\partial^2 g(x,y)}{\partial x \partial y}$$

'xxx': Third derivative along x.

$$g'(x,y) = \frac{\partial^3 g(x,y)}{\partial x^3}$$

'yyy': Third derivative along y.

$$g'(x,y) = \frac{\partial^3 g(x,y)}{\partial y^3}$$

'xxy': Third derivative along x, x and y.

$$g'(x,y) = \frac{\partial^3 g(x,y)}{\partial x^2 \partial y}$$

'xyy': Third derivative along x, y and y.

$$g'(x,y) = \frac{\partial^3 g(x,y)}{\partial x \partial y^2}$$

'det': Determinant of the Hessian matrix:

$$DET = \frac{\partial^2 g(x,y)}{\partial x^2}\frac{\partial^2 g(x,y)}{\partial y^2} - \left(\frac{\partial^2 g(x,y)}{\partial y \partial x}\right)^2$$

'laplace': Laplace operator (trace of the Hessian matrix):

$$TR = \frac{\partial^2 g(x,y)}{\partial x^2} + \frac{\partial^2 g(x,y)}{\partial y^2}$$

'mean_curvature': Mean curvature H

$$\begin{aligned} a &= (1 + \frac{\partial g(x,y)^2}{\partial x})\frac{\partial^2 g(x,y)}{\partial y^2} \\ b &= 2\frac{\partial g(x,y)}{\partial x}\frac{\partial g(x,y)}{\partial y}\frac{\partial^2 g(x,y)}{\partial y \partial x} \\ c &= (1 + \frac{\partial g(x,y)^2}{\partial y})\frac{\partial^2 g(x,y)}{\partial x^2} \\ d &= (1 + \frac{\partial g(x,y)^2}{\partial x} + \frac{\partial g(x,y)^2}{\partial y})^{\frac{3}{2}} \\ H &= \frac{a - b + c}{d} \\ H &= \frac{1}{2}(\kappa_{min} + \kappa_{max}) \end{aligned}$$

'gauss_curvature': Gaussian curvature K

$$K = \frac{DET}{(1 + \frac{\partial g(x,y)^2}{\partial x} + \frac{\partial g(x,y)^2}{\partial y})^2}$$

'area': Differential Area A

$$\begin{aligned} A &= EG - F^2 \\ E &= 1 + \frac{\partial g(x,y)}{\partial x}^2 \\ F &= \frac{\partial g(x,y)}{\partial x}\frac{\partial g(x,y)}{\partial y} \\ G &= 1 + \frac{\partial g(x,y)}{\partial y}^2 \end{aligned}$$

'eigenvalue1': First eigenvalue

$$\begin{aligned} a &= \frac{\frac{\partial^2 g(x,y)}{\partial x^2} + \frac{\partial^2 g(x,y)}{\partial y^2}}{2} \\ \lambda_1 &= a + \sqrt{a^2 - (\frac{\partial^2 g(x,y)}{\partial x^2}\frac{\partial^2 g(x,y)}{\partial y^2} - \frac{\partial^2 g(x,y)^2}{\partial y \partial x})} \end{aligned}$$

'eigenvalue2': Second eigenvalue

$$\begin{aligned} a &= \frac{\frac{\partial^2 g(x,y)}{\partial x^2} + \frac{\partial^2 g(x,y)}{\partial y^2}}{2} \\ \lambda_2 &= a - \sqrt{a^2 - (\frac{\partial^2 g(x,y)}{\partial x^2}\frac{\partial^2 g(x,y)}{\partial y^2} - \frac{\partial^2 g(x,y)^2}{\partial y \partial x})} \end{aligned}$$

'eigenvec_dir': Direction of the eigenvector corresponding to the first eigenvalue in radians

'main1_curvature' First main curvature

$$\kappa_{max} = H + \sqrt{H^2 - K}$$

'main2_curvature' Second main curvature

$$\kappa_{min} = H - \sqrt{H^2 - K}$$

'kitchen_rosenfeld': Second derivative perpendicular to the gradient

$$k = \frac{\frac{\partial^2 g(x,y)}{\partial x^2}\frac{\partial g(x,y)^2}{\partial y} + \frac{\partial^2 g(x,y)}{\partial y^2}\frac{\partial g(x,y)^2}{\partial x} - 2\frac{\partial^2 g(x,y)}{\partial y \partial x}\frac{\partial g(x,y)^2}{\partial x}\frac{\partial g(x,y)^2}{\partial y}}{\frac{\partial g(x,y)^2}{\partial x} + \frac{\partial g(x,y)^2}{\partial y}}$$

'zuniga_haralick': Normalized second derivative perpendicular to the gradient

$$k = \frac{\frac{\partial^2 g(x,y)}{\partial x^2}\frac{\partial g(x,y)^2}{\partial y} + \frac{\partial^2 g(x,y)}{\partial y^2}\frac{\partial g(x,y)^2}{\partial x} - 2\frac{\partial^2 g(x,y)}{\partial y \partial x}\frac{\partial g(x,y)^2}{\partial x}\frac{\partial g(x,y)^2}{\partial y}}{\left(\frac{\partial g(x,y)^2}{\partial x} + \frac{\partial g(x,y)^2}{\partial y}\right)^{\frac{3}{2}}}$$

'2nd_ddg': Second derivative along the gradient

$$k = \frac{\frac{\partial^2 g(x,y)}{\partial x^2}\frac{\partial g(x,y)^2}{\partial x} + 2\frac{\partial g(x,y)}{\partial x}\frac{\partial g(x,y)}{\partial y}\frac{\partial^2 g(x,y)}{\partial y \partial x} + \frac{\partial^2 g(x,y)}{\partial y^2}\frac{\partial g(x,y)^2}{\partial y}}{\frac{\partial g(x,y)^2}{\partial x} + \frac{\partial g(x,y)^2}{\partial y}}$$

'de_saint_venant': Second derivative along and perpendicular to the gradient

$$k = \frac{\frac{\partial g(x,y)}{\partial x}\frac{\partial g(x,y)}{\partial y}\left(\frac{\partial^2 g(x,y)}{\partial x^2} - \frac{\partial^2 g(x,y)}{\partial y^2}\right) - \left(\frac{\partial g(x,y)^2}{\partial x} - \frac{\partial g(x,y)^2}{\partial y}\right)\frac{\partial^2 g(x,y)}{\partial x \partial y}}{\frac{\partial g(x,y)^2}{\partial x} + \frac{\partial g(x,y)^2}{\partial y}}$$

Attention

Besides the pure C version there are specific implementations of `derivate_gauss` for speed up. Such an optimization is applied in case it is supported by the system and the respective system parameter `*_enable` is set to *'true'*, see `set_system`. The following optimizations are supported (listed according to their priority):

- using *AVX512f* instructions (*'avx512f_enable'*)
- using *AVX* instructions (*'avx_enable'*)
- using *SSE2* instructions (*'sse2_enable'*)

These implementations are slightly inaccurate compared to the pure C version due to numerical issues. For example, using SSE2 instructions the inaccuracy is in order of magnitude of $1.0e-5$ for 'byte' images and `Component` set to *'none'*, *'x'*, or *'y'*.

In case accuracy is preferred over performance, set all corresponding system parameter to *'false'* (using `set_system`) before calling `derivate_gauss`. This way `derivate_gauss` does not use the accelerations. Do not forget to set the parameter back to *'true'* afterwards.

`derivate_gauss` is only executed on an OpenCL device if `Sigma` induces a filter width respectively height of up to 129 pixels. This corresponds to a `Sigma` of less than 20.7 for `Component` = *'none'*. The OpenCL implementation is slightly inaccurate compared to the pure C version due to numerical issues.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real

Input images.

▷ **`DerivGauss`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* real

Filtered result images.

▷ **Sigma** (input_control) . . . . . real(-array) ⇝ *real*
Sigma of the Gaussian.
Default: 1.0
Suggested values: Sigma ∈ {0.7, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0}
Value range: 0.01 ≤ Sigma ≤ 50.0
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Component** (input_control) . . . . . string ⇝ *string*
Derivative or feature to be calculated.
Default: 'x'
List of values: Component ∈ {'none', 'x', 'y', 'gradient', 'xx', 'yy', 'xy', 'xxx', 'yyy', 'xxy', 'xyy', 'det', 'mean_curvature', 'gauss_curvature', 'eigenvalue1', 'eigenvalue2', 'main1_curvature', 'main2_curvature', 'kitchen_rosenfeld', 'zuniga_haralick', '2nd_ddg', 'de_saint_venant', 'area', 'laplace', 'gradient_dir', 'eigenvec_dir'}

Example

```
read_image(&Image,"mreut");
derivate_gauss(Image,&Gauss,3.0,"x");
zero_crossing(Gauss,&ZeroCrossings);
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

zero_crossing, dual_threshold

Alternatives

laplace, laplace_of_gauss, binomial_filter, gauss_filter, smooth_image, isotropic_diffusion

See also

zero_crossing, dual_threshold

Module

Foundation

diff_of_gauss (Image : DiffOfGauss : Sigma, SigFactor :)

Approximate the LoG operator (Laplace of Gaussian).

diff_of_gauss approximates the Laplace-of-Gauss operator by a difference of Gaussians. The standard deviations of these Gaussians can be calculated, according to Marr, from the Parameter Sigma of the LoG and the ratio of the two standard deviations (SigFactor) as:

$$
\begin{aligned}
sigma1 &= \frac{\mathtt{Sigma}}{\sqrt{-2\frac{\log\left(\frac{1}{\mathtt{SigFactor}}\right)}{\mathtt{SigFactor}^2-1}}} \\
sigma2 &= \frac{sigma1}{\mathtt{SigFactor}} \\
\mathtt{DiffOfGauss} &= \mathtt{Image} * gauss(sigma1) - \mathtt{Image} * gauss(sigma2)
\end{aligned}
$$

For a SigFactor = 1.6, according to Marr, an approximation to the Mexican-Hat-Operator results. The resulting image is stored in DiffOfGauss.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2
  Input image
- ▷ **DiffOfGauss** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* int2
  LoG image.
- ▷ **Sigma** (input_control) ..... real ⇝ *real*
  Smoothing parameter of the Laplace operator to approximate.
  Default: 3.0
  Suggested values: Sigma ∈ {2.0, 3.0, 4.0, 5.0}
  Minimum increment: 0.01
  Recommended increment: 0.1
  Restriction: Sigma > 0.0
- ▷ **SigFactor** (input_control) ..... real ⇝ *real*
  Ratio of the standard deviations used (Marr recommends 1.6).
  Default: 1.6
  Minimum increment: 0.01
  Recommended increment: 0.1
  Restriction: SigFactor > 0.0

Example

```
read_image(Image,'fabrik')
diff_of_gauss(Image,Laplace,2.0,1.6)
zero_crossing(Laplace,ZeroCrossings)
```

Complexity

The execution time depends linearly on the number of pixels and the size of sigma.

Result

diff_of_gauss returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

zero_crossing, dual_threshold

Alternatives

laplace, derivate_gauss

Module

Foundation

edges_color (Image : ImaAmp, ImaDir : Filter, Alpha, NMS, Low, High :)

Extract color edges using Canny, Deriche, or Shen filters.

edges_color extracts color edges from the input image Image. To define color edges, the multi-channel image Image is regarded as a mapping $f : R^2 \mapsto R^n$, where n is the number of channels in Image. For such functions, there is a natural extension of the gradient: the metric tensor G, which can be used to calculate for every direction, given by the direction vector v, the rate of change of f in the direction v. For notational convenience, G will be regarded as a two-dimensional matrix. Thus, the rate of change of the function f in the direction v is given by $v^T G v$, where

$$G = \begin{pmatrix} f_x^T f_x & f_x^T f_y \\ f_x^T f_y & f_y^T f_y \end{pmatrix} = \begin{pmatrix} \sum_{i=1}^{n} \frac{\partial f_i}{\partial x}\frac{\partial f_i}{\partial x} & \sum_{i=1}^{n} \frac{\partial f_i}{\partial x}\frac{\partial f_i}{\partial y} \\ \sum_{i=1}^{n} \frac{\partial f_i}{\partial x}\frac{\partial f_i}{\partial y} & \sum_{i=1}^{n} \frac{\partial f_i}{\partial y}\frac{\partial f_i}{\partial y} \end{pmatrix} .$$

The partial derivatives of the images, which are necessary to calculate the metric tensor, are calculated with the corresponding edge filters, analogously to edges_image. For Filter = *'canny'*, the partial derivatives of the Gaussian smoothing masks are used (see derivate_gauss), for *'deriche1'* and Filter = *'deriche2'* the corresponding Deriche filters, for Filter = *'shen'* the corresponding Shen filters, and for Filter = *'sobel_fast'* the Sobel filter. Analogously to single-channel images, the gradient direction is defined by the vector v in which the rate of change f is maximum. The vector v is given by the eigenvector corresponding to the largest eigenvalue of G. The square root of the eigenvalue is the equivalent of the gradient magnitude (the amplitude) for single-channel images, and is returned in ImaAmp. For single-channel images, both definitions are equivalent. Since the gradient magnitude may be larger than what can be represented in the input image data type (byte or uint2), it is stored in the next larger data type (uint2 or int4) in ImaAmp. The eigenvector also is used to define the edge direction. In contrast to single-channel images, the edge direction can only be defined modulo 180 degrees. Like in the output of edges_image, the edge directions are stored in 2-degree steps, and are returned in ImaDir. Points with edge amplitude 0 are assigned the edge direction 255 (undefined direction). For speed reasons, the edge directions are not computed explicitly for Filter = *'sobel_fast'*. Therefore, ImaDir is an empty object in this case.

The "filter width" (i.e., the amount of smoothing) can be chosen arbitrarily for all filters except *'sobel_fast'* (where the filter width is 3×3 and Alpha is ignored), and can be estimated by calling info_edges for concrete values of the parameter Alpha. It decreases for increasing Alpha for the Deriche and Shen filters and increases for the Canny filter, where it is the standard deviation of the Gaussian on which the Canny operator is based. "Wide" filters exhibit a larger invariance to noise, but also a decreased ability to detect small details. Non-recursive filters, such as the Canny filter, are realized using filter masks, and thus the execution time increases for increasing filter width. In contrast, the execution time for recursive filters does not depend on the filter width. Thus, arbitrary filter widths are possible using the Deriche and Shen filters without increasing the run time of the operator. The resulting advantage in speed compared to the Canny operator naturally increases for larger filter widths. As border treatment, the recursive operators assume that the images are zero outside of the image, while the Canny operator mirrors the gray value at the image border. The signal-noise-ratio of the filters is comparable for the following choices of Alpha:

$$\begin{aligned} \texttt{Alpha}('deriche2') &= \texttt{Alpha}('deriche1')/2 \\ \texttt{Alpha}('shen') &= \texttt{Alpha}('deriche1')/2 \\ \texttt{Alpha}('canny') &= 1.77/\texttt{Alpha}('deriche1') \end{aligned}$$

edges_color optionally offers to apply a non-maximum-suppression (NMS = *'nms'*/*'inms'*/*'hvnms'*; *'none'* if not desired) and hysteresis threshold operation (Low,High; at least one negative if not desired) to the resulting edge image. Conceptually, this corresponds to the following calls:

```
nonmax_suppression_dir(...,NMS,...)
hysteresis_threshold(...,Low,High,1000,...).
```

Note that the hysteresis threshold operation is not applied if NMS is set to *'none'*.

For *'sobel_fast'*, the same non-maximum-suppression is performed for all values of NMS except *'none'*. Additionally, for *'sobel_fast'* the resulting edges are thinned to a width of one pixel.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Input image.

▷ **ImaAmp** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* uint2 / int4
Edge amplitude (gradient magnitude) image.

▷ **ImaDir** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* direction
Edge direction image.

▷ **Filter** (input_control) . . . . . string ⇝ *string*
Edge operator to be applied.
Default: 'canny'
List of values: `Filter` ∈ {'canny', 'deriche1', 'deriche2', 'shen', 'sobel_fast'}

▷ **Alpha** (input_control) . . . . . real ⇝ *real*
Filter parameter: small values result in strong smoothing, and thus less detail (opposite for 'canny').
Default: 1.0
Suggested values: `Alpha` ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.7, 0.9, 1.0, 1.1, 1.2, 1.5, 2.0, 2.5, 3.0}
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Alpha > 0.0

▷ **NMS** (input_control) . . . . . string ⇝ *string*
Non-maximum suppression ('none', if not desired).
Default: 'nms'
List of values: `NMS` ∈ {'nms', 'inms', 'hvnms', 'none'}

▷ **Low** (input_control) . . . . . integer ⇝ *integer*
Lower threshold for the hysteresis threshold operation (negative if no thresholding is desired).
Default: 20
Suggested values: `Low` ∈ {5, 10, 15, 20, 25, 30, 40}
Minimum increment: 1
Recommended increment: 5
Restriction: Low >= 1 || Low < 0

▷ **High** (input_control) . . . . . integer ⇝ *integer*
Upper threshold for the hysteresis threshold operation (negative if no thresholding is desired).
Default: 40
Suggested values: `High` ∈ {10, 15, 20, 25, 30, 40, 50, 60, 70}
Minimum increment: 1
Recommended increment: 5
Restriction: High >= 1 || High < 0 && High >= Low

Result

`edges_color` returns 2 (`H_MSG_TRUE`) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Possible Successors

`threshold`

Alternatives

`edges_color_sub_pix`

Module

Foundation

edges_color_sub_pix (Image : Edges : Filter, Alpha, Low, High :)

Extract subpixel precise color edges using Deriche, Shen, or Canny filters.

edges_color_sub_pix extracts subpixel precise color edges from the input image Image. The definition of color edges is given in the description of edges_color. The same edge filters as in edges_color can be selected: *'canny'*, *'deriche1'*, *'deriche2'*, and *'shen'*. In addition, a fast Sobel filter can be selected with *'sobel_fast'*. The filters are specified by the parameter Filter.

The "filter width" (i.e., the amount of smoothing) can be chosen arbitrarily. For a detailed description of this parameter see edges_color. This parameter is ignored for Filter = *'sobel_fast'*.

The extracted edges are returned as subpixel precise XLD contours in Edges. For all edge operators except for *'sobel_fast'*, the following attributes are defined for each edge point (see get_contour_attrib_xld for further information):

- *'edge_direction'*: Gives the direction of the edge (not of the XLD contour), calculated from the image gradients in horizontal and vertical direction. The angles [rad] are given with respect to the column axis of the image.
- *'angle'*: Direction of the normal vectors to the contour in radians (oriented such that the normal vectors point to the right side of the contour as the contour is traversed from start to end point; the angles are given with respect to the row axis of the image).
- *'response'*: Edge amplitude (gradient magnitude).

edges_color_sub_pix links the edge points into edges by using an algorithm similar to a hysteresis threshold operation, which is also used in edges_sub_pix and lines_gauss. Points with an amplitude larger than High are immediately accepted as belonging to an edge, while points with an amplitude smaller than Low are rejected. All other points are accepted as edges if they are connected to accepted edge points (see also lines_gauss and hysteresis_threshold).

Because edge extractors are often unable to extract certain junctions, a mode that tries to extract these missing junctions by different means can be selected by appending *'_junctions'* to the values of `Filter` that are described above. This mode is analogous to the mode for completing junctions that is available in `edges_sub_pix` and `lines_gauss`.

The edge operator *'sobel_fast'* has the same semantics as all the other edge operators. Internally, however, it is based on significantly simplified variants of the individual processing steps (hysteresis thresholding, edge point linking, and extraction of the subpixel edge positions). Therefore, *'sobel_fast'* in some cases may return slightly less accurate edge positions and may select different edge parts.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2
Input image.

▷ **`Edges`** (output_object) . . . . . xld_cont-array ⇝ *object*
Extracted edges.

▷ **`Filter`** (input_control) . . . . . string ⇝ *string*
Edge operator to be applied.
Default: 'canny'
List of values: `Filter` ∈ {'canny', 'deriche1', 'deriche2', 'shen', 'sobel_fast', 'canny_junctions', 'deriche1_junctions', 'deriche2_junctions', 'shen_junctions'}

▷ **`Alpha`** (input_control) . . . . . real ⇝ *real*
Filter parameter: small values result in strong smoothing, and thus less detail (opposite for 'canny').
Default: 1.0
Suggested values: `Alpha` ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.7, 0.9, 1.0, 1.1, 1.2, 1.5, 2.0, 2.5, 3.0}
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Alpha > 0.0

▷ **`Low`** (input_control) . . . . . number ⇝ *real* / integer
Lower threshold for the hysteresis threshold operation.
Default: 20
Suggested values: `Low` ∈ {5, 10, 15, 20, 25, 30, 40}
Value range: 0 ≤ Low
Minimum increment: 1
Recommended increment: 5
Restriction: Low > 0

▷ **`High`** (input_control) . . . . . number ⇝ *real* / integer
Upper threshold for the hysteresis threshold operation.
Default: 40
Suggested values: `High` ∈ {10, 15, 20, 25, 30, 40, 50, 60, 70}
Value range: 0 ≤ High
Minimum increment: 1
Recommended increment: 5
Restriction: High > 0 && High >= Low

Complexity

The amount of temporary memory required is dependent on the height H of the domain of `Image`.

Result

`edges_color_sub_pix` returns `2` (`H_MSG_TRUE`) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

2D Metrology

edges_image (Image : ImaAmp, ImaDir : Filter, Alpha, NMS, Low, High :)

Extract edges using Deriche, Lanser, Shen, or Canny filters.

edges_image detects step edges using recursively implemented filters (according to Deriche, Lanser and Shen) or the conventionally implemented "derivative of Gaussian" filter (using filter masks) proposed by Canny. Furthermore, a very fast variant of the Sobel filter can be used. Thus, the following edge operators are available:

'deriche1', *'lanser1'*, *'deriche1_int4'*, *'deriche2'*, *'lanser2'*, *'deriche2_int4'*, *'shen'*, *'mshen'*, *'canny'*, and *'sobel_fast'*

(parameter Filter).

The edge amplitudes (gradient magnitude) are returned in ImaAmp.

For all filters except *'sobel_fast'*, the edge directions are returned in ImaDir. For *'sobel_fast'*, the edge direction is not computed to speed up the filter. Consequently, ImaDir is an empty image object. The edge operators *'deriche1'* respectively *'deriche2'* are also available for int4-images, and return the signed filter response instead of its absolute value. This behavior can be obtained for byte-images as well by selecting *'deriche1_int4'* respectively *'deriche2_int4'* as filter. This can be used to calculate the second derivative of an image by applying edges_image (with parameter value *'lanser2'*) to the signed first derivative. Edge directions are stored in 2-degree steps, i.e., an edge direction of x degrees in mathematically positive sense and with respect to the horizontal axis is stored as $x/2$ in the edge direction image. Furthermore, the direction of the change of intensity is taken into account. Let $[E_x, E_y]$ denote the image gradient. Then the following edge directions are returned as $r/2$:

intensity increase	E_x/E_y	
edge direction r		
from bottom to top	$0/+$	0
from lower right to upper left	$-/+$	$]0, 90[$
from right to left	$-/0$	90
from upper right to lower left	$-/-$	$]90, 180[$
from top to bottom	$0/-$	180
from upper left to lower right	$+/-$	$]180, 270[$
from left to right	$+/0$	270
from lower left to upper right	$+/+$	$]270, 360[$

Points with edge amplitude 0 are assigned the edge direction 255 (undefined direction).

The "filter width" (i.e., the amount of smoothing) can be chosen arbitrarily for all filters except *'sobel_fast'* (where the filter width is 3×3 and `Alpha` is ignored), and can be estimated by calling `info_edges` for concrete values of the parameter `Alpha`. It decreases for increasing `Alpha` for the Deriche, Lanser and Shen filters and increases for the Canny filter, where it is the standard deviation of the Gaussian on which the Canny operator is based. "Wide" filters exhibit a larger invariance to noise, but also a decreased ability to detect small details. Non-recursive filters, such as the Canny filter, are realized using filter masks, and thus the execution time increases for increasing filter width. In contrast, the execution time for recursive filters does not depend on the filter width. Thus, arbitrary filter widths are possible using the Deriche, Lanser and Shen filters without increasing the run time of the operator. The resulting advantage in speed compared to the Canny operator naturally increases for larger filter widths. As border treatment, the recursive operators assume that the images to be zero outside of the image, while the Canny operator repeats the gray value at the image's border. The signal-noise-ratio of the filters is comparable for the following choices of `Alpha`:

$$\begin{aligned}
\texttt{Alpha}('lanser1') &= \texttt{Alpha}('deriche1') \\
\texttt{Alpha}('deriche2') &= \texttt{Alpha}('deriche1')/2 \\
\texttt{Alpha}('lanser2') &= \texttt{Alpha}('deriche2') \\
\texttt{Alpha}('shen') &= \texttt{Alpha}('deriche1')/2 \\
\texttt{Alpha}('mshen') &= \texttt{Alpha}('shen') \\
\texttt{Alpha}('canny') &= 1.77/\texttt{Alpha}('deriche1')
\end{aligned}$$

The originally proposed recursive filters (*'deriche1'*, *'deriche2'*, *'shen'*) return a biased estimate of the amplitude of diagonal edges. This bias is removed in the corresponding modified version of the operators (*'lanser1'*, *'lanser2'* and *'mshen'*), while maintaining the same execution speed.

For relatively small filter widths (11×11), i.e., for `Alpha`('lanser2') = *0.5*, all filters yield similar results. Only for "wider" filters differences begin to appear: the Shen filters begin to yield qualitatively inferior results. However, they are the fastest of the implemented operators — closely followed by the Deriche operators.

`edges_image` optionally offers to apply a non-maximum-suppression (`NMS` = *'nms'*/*'inms'*/*'hvnms'*; *'none'* if not desired) and hysteresis threshold operation (`Low`,`High`; at least one negative if not desired) to the resulting edge image. Conceptually, this corresponds to the following calls:

```
nonmax_suppression_dir(...,NMS,...)
hysteresis_threshold(...,Low,High,999,...).
```

Note that the hysteresis threshold operation is not applied if `NMS` is set to *'none'*.

For *'sobel_fast'*, the same non-maximum-suppression is performed for all values of `NMS` except *'none'*. Additionally, for *'sobel_fast'* the resulting edges are thinned to a width of one pixel.

`edges_image` can be executed on OpenCL devices for the filter types *'canny'* and *'sobel_fast'*.

Attention

The OpenCL implementation of `edges_image` will generally compute results that differ somewhat from the CPU implementation.

Since `edges_image` uses Gauss convolution internally for the *'canny'* filter, the same limitations for OpenCL apply as for `derivate_gauss`: `Alpha` must be chosen small enough that the required filter mask is less than 129 pixels in size.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
Input image.

▷ **ImaAmp** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2 / int4 / real
Edge amplitude (gradient magnitude) image.

▷ **ImaDir** (output_object) . . . . . image(-array) ⇝ *object :* direction
Edge direction image.

▷ **Filter** (input_control) . . . . . string ⇝ *string*
Edge operator to be applied.
Default: 'canny'
List of values: `Filter` ∈ {'deriche1', 'deriche1_int4', 'deriche2', 'deriche2_int4', 'lanser1', 'lanser2', 'shen', 'mshen', 'canny', 'sobel_fast'}

▷ **Alpha** (input_control) . . . . . real ⇝ *real*
Filter parameter: small values result in strong smoothing, and thus less detail (opposite for 'canny').
Default: 1.0
Suggested values: `Alpha` ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.7, 0.9, 1.1}
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Alpha > 0.0

▷ **NMS** (input_control) . . . . . string ⇝ *string*
Non-maximum suppression ('none', if not desired).
Default: 'nms'
List of values: `NMS` ∈ {'nms', 'inms', 'hvnms', 'none'}

▷ **Low** (input_control) . . . . . integer ⇝ *integer* / real
Lower threshold for the hysteresis threshold operation (negative, if no thresholding is desired).
Default: 20
Suggested values: `Low` ∈ {5, 10, 15, 20, 25, 30, 40}
Minimum increment: 1
Recommended increment: 5
Restriction: Low != 0

▷ **High** (input_control) . . . . . integer ⇝ *integer* / real
Upper threshold for the hysteresis threshold operation (negative, if no thresholding is desired).
Default: 40
Suggested values: `High` ∈ {10, 15, 20, 25, 30, 40, 50, 60, 70}
Minimum increment: 1
Recommended increment: 5
Restriction: High >= Low

Example

```
read_image(Image,'fabrik')
edges_image(Image,Amp,Dir,'lanser2',0.5,'none',-1,-1)
hysteresis_threshold(Amp,Margin,20,30,30)
```

Result

`edges_image` returns 2 (`H_MSG_TRUE`) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

- Automatically parallelized on internal data level.

edges_sub_pix (Image : Edges : Filter, Alpha, Low, High :)

Extract sub-pixel precise edges using Deriche, Lanser, Shen, or Canny filters.

edges_sub_pix detects step edges using recursively implemented filters (according to Deriche, Lanser and Shen) or the conventionally implemented "derivative of Gaussian" filter (using filter masks) proposed by Canny. Thus, the following edge operators are available for Filter:

'deriche1', *'lanser1'*, *'deriche2'*, *'lanser2'*, *'shen'*, *'mshen'*, *'canny'*, *'sobel'* und *'sobel_fast'*.

The extracted edges are returned as sub-pixel precise XLD contours in Edges. For all edge operators except *'sobel_fast'*, the following attributes are defined for each edge point (see get_contour_attrib_xld for further details):

'edge_direction': Gives the direction of the edge (not of the XLD contour), calculated from the image gradients in horizontal and vertical direction. The angles [rad] are given with respect to the column axis of the image.

'angle': Direction of the normal vectors to the contour in radians (oriented such that the normal vectors point to the right side of the contour as the contour is traversed from start to end point; the angles are given with respect to the row axis of the image).

'response': Edge amplitude (gradient magnitude).

The "filter width" (i.e., the amount of smoothing) can be chosen arbitrarily for all edge operators except *'sobel'* and *'sobel_fast'*, and can be estimated by calling info_edges for concrete values of the parameter Alpha. For all filters (Deriche, Lanser and Shen filters), the "filter width" decreases for increasing Alpha. The only exception

is the Canny filter, where an increasing Alpha also causes an increase of the "filter width". "Wide" filters exhibit a larger invariance to noise, but also a decreased ability to detect small details. Non-recursive filters, such as the Canny filter, are realized using filter masks, and thus the execution time increases for increasing filter width. In contrast, the execution time for recursive filters does not depend on the filter width. Thus, arbitrary filter widths are possible using the Deriche, Lanser and Shen filters without increasing the run time of the operator. The resulting advantage in speed compared to the Canny operator naturally increases for larger filter widths. As border treatment, the recursive operators assume that the images to be zero outside of the image, while the Canny operator repeats the gray value at the image's border. The signal-noise-ratio of the filters is comparable for the following choices of Alpha:

$$\begin{aligned}
\texttt{Alpha}('lanser1') &= \texttt{Alpha}('deriche1') \\
\texttt{Alpha}('deriche2') &= \texttt{Alpha}('deriche1')/2 \\
\texttt{Alpha}('lanser2') &= \texttt{Alpha}('deriche2') \\
\texttt{Alpha}('shen') &= \texttt{Alpha}('deriche1')/2 \\
\texttt{Alpha}('mshen') &= \texttt{Alpha}('shen') \\
\texttt{Alpha}('canny') &= 1.77/\texttt{Alpha}('deriche1')
\end{aligned}$$

The originally proposed recursive filters (*'deriche1'*, *'deriche2'*, *'shen'*) return a biased estimate of the amplitude of diagonal edges. This bias is removed in the corresponding modified version of the operators (*'lanser1'*, *'lanser2'* and *'mshen'*), while maintaining the same execution speed.

For relatively small filter widths (11×11), i.e., for Alpha (*'lanser2'* = *0.5*), all filters yield similar results. Only for "wider" filters differences begin to appear: the Shen filters begin to yield qualitatively inferior results. However, they are the fastest of the implemented operators that support arbitrary mask sizes, closely followed by the Deriche operators. The two Sobel filters, which use a fixed mask size of (3×3), are faster than the other filters. Of these two, the filter *'sobel_fast'* is significantly faster than *'sobel'*.

edges_sub_pix links the edge points into edges by using an algorithm similar to a hysteresis threshold operation, which is also used in lines_gauss. Points with an amplitude larger than High are immediately accepted as belonging to an edge, while points with an amplitude smaller than Low are rejected. All other points are accepted as edges if they are connected to accepted edge points (see also lines_gauss and hysteresis_threshold).

Because edge extractors are often unable to extract certain junctions, a mode that tries to extract these missing junctions by different means can be selected by appending *'_junctions'* to the values of Filter that are described above. This mode is analogous to the mode for completing junctions that is available in lines_gauss.

The edge operator *'sobel_fast'* has the same semantics as all the other edge operators. Internally, however, it is based on significantly simplified variants of the individual processing steps (hysteresis thresholding, edge point linking, and extraction of the subpixel edge positions). Therefore, *'sobel_fast'* in some cases may return slightly less accurate edge positions and may select different edge parts.

edges_sub_pix can be executed on OpenCL devices for the filter types *'canny'* and *'sobel_fast'*. This will require up to width*height*29 bytes of pinned memory. Since allocating memory is an expensive operation, it would make sense to set the pinned memory cache to at least this size (using set_compute_device_param for parameter *'pinned_mem_cache_capacity'*, or to disable pinned memory completely (using set_compute_device_param for parameter *'alloc_pinned'*), in which case the normal memory cache is used. Note that the results can vary from the CPU implementation.

Attention

Since edges_sub_pix uses Gauss convolution internally for the *'canny'* filter, the same limitations for OpenCL apply as for derivate_gauss: Alpha must be chosen small enough that the required filter mask is less than 129 pixels in size. Also, edges_sub_pix is not available on OpenCL devices for HALCON XL, as double precision floating point arithmetic would be required, but OpenCL devices are optimized for single precision arithmetic.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **Edges** (output_object) ..... xld_cont-array ⇝ *object*
  Extracted edges.

▷ **Filter** (input_control) . . . . . string ⇝ *string*
Edge operator to be applied.
Default: 'canny'
List of values: Filter ∈ {'deriche1', 'lanser1', 'deriche2', 'lanser2', 'shen', 'mshen', 'canny', 'sobel', 'sobel_fast', 'deriche1_junctions', 'lanser1_junctions', 'deriche2_junctions', 'lanser2_junctions', 'shen_junctions', 'mshen_junctions', 'canny_junctions', 'sobel_junctions'}

▷ **Alpha** (input_control) . . . . . real ⇝ *real*
Filter parameter: small values result in strong smoothing, and thus less detail (opposite for 'canny').
Default: 1.0
Suggested values: Alpha ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.7, 0.9, 1.1}
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Alpha > 0.0

▷ **Low** (input_control) . . . . . integer ⇝ *integer* / real
Lower threshold for the hysteresis threshold operation.
Default: 20
Suggested values: Low ∈ {5, 10, 15, 20, 25, 30, 40}
Minimum increment: 1
Recommended increment: 5
Restriction: Low > 0

▷ **High** (input_control) . . . . . integer ⇝ *integer* / real
Upper threshold for the hysteresis threshold operation.
Default: 40
Suggested values: High ∈ {10, 15, 20, 25, 30, 40, 50, 60, 70}
Minimum increment: 1
Recommended increment: 5
Restriction: High > 0 && High >= Low

Example

```
read_image(Image,'fabrik')
edges_sub_pix(Image,Edges,'lanser2',0.5,20,40)
```

Complexity

Let A be the number of pixels in the domain of Image. Then the runtime complexity is $O(A * \text{Alpha})$ for the Canny filter and $O(A)$ for the recursive Lanser, Deriche, and Shen filters.

The amount of temporary memory required is dependent on the height H of the domain of Image and the width W of Image. Let $S = W * H$, then edges_sub_pix requires at least $60 * S$ bytes of temporary memory during execution for all edge operators except *'sobel_fast'*. For *'sobel_fast'*, at least $9 * S$ bytes of temporary memory are required.

Result

edges_sub_pix returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Successors

2D Metrology

frei_amp (Image : ImageEdgeAmp : :)

Detect edges (amplitude) using the Frei-Chen operator.

frei_amp calculates an approximation of the first derivative of the image data and is used as an edge detector. The filter is based on the following filter masks:

$$A = \begin{matrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{matrix}$$

$$B = \begin{matrix} 1 & 0 & -1 \\ 1 & 0 & -1 \\ 1 & 0 & -1 \end{matrix}$$

The result image contains the maximum response of the masks A and B.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Input image.
- ▷ **ImageEdgeAmp** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Edge amplitude (gradient magnitude) image.

Example

```
read_image(Image,'fabrik')
frei_amp(Image,Frei_amp)
threshold(Frei_amp,Edges,128,255)
```

Result

frei_amp always returns 2 (H_MSG_TRUE). If the input is empty the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

frei_dir (Image : ImageEdgeAmp, ImageEdgeDir : :)

Detect edges (amplitude and direction) using the Frei-Chen operator.

frei_dir calculates an approximation of the first derivative of the image data and is used as an edge detector. The filter is based on the following filter masks:

$$A = \begin{matrix} 1 & \sqrt{2} & 1 \\ 0 & 0 & 0 \\ -1 & -\sqrt{2} & -1 \end{matrix}$$

$$B = \begin{matrix} 1 & 0 & -1 \\ \sqrt{2} & 0 & -\sqrt{2} \\ 1 & 0 & -1 \end{matrix}$$

The result image contains the maximum response of the masks A and B. The edge directions are returned in ImageEdgeDir, and are stored in 2-degree steps, i.e., an edge direction of x degrees in mathematically positive sense and with respect to the horizontal axis is stored as $x/2$ in the edge direction image. Furthermore, the direction of the change of intensity is taken into account. Let $[E_x, E_y]$ denote the image gradient. Then the following edge directions are returned as $r/2$:

intensity increase	E_x/E_y	
edge direction r		
from bottom to top	$0/+$	0
from lower right to upper left	$-/+$	$]0, 90[$
from right to left	$-/0$	90
from upper right to lower left	$-/-$	$]90, 180[$
from top to bottom	$0/-$	180
from upper left to lower right	$+/-$	$]180, 270[$
from left to right	$+/0$	270
from lower left to upper right	$+/+$	$]270, 360[$

Points with edge amplitude 0 are assigned the edge direction 255 (undefined direction).

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Input image.

▷ **ImageEdgeAmp** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Edge amplitude (gradient magnitude) image.

▷ **ImageEdgeDir** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* direction
Edge direction image.

Example

```
read_image(Image,'fabrik')
frei_dir(Image,Frei_dirA,Frei_dirD)
threshold(Frei_dirA,Res,128,255)
```

Result

`frei_dir` always returns `2` (`H_MSG_TRUE`). If the input is empty the behavior can be set via `set_system ('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

highpass_image (Image : Highpass : Width, Height :)

Extract high frequency components from an image.

`highpass_image` extracts high frequency components in an image by applying a linear filter with the following matrix (in case of a 7×5 matrix):

$$\begin{matrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & -35 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{matrix}$$

This corresponds to applying a mean operator (`mean_image`), and then subtracting the original gray value. For byte images, a value of 128 is added to the result, i.e., zero crossings occur for 128. Correspondingly for uint2 images, 32767 is added.

This filter emphasizes high frequency components (edges and corners). The cutoff frequency is determined by the size (Height × Width) of the filter matrix: the larger the matrix, the smaller the cutoff frequency is.

At the image borders the pixels' gray values are mirrored. In case of over- or underflow the gray values are clipped (255 and 0, resp.).

Attention

If even values are passed for Height or Width, the operator uses the next larger odd value instead. Thus, the center of the filter mask is always uniquely determined.

highpass_image can be executed on OpenCL devices. The same limitations as for mean_image and sub_image apply.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Input image.

▷ **Highpass** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
High-pass-filtered result image.

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the filter mask.
Default: 9
Suggested values: Width ∈ {3, 5, 7, 9, 11, 13, 17, 21, 29, 41, 51, 73, 101}
Value range: 1 ≤ Width
Minimum increment: 2
Recommended increment: 2

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the filter mask.
Default: 9
Suggested values: Height ∈ {3, 5, 7, 9, 11, 13, 17, 21, 29, 41, 51, 73, 101}
Value range: 1 ≤ Height
Minimum increment: 2
Recommended increment: 2

Example

```
highpass_image(Image,&Highpass,7,5);
threshold(Highpass,&Region,60.0,255.0);
skeleton(Region,&Skeleton);
```

Result

highpass_image returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

info_edges (: : Filter, Mode, Alpha : Size, Coeffs)

Return the filter coefficients of a filter in edges_image.

info_edges returns the coefficients Coeffs and an estimate of the width Size of any of the filters used in edges_image. To do so, the corresponding continuous impulse responses of the filters are sampled until the first filter coefficient is smaller than five percent of the largest coefficient. Alpha is the filter parameter (see edges_image). Seven edge operators are supported (parameter Filter):

'deriche1', *'lanser1'*, *'deriche2'*, *'lanser2'*, *'shen'*, *'mshen'* and *'canny'*.

The parameter Mode (*'edge'*/*'smooth'*) is used to determine whether the corresponding edge or smoothing operator is to be sampled.

The Canny operator (which uses Gaussian smoothing) is implemented using conventional filter masks. Therefore, for the Canny filter, the coefficients Coeffs of the one-dimensional impulse responses are returned as $f(n)$ with $n \geq 0$. All other filters are implemented recursively; here, the Coeffs are coefficients of a corresponding non-recursive filter.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Filter** (input_control) ..... string ⇝ *string*
Name of the edge operator.
Default: 'lanser2'
List of values: Filter ∈ {'deriche1', 'lanser1', 'deriche2', 'lanser2', 'shen', 'mshen', 'canny'}

▷ **Mode** (input_control) ..... string ⇝ *string*
1D edge filter ('edge') or 1D smoothing filter ('smooth').
Default: 'edge'
List of values: Mode ∈ {'edge', 'smooth'}

▷ **Alpha** (input_control) ..... real ⇝ *real*
Filter parameter: small values result in strong smoothing, and thus less detail (opposite for 'canny').
Default: 0.5
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Alpha > 0.0

▷ **Size** (output_control) ..... integer ⇝ *integer*
Filter width in pixels.

▷ **Coeffs** (output_control) ..... integer-array ⇝ *integer*
For Canny filters: Coefficients of the "positive" half of the 1D impulse response. All others: Coefficients of a corresponding non-recursive filter.

Example

```
read_image(Image,'fabrik')
info_edges('lanser2','edge',0.5,Size,Coeffs)
edges_image(Image,Amp,Dir,'lanser2',0.5,'none',-1,-1)
hysteresis_threshold(Amp,Margin,20,30,30)
```

Result

info_edges returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

edges_image, threshold, skeleton

kirsch_amp (Image : ImageEdgeAmp : :)

Detect edges (amplitude) using the Kirsch operator.

kirsch_amp calculates an approximation of the first derivative of the image data and is used as an edge detector. The filter is based on the following filter masks:

$$\begin{matrix} -3 & -3 & 5 \\ -3 & 0 & 5 \\ -3 & -3 & 5 \end{matrix}$$

$$\begin{matrix} -3 & 5 & 5 \\ -3 & 0 & 5 \\ -3 & -3 & -3 \end{matrix}$$

$$\begin{matrix} 5 & 5 & 5 \\ -3 & 0 & -3 \\ -3 & -3 & -3 \end{matrix}$$

$$\begin{matrix} 5 & 5 & -3 \\ 5 & 0 & -3 \\ -3 & -3 & -3 \end{matrix}$$

$$\begin{matrix} 5 & -3 & -3 \\ 5 & 0 & -3 \\ 5 & -3 & -3 \end{matrix}$$

$$\begin{matrix} -3 & -3 & -3 \\ 5 & 0 & -3 \\ 5 & 5 & -3 \end{matrix}$$

$$\begin{matrix} -3 & -3 & -3 \\ -3 & 0 & -3 \\ 5 & 5 & 5 \end{matrix}$$

$$\begin{matrix} -3 & -3 & -3 \\ -3 & 0 & 5 \\ -3 & 5 & 5 \end{matrix}$$

The result image contains the maximum response of all masks.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Input image.

▷ **ImageEdgeAmp** (output_object) ..... image(-array) ⇝ *object :* byte / int2 / uint2
Edge amplitude (gradient magnitude) image.

Example

```
read_image(Image,'fabrik')
kirsch_amp(Image,Kirsch_amp)
threshold(Kirsch_amp,Edges,128,255)
```

Result

`kirsch_amp` always returns 2 (`H_MSG_TRUE`). If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

kirsch_dir (Image : ImageEdgeAmp, ImageEdgeDir : :)

Detect edges (amplitude and direction) using the Kirsch operator.

`kirsch_dir` calculates an approximation of the first derivative of the image data and is used as an edge detector. The filter is based on the following filter masks:

$$\begin{matrix} -3 & -3 & 5 \\ -3 & 0 & 5 \\ -3 & -3 & 5 \end{matrix}$$

$$\begin{matrix} -3 & 5 & 5 \\ -3 & 0 & 5 \\ -3 & -3 & -3 \end{matrix}$$

$$\begin{matrix} 5 & 5 & 5 \\ -3 & 0 & -3 \\ -3 & -3 & -3 \end{matrix}$$

$$\begin{matrix} 5 & 5 & -3 \\ 5 & 0 & -3 \\ -3 & -3 & -3 \end{matrix}$$

$$\begin{matrix} 5 & -3 & -3 \\ 5 & 0 & -3 \\ 5 & -3 & -3 \end{matrix}$$

$$\begin{matrix} -3 & -3 & -3 \\ 5 & 0 & -3 \\ 5 & 5 & -3 \end{matrix}$$

$$\begin{matrix} -3 & -3 & -3 \\ -3 & 0 & -3 \\ 5 & 5 & 5 \end{matrix}$$

$$\begin{matrix} -3 & -3 & -3 \\ -3 & 0 & 5 \\ -3 & 5 & 5 \end{matrix}$$

The result image contains the maximum response of all masks. The edge directions are returned in ImageEdgeDir, and are stored as $x/2$. They correspond to the direction of the mask yielding the maximum response.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Input image.
- ▷ **ImageEdgeAmp** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Edge amplitude (gradient magnitude) image.
- ▷ **ImageEdgeDir** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* direction
  Edge direction image.

Example

```
read_image(Image,'fabrik')
kirsch_dir(Image,Kirsch_dirA,Kirsch_dirD)
threshold(Kirsch_dirA,Res,128,255)
```

Result

kirsch_dir always returns 2 (H_MSG_TRUE). If the input is empty the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

laplace (Image : ImageLaplace : ResultType, MaskSize, FilterMask :)

Calculate the Laplace operator by using finite differences.

`laplace` filters the input images `Image` using a Laplace operator. Depending on the parameter `FilterMask` the following approximations of the Laplace operator are used:

'n_4'

$$\begin{matrix} & 1 & \\ 1 & -4 & 1 \\ & 1 & \end{matrix}$$

'n_8'

$$\begin{matrix} 1 & 1 & 1 \\ 1 & -8 & 1 \\ 1 & 1 & 1 \end{matrix}$$

'n_8_isotropic'

$$\begin{matrix} 10 & 22 & 10 \\ 22 & -128 & 22 \\ 10 & 22 & 10 \end{matrix}$$

For the three filter masks the following normalizations of the resulting gray values is applied, (i.e., by dividing the result by the given divisor): *'n_4'* normalization by 1, *'n_8'*, normalization by 2 and for *'n_8_isotropic'* normalization by 32.

For a Laplace operator with size 3×3, the corresponding filter is applied directly, while for larger filter sizes the input image is first smoothed using a Gaussian filter (see `gauss_image`) or a binomial filter (see `binomial_filter`) of size `MaskSize`-2. The Gaussian filter is selected for the above values of `ResultType`. Here, `MaskSize` = 5, 7, 9, 11, or 13 must be used. The binomial filter is selected by appending *'_binomial'* to the above values of `ResultType`. Here, `MaskSize` can be selected between 5 and 39. Furthermore, it is possible to select different amounts of smoothing for the column and row direction by passing two values in `MaskSize`. Here, the first value of `MaskSize` corresponds to the mask width (smoothing in the column direction), while the second value corresponds to the mask height (smoothing in the row direction) of the binomial filter. Therefore,

```
laplace(O:R:'absolute',MaskSize,N:)
```

for `MaskSize` $>$ *3* is equivalent to

```
gauss_image(O:G:MaskSize-2:)
laplace(G:R:'absolute',3,N:)
```

and

```
laplace(O:R:'absolute_binomial',MaskSize,N:)
```

is equivalent to

```
binomial_filter(O:B:MaskSize-2,MaskSize-2:)
laplace(B:R:'absolute',3,N:).
```

`laplace` either returns the absolute value of the Laplace filtered image (`ResultType` = *'absolute'*) in a byte or uint2 image or the signed result (`ResultType` = *'signed'* or *'signed_clipped'*). Here, the output image type has the same number of bytes per pixel as the input image (i.e., int1 or int2) for *'signed_clipped'*, while the output image has the next larger number of pixels (i.e., int2 or int4) for *'signed'*.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Input image.

▷ **ImageLaplace** (output_object) . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2 / int2 / int2 / int4
Laplace-filtered result image.

▷ **ResultType** (input_control) . . . . . string ⇝ *string*
Type of the result image, whereas for byte and uint2 the absolute value is used.
Default: 'absolute'
List of values: `ResultType` ∈ {'absolute', 'signed_clipped', 'signed', 'absolute_binomial', 'signed_clipped_binomial', 'signed_binomial'}

▷ **MaskSize** (input_control) . . . . . integer(-array) ⇝ *integer*
Size of filter mask.
Default: 3
List of values: `MaskSize` ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39}

▷ **FilterMask** (input_control) . . . . . string ⇝ *string*
Filter mask used in the Laplace operator
Default: 'n_4'
List of values: `FilterMask` ∈ {'n_4', 'n_8', 'n_8_isotropic'}

Example

```
read_image(&Image,"mreut");
laplace(Image,&Laplace,"signed",3,"n_8_isotropic");
zero_crossing(Laplace,&ZeroCrossings);
```

Result

`laplace` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

`zero_crossing`, `dual_threshold`, `threshold`

Alternatives

laplace_of_gauss (Image : ImageLaplace : Sigma :)

LoG-Operator (Laplace of Gaussian).

`laplace_of_gauss` calculates the Laplace-of-Gaussian operator, i.e., the Laplace operator on a Gaussian smoothed image, for arbitrary smoothing parameters `Sigma`. The Laplace operator is given by:

$$\Delta g(x,y) = \frac{\partial^2 g(x,y)}{\partial x^2} + \frac{\partial^2 g(x,y)}{\partial y^2}$$

The derivatives in `laplace_of_gauss` are calculated by appropriate derivatives of the Gaussian, resulting in the following formula for the convolution mask:

$$\Delta G_\sigma(x,y) =$$
$$\frac{1}{2\pi\sigma^4}\left(\frac{x^2+y^2}{2\sigma^2}-1\right)\left[\exp\left(-\frac{x^2+y^2}{2\sigma^2}\right)\right]$$

Attention

Note that filter operators may return may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **`Image`** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
  Input image.
- ▷ **`ImageLaplace`** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* int2
  Laplace filtered image.
- ▷ **`Sigma`** (input_control) . . . . . number ⇝ *real* / integer
  Smoothing parameter of the Gaussian.
  Default: 2.0
  Suggested values: `Sigma` ∈ {0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 4.0, 5.0, 7.0}
  Value range: 0.01 ≤ `Sigma` ≤ 25.0
  Minimum increment: 0.01
  Recommended increment: 0.1

Example

```
read_image(&Image,"mreut");
laplace_of_gauss(Image,&Laplace,2.0);
zero_crossing(Laplace,&ZeroCrossings);
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

`prewitt_amp` (Image : ImageEdgeAmp : :)

Detect edges (amplitude) using the Prewitt operator.

`prewitt_amp` calculates an approximation of the first derivative of the image data and is used as an edge detector. The filter is based on the following filter masks:

$$A = \begin{matrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{matrix}$$

$$B = \begin{matrix} 1 & 0 & -1 \\ 1 & 0 & -1 \\ 1 & 0 & -1 \end{matrix}$$

The result image contains the maximum response of the masks A and B.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Input image.

▷ **ImageEdgeAmp** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Edge amplitude (gradient magnitude) image.

Example

```
read_image(Image,'fabrik')
prewitt_amp(Image,Prewitt)
threshold(Prewitt,Edges,128,255)
```

Result

`prewitt_amp` always returns 2 (`H_MSG_TRUE`). If the input is empty the behavior can be set via `set_system ('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

prewitt_dir (Image : ImageEdgeAmp, ImageEdgeDir : :)

Detect edges (amplitude and direction) using the Prewitt operator.

`prewitt_dir` calculates an approximation of the first derivative of the image data and is used as an edge detector. The filter is based on the following filter masks:

$$A = \begin{matrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{matrix}$$

$$B = \begin{matrix} 1 & 0 & -1 \\ 1 & 0 & -1 \\ 1 & 0 & -1 \end{matrix}$$

The result image contains the maximum response of the masks A and B. The edge directions are returned in `ImageEdgeDir`, and are stored in 2-degree steps, i.e., an edge direction of x degrees mathematically positive sense and with respect to the horizontal axis is stored as $x/2$ in the edge direction image. Furthermore, the direction of the change of intensity is taken into account. Let $[E_x, E_y]$ denote the image gradient. Then the following edge directions are returned as $r/2$:

intensity increase	E_x/E_y	
edge direction r		
from bottom to top	$0/+$	0
from lower right to upper left	$-/+$	$]0, 90[$
from right to left	$-/0$	90
from upper right to lower left	$-/-$	$]90, 180[$
from top to bottom	$0/-$	180
from upper left to lower right	$+/-$	$]180, 270[$
from left to right	$+/0$	270
from lower left to upper right	$+/+$	$]270, 360[$

Points with edge amplitude 0 are assigned the edge direction 255 (undefined direction).

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Input image.
- ▷ **`ImageEdgeAmp`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Edge amplitude (gradient magnitude) image.
- ▷ **`ImageEdgeDir`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* direction
  Edge direction image.

Example

```
read_image(Image,'fabrik')
prewitt_dir(Image,PrewittA,PrewittD)
threshold(PrewittA,Edges,128,255)
```

Result

`prewitt_dir` always returns 2 (`H_MSG_TRUE`). If the input is empty the behavior can be set via `set_system ('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

roberts (Image : ImageRoberts : FilterType :)

Detect edges using the Roberts filter.

roberts calculates the first derivative of an image and is used as an edge operator. If the following mask describes a part of the image,

$$\begin{array}{cc} A & B \\ C & D \end{array}$$

the different filter types are defined as follows:

'roberts_max'	$max(\|A-D\|, \|B-C\|)$
'gradient_max'	$max(\|A+B-(C+D)\|, \|A+C-(B+D)\|)$
'gradient_sum'	$\|A+B-(C+D)\| + \|A+C-(B+D)\|$

If an overflow occurs the result is clipped. The result of the operator is stored at the pixel with the coordinates of "D".

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Input image.
- ▷ **ImageRoberts** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Roberts-filtered result images.
- ▷ **FilterType** (input_control) ..... string ⇝ *string*
  Filter type.
  Default: 'gradient_sum'
  List of values: FilterType ∈ {'roberts_max', 'gradient_max', 'gradient_sum'}

Example

```
read_image(Image,'fabrik')
roberts(Image,Roberts,'roberts_max')
threshold(Roberts,Margin,128,255)
```

Result

roberts returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

robinson_amp (Image : ImageEdgeAmp : :)

Detect edges (amplitude) using the Robinson operator.

robinson_amp calculates an approximation of the first derivative of the image data and is used as an edge detector. In robinson_amp the following four of the originally proposed eight 3×3 filter masks are convolved with the image. The other four masks are obtained by a multiplication by -1. All masks contain only the values 0,1,-1,2,-2.

$$\begin{matrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{matrix}$$

$$\begin{matrix} 2 & 1 & 0 \\ 1 & 0 & -1 \\ 0 & -1 & -2 \end{matrix}$$

$$\begin{matrix} 0 & 1 & 2 \\ -1 & 0 & 1 \\ -2 & -1 & 0 \end{matrix}$$

$$\begin{matrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{matrix}$$

The result image contains the maximum response of all masks.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Input image.

▷ **ImageEdgeAmp** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Edge amplitude (gradient magnitude) image.

Example

```
read_image(Image,'fabrik')
robinson_amp(Image,Robinson_amp)
threshold(Robinson_amp,Edges,128,255)
```

Result

`robinson_amp` always returns `2` (`H_MSG_TRUE`). If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

sobel_amp (Image : EdgeAmplitude : FilterType, Size :)

Detect edges (amplitude) using the Sobel operator.

`sobel_amp` calculates first derivative of an image and is used as an edge detector. The filter is based on the following filter masks:

$$A = \begin{matrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{matrix}$$

$$B = \begin{matrix} 1 & 0 & -1 \\ 2 & 0 & -2 \\ 1 & 0 & -1 \end{matrix}$$

These masks are used differently, according to the selected filter type. (In the following, a and b denote the results of convolving an image with A and B for one particular pixel.)

$'sum\_sqrt'$	$\sqrt{a^2+b^2}/4$
$'sum\_abs'$	$(\|a\|+\|b\|)/4$
$'thin\_sum\_abs'$	$(thin(\|a\|)+thin(\|b\|))/4$
$'thin\_max\_abs'$	$max(thin(\|a\|),thin(\|b\|))/4$
$'x'$	$b/4$ (b for `real` images)
$'y'$	$a/4$ (a for `real` images)

Here, $thin(x)$ is equal to x for a vertical maximum (mask A) and a horizontal maximum (mask B), respectively, and 0 otherwise. Thus, for *'thin_sum_abs'* and *'thin_max_abs'* the gradient image is thinned. For the filter types *'x'* and *'y'* if the input image is of type byte the output image is of type int1, of type int2 otherwise. For a Sobel operator with size 3×3, the corresponding filters A and B are applied directly, while for larger filter sizes the input image is first smoothed using a Gaussian filter (see `gauss_image`) or a binomial filter (see `binomial_filter`) of size `Size`-2. The Gaussian filter is selected for the above values of `FilterType`. Here, `Size` = 5, 7, 9, 11, or 13 must be used. The binomial filter is selected by appending *'_binomial'* to the above values of `FilterType`. Here, `Size` can be selected between 5 and 39. Furthermore, it is possible to select different amounts of smoothing the column and row direction by passing two values in `Size`. Here, the first value of `Size` corresponds to the mask width (smoothing in the column direction), while the second value corresponds to the mask height (smoothing in the row direction) of the binomial filter. The binomial filter can only be used for images of type byte, uint2 and real. Since smoothing reduces the edge amplitudes, in this case the edge amplitudes are multiplied by a factor of 2 to prevent information loss. Therefore,

```
sobel_amp(I,E,FilterType,S)
```

for `Size` > 3 is conceptually equivalent to

```
scale_image(I,F,2,0)
gauss_image(F,G,S-2)
sobel_amp(G,E,FilterType,3)
```

or to

```
scale_image(I,F,2,0)
binomial_filter(F,G,S[0]-2,S[1]-2)
sobel_amp(G,E,FilterType,3).
```

For `sobel_amp` special optimizations are implemented `FilterType` $= 'sum\_abs'$ that use SIMD technology. The actual application of these special optimizations is controlled by the system parameter *'sse2_enable'* and *'avx2_enable'*, respectively (see `set_system`). If *'sse2_enable'* or *'avx2_enable'*is set to *'true'* (and the SIMD instruction set is available), the internal calculations are performed using SIMD technology. Note that SIMD technology performs best on large, compact input regions. Depending on the input region and the capabilities of the hardware the execution of `sobel_amp` might even take significantly more time with SIMD technology than without.

`sobel_amp` can be executed on OpenCL devices for the filter types *'sum_abs'*, *'sum_sqrt'*, *'x'* and *'y'* (as well as their binomial variants). Note that when using gaussian filtering for `Size` > 3, the results can vary from the CPU implementation.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Input image.
- ▷ **`EdgeAmplitude`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* int1 / int2 / uint2 / real
  Edge amplitude (gradient magnitude) image.

▷ **FilterType** (input_control) . . . . . string ⇝ *string*
Filter type.
Default: 'sum_abs'
List of values: FilterType ∈ {'sum_abs', 'thin_sum_abs', 'thin_max_abs', 'sum_sqrt', 'x', 'y', 'sum_abs_binomial', 'thin_sum_abs_binomial', 'thin_max_abs_binomial', 'sum_sqrt_binomial', 'x_binomial', 'y_binomial'}

▷ **Size** (input_control) . . . . . integer(-array) ⇝ *integer*
Size of filter mask.
Default: 3
List of values: Size ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39}

Example

```
read_image(Image,'fabrik')
sobel_amp(Image,Amp,'sum_abs',3)
threshold(Amp,Edg,128,255)
```

Result

sobel_amp returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

sobel_dir (Image : EdgeAmplitude, EdgeDirection : FilterType, Size :)

Detect edges (amplitude and direction) using the Sobel operator.

sobel_dir calculates first derivative of an image and is used as an edge detector. The filter is based on the following filter masks:

$$A = \begin{matrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{matrix}$$

$$B = \begin{matrix} 1 & 0 & -1 \\ 2 & 0 & -2 \\ 1 & 0 & -1 \end{matrix}$$

These masks are used differently, according to the selected filter type. (In the following, a and b denote the results of convolving an image with A and B for one particular pixel.)

- *'sum_sqrt'*: $\sqrt{a^2 + b^2}/4$
- *'sum_abs'*: $(|a| + |b|)/4$

For a Sobel operator with size 3×3, the corresponding filters A and B are applied directly, while for larger filter sizes the input image is first smoothed using a Gaussian filter (see `gauss_image`) or a binomial filter (see `binomial_filter`) of size `Size`-2. The Gaussian filter is selected for the above values of `FilterType`. Here, `Size` = 5, 7, 9, 11, or 13 must be used. The binomial filter is selected by appending *'_binomial'* to the above values of `FilterType`. Here, `Size` can be selected between 5 and 39. Furthermore, it is possible to select different amounts of smoothing the column and row direction by passing two values in `Size`. Here, the first value of `Size` corresponds to the mask width (smoothing in the column direction), while the second value corresponds to the mask height (smoothing in the row direction) of the binomial filter. The binomial filter can only be used for images of type byte, uint2 and real. Since smoothing reduces the edge amplitudes, in this case the edge amplitudes are multiplied by a factor of 2 to prevent information loss. Therefore,

```
sobel_dir(I,Amp,Dir,FilterType,S)
```

for `Size` $>$ *3* is conceptually equivalent to

```
scale_image(I,F,2,0)
gauss_image(F,G,S-2)
sobel_dir(G,Amp,Dir,FilterType,3)
```

or to

```
scale_image(I,F,2,0)
binomial_filter(F,G,S[0]-2,S[1]-2)
sobel_dir(G,Amp,Dir,FilterType,3).
```

The edge directions are returned in `EdgeDirection`, and are stored in 2-degree steps, i.e., an edge direction of x degrees in mathematically positive sense and with respect to the horizontal axis is stored as $x/2$ in the edge direction image. Furthermore, the direction of the change of intensity is taken into account. Let $[E_x, E_y]$ denote the image gradient. Then the following edge directions r are returned as $r/2$:

intensity increase	E_x/E_y	**edge direction** r **[deg]**
from bottom to top	0 / +	0
from lower right to upper left	- / +	]0,90[
from right to left	- / 0	90
from upper right to lower left	- / -	]90,180[
from top to bottom	0 / -	180
from upper left to lower right	+ / -	]180,270[
from left to right	+ / 0	270
from lower left to upper right	+ / +	]270,360[.

Points with edge amplitude 0 are assigned the edge direction 255 (undefined direction).

`sobel_amp` can be executed on OpenCL devices. Note that when using gaussian filtering for `Size` $>$ 3, the results can vary from the CPU implementation.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Input image.

▷ **`EdgeAmplitude`** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Edge amplitude (gradient magnitude) image.

▷ **EdgeDirection** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* direction
Edge direction image.

▷ **FilterType** (input_control) . . . . . string ⇝ *string*
Filter type.
Default: 'sum_abs'
List of values: FilterType ∈ {'sum_abs', 'sum_sqrt', 'sum_abs_binomial', 'sum_sqrt_binomial'}

▷ **Size** (input_control) . . . . . integer(-array) ⇝ *integer*
Size of filter mask.
Default: 3
List of values: Size ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39}

Example

```
read_image(Image,'fabrik')
sobel_dir(Image,Amp,Dir,'sum_abs',3)
threshold(Amp,Edg,128,255)
```

Result

sobel_dir returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

12.5 Enhancement

coherence_enhancing_diff (Image : ImageCED : Sigma, Rho, Theta, Iterations :)

Perform a coherence enhancing diffusion of an image.

The operator coherence_enhancing_diff performs an anisotropic diffusion process on the input image Image to increase the coherence of the image structures contained in Image. In particular, noncontinuous image edges are connected by diffusion, without being smoothed perpendicular to their dominating direction. For this, coherence_enhancing_diff uses the anisotropic diffusion equation

$$u_t = div(G(u)\nabla u)$$

formulated by Weickert. With a 2×2 coefficient matrix G that depends on the gray values in Image, this is an enhancement of the mean curvature flow or intrinsic heat equation

$$u_t = div(\frac{\nabla u}{|\nabla u|})|\nabla u| = curv(u)|\nabla u|$$

on the gray value function u defined by the input image Image at a time $t_0 = 0$. The smoothing operator mean_curvature_flow is a direct application of the mean curvature flow equation. The discrete diffusion equation is solved in Iterations time steps of length Theta, so that the output image ImageCED contains the gray value function at the time Iterations · Theta.

To detect the edge direction more robustly, in particular on noisy input data, an additional isotropic smoothing step can precede the computation of the gray value gradients. The parameter Sigma determines the magnitude of the smoothing by means of the standard deviation of a corresponding Gaussian convolution kernel, as used in the operator isotropic_diffusion for isotropic image smoothing.

While the matrix G is given by

$$G_{MCF}(u) = I - \frac{1}{|\nabla u|^2}\nabla u(\nabla u)^T,$$

in the case of the operator mean_curvature_flow, where I denotes the unit matrix, G_{MCF} is again smoothed componentwise by a Gaussian filter of standard deviation Rho for coherence_enhancing_diff. Then, the final coefficient matrix

$$G_{CED} = g_1\left((\lambda_1 - \lambda_2)^2\right) w_1(w_1)^T + g_2\left((\lambda_1 - \lambda_2)^2\right) w_2(w_2)^T$$

is constructed from the eigenvalues λ_1, λ_2 and eigenvectors w_1, w_2 of the resulting intermediate matrix, where the functions

$$\begin{aligned} g_1(p) &= 0.001 \\ g_2(p) &= 0.001 + 0.999 \exp\left(\frac{-1}{p}\right) \end{aligned}$$

were determined empirically and taken from the publication of Weickert.

Hence, the diffusion direction in mean_curvature_flow is only determined by the local direction of the gray value gradient, while G_{CED} considers the macroscopic structure of the image objects on the scale Rho and the magnitude of the diffusion in coherence_enhancing_diff depends on how well this structure is defined.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **ImageCED** (output_object) . . . . . image(-array) ⇝ *object :* byte / uint2 / real
Output image.

▷ **Sigma** (input_control) . . . . . real ⇝ *real*
Smoothing for derivative operator.
Default: 0.5
Suggested values: Sigma ∈ {0.0, 0.1, 0.5, 1.0}
Restriction: Sigma >= 0

▷ **Rho** (input_control) . . . . . real ⇝ *real*
Smoothing for diffusion coefficients.
Default: 3.0
Suggested values: Rho ∈ {0.0, 1.0, 3.0, 5.0, 10.0, 30.0}
Restriction: Rho >= 0

▷ **Theta** (input_control) . . . . . real ⇝ *real*
Time step.
Default: 0.5
Suggested values: Theta ∈ {0.1, 0.2, 0.3, 0.4, 0.5}
Restriction: 0 < Theta <= 0.5

▷ **Iterations** (input_control) . . . . . integer ⇝ *integer*
Number of iterations.
Default: 10
Suggested values: Iterations ∈ {1, 5, 10, 20, 50, 100, 500}
Restriction: Iterations >= 1

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Module

Foundation

emphasize (Image : ImageEmphasize : MaskWidth, MaskHeight, Factor :)

Enhance contrast of the image.

The operator emphasize emphasizes high frequency areas of the image (edges and corners). The resulting images appears sharper.

First the procedure carries out a filtering with the low pass (mean_image). The resulting gray values (res) are calculated from the obtained gray values ($mean$) and the original gray values ($orig$) as follows:

$$res := round((orig - mean) * \texttt{Factor}) + orig$$

Factor serves as measurement of the increase in contrast. The division frequency is determined via the size of the filter matrix: The larger the matrix, the lower the division frequency.

As an edge treatment the gray values are mirrored at the edges of the image. Overflow and/or underflow of gray values is clipped.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Image to be enhanced.

▷ **ImageEmphasize** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
contrast enhanced image.

▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *integer*
Width of low pass mask.
Default: 7
Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 15, 21, 25, 31, 39}
Value range: 3 ≤ MaskWidth
Minimum increment: 2
Recommended increment: 2

▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
Height of the low pass mask.
Default: 7
Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 15, 21, 25, 31, 39}
Value range: 3 ≤ MaskHeight
Minimum increment: 2
Recommended increment: 2

▷ **Factor** (input_control) . . . . . real ⇝ *real*
Intensity of contrast emphasis.
Default: 1.0
Suggested values: Factor ∈ {0.3, 0.5, 0.7, 1.0, 1.4, 1.8, 2.0}
Value range: 0.0 ≤ Factor (sqrt)
Recommended increment: 0.2

Example

```
read_image(Image,'mreut')
dev_display (Image)
draw_region(Region,WindowHandle)
reduce_domain(Image,Region,Mask)
emphasize(Mask,Sharp,7,7,2.0)
dev_display (Sharp)
```

Result

If the parameter values are correct the operator emphasize returns the value 2 (H_MSG_TRUE) The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

equu_histo_image (Image : ImageEquHisto : :)

Histogram linearization of images

The operator equ_histo_image enhances the contrast. The starting point is the histogram of the input images. The following simple gray value transformation $f(g)$ is carried out for byte images:

$$f(g) = 255 \sum_{x=0\ldots g} h(x)$$

$h(x)$ describes the relative frequency of the occurrence of the gray value x. For uint2 images, the only difference is that the value 255 is replaced with a different maximum value. The maximum value is computed from the number of significant bits stored with the input image, provided that this value is set. If not, the value of the system parameter *'int2_bits'* is used (see set_system), if this value is set (i.e., different from -1). If none of the two values is set, the number of significant bits is set to 16.

This transformation linearizes the cumulative histogram. Maxima in the original histogram are "spreaded" and thus the contrast in image regions with these frequently occurring gray values is increased. Supposedly homogeneous regions receive more easily visible structures. On the other hand, of course, the noise in the image increases correspondingly. Minima in the original histogram are dually "compressed". The transformed histogram contains gaps, but the remaining gray values used occur approximately at the same frequency ("histogram equalization").

Attention

The operator equ_histo_image primarily serves for optical processing of images for a human viewer. For example, the (local) contrast spreading can lead to a detection of fictitious edges.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
  Image to be enhanced.
- ▷ **ImageEquHisto** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
  Image with linearized gray values.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Possible Successors

equ_histo_image_rect (Image : ImageEquHisto : Mode, MaskWidth, MaskHeight, MaxContrast :)

Histogram linearization within a rectangluar mask.

The operator equ_histo_image_rect enhances the contrast. Similar to equ_histo_image, it applies a transformation to linearize the cumulative histogram. However, instead of using the histogram of the whole image, only the local neighborhood of each pixel is considered to compute the transformation. The size of this rectangular neighborhood region can be set by MaskWidth and MaskHeight.

The local contrast maximization improves the visibility of low-contrast structures, but also amplifies noise. The parameter MaxContrast can be used to limit the maximum contrast in a local neighborhood, which effectively reduces the amplification of noise. Therefore, the method is also known as Contrast-Limited Adaptive Histogram Equalization (CLAHE).

The parameter Mode determines the processing mode. In the *'accurate'* mode, the transformation is computed for each pixel as described above. In the *'fast'* mode, the transformation is computed only for a subset of all pixels and interpolated between those points. Due to the interpolation, the results of both modes can differ significantly.

Attention

The operator equ_histo_image_rect primarily serves for optical processing of images for a human viewer. For example, the contrast spreading can lead to a detection of fictitious edges.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte
  Image to be enhanced.
- ▷ **ImageEquHisto** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte
  Image with linearized gray values.
- ▷ **Mode** (input_control) . . . . . string ⇝ *string*
  Processing mode.
  Default: 'accurate'
  Suggested values: Mode ∈ {'accurate', 'fast'}
- ▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *integer*
  Width of the filter mask.
  Default: 51
  Suggested values: MaskWidth ∈ {31, 51, 101, 151}
  Value range: 1 ≤ MaskWidth
  Minimum increment: 2
  Restriction: MaskWidth <= width(Image)
- ▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
  Height of the filter mask.
  Default: 51
  Suggested values: MaskHeight ∈ {31, 51, 101, 151}
  Value range: 1 ≤ MaskHeight
  Minimum increment: 2
  Restriction: MaskHeight <= height(Image)
- ▷ **MaxContrast** (input_control) . . . . . real ⇝ *real* / integer
  Maximum contrast.
  Default: 0.01
  Suggested values: MaxContrast ∈ {0, 0.01, 0.02, 0.05, 0.1, 0.5, 1}
  Value range: 0 ≤ MaxContrast ≤ 1

Complexity

In Mode='*accurate*', equ_histo_image_rect uses an algorithm with constant complexity per pixel, i.e., the runtime only depends on the size of the input image and not on the mask size.

In Mode='*fast*', the number of histograms to be computed depends on the mask size. Hence, the runtime increases with smaller mask sizes and decreases with larger mask sizes.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

illuminate (Image : ImageIlluminate : MaskWidth, MaskHeight, Factor :)

Illuminate image.

The operator illuminate enhances contrast. Very dark parts of the image are "illuminated" more strongly, very light ones are "darkened". If $orig$ is the original gray value and $mean$ is the corresponding gray value of the low pass filtered image detected via the operators mean_image and filter size MaskHeight x MaskWidth. For byte-images val equals 127, for int2-images and uint2-images val equals the median value. The resulting gray value is new:

$$new := round((val - mean) * \texttt{Factor} + orig)$$

The low pass should have rather large dimensions (30 x 30 to 200 x 200). Reasonable parameter combinations might be:

MaskHeight	MaskWidth	Factor
40	40	0.55
100	100	0.7
150	150	0.8

i.e. the larger the low pass mask is chosen, the larger Factor should be as well.

The following "spotlight effect" should be noted: If, for example, a dark object is in front of a light wall the object as well as the wall, which is already light in the immediate proximity of the object contours, are lightened by the operator illuminate. This corresponds roughly to the effect that is produced when the object is illuminated by a strong spotlight. The same applies to light objects in front of a darker background. In this case, however, the fictitious "spotlight" darkens objects.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Image to be enhanced.

▷ **ImageIlluminate** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
"Illuminated" image.

▷ **MaskWidth** (input_control) ..... extent.x ⇝ *integer*
Width of low pass mask.
Default: 101
Suggested values: MaskWidth ∈ {31, 41, 51, 71, 101, 121, 151, 201}
Minimum increment: 2
Recommended increment: 10
Restriction: MaskWidth < width(Image) * 2

▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
Height of low pass mask.
Default: 101
Suggested values: MaskHeight ∈ {31, 41, 51, 71, 101, 121, 151, 201}
Minimum increment: 2
Recommended increment: 10
Restriction: MaskHeight < height(Image) * 2

▷ **Factor** (input_control) . . . . . real ⇝ *real*
Scales the "correction gray value" added to the original gray values.
Default: 0.7
Suggested values: Factor ∈ {0.3, 0.5, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0}
Value range: 0.0 ≤ Factor
Minimum increment: 0.01
Recommended increment: 0.2

Example

```
read_image(Image,'fabrik')
dev_display (Image)
illuminate(Image,Better,40,40,0.55)
dev_display (Better)
```

Result

If the parameter values are correct the operator illuminate returns the value 2 (H_MSG_TRUE) The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

mean_curvature_flow (Image : ImageMCF : Sigma, Theta, Iterations :)

Apply the mean curvature flow to an image.

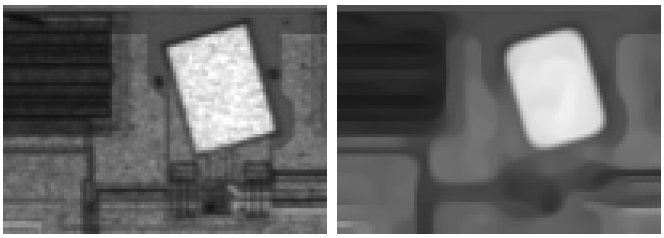
The operator mean_curvature_flow applies the mean curvature flow or intrinsic heat equatio

$$u_t = div(\frac{\nabla u}{|\nabla u|})|\nabla u| = curv(u)|\nabla u|$$

to the gray value function u defined by the input image Image at a time $t_0 = 0$. The discretized equation is solved in Iterations time steps of length Theta, so that the output image contains the gray value function at the time Iterations · Theta.

The mean curvature flow causes a smoothing of Image in the direction of the edges in the image, i.e. along the contour lines of u, while perpendicular to the edge direction no smoothing is performed and hence the boundaries of image objects are not smoothed. To detect the image direction more robustly, in particular on noisy input data, an additional isotropic smoothing step can precede the computation of the gray value gradients. The parameter Sigma determines the magnitude of the smoothing by means of the standard deviation of a corresponding Gaussian convolution kernel, as used in the operator isotropic_diffusion for isotropic image smoothing.

The following images show the effect of the parameters Sigma, Theta, and Iterations. First, the input image is shown together with the result that is achieved if all parameters are set to their default values.

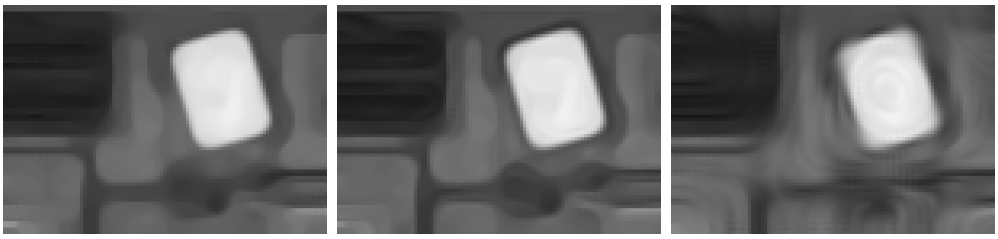


(1) (2)

(1) Input image. (2) Result when using the default values.

In the following images, the results are shown that are achieved if one parameter is varied while setting the other two parameters to their default values.

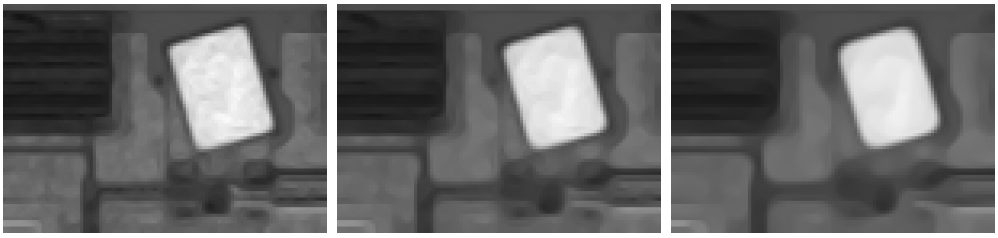
Sigma controls the amount of smoothing, prior to the computation of the gray value gradient. Be careful with very large values for Sigma, because they may lead to undesired effects.



(1) (2) (3)

(1) Sigma = 0.0. (2) Sigma = 1.0. (3) Sigma = 10.0.

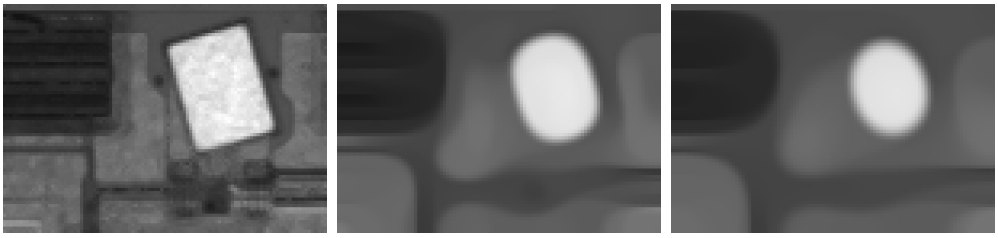
Theta controls the step size during the iterative smoothing process. Larger values lead to a stronger smoothing.



(1) (2) (3)

(1) Theta = 0.1. (2) Theta = 0.2. (3) Theta = 0.4.

Iterations controls the number of iterations that are performed. With an increasing number of iterations, the runtime increases, as well. Furthermore, a large number of iterations may lead to a loss of structure in the smoothed image.



(1) (2) (3)

(1) Iterations = 1. (2) Iterations = 50. (3) Iterations = 100.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **ImageMCF** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
Output image.

▷ **Sigma** (input_control) ..... real ⇝ *real*
Smoothing parameter for derivative operator.
Default: 0.5
Suggested values: `Sigma` ∈ {0.0, 0.1, 0.5, 1.0}
Restriction: Sigma >= 0

▷ **Theta** (input_control) ..... real ⇝ *real*
Time step.
Default: 0.5
Suggested values: `Theta` ∈ {0.1, 0.2, 0.3, 0.4, 0.5}
Restriction: 0 < Theta <= 0.5

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 10
Suggested values: `Iterations` ∈ {1, 5, 10, 20, 50, 100, 500}
Restriction: Iterations >= 1

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

scale_image_max (Image : ImageScaleMax : :)

Maximum gray value spreading in the value range 0 to 255.

The operator `scale_image_max` calculates the minimum and maximum and scales the image to the maximum value range of a byte image. This way the dynamics (value range) is fully exploited. The number of different gray scales does not change, but in general the visual impression is enhanced. The gray values of images of the *'real'*, *'int2'*, *'uint2'*, *'int4'*, and *'int8'* type are scaled to the range *0* to *255* and returned as *'byte'* images.

Attention

The output always is an image of the type *'byte'*.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / int8 / real
Image to be scaled.

▷ **ImageScaleMax** (output_object) . . . . . image(-array) ⇝ *object :* byte
contrast enhanced image.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

shock_filter (Image : SharpenedImage : Theta, Iterations, Mode, Sigma :)

Apply a shock filter to an image.

The operator `shock_filter` applies a shock filter to the input image `Image` to sharpen the edges contained in it. The principle of the shock filter is based on the transport of the gray values of the image towards an edge from both sides through dilation and erosion and satisfies the differential equation

$$u_t = s\,|\nabla u|$$

on the function u defined by the gray values in `Image` at a time $t_0 = 0$. The discretized equation is solved in `Iterations` time steps of length `Theta`, so that the output image `SharpenedImage` contains the gray value function at the time `Iterations` · `Theta`.

The decision between dilation and erosion is made using the sign function $s \in \{-1, 0, +1\}$ on a conventional edge detector. The detector of Canny

$$s = -sgn\left(D^2u(\frac{\nabla u}{|\nabla u|}, \frac{\nabla u}{|\nabla u|})\right)$$

is available with `Mode` $= 'canny'$ and the detector of Marr/Hildreth (the Laplace operator)

$$s = -sgn(\Delta u)$$

can be selected by `Mode` $= 'laplace'$.

To make the edge detection more robust, in particular on noisy images, it can be performed on a smoothed image matrix. This is done by giving the standard deviation of a Gaussian kernel for convolution with the image matrix in the parameter `Sigma`.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **SharpenedImage** (output_object) . . . . . image(-array) ⇝ *object :* byte / uint2 / real
Output image.

▷ **Theta** (input_control) . . . . . real ⇝ *real*
Time step.
Default: 0.5
Suggested values: Theta ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7}
Restriction: 0 < Theta <= 0.7

▷ **Iterations** (input_control) . . . . . integer ⇝ *integer*
Number of iterations.
Default: 10
Suggested values: Iterations ∈ {1, 3, 10, 100}
Restriction: Iterations >= 1

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Type of edge detector.
Default: 'canny'
List of values: Mode ∈ {'laplace', 'canny'}

▷ **Sigma** (input_control) . . . . . real ⇝ *real*
Smoothing of edge detector.
Default: 1.0
Suggested values: Sigma ∈ {0.0, 0.5, 1.0, 2.0, 5.0}
Restriction: Theta >= 0

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

12.6 FFT

convol_fft (ImageFFT, ImageFilter : ImageConvol : :)

Multiply an image with a filter image in the frequency domain.

As part of calculating the convolution of an image with a filter image, convol_fft multiplies the Fourier transform of an image ImageFFT with the Fourier transform of a second image ImageFilter, which serves as the filter.

According to the convolution theorem, the non-normalized convolution of two images in pixel space can be obtained in three steps:

1. Transforming the images into frequency space using a Fourier transform (see, e.g., fft_generic).
2. Multiplying one transformed image with the transformed filter image (pixel-wise).
3. Transforming the result back into pixel space using an inverse Fourier transform (see, e.g., fft_generic).

The operator convol_fft is used to perform the second step, i.e., ImageFFT is pixel-wise multiplied with ImageFilter.

Attention

The filtering is always done on the entire image, i.e., the domain of the image is ignored.

Parameters

- ▷ **ImageFFT** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
  Complex input image.
- ▷ **ImageFilter** (input_object) ..... (multichannel-)image ⇝ *object :* real / complex
  Filter in frequency domain.
- ▷ **ImageConvol** (output_object) ..... image(-array) ⇝ *object :* complex
  Result in the frequency domain.

Example

```
gen_highpass(Highpass,0.2,'n','dc_edge',Width,Height)
fft_generic(Image,ImageFFT,'to_freq',-1,'none','dc_edge','complex')
convol_fft(ImageFFT,Highpass,ImageConvol)
fft_generic(ImageConvol,ImageResult,'from_freq',1,'none','dc_edge','byte')
```

Result

convol_fft returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

convol_gabor (ImageFFT, GaborFilter : ImageResultGabor, ImageResultHilbert : :)

Convolve an image with a Gabor filter in the frequency domain.

convol_gabor convolves a Fourier-transformed image with a Gabor filter GaborFilter (see gen_gabor) and its Hilbert transform in the frequency domain. The result image is of type *'complex'*.

Attention

The filtering is always done on the entire image, i.e., the domain of the image is ignored.

Parameters

- ▷ **ImageFFT** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
  Input image.
- ▷ **GaborFilter** (input_object) ..... multichannel-image ⇝ *object :* real
  Gabor/Hilbert-Filter.
- ▷ **ImageResultGabor** (output_object) ..... image(-array) ⇝ *object :* complex
  Result of the Gabor filter.
- ▷ **ImageResultHilbert** (output_object) ..... image(-array) ⇝ *object :* complex
  Result of the Hilbert filter.

Example

```
gen_gabor(Filter,1.4,0.4,1.0,1.5,'n','dc_edge',512,512)
fft_generic(Image,ImageFFT,'to_freq',-1,'none','dc_edge','complex')
convol_gabor(ImageFFT,Filter,Gabor,Hilbert)
fft_generic(Gabor,GaborInv,'from_freq',1,'none','dc_edge','byte')
fft_generic(Hilbert,HilbertInv,'from_freq',1,'none','dc_edge','byte')
energy_gabor(GaborInv,HilbertInv,Energy)
```

Result

`convol_gabor` returns `2` (`H_MSG_TRUE`) if all images are of correct type. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

correlation_fft (ImageFFT1, ImageFFT2 : ImageCorrelation : :)

Multiply one image with the complex conjugate of another image in the frequency domain.

As part of calculating the correlation between two images, `correlation_fft` multiplies the Fourier transform of the first image `ImageFFT1` with the complex conjugate of the Fourier-transformed second image `ImageFFT2`.

According to the correlation theorem, the non-normalized correlation of two images in pixel space can be obtained in three steps:

1. Transforming the images into frequency space using a Fourier transform (see, e.g., `fft_generic`).
2. Multiplying one transformed image with the complex conjugate of the other transformed image (pixel-wise).
3. Transforming the result back into pixel space using an inverse Fourier transform (see, e.g., `fft_generic`).

The operator correlation_fft is used to perform the second step, i.e., ImageFFT1 is pixel-wise multiplied with the complex conjugate of ImageFFT2.

It should be noted that in order to achieve a correct scaling of the correlation in the spatial domain, the operators fft_generic or rft_generic with Norm = *'none'* must be used for the forward transform (step 1) and fft_generic or rft_generic with Norm = *'n'* for the reverse transform (step 3). If ImageFFT1 and ImageFFT2 contain the same number of images, the corresponding images are multiplied pairwise. Otherwise, ImageFFT2 must contain only one single image. In this case, the multiplication is performed for each image of ImageFFT1 with ImageFFT2.

Attention

The filtering is always performed on the entire image, i.e., the domain of the image is ignored.

Parameters

- ▷ **ImageFFT1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
  Fourier-transformed input image 1.
- ▷ **ImageFFT2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
  Fourier-transformed input image 2.
  Number of elements: ImageFFT2 == ImageFFT1 || ImageFFT2 == 1
- ▷ **ImageCorrelation** (output_object) ..... image(-array) ⇝ *object :* complex
  Result in the frequency domain.

Example

```
* Compute the auto-correlation of an image.
get_image_size(Image,Width,Height)
rft_generic(Image,ImageFFT,'to_freq','none','complex',Width)
correlation_fft(ImageFFT,ImageFFT,Correlation)
rft_generic(Correlation,AutoCorrelation,'from_freq','n','real',Width)
```

Result

correlation_fft returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

deserialize_fft_optimization_data (: : SerializedItemHandle :)

Deserialize FFT speed optimization data.

deserialize_fft_optimization_data deserializes data, that was serialized by serialize_fft_optimization_data, for optimizing the runtime of the FFT (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized data is defined by the handle SerializedItemHandle. The optimization data must

have been determined previously with optimize_fft_speed and must have been serialized with serialize_fft_optimization_data. If the serialized data has been determined for the image sizes to be used in the application, calling optimize_fft_speed is unnecessary. Note that the data should only be used on the same machine on which they were determined with optimize_fft_speed. Otherwise, the runtimes will not be optimal. Also note that optimization data that were created with Standard HALCON cannot be used with Parallel HALCON and vice versa.

deserialize_fft_optimization_data influences the runtime of the following operators, which use the FFT: fft_generic, fft_image, fft_image_inv, sfs_pentland, sfs_mod_lr, sfs_orig_lrwiener_filter.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

deserialize_fft_optimization_data returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

energy_gabor (ImageGabor, ImageHilbert : Energy : :)

Calculate the energy of a two-channel image.

energy_gabor calculates the local contrast (Energy) of the two input images. The energy of the resulting image is then defined as

$$\text{Energy} = \text{channel1}^2 + \text{channel2}^2 \ .$$

Often the calculation of the energy is preceded by the convolution of an image with a Gabor filter and the Hilbert transform of the Gabor filter (see convol_gabor). In this case, the first channel of the image passed to energy_gabor is the Gabor-filtered image, transformed back into the spatial domain (see fft_image_inv), and the second channel the result of the convolution with the Hilbert transform, also transformed back into the spatial domain. The local energy is a measure for the local contrast of structures (e.g., edges and lines) in the image.

Parameters

▷ **ImageGabor** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / real
1st channel of input image (usually: Gabor image).

▷ **ImageHilbert** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / real
2nd channel of input image (usually: Hilbert image).

▷ **Energy** (output_object) ..... image(-array) ⇝ *object :* real
Image containing the local energy.

Example

```
fft_image(Image,&FFT);
gen_gabor(&Filter,1.4,0.4,1.0,1.5,512);
convol_gabor(FFT,Filter,&Gabor,&Hilbert);
fft_image_inv(Gabor,&GaborInv);
fft_image_inv(Hilbert,&HilbertInv);
energy_gabor(GaborInv,HilbertInv,&Energy);
```

Result

`energy_gabor` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Predecessors

fft_generic (Image : ImageFFT : Direction, Exponent, Norm, Mode, ResultType :)

Compute the fast Fourier transform of an image.

`fft_generic` computes the fast Fourier transform of the input image `Image`. Because several definitions of the forward and reverse transforms exist in the literature, this operator allows the user to select the most convenient definition.

The general definition of a Fourier transform is as follows:

$$F(m,n) = \frac{1}{c} \sum_{k=0}^{M-1} \sum_{l=0}^{N-1} e^{s2\pi i(km/M+ln/N)} f(k,l)$$

Opinions vary on whether the sign s in the exponent should be set to 1 or -1 for the forward transform, i.e., the transform for going to the frequency domain. There is also disagreement on the magnitude of the normalizing factor c. This is sometimes set to 1 for the forward transform, sometimes to MN, and sometimes (in case of the unitary FFT) to $\sqrt{MN}$. Especially in image processing applications the DC term is shifted to the center of the image.

`fft_generic` allows to select these choices individually. The parameter `Direction` allows to select the logical direction of the FFT. (This parameter is not unnecessary; it is needed to discern how to shift the image if the DC term should rest in the center of the image.) Possible values are *'to_freq'* and *'from_freq'*. The parameter

Exponent is used to determine the sign of the exponent. It can be set to 1 or -1. The normalizing factor can be set with Norm, and can take on the values *'none'*, *'sqrt'* and *'n'*. The parameter Mode determines the location of the DC term of the FFT. It can be set to *'dc_center'* or *'dc_edge'*.

In any case, the user must ensure the consistent use of the parameters. This means that the normalizing factors used for the forward and backward transform must yield MN when multiplied, the exponents must be of opposite sign, and Mode must be equal for both transforms.

A consistent combination is, for example *'(to_freq,-1,n,dc_edge)'* for the forward transform and *'(from_freq,1,none,dc_edge)'* for the reverse transform. In this case, the FFT can be interpreted as interpolation with trigonometric basis functions. Another possible combination is *'(to_freq,-1,sqrt,dc_center)'* and *'(from_freq,1,sqrt,dc_center)'*.

The parameter ResultType can be used to specify the result image type of the reverse transform (Direction = *'from_freq'*). In the forward transform (Direction = *'to_freq'*), ResultType must be set to *'complex'*.

Attention

The transformation is always performed for the entire image, i.e., the domain of the image is ignored.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex

Input image.

▷ **ImageFFT** (output_object) ..... image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex

Fourier-transformed image.

▷ **Direction** (input_control) ..... string ⇝ *string*

Calculate forward or reverse transform.
Default: 'to_freq'
List of values: Direction ∈ {'to_freq', 'from_freq'}

▷ **Exponent** (input_control) ..... integer ⇝ *integer*

Sign of the exponent.
Default: -1
List of values: Exponent ∈ {-1, 1}

▷ **Norm** (input_control) ..... string ⇝ *string*

Normalizing factor of the transform.
Default: 'sqrt'
List of values: Norm ∈ {'none', 'sqrt', 'n'}

▷ **Mode** (input_control) ..... string ⇝ *string*

Location of the DC term in the frequency domain.
Default: 'dc_center'
List of values: Mode ∈ {'dc_center', 'dc_edge'}

▷ **ResultType** (input_control) ..... string ⇝ *string*

Image type of the output image.
Default: 'complex'
List of values: ResultType ∈ {'complex', 'byte', 'int1', 'int2', 'uint2', 'int4', 'real', 'direction', 'cyclic'}

Example

```
/* simulation of fft_image */
void my_fft(Hobject In, Hobject *Out)
{
  fft_generic(In,Out,"to_freq",-1,"sqrt","dc_center","complex");
}

/* simulation of fft_image_inv */
void my_fft_image_inv(Hobject In, Hobject *Out)
{
  fft_generic(In,Out,"from_freq",1,"sqrt","dc_center","byte");
}
```

Result

`fft_generic` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system(::'no_object_result',<Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

fft_image (Image : ImageFFT : :)

Compute the fast Fourier transform of an image.

`fft_image` calculates the Fourier transform of the input image (`Image`), i.e., it transforms the image into the frequency domain. The algorithm used is the fast Fourier transform. This corresponds to the call `fft_generic(Image,ImageFFT,'to_freq',-1,'sqrt','dc_center','complex')`.

Attention

The transformation is always performed for the entire image, i.e., the domain of the image is ignored.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / real
Input image.

▷ **ImageFFT** (output_object) . . . . . image(-array) ⇝ *object :* complex
Fourier-transformed image.

Result

`fft_image` returns `2` (`H_MSG_TRUE`) if the input image is of correct type. If the input is empty the behavior can be set via `set_system(::'no_object_result',<Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

gen_bandfilter (: ImageFilter : MinFrequency, MaxFrequency, Norm, Mode, Width, Height :)

Generate an ideal band filter.

gen_bandfilter generates an ideal band filter in the frequency domain. The parameters MinFrequency and MaxFrequency determine the cutoff frequencies of the filter as a fraction of the maximum (horizontal and

vertical) frequency that can be represented in an image of size Width × Height, i.e., MinFrequency and MaxFrequency should lie between 0 and 1. To achieve a maximum overall efficiency of the filtering operation, the parameter Norm can be used to specify the normalization factor of the filter. If fft_generic and Norm = *'n'* is used the normalization in the FFT can be avoided. Mode can be used to determine where the DC term of the filter lies or whether the filter should be used in the real-valued FFT. If fft_generic is used, *'dc_edge'* can be used to gain efficiency. If fft_image and fft_image_inv are used for filtering, Norm = *'none'* and Mode = *'dc_center'* must be used. If rft_generic is used, Mode = *'rft'* must be used. The resulting image contains an annulus with the value 0, and a value determined by the normalization outside of this annulus.

Parameters

▷ **ImageFilter** (output_object) ..... image ⇝ *object :* real
Band filter in the frequency domain.

▷ **MinFrequency** (input_control) ..... real ⇝ *real*
Minimum frequency.
Default: 0.1
Suggested values: MinFrequency ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: MinFrequency >= 0

▷ **MaxFrequency** (input_control) ..... real ⇝ *real*
Maximum frequency.
Default: 0.2
Suggested values: MaxFrequency ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: MaxFrequency >= 0 && MaxFrequency >= MinFrequency

▷ **Norm** (input_control) ..... string ⇝ *string*
Normalizing factor of the filter.
Default: 'none'
List of values: Norm ∈ {'none', 'n'}

▷ **Mode** (input_control) ..... string ⇝ *string*
Location of the DC term in the frequency domain.
Default: 'dc_center'
List of values: Mode ∈ {'dc_center', 'dc_edge', 'rft'}

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the image (filter).
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}

▷ **Height** (input_control) ..... integer ⇝ *integer*
Height of the image (filter).
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Example

```
* Filtering with maximum efficiency with fft_generic.
gen_bandpass(Bandfilter,0.2,0.4,'n','dc_edge',Width,Height)
fft_generic(Image,ImageFFT,'to_freq',-1,'none','dc_edge','complex')
convol_fft(ImageFFT,Bandfilter,ImageConvol)
fft_generic(ImageConvol,ImageResult,'from_freq',1,'none','dc_edge','byte')
```

Result

gen_bandfilter returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_bandpass (: ImageBandpass : MinFrequency, MaxFrequency, Norm, Mode, Width, Height :)

Generate an ideal bandpass filter.

gen_bandpass generates an ideal bandpass filter in the frequency domain. The parameters MinFrequency and MaxFrequency determine the cutoff frequencies of the filter as a fraction of the maximum (horizontal and vertical) frequency that can be represented in an image of size Width × Height, i.e., MinFrequency and MaxFrequency should lie between 0 and 1. To achieve a maximum overall efficiency of the filtering operation, the parameter Norm can be used to specify the normalization factor of the filter. If fft_generic and Norm = *'n'* is used the normalization in the FFT can be avoided. Mode can be used to determine where the DC term of the filter lies or whether the filter should be used in the real-valued FFT. If fft_generic is used, *'dc_edge'* can be used to gain efficiency. If fft_image and fft_image_inv are used for filtering, Norm = *'none'* and Mode = *'dc_center'* must be used. If rft_generic is used, Mode = *'rft'* must be used. The resulting image contains an annulus with the value 255, and the value 0 outside of this annulus.

Parameters

▷ **ImageBandpass** (output_object) ..... image ⇝ *object :* real
Bandpass filter in the frequency domain.

▷ **MinFrequency** (input_control) ..... real ⇝ *real*
Minimum frequency.
Default: 0.1
Suggested values: MinFrequency ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: MinFrequency >= 0

▷ **MaxFrequency** (input_control) ..... real ⇝ *real*
Maximum frequency.
Default: 0.2
Suggested values: MaxFrequency ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: MaxFrequency >= 0 && MaxFrequency >= MinFrequency

▷ **Norm** (input_control) ..... string ⇝ *string*
Normalizing factor of the filter.
Default: 'none'
List of values: Norm ∈ {'none', 'n'}

▷ **Mode** (input_control) ..... string ⇝ *string*
Location of the DC term in the frequency domain.
Default: 'dc_center'
List of values: Mode ∈ {'dc_center', 'dc_edge', 'rft'}

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the image (filter).
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}

▷ **Height** (input_control) ..... integer ⇝ *integer*
Height of the image (filter).
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Example

```
* Filtering with maximum efficiency with fft_generic.
```

```
gen_bandpass(Bandpass,0.2,0.4,'n','dc_edge',Width,Height)
fft_generic(Image,ImageFFT,'to_freq',-1,'none','dc_edge','complex')
convol_fft(ImageFFT,Bandpass,ImageConvol)
fft_generic(ImageConvol,ImageResult,'from_freq',1,'none','dc_edge','byte')
```

Result

`gen_bandpass` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

gen_derivative_filter (: ImageDerivative : Derivative, Exponent, Norm, Mode, Width, Height :)

Generate a derivative filter in the frequency domain.

`gen_derivative_filter` generates a derivative filter in the frequency domain. The derivative to be computed is determined by `Derivative`. `Exponent` specifies the exponent used in the reverse transform. It must be set to the same value that is used in `fft_generic`. If `fft_image_inv` is used in the reverse transform, `Exponent` = *1* must be used. However, since the derivative image typically contains negative values, `fft_generic` should always be used for the reverse transform. To achieve a maximum overall efficiency of the filtering operation, the parameter `Norm` can be used to specify the normalization factor of the filter. If `fft_generic` and `Norm` = *'n'* is used the normalization in the FFT can be avoided. `Mode` can be used to determine where the DC term of the filter lies or whether the filter should be used in the real-valued FFT. If `fft_generic` is used, *'dc_edge'* can be used to gain efficiency. If `fft_image` and `fft_image_inv` are used for filtering, `Norm` = *'none'* and `Mode` = *'dc_center'* must be used. If `rft_generic` is used, `Mode` = *'rft'* must be used.

Parameters

▷ **ImageDerivative** (output_object) ..... image ⇝ *object : complex*
Derivative filter as image in the frequency domain.

▷ **Derivative** (input_control) ..... string ⇝ *string*
Derivative to be computed.
Default: 'x'
Suggested values: `Derivative` ∈ {'x', 'y', 'xx', 'xy', 'yy', 'xxx', 'xxy', 'xyy', 'yyy'}

▷ **Exponent** (input_control) ..... integer ⇝ *integer*
Exponent used in the reverse transform.
Default: 1
Suggested values: `Exponent` ∈ {-1, 1}

▷ **Norm** (input_control) ..... string ⇝ *string*
Normalizing factor of the filter.
Default: 'none'
List of values: `Norm` ∈ {'none', 'n'}

▷ **Mode** (input_control) ..... string ⇝ *string*
Location of the DC term in the frequency domain.
Default: 'dc_center'
List of values: `Mode` ∈ {'dc_center', 'dc_edge', 'rft'}

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the image (filter).
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}

▷ **Height** (input_control) ..... integer ⇝ *integer*
Height of the image (filter).
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Example

```
* Generate a smoothed derivative filter.
gen_gauss_filter (ImageGauss, Sigma, Sigma, 0, 'n', 'dc_edge', 512, 512)
convert_image_type (ImageGauss, ImageGaussComplex, 'complex')
gen_derivative_filter (ImageDerivX, 'x', 1, 'none', 'dc_edge', 512, 512)
mult_image (ImageGaussComplex, ImageDerivX, ImageDerivXGauss, 1, 0)
* Filter an image with the smoothed derivative filter.
fft_generic (Image, ImageFFT, 'to_freq', -1, 'none', 'dc_edge', 'complex')
convol_fft (ImageFFT, ImageDerivXGauss, Filtered)
fft_generic (Filtered, ImageX, 'from_freq', 1, 'none', 'dc_edge', 'real')
```

Result

gen_derivative_filter returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

gen_filter_mask (: ImageFilter : FilterMask, Scale, Width, Height :)

Store a filter mask in the spatial domain as a real-image.

gen_filter_mask stores a filter mask in the spatial domain as a real-image. The center of the filter mask lies in the center of the resulting image. The parameter Scale determines by which amount the values of the filter mask are multiplied (this results in larger values of the Fourier transform of the filter). The corresponding filter matrix, which is given in FilterMask can be generated either from a file or a tuple. The format of the filter matrix is described with the operator convol_image. Example filter masks can be found in the directory "filter" in the HALCON home directory. This operator is useful for visualizing the frequency response of filter masks (by applying a Fourier transform to the result image of this operator).

Parameters

▷ **ImageFilter** (output_object) . . . . . image ⇝ *object :* real
Filter in the spatial domain.

▷ **FilterMask** (input_control) . . . . . filename.read(-array) ⇝ *string* / integer
Filter mask as file name or tuple.
Default: 'gauss'
Suggested values: FilterMask ∈ {'gauss', 'laplace4', 'laplace8', 'lowpas_3_3', 'lowpas_5_5', 'lowpas_7_7', 'lowpas_9_9', 'sobel_c', 'sobel_l'}

▷ **Scale** (input_control) . . . . . real ⇝ *real*
Scaling factor.
Default: 1.0
Suggested values: Scale ∈ {0.3, 0.5, 0.75, 1.0, 1.25, 1.5, 2.0}
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Width** (input_control) . . . . . integer ⇝ *integer*
Width of the image (filter).
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}

▷ **Height** (input_control) . . . . . integer ⇝ *integer*
Height of the image (filter).
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Example

```
* If the filter should be read from a file:
gen_filter_mask (Filter, 'lowpas_3_3', 1.0, 512, 512)
* If the filter should be directly passed as a tuple:
gen_filter_mask (Filter, [3,3,9,1,1,1,1,1,1,1,1,1], 1.0, 512, 512)
fft_image (Filter, FilterFFT)
dev_set_paint ('3d_plot')
dev_display (FilterFFT)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_gabor (: ImageFilter : Angle, Frequency, Bandwidth, Orientation, Norm, Mode, Width, Height :)

Generate a Gabor filter.

gen_gabor generates a Gabor filter with a user-definable bandpass frequency range and sign for the Hilbert transform. This is done by calculating a symmetrical filter in the frequency domain, which can be adapted by the parameters Angle, Frequency, Bandwidth and Orientation such that a certain frequency band and a certain direction range in the spatial domain is filtered out in the frequency domain.

The parameters Frequency (central frequency = distance from the DC term) and Orientation (direction) determine the center of the filter. Larger values of Frequency result in higher frequencies being passed. A value of 0 for Orientation generates a horizontally oriented "crescent" (the bulge of the crescent points upward). Higher values of Orientation result in the counterclockwise rotation of the crescent.

The parameters Angle and Bandwidth are used to determine the range of frequencies and angles being passed by the filter. The larger Angle is, the smaller the range of angles passed by the filter gets (because the "crescent" gets narrower). The larger Bandwidth is, the smaller the frequency band being passed gets (because the "crescent" gets thinner).

To achieve a maximum overall efficiency of the filtering operation, the parameter Norm can be used to specify the normalization factor of the filter. If fft_generic and Norm = *'n'* is used the normalization in the FFT can be avoided. Mode can be used to determine where the DC term of the filter lies. If fft_generic is used, *'dc_edge'* can be used to gain efficiency. If fft_image and fft_image_inv are used for filtering, Norm = *'none'* and Mode = *'dc_center'* must be used. Note that gen_gabor cannot create a filter that can be used with rft_generic.

The resulting image is a two-channel real-image, containing the Gabor filter in the first channel and the corresponding Hilbert filter in the second channel.

Parameters

▷ **ImageFilter** (output_object) ..... multichannel-image ⇝ *object :* real
Gabor and Hilbert filter.

▷ **Angle** (input_control) ..... real ⇝ *real*
Angle range, inversely proportional to the range of orientations.
Default: 1.4
Suggested values: Angle ∈ {1.0, 1.2, 1.4, 1.6, 2.0, 2.5, 3.0, 5.0, 6.0, 10.0, 20.0, 30.0, 50.0, 70.0, 100.0}
Value range: 1.0 ≤ Angle ≤ 500.0
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Frequency** (input_control) ..... real ⇝ *real*
Distance of the center of the filter to the DC term.
Default: 0.4
Suggested values: Frequency ∈ {0.0, 0.05, 0.1, 0.15, 0.2, 0.25, 0.3, 0.35, 0.4, 0.45, 0.50, 0.55, 0.60, 0.65, 0.699}
Value range: 0.0 ≤ Frequency ≤ 0.7
Minimum increment: 0.00001
Recommended increment: 0.005

▷ **Bandwidth** (input_control) ..... real ⇝ *real*
Bandwidth range, inversely proportional to the range of frequencies being passed.
Default: 1.0
Suggested values: Bandwidth ∈ {0.1, 0.3, 0.7, 1.0, 1.5, 2.0, 3.0, 5.0, 7.0, 10.0, 15.0, 20.0, 30.0, 50.0}
Value range: 0.05 ≤ Bandwidth ≤ 100.0
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Orientation** (input_control) ..... real ⇝ *real*
Angle of the principal orientation.
Default: 1.5
Suggested values: Orientation ∈ {0.0, 0.2, 0.4, 0.6, 0.8, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0, 2.2, 2.4, 2.6, 2.8, 3.0, 3.14}
Value range: 0.0 ≤ Orientation ≤ 3.1416
Minimum increment: 0.0001
Recommended increment: 0.05

▷ **Norm** (input_control) ..... string ⇝ *string*
Normalizing factor of the filter.
Default: 'none'
List of values: Norm ∈ {'none', 'n'}

▷ **Mode** (input_control) ..... string ⇝ *string*
Location of the DC term in the frequency domain.
Default: 'dc_center'
List of values: Mode ∈ {'dc_center', 'dc_edge'}

▷ **Width** (input_control) . . . . . integer ⇝ *integer*
Width of the image (filter).
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}

▷ **Height** (input_control) . . . . . integer ⇝ *integer*
Height of the image (filter).
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Example

```
gen_gabor(Filter,1.4,0.4,1.0,1.5,'n','dc_edge',512,512)
fft_generic(Image,ImageFFT,'to_freq',-1,'none','dc_edge','complex')
convol_gabor(ImageFFT,Filter,Gabor,Hilbert)
fft_generic(Gabor,GaborInv,'from_freq',1,'none','dc_edge','byte')
fft_generic(Hilbert,HilbertInv,'from_freq',1,'none','dc_edge','byte')
energy_gabor(GaborInv,HilbertInv,Energy)
```

Result

gen_gabor returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

gen_gauss_filter (: ImageGauss : Sigma1, Sigma2, Phi, Norm, Mode, Width, Height :)

Generate a Gaussian filter in the frequency domain.

gen_gauss_filter generates a (possibly anisotropic) Gaussian filter in the frequency domain. The standard deviations (i.e., the amount of smoothing) of the Gaussian in the spatial domain are determined by Sigma1 and Sigma2. Sigma1 is the standard deviation in the principal direction of the filter in the spatial domain determined by the angle Phi. To achieve a maximum overall efficiency of the filtering operation, the parameter Norm can be used to specify the normalization factor of the filter. If fft_generic and Norm = *'n'* is used the normalization in the FFT can be avoided. Mode can be used to determine where the DC term of the filter lies or whether the filter should be used in the real-valued FFT. If fft_generic is used, *'dc_edge'* can be used to gain efficiency. If fft_image and fft_image_inv are used for filtering, Norm = *'none'* and Mode = *'dc_center'* must be used. If rft_generic is used, Mode = *'rft'* must be used.

Parameters

▷ **ImageGauss** (output_object) . . . . . image ⇝ *object :* real
Gaussian filter as image in the frequency domain.

▷ **Sigma1** (input_control) . . . . . real ⇝ *real*
Standard deviation of the Gaussian in the principal direction of the filter in the spatial domain.
Default: 1.0
Suggested values: `Sigma1` ∈ {0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0}
Restriction: Sigma1 >= 0

▷ **Sigma2** (input_control) . . . . . real ⇝ *real*
Standard deviation of the Gaussian perpendicular to the principal direction of the filter in the spatial domain.
Default: 1.0
Suggested values: `Sigma2` ∈ {0.7, 0.8, 0.9, 1.0, 1.1, 1.2, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0}
Restriction: Sigma2 >= 0

▷ **Phi** (input_control) . . . . . angle.rad ⇝ *real*
Principal direction of the filter in the spatial domain.
Default: 0.0
Suggested values: `Phi` ∈ {0.0, 0.523599, 0.785398, 1.047198, 1.570796, 2.094395, 2.356194, 2.617994, 3.141593}

▷ **Norm** (input_control) . . . . . string ⇝ *string*
Normalizing factor of the filter.
Default: 'none'
List of values: `Norm` ∈ {'none', 'n'}

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Location of the DC term in the frequency domain.
Default: 'dc_center'
List of values: `Mode` ∈ {'dc_center', 'dc_edge', 'rft'}

▷ **Width** (input_control) . . . . . integer ⇝ *integer*
Width of the image (filter).
Default: 512
Suggested values: `Width` ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}

▷ **Height** (input_control) . . . . . integer ⇝ *integer*
Height of the image (filter).
Default: 512
Suggested values: `Height` ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Example

```
* Generate a smoothed derivative filter.
gen_gauss_filter (ImageGauss, Sigma, Sigma, 0, 'n', 'dc_edge', 512, 512)
convert_image_type (ImageGauss, ImageGaussComplex, 'complex')
gen_derivative_filter (ImageDerivX, 'x', 1, 'none', 'dc_edge', 512, 512)
mult_image (ImageGaussComplex, ImageDerivX, ImageDerivXGauss, 1, 0)
* Filter an image with the smoothed derivative filter.
fft_generic (Image, ImageFFT, 'to_freq', -1, 'none', 'dc_edge', 'complex')
convol_fft (ImageFFT, ImageDerivXGauss, Filtered)
fft_generic (Filtered, ImageX, 'from_freq', 1, 'none', 'dc_edge', 'real')
```

Result

`gen_gauss_filter` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

gen_mean_filter (: ImageMean : MaskShape, Diameter1, Diameter2, Phi, Norm, Mode, Width, Height :)

Generate a mean filter in the frequency domain.

`gen_mean_filter` generates a mean filter in the frequency domain. The shape of the mean filter is determined by `MaskShape`. For `MaskShape` = *'rectangle'*, a rectangular mean filter is generated. For `MaskShape` = *'ellipse'*, an elliptical mean filter is generated. The diameters (i.e., the amount of smoothing) of the mean filter in the spatial domain are determined by `Diameter1` and `Diameter2`. `Diameter1` is the diameter in the principal direction of the filter in the spatial domain determined by the angle `Phi`. To achieve a maximum overall efficiency of the filtering operation, the parameter `Norm` can be used to specify the normalization factor of the filter. If `fft_generic` and `Norm` = *'n'* is used the normalization in the FFT can be avoided. `Mode` can be used to determine where the DC term of the filter lies or whether the filter should be used in the real-valued FFT. If `fft_generic` is used, *'dc_edge'* can be used to gain efficiency. If `fft_image` and `fft_image_inv` are used for filtering, `Norm` = *'none'* and `Mode` = *'dc_center'* must be used. If `rft_generic` is used, `Mode` = *'rft'* must be used.

Parameters

▷ **ImageMean** (output_object) ..... image ⇝ *object :* real
Mean filter as image in the frequency domain.

▷ **MaskShape** (input_control) ..... string ⇝ *string*
Shape of the filter mask in the spatial domain.
Default: 'ellipse'
List of values: `MaskShape` ∈ {'ellipse', 'rectangle'}

▷ **Diameter1** (input_control) ..... real ⇝ *real*
Diameter of the mean filter in the principal direction of the filter in the spatial domain.
Default: 11.0
Suggested values: `Diameter1` ∈ {3.0, 5.0, 7.0, 9.0, 11.0, 15.0, 21.0, 31.0, 51.0}
Restriction: Diameter1 > 0

▷ **Diameter2** (input_control) ..... real ⇝ *real*
Diameter of the mean filter perpendicular to the principal direction of the filter in the spatial domain.
Default: 11.0
Suggested values: `Diameter2` ∈ {3.0, 5.0, 7.0, 9.0, 11.0, 15.0, 21.0, 31.0, 51.0}
Restriction: Diameter2 > 0

▷ **Phi** (input_control) ..... angle.rad ⇝ *real*

gen_sin_bandpass (: ImageFilter : Frequency, Norm, Mode, Width, Height :)

Generate a bandpass filter with sinusoidal shape.

gen_sin_bandpass generates a rotationally invariant bandpass filter with the response being a sinusoidal function in the frequency domain. The maximum of the sine is determined by Frequency, which is given as a fraction

of the maximum (horizontal and vertical) frequency that can be represented in an image of size Width × Height, i.e., Frequency should lie between 0 and 1. To achieve a maximum overall efficiency of the filtering operation, the parameter Norm can be used to specify the normalization factor of the filter. If fft_generic and Norm = *'n'* is used the normalization in the FFT can be avoided. Mode can be used to determine where the DC term of the filter lies or whether the filter should be used in the real-valued FFT. If fft_generic is used, *'dc_edge'* can be used to gain efficiency. If fft_image and fft_image_inv are used for filtering, Norm = *'none'* and Mode = *'dc_center'* must be used. If rft_generic is used, Mode = *'rft'* must be used. The filter is always zero for the DC term, rises with the sine function up to Frequency, and drops for higher frequencies accordingly. The range of the sine used is from 0 to π. All other points are set to zero.

Parameters

- ▷ **ImageFilter** (output_object) ..... image ⇝ *object : real*
  Bandpass filter as image in the frequency domain.
- ▷ **Frequency** (input_control) ..... real ⇝ *real*
  Distance of the filter's maximum from the DC term.
  Default: 0.1
  Suggested values: Frequency ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
  Restriction: Frequency >= 0
- ▷ **Norm** (input_control) ..... string ⇝ *string*
  Normalizing factor of the filter.
  Default: 'none'
  List of values: Norm ∈ {'none', 'n'}
- ▷ **Mode** (input_control) ..... string ⇝ *string*
  Location of the DC term in the frequency domain.
  Default: 'dc_center'
  List of values: Mode ∈ {'dc_center', 'dc_edge', 'rft'}
- ▷ **Width** (input_control) ..... integer ⇝ *integer*
  Width of the image (filter).
  Default: 512
  Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}
- ▷ **Height** (input_control) ..... integer ⇝ *integer*
  Height of the image (filter).
  Default: 512
  Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Result

gen_sin_bandpass returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_std_bandpass (: ImageFilter : Frequency, Sigma, Type, Norm, Mode, Width, Height :)

Generate a bandpass filter with Gaussian or sinusoidal shape.

gen_std_bandpass generates a rotationally invariant bandpass filter with the response being determined by the parameters Frequency and Sigma: Frequency determines the location of the maximum response with respect to the DC term, while Sigma determines the width of the frequency band that passes the filter. Frequency and Sigma are specified as a fraction of the maximum (horizontal and vertical) frequency that can be represented in an image of size Width × Height. Frequency should lie between 0 and 1. For Type = *'gauss'*, a Gaussian response is generated with Sigma being the standard deviation. For Type = *'sin'*, a sine function is generated with the maximum at Frequency and the extent Sigma. To achieve a maximum overall efficiency of the filtering operation, the parameter Norm can be used to specify the normalization factor of the filter. If fft_generic and Norm = *'n'* is used the normalization in the FFT can be avoided. Mode can be used to determine where the DC term of the filter lies or whether the filter should be used in the real-valued FFT. If fft_generic is used, *'dc_edge'* can be used to gain efficiency. If fft_image and fft_image_inv are used for filtering, Norm = *'none'* and Mode = *'dc_center'* must be used. If rft_generic is used, Mode = *'rft'* must be used.

Parameters

▷ **ImageFilter** (output_object) ..... image ⇝ *object : real*
Bandpass filter as image in the frequency domain.

▷ **Frequency** (input_control) ..... real ⇝ *real*
Distance of the filter's maximum from the DC term.
Default: 0.1
Suggested values: Frequency ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: Frequency >= 0

▷ **Sigma** (input_control) ..... real ⇝ *real*
Bandwidth of the filter (standard deviation).
Default: 0.01
Suggested values: Sigma ∈ {0.002, 0.005, 0.01, 0.02, 0.05, 0.1, 0.2, 0.3, 0.4, 0.5, 0.7, 1.0}
Restriction: Sigma >= 0

▷ **Type** (input_control) ..... string ⇝ *string*
Filter type.
Default: 'sin'
List of values: Type ∈ {'sin', 'gauss'}

▷ **Norm** (input_control) ..... string ⇝ *string*
Normalizing factor of the filter.
Default: 'none'
List of values: Norm ∈ {'none', 'n'}

▷ **Mode** (input_control) ..... string ⇝ *string*
Location of the DC term in the frequency domain.
Default: 'dc_center'
List of values: Mode ∈ {'dc_center', 'dc_edge', 'rft'}

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the image (filter).
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048, 4096, 8192}

▷ **Height** (input_control) ..... integer ⇝ *integer*
Height of the image (filter).
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048, 4096, 8192}

Result

gen_std_bandpass returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

optimize_fft_speed (: : Width, Height, Mode :)

Optimize the runtime of the FFT.

optimize_fft_speed determines a method that achieves an optimum runtime of the FFT for an image of size Width × Height. The data that are determined for one image size do not influence the methods used for other image sizes. Consequently, optimize_fft_speed can be called multiple times with different values for Width and Height to achieve an optimum runtime for all image sizes that are used in an application. The parameter Mode determines the thoroughness of the search for the fastest method. For Mode = *'standard'* a fast search is used, which typically takes a few seconds. The method thus determined results in very good runtimes, which are not always optimal. For Mode = *'patient'* a more thorough search is performed, which typically takes several seconds and in most cases leads to optimum runtimes. For Mode = *'exhaustive'* an exhaustive search is performed, which typically takes several minutes and always results in the optimum runtime. In most applications, Mode = *'standard'* results in the best compromise between the runtime of the FFT and the time required for the search of the optimum runtime. The data determined with optimize_fft_speed can be saved with write_fft_optimization_data and can be loaded with read_fft_optimization_data.

Please note that this optimization is performed for the particular computer on which the operator is called. The results are not suited to be transferred and used on other computers unless they have the same hardware and software configuration including the driver versions.

optimize_fft_speed influences the runtime of the following operators, which use the FFT: fft_generic, fft_image, fft_image_inv, photometric_stereo, sfs_pentland, sfs_mod_lr, sfs_orig_lr wiener_filter.

Parameters

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the image for which the runtime should be optimized.
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048}

▷ **Height** (input_control) ..... integer ⇝ *integer*
Height of the image for which the runtime should be optimized.
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576, 1024, 2048}

▷ **Mode** (input_control) ..... string ⇝ *string*
Thoroughness of the search for the optimum runtime.
Default: 'standard'
List of values: Mode ∈ {'standard', 'patient', 'exhaustive'}

Result

optimize_fft_speed returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

phase_correlation_fft (ImageFFT1, ImageFFT2 : ImagePhaseCorrelation : :)

Compute the phase correlation of two images in the frequency domain.

phase_correlation_fft calculates the phase correlation of the Fourier-transformed input images in the frequency domain. The phase correlation is calculated by multiplying ImageFFT1 with the complex conjugate of ImageFFT2 and dividing by the absolute value of this product. It should be noted that in order to achieve a correct scaling of the phase correlation in the spatial domain, the operators fft_generic or rft_generic with Norm = *'none'* must be used for the forward transform and fft_generic or rft_generic with Norm = *'n'* for the reverse transform. If ImageFFT1 and ImageFFT2 contain the same number of images, the corresponding images are phase-correlated pairwise. Otherwise, ImageFFT2 must contain only one single image. In this case, the phase correlation is performed for each image of ImageFFT1 with ImageFFT2 .

Attention

The filtering is always performed on the entire image, i.e., the domain of the image is ignored.

Parameters

▷ **ImageFFT1** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
Fourier-transformed input image 1.

▷ **ImageFFT2** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
Fourier-transformed input image 2.
Number of elements: ImageFFT2 == ImageFFT1 || ImageFFT2 == 1

▷ **ImagePhaseCorrelation** (output_object) ..... image(-array) ⇝ *object :* complex
Phase correlation of the input images in the frequency domain.

Example

```
* Compute the phase correlation of two images.
get_image_size(Image1,Width,Height)
rft_generic(Image1,ImageFFT1,'to_freq','none','complex',Width)
rft_generic(Image2,ImageFFT2,'to_freq','none','complex',Width)
phase_correlation_fft(ImageFFT1,ImageFFT2,PhaseCorrelationFFT)
rft_generic(PhaseCorrelationFFT,PhaseCorrelation,'from_freq','n', \
            'real',Width)
* Determine the translation between the two images.
local_max_sub_pix (PhaseCorrelation, 'facet', 1, 0.02, Row, Column)
```

Result

phase_correlation_fft returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

phase_deg (ImageComplex : ImagePhase : :)

Return the phase of a complex image in degrees.

phase_deg computes the phase of a complex image in degrees. The following formula is used:

$$phase = \frac{90}{\pi}\text{atan2}(imaginary\ part, real\ part) \quad .$$

Hence, ImagePhase contains half the phase angle. For negative phase angles, 180 is added.

Parameters

▷ **ImageComplex** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
Input image in frequency domain.

▷ **ImagePhase** (output_object) ..... image(-array) ⇝ *object :* direction
Phase of the image in degrees.

Example

```
read_image(&Image,"monkey");
disp_image(Image,WindowHandle);
fft_image(Image,&FFT);
phase_deg(FFT,&Phase);
disp_image(Phase,WindowHandle);
```

Result

phase_deg returns 2 (H_MSG_TRUE) if the image is of correct type. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

phase_rad (ImageComplex : ImagePhase : :)

Return the phase of a complex image in radians.

phase_rad computes the phase of a complex image in radians. The following formula is used:

$$phase = \text{atan2}(imaginary\ part, real\ part) \quad .$$

Parameters

- ▷ **ImageComplex** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
  Input image in frequency domain.
- ▷ **ImagePhase** (output_object) ..... image(-array) ⇝ *object :* real
  Phase of the image in radians.

Example

```
read_image(&Image,"monkey");
disp_image(Image,WindowHandle);
fft_image(Image,&FFT);
phase_rad(FFT,&Phase);
disp_image(Phase,WindowHandle);
```

Result

phase_rad returns 2 (H_MSG_TRUE) if the image is of correct type. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

power_byte (Image : PowerByte : :)

Return the power spectrum of a complex image.

power_byte computes the power spectrum from the real and imaginary parts of a Fourier-transformed image (see fft_image), i.e., the modulus of the frequencies. The result image is of type *'byte'*. The following formula is used:

$$\sqrt{realpart^2 + imaginarypart^2} \ .$$

Please note, that resulting gray values that exceed the value of 255 are clipped at 255 because of the resulting image type *'byte'*.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
Input image in frequency domain.

▷ **PowerByte** (output_object) ..... image(-array) ⇝ *object :* byte
Power spectrum of the input image.

Example

```
read_image(&Image,"monkey");
disp_image(Image,WindowHandle);
fft_image(Image,&FFT);
power_byte(FFT,&Power);
disp_image(Power,WindowHandle);
```

Result

power_byte returns 2 (H_MSG_TRUE) if the image is of correct type. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

power_ln (Image : ImageResult : :)

Return the power spectrum of a complex image.

power_ln computes the power spectrum from the real and imaginary parts of a Fourier-transformed image (see fft_image), i.e., the modulus of the frequencies. Additionally, the natural logarithm is applied to the result. The result image is of type real. The following formula is used:

$$\ln\left(\sqrt{realpart^2 + imaginarypart^2}\right) \quad .$$

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* complex
Input image in frequency domain.

▷ **ImageResult** (output_object) ..... image(-array) ⇝ *object :* real
Power spectrum of the input image.

Example

```
read_image(&Image,"monkey");
disp_image(Image,WindowHandle);
fft_image(Image,&FFT);
power_ln(FFT,&Power);
disp_image(Power,WindowHandle);
```

Result

power_ln returns 2 (H_MSG_TRUE) if the image is of correct type. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

read_fft_optimization_data (: : FileName :)

Load FFT speed optimization data from a file.

read_fft_optimization_data loads data for optimizing the runtime of the FFT from the file given by FileName. The optimization data must have been determined previously with optimize_fft_speed and must have been stored with write_fft_optimization_data. If the stored data have been determined for the image sizes to be used in the application, a call to optimize_fft_speed is unnecessary. It should be noted that the data should only be used on the same machine on which they were determined with optimize_fft_speed. If this is not observed the runtimes will not be optimal. Furthermore, it should be noted that optimization data that were created with Standard HALCON cannot be used with Parallel HALCON and vice versa.

read_fft_optimization_data influences the runtime of the following operators, which use the FFT: fft_generic, fft_image, fft_image_inv, sfs_pentland, sfs_mod_lr, sfs_orig_lrwiener_filter.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name of the optimization data.
Default: 'fft_opt.dat'

Result

`read_fft_optimization_data` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`fft_generic`, `fft_image`, `fft_image_inv`, `rft_generic`, `wiener_filter`, `wiener_filter_ni`, `photometric_stereo`, `sfs_pentland`, `sfs_mod_lr`, `sfs_orig_lr`

Alternatives

rft_generic (Image : ImageFFT : Direction, Norm, ResultType, Width :)

Compute the real-valued fast Fourier transform of an image.

`rft_generic` computes the fast Fourier transform of the input image `Image`. In contrast to `fft_generic`, `fft_image`, and `fft_image_inv`, the fact that the input image in the forward transform is a real-valued image (i.e., not a complex image) is used. In this case, the complex output image has a redundancy. The values in the right half of the image are the complex conjugates of the corresponding values in the left half of the image. Consequently, runtime and memory can be saved by only computing and storing the left half of the complex image.

The parameter `ResultType` can be used to specify the result image type of the reverse transform (`Direction` = *'from_freq'*). In the forward transform (`Direction` = *'to_freq'*), `ResultType` must be set to *'complex'*.

The parameter direction determines whether the transform should be performed to the frequency domain or back into the spatial domain. For `Direction` = *'to_freq'* the input image must have a real-valued type, i.e., a complex image may not be used as input. All image types that can be converted into an image of type real are supported. In this case, the output is a complex image of dimension $(w/2 + 1) \times h$, where w and h are the width and height of the input image. In this mode, the exponent -1 is used in the transform (see `fft_generic`). For `Direction` = *'from_freq'*, the input image must be complex. In this case, the size of the input image is insufficient to determine the size of the output image. This must be done by setting `Width` to a valid value, i.e., to $2w - 2$ or $2w - 1$, where w is the width of the complex image. In this mode, the exponent 1 is used in the transform.

The normalizing factor can be set with `Norm`, and can take on the values *'none'*, *'sqrt'* and *'n'*. The user must ensure the consistent use of the parameters. This means that the normalizing factors used for the forward and backward transform must yield wh when multiplied.

Attention

The transformation is always performed for the entire image, i.e., the domain of the image is ignored.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex

Input image.

▷ **ImageFFT** (output_object) ..... image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex
Fourier-transformed image.

▷ **Direction** (input_control) ..... string ⇝ *string*
Calculate forward or reverse transform.
Default: 'to_freq'
List of values: Direction ∈ {'to_freq', 'from_freq'}

▷ **Norm** (input_control) ..... string ⇝ *string*
Normalizing factor of the transform.
Default: 'sqrt'
List of values: Norm ∈ {'none', 'sqrt', 'n'}

▷ **ResultType** (input_control) ..... string ⇝ *string*
Image type of the output image.
Default: 'complex'
List of values: ResultType ∈ {'complex', 'byte', 'int1', 'int2', 'uint2', 'int4', 'real', 'direction', 'cyclic'}

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the image for which the runtime should be optimized.
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768, 1024, 2048}

Result

rft_generic returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

serialize_fft_optimization_data (: : : SerializedItemHandle)

Serialize FFT speed optimization data.

serialize_fft_optimization_data serializes the data for the optimization of the runtime of the FFT that were determined with optimize_fft_speed (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_fft_optimization_data is converted to a serialized item. The serialized data is returned by the handle SerializedItemHandle and can be deserialized by deserialize_fft_optimization_data.

Parameters

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

serialize_fft_optimization_data returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

write_fft_optimization_data (: : FileName :)

Store FFT speed optimization data in a file.

write_fft_optimization_data stores the data for the optimization of the runtime of the FFT that were determined with optimize_fft_speed in the file given by FileName. The data can be loaded with read_fft_optimization_data.

Parameters

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name of the optimization data.
Default: 'fft_opt.dat'

Result

write_fft_optimization_data returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

12.7 Geometric Transformations

affine_trans_image (Image : ImageAffineTrans : HomMat2D, Interpolation, AdaptImageSize :)

Apply an arbitrary affine 2D transformation to images.

affine_trans_image applies an arbitrary affine 2D transformation, i.e., scaling, rotation, translation, and slant (skewing), to the images given in Image and returns the transformed images in ImageAffineTrans. The affine transformation is described by the homogeneous transformation matrix given in HomMat2D, which can be created using the operators hom_mat2d_identity, hom_mat2d_scale, hom_mat2d_rotate, hom_mat2d_translate, etc., or be the result of operators like vector_angle_to_rigid.

The components of the homogeneous transformation matrix are interpreted as follows: The *row* coordinate of the image corresponds to x and the *column* coordinate corresponds to y of the coordinate system in which the transformation matrix was defined. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

The domain of the input image is ignored, i.e., assumed to be the full rectangle of the image. The domain of the output image is the intersection of the transformed rectangle and the rectangle of the output image.

Generally, transformed points will lie between pixel coordinates. Therefore, an appropriate interpolation scheme must be used. The interpolation can also be used to avoid aliasing effects for scaled images. The quality and speed of the interpolation can be set by the parameter Interpolation:

nearest_neighbor Nearest-neighbor interpolation: The gray value is determined from the nearest pixel's gray value (possibly low quality, very fast).

bilinear Bilinear interpolation. The gray value is determined from the four nearest pixels through bilinear interpolation. If the affine transformation contains a scaling with a scale factor < 1, no smoothing is performed, which may cause severe aliasing effects (medium quality and run time).

bicubic Bicubic interpolation. The gray value is determined from the 4×4 nearest pixels through bicubic interpolation. If the affine transformation contains a scaling with a scale factor < 1, no smoothing is performed, which may cause severe aliasing effects (high quality for enlargements, slow).

constant Bilinear interpolation. The gray value is determined from the four nearest pixels through bilinear interpolation. If the affine transformation contains a scaling with a scale factor < 1, a kind of mean filter is used to prevent aliasing effects (medium quality and run time).

weighted Bilinear interpolation. The gray value is determined from the four nearest pixels through bilinear interpolation. If the affine transformation contains a scaling with a scale factor < 1, a kind of Gaussian filter is used to prevent aliasing effects (high quality, slow).

In addition, the system parameter *'int_zooming'* (see set_system) affects the accuracy of the transformation. If *'int_zooming'* is set to *'true'*, the transformation for byte, int2 and uint2 images is carried out internally using fixed point arithmetic, leading to much shorter execution times. However, the accuracy of the transformed gray values is smaller in this case. For byte images, the differences to the more accurate calculation (using *'int_zooming'* = *'false'*) is typically less than two gray levels. Correspondingly, for int2 and uint2 images, the gray value differences are less than 1/128 times the dynamic gray value range of the image, i.e., they can be as large as 512 gray levels if the entire dynamic range of 16 bit is used. When using fixed point arithmetic, the domain of resulting images can differ as well. Additionally, if a large scale factor is applied and a large output image is obtained, then undefined gray values at the lower and at the right image border may result. The maximum width B_{max} of this border of undefined gray values can be estimated as $B_{max} = 0.5 \cdot S \cdot I/2^{15}$, where S is the scale factor in one dimension and I is the size of the output image in the corresponding dimension. For real images, the parameter *'int_zooming'* does not affect the accuracy, since the internal calculations are always done using floating point arithmetic.

The size of the target image can be controlled by the parameter AdaptImageSize: If set to *'true'*, the size will be adapted so that no clipping occurs at the right or lower edge. If set to *'false'*, the target image has the same size as the input image. Note that, independent of AdaptImageSize, the image is always clipped at the left and upper edge, i.e., all image parts that have negative coordinates after the transformation are clipped.

Attention

The region of the input image is ignored.

affine_trans_image does not use the HALCON standard coordinate system (with the origin in the center of the first pixel), but instead uses the same coordinate system as in affine_trans_pixel, i.e., the origin lies in the upper left corner of the first pixel. Therefore, applying affine_trans_image corresponds to a chain of transformations (see affine_trans_pixel), which is applied to each point of the image (input and output pixels as homogeneous vectors). As an effect, you might get unexpected results when creating affine transformations based on coordinates that are derived from the image, e.g., by operators like area_center_gray. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric image and then rotate the image around this point using hom_mat2d_rotate, the resulting image will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to HomMat2D before using it in affine_trans_image:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
affine_trans_image(Image, ImageAffineTrans, HomMat2DAdapted,
'constant', 'false')
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Input image.
- ▷ **ImageAffineTrans** (output_object) .... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Transformed image.
- ▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
  Input transformation matrix.
- ▷ **Interpolation** (input_control) ..... string ⇝ *string*
  Type of interpolation.
  Default: 'constant'
  List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}
- ▷ **AdaptImageSize** (input_control) ..... string ⇝ *string*
  Adaption of size of result image.
  Default: 'false'
  List of values: AdaptImageSize ∈ {'true', 'false'}

Example

```
* Reduction of an image (512 x 512 Pixels) by 50%, rotation
* by 180 degrees and translation to the upper-left corner:

read_image (Image, 'ic0')
hom_mat2d_identity(Matrix1)
hom_mat2d_scale(Matrix1,0.5,0.5,256.0,256.0,Matrix2)
hom_mat2d_rotate(Matrix2,3.14,256.0,256.0,Matrix3)
hom_mat2d_translate(Matrix3,-128.0,-128.0,Matrix4)
affine_trans_image(Image,TransImage,Matrix4,'constant','true')

* Enlarging the part of an image in the interactively
* chosen rectangular window sector:

dev_get_window (WindowHandle)
draw_rectangle2(WindowHandle,L,C,Phi,L1,L2)
hom_mat2d_identity(Matrix1)
get_system('width',Width)
get_system('height',Height)
hom_mat2d_translate(Matrix1,Height/2.0-L,Width/2.0-C,Matrix2)
hom_mat2d_rotate(Matrix2,3.14-Phi,Height/2.0,Width/2.0,Matrix3)
```

```
hom_mat2d_scale(Matrix3,Height/(2.0*L2),Width/(2.0*L1), \
                Height/2.0,Width/2.0,Matrix4)
affine_trans_image(Image,TransImage,Matrix4,'constant','true')
```

Result

If the matrix HomMat2D represents an affine transformation (i.e., not a projective transformation), affine_trans_image returns 2 (H_MSG_TRUE). If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

affine_trans_image_size (Image : ImageAffineTrans : HomMat2D, Interpolation, Width, Height :)

Apply an arbitrary affine 2D transformation to an image and specify the output image size.

affine_trans_image_size applies an arbitrary affine 2D transformation, i.e., scaling, rotation, translation, and slant (skewing), to the images given in Image and returns the transformed images in ImageAffineTrans. The affine transformation is described by the homogeneous transformation matrix given in HomMat2D, which can be created using the operators hom_mat2d_identity, hom_mat2d_scale, hom_mat2d_rotate, hom_mat2d_translate, etc., or be the result of operators like vector_angle_to_rigid.

The components of the homogeneous transformation matrix are interpreted as follows: The *row* coordinate of the image corresponds to x and the *column* coordinate corresponds to y of the coordinate system in which the transformation matrix was defined. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

The region of the input image is ignored, i.e., assumed to be the full rectangle of the image. The region of the resulting image is set to the transformed rectangle of the input image. If necessary, the resulting image is filled with zero (black) outside of the region of the original image.

Generally, transformed points will lie between pixel coordinates. Therefore, an appropriate interpolation scheme has to be used. The interpolation can also be used to avoid aliasing effects for scaled images. The quality and speed of the interpolation can be set by the parameter Interpolation:

nearest_neighbor Nearest-neighbor interpolation: The gray value is determined from the nearest pixel's gray value (possibly low quality, very fast).

bilinear Bilinear interpolation. The gray value is determined from the four nearest pixels through bilinear interpolation. If the affine transformation contains a scaling with a scale factor < 1, no smoothing is performed, which may cause severe aliasing effects (medium quality and run time).

bicubic Bicubic interpolation. The gray value is determined from the 4×4 nearest pixels through bicubic interpolation. If the affine transformation contains a scaling with a scale factor < 1, no smoothing is performed, which may cause severe aliasing effects (high quality for enlargements, slow).

constant Bilinear interpolation. The gray value is determined from the four nearest pixels through bilinear interpolation. If the affine transformation contains a scaling with a scale factor < 1, a kind of mean filter is used to prevent aliasing effects (medium quality and run time).

weighted Bilinear interpolation. The gray value is determined from the four nearest pixels through bilinear interpolation. If the affine transformation contains a scaling with a scale factor < 1, a kind of Gaussian filter is used to prevent aliasing effects (high quality, slow).

In addition, the system parameter *'int_zooming'* (see `set_system`) affects the accuracy of the transformation. If *'int_zooming'* is set to *'true'*, the transformation for byte, int2 and uint2 images is carried out internally using fixed point arithmetic, leading to much shorter execution times. However, the accuracy of the transformed gray values is smaller in this case. For byte images, the differences to the more accurate calculation (using *'int_zooming'* = *'false'*) is typically less than two gray levels. Correspondingly, for int2 and uint2 images, the gray value differences are less than 1/128 times the dynamic gray value range of the image, i.e., they can be as large as 512 gray levels if the entire dynamic range of 16 bit is used. When using fixed point arithmetic, the domain of resulting images can differ as well. Additionally, if a large scale factor is applied and a large output image is obtained, then undefined gray values at the lower and at the right image border may result. The maximum width B_{max} of this border of undefined gray values can be estimated as $B_{max} = 0.5 \cdot S \cdot I/2^{15}$, where S is the scale factor in one dimension and I is the size of the output image in the corresponding dimension. For real images, the parameter *'int_zooming'* does not affect the accuracy, since the internal calculations are always done using floating point arithmetic.

The size of the target image is specified by the parameters `Width` and `Height`. Note that the image is always clipped at the left and upper edge, i.e., all image parts that have negative coordinates after the transformation are clipped. If the affine transformation (in particular, the translation) is chosen appropriately, a part of the image can be transformed as well as cropped in one call. This is useful, for example, when using the variation model (see `compare_variation_model`), because with this mechanism only the parts of the image that should be examined, are transformed.

Attention

The region of the input image is ignored.

`affine_trans_image_size` does not use the HALCON standard coordinate system (with the origin in the center of the upper left pixel), but instead uses the same coordinate system as in `affine_trans_pixel`, i.e., the origin lies in the upper left corner of the upper left pixel. Therefore, applying `affine_trans_image_size` corresponds to a chain of transformations (see `affine_trans_pixel`), which is applied to each point of the image (input and output pixels as homogeneous vectors). As an effect, you might get unexpected results when creating affine transformations based on coordinates that are derived from the image, e.g., by operators like `area_center_gray`. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric image and then rotate the image around this point using `hom_mat2d_rotate`, the resulting image will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to `HomMat2D` before using it in `affine_trans_image_size`:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
affine_trans_image_size(Image, ImageAffineTrans, HomMat2DAdapted,
'constant', Width, Height)
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Input image.

▷ **ImageAffineTrans** (output_object) .... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Transformed image.

▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Type of interpolation.
Default: 'constant'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the output image.
Default: 640
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768}

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the output image.
Default: 480
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576}

Result

If the matrix HomMat2D represents an affine transformation (i.e., not a projective transformation), affine_trans_image_size returns 2 (H_MSG_TRUE). If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

convert_map_type (Map : MapConverted : NewType, ImageWidth :)

Convert image maps into other map types.

convert_map_type converts the input Map into a different map type. The main usage of convert_map_type is to convert a nearest neighbor or bilinear map (e.g., obtained by gen_image_to_world_plane_map) to a coordinate map, as this is the only type supported on compute devices.

NewType specifies the type of conversion. The following values are supported:

'coord_map_sub_pix' creates a map that consists of a vector_field image which contains the absolute subpixel precise row and column coordinates of each pixel's mapping. (input map must be *'bilinear'* or *'nearest_neighbor'*)

'bilinear' creates a map with linear coordinates and bilinear interpolation coefficients (see map_image). (input map must be *'coord_map_sub_pix'*)

'nearest_neighbor' creates a nearest neighbor map with linear coordinates (see map_image). (input map must be *'coord_map_sub_pix'*)

In ImageWidth the width of the images to be mapped by MapConverted must be given. If this width is identical to the width of Map, you can pass the string *'map_width'*.

Parameters

- ▷ **Map** (input_object) ..... (multichannel-)image ⇝ *object :* vector_field / int4 / int8 / uint2
  Input map.
- ▷ **MapConverted** (output_object) ..... (multichannel-)image ⇝ *object :* vector_field / int4 / int8 / uint2
  Converted map.
- ▷ **NewType** (input_control) ..... string ⇝ *string*
  Type of MapConverted.
  Default: 'coord_map_sub_pix'
  List of values: NewType ∈ {'coord_map_sub_pix', 'bilinear', 'nearest_neighbor'}
- ▷ **ImageWidth** (input_control) ..... integer ⇝ *integer* / string
  Width of images to be mapped.
  Default: 'map_width'

Example

```
gen_radial_distortion_map (MapFixed, CamParOriginal, CamParVirtualFixed, \
                           'bilinear')
convert_map_type(MapFixed, MapConverted, 'coord_map_sub_pix', 'map_width')
query_available_compute_devices (DeviceIdentifier)
open_compute_device (DeviceIdentifier[0], DeviceHandle)
activate_compute_device (DeviceHandle)
map_image (GrayImage, MapConverted, ImageRectifiedFixed)
```

Result

convert_map_type returns 2 (H_MSG_TRUE) if all parameter values are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

map_image

Module

Foundation

map_image (Image, Map : ImageMapped : :)

Apply a general transformation to an image.

map_image transforms an image Image using an arbitrary transformation Map which, for example, was previously generated using gen_image_to_world_plane_map or gen_radial_distortion_map. The multi-channel image Map must be organized as follows:

The height and the width of Map define the size of the output image ImageMapped. The number of channels in Map defines whether no interpolation or bilinear interpolation should be used. If Map only consists of one channel, no interpolation is applied during the transformation. This channel contains 'int4' (resp. 'int8' in HALCON XL if the value range of 'int4' is not sufficient) values that describe the geometric transformation: For each pixel in the output image ImageMapped the linearized coordinate of the pixel in the input image Image from which the gray value should be taken is stored.

If bilinear interpolation between the pixels in the input image should be applied, Map must consist of 5 channels. The first channel again consists of an 'int4' resp. 'int8' image and describes the geometric transformation. The channels 2-5 consist of an 'uint2' image each and contain the weights [0...1] of the four neighboring pixels that are used during bilinear interpolation. If the overall brightness of the output image ImageMapped should not differ from the overall brightness of the input image Image, the sum of the four unscaled weights must be 1 for each pixel. The weights [0...1] are scaled to the range of values of the 'uint2' image and therefore hold integer values from 0 to 65535.

Furthermore, the weights must be chosen in a way that the range of values of the output image ImageMapped is not exceeded. The geometric relation between the four channels 2-5 is illustrated in the following sketch:

2	3
4	5

The reference point of the four pixels is the upper left pixel. The linearized coordinate of the reference point is stored in the first channel.

It is also possible to use a Map that consists of a vector field containing absolute subpixel precise row and column coordinates (i.e., the field must be of the semantic type 'vector_field_absolute'). The two Map types described above can be converted into this type using convert_map_type. This type is the only type supported on compute devices!

Attention

The weights must be chosen in a way that the range of values of the output image ImageMapped is not exceeded.

For runtime reasons during the mapping process, it is not checked whether the linearized coordinates lie inside the input image. Thus, it must be ensured by the user that this constraint is fulfilled. In case interpolation is used, this also applies to the pixels to the right, below, and below to the right of this coordinate. Otherwise, the program may crash!

map_image is parallelized automatically if and only if the specified type for Map is either *'bilinear'* or *'coord_map_sub_pix'*.

map_image is executed on an OpenCL compute device only if the input map is of type *'coord_map_sub_pix'* and if the input image does not exceed the maximum size of image objects of the selected device.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Image to be mapped.
- ▷ **Map** (input_object) ..... (multichannel-)image ⇝ *object :* int4 / int8 / uint2 / vector_field
  Image containing the mapping data.
- ▷ **ImageMapped** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Mapped image.

Result

map_image returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

mirror_image (Image : ImageMirror : Mode :)

Mirror an image.

mirror_image reflects an image Image about one of three possible axes. If Mode is set to *'row'*, it is reflected about the horizontal axis, if Mode is set to *'column'*, about the vertical axis, and if Mode is set to *'diagonal'*, about the main diagonal $x = y$.

Attention

mirror_image can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device. However, execution might be faster on the CPU, especially for the mode *'row'*.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
  Input image.
- ▷ **ImageMirror** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
  Reflected image.
- ▷ **Mode** (input_control) . . . . . string ⇝ *string*
  Axis of reflection.
  Default: 'row'
  List of values: Mode ∈ {'row', 'column', 'diagonal'}

Example

```
read_image(Image,'monkey')
dev_display (Image)
mirror_image(Image,MirrorImage,'row')
dev_display (MirrorImage)
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Module

Foundation

polar_trans_image_ext (Image : PolarTransImage : Row, Column, AngleStart, AngleEnd, RadiusStart, RadiusEnd, Width, Height, Interpolation :)

Transform an annular arc in an image to polar coordinates.

polar_trans_image_ext transforms the annular arc specified by the center point (Row, Column), the radii RadiusStart and RadiusEnd and the angles AngleStart and AngleEnd in the image Image to its polar coordinate version in the image PolarTransImage of the dimensions Width × Height.

The upper left pixel in the output image always corresponds to the point in the input image that is specified by RadiusStart and AngleStart. Analogously, the lower right pixel in the output image always corresponds to the point in the input image that is specified by RadiusEnd and AngleEnd. In the usual mode (AngleStart < AngleEnd and RadiusStart < RadiusEnd), the polar transformation is performed in the mathematically positive orientation (counterclockwise). Furthermore, points with smaller radii lie in the upper part of the output image. By suitably exchanging the values of these parameters (e.g., AngleStart > AngleEnd or RadiusStart > RadiusEnd), any desired orientation of the output image can be achieved.

The parameter Interpolation is used to select the interpolation method *'bilinear'* or *'nearest_neighbor'*. With *'nearest_neighbor'*, the gray value of a pixel in the output image is determined by the gray value of the closest pixel in the input image. With *'bilinear'*, the gray value of a pixel in the output image is determined by bilinear interpolation of the gray values of the four closest pixels in the input image. The mode *'bilinear'* results in images of better quality, but is slower than the mode *'nearest_neighbor'*.

The angles can be chosen from all real numbers. Center point and radii can be real as well. However, if they are both integers and the difference of RadiusEnd and RadiusStart equals the height Height of the destination image, calculation will be sped up through an optimized routine.

The radii and angles are inclusive, which means that the first row of the target image contains the circle with radius RadiusStart and the last row contains the circle with radius RadiusEnd. For complete circles, where the difference between AngleStart and AngleEnd equals 2π (360 degrees), this also means that the first column of the target image will be the same as the last.

To avoid this, do not make this difference 2π, but $2\pi(1 - \frac{1}{\texttt{Width}})$ degrees instead.

The call `polar_trans_image(Image, PolarTransImage, Row, Column, Width, Height)` produces the same result as the call `polar_trans_image_ext(Image, PolarTransImage, Row-0.5, Column-0.5, 6.2831853, 6.2831853/Width, 0, Height-1, Width, Height, 'nearest_neighbor')`.

The offset of 0.5 is necessary since polar_trans_image does not do exact nearest neighbor interpolation and the radii and angles can be calculated using the information in the above paragraph and knowing that polar_trans_image does not handle its arguments inclusively. The start angle is bigger than the end angle to make polar_trans_image_ext go clockwise, just like polar_trans_image does.

polar_trans_image_ext can be executed on an OpenCL device if the input image does not exceed the maximum size of image objects of the selected device. Due to numerical reasons, there can be slight differences in the output compared to the execution on the CPU.

Additionally, for images of type byte, int2 or uint2 the system parameter *'int_zooming'* selects between fast calculation in fixed point arithmetics (*'int_zooming'* = *'true'*) and highly accurate calculation in floating point arithmetics (*'int_zooming'* = *'false'*). Fixed point calculation can lead to minor gray value deviations and pixels with undefined gray values.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

For speed reasons, the domain of the input image is ignored. The output image always has a complete rectangle as its domain.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Input image.
- ▷ **PolarTransImage** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Output image.
- ▷ **Row** (input_control) ..... number ⇝ *real* / integer
  Row coordinate of the center of the arc.
  Default: 256
  Suggested values: Row ∈ {0, 16, 32, 64, 128, 240, 256, 480, 512}
- ▷ **Column** (input_control) ..... number ⇝ *real* / integer
  Column coordinate of the center of the arc.
  Default: 256
  Suggested values: Column ∈ {0, 16, 32, 64, 128, 256, 320, 512, 640}

▷ **AngleStart** (input_control) ..... angle.rad ⇝ *real*
Angle of the ray to be mapped to the first column of the output image.
Default: 0.0
Suggested values: AngleStart ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853, 12.566370616}

▷ **AngleEnd** (input_control) ..... angle.rad ⇝ *real*
Angle of the ray to be mapped to the last column of the output image.
Default: 6.2831853
Suggested values: AngleEnd ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853, 12.566370616}

▷ **RadiusStart** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to be mapped to the first row of the output image.
Default: 0
Suggested values: RadiusStart ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusStart

▷ **RadiusEnd** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to be mapped to the last row of the output image.
Default: 100
Suggested values: RadiusEnd ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusEnd

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the output image.
Default: 512
Suggested values: Width ∈ {256, 320, 512, 640, 800, 1024}
Value range: 0 ≤ Width ≤ 32767

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the output image.
Default: 512
Suggested values: Height ∈ {240, 256, 480, 512, 600, 1024}
Value range: 0 ≤ Height ≤ 32767

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Interpolation method for the transformation.
Default: 'nearest_neighbor'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear'}

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Module

Foundation

polar_trans_image_inv (PolarImage : XYTransImage : Row, Column, AngleStart, AngleEnd, RadiusStart, RadiusEnd, Width, Height, Interpolation :)

Transform an image in polar coordinates back to Cartesian coordinates

polar_trans_image_inv transforms the polar coordinate representation of an image, stored in PolarImage, back onto an annular arc in Cartesian coordinates, described by the radii RadiusStart and

RadiusEnd and the angles AngleStart and AngleEnd with the center point located at (Row, Column). All of these values can be chosen as real numbers. The overall size of the target image will be Width × Height pixels.

The parameter Interpolation is used to select the interpolation method *'bilinear'* or *'nearest_neighbor'*. With *'nearest_neighbor'*, the gray value of a pixel in the output image is determined by the gray value of the closest pixel in the input image. With *'bilinear'*, the gray value of a pixel in the output image is determined by bilinear interpolation of the gray values of the four closest pixels in the input image. The mode *'bilinear'* results in images of better quality, but is slower than the mode *'nearest_neighbor'*.

The angles and radii are inclusive, which means that the first row of the input image will be mapped onto a circle with a distance of RadiusStart pixels from the specified center and the last row will be mapped onto a circle of radius RadiusEnd.

polar_trans_image_inv is the inverse function of polar_trans_image_ext.

The call sequence:

```
polar_trans_image_ext(Image, PolarImage, Row, Column, rad(360)
polar_trans_image_inv(PolarImage, XYTransImage, Row, Column,
rad(360), 0, 0, Radius, Width, Height, Interpolation)
```

returns the image Image, restricted to the circle around (Row, Column) with radius Radius, as its output image XYTransImage.

polar_trans_image_inv can be executed on an OpenCL device. There can be slight differences in the output compared to the execution on the CPU.

Additionally, for images of type byte, int2 or uint2 the system parameter *'int_zooming'* selects between fast calculation in fixed point arithmetics (*'int_zooming'* = *'true'*) and highly accurate calculation in floating point arithmetics (*'int_zooming'* = *'false'*). Fixed point calculation can lead to minor gray value deviations. In this case, the domain of resulting images can differ as well.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

▷ **PolarImage** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Input image.

▷ **XYTransImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Output image.

▷ **Row** (input_control) . . . . . number ⇝ *real* / integer
Row coordinate of the center of the arc.
Default: 256
Suggested values: Row ∈ {0, 16, 32, 64, 128, 240, 256, 480, 512}
Value range: 0 ≤ Row ≤ 32767

▷ **Column** (input_control) . . . . . number ⇝ *real* / integer
Column coordinate of the center of the arc.
Default: 256
Suggested values: Column ∈ {0, 16, 32, 64, 128, 256, 320, 512, 640}
Value range: 0 ≤ Column ≤ 32767

▷ **AngleStart** (input_control) . . . . . angle.rad ⇝ *real*
Angle of the ray to map the first column of the input image to.
Default: 0.0
Suggested values: AngleStart ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853}

▷ **AngleEnd** (input_control) . . . . . angle.rad ⇝ *real*
Angle of the ray to map the last column of the input image to.
Default: 6.2831853
Suggested values: AngleEnd ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853}

▷ **RadiusStart** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to map the first row of the input image to.
Default: 0
Suggested values: RadiusStart ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusStart

▷ **RadiusEnd** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to map the last row of the input image to.
Default: 100
Suggested values: RadiusEnd ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusEnd

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the output image.
Default: 512
Suggested values: Width ∈ {256, 320, 512, 640, 800, 1024}
Value range: 0 ≤ Width ≤ 32767

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the output image.
Default: 512
Suggested values: Height ∈ {240, 256, 480, 512, 600, 1024}
Value range: 0 ≤ Height ≤ 32767

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Interpolation method for the transformation.
Default: 'nearest_neighbor'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear'}

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

projective_trans_image (Image : TransImage : HomMat2D, Interpolation, AdaptImageSize, TransformDomain :)

Apply a projective transformation to an image.

projective_trans_image applies the projective transformation (homography) determined by the homogeneous transformation matrix HomMat2D on the input image Image and stores the result into the output image TransImage.

If the parameter AdaptImageSize is set to *'false'*, TransImage will have the same size as Image; if AdaptImageSize is *'true'*, the output image size will be automatically adapted so that all non-negative points of the transformed image are visible.

The parameter Interpolation determines, which interpolation method is used to determine the gray values of the output image. For Interpolation = *'nearest_neighbor'*, the gray value is determined from the nearest pixel in the input image. This mode is very fast, but also leads to the typical "jagged" appearance for large enlargements of the image. For Interpolation = *'bilinear'*, the gray values are interpolated bilinearly, leading to longer runtimes, but also to significantly improved results.

The parameter TransformDomain can be used to determine whether the domain of Image is also transformed. Since the transformation of the domain costs runtime, this parameter should be used to specify whether this is desired or not. If TransformDomain is set to *'false'* the domain of the input image is ignored and the complete image is transformed.

The projective transformation matrix could for example be created using the operator vector_to_proj_hom_mat2d.

In a homography the points to be projected are represented by homogeneous vectors of the form (x, y, w). A Euclidean point can be derived as (x',y') = $(\frac{x}{w}, \frac{y}{w})$.

Just like in affine_trans_image, x represents the row coordinate while y represents the column coordinate in projective_trans_image. With this convention, affine transformations are a special case of projective transformations in which the last row of HomMat2D is of the form $(0, 0, c)$.

For images of type byte or uint2 the system parameter *'int_zooming'* selects between fast calculation in floating point arithmetics (*'int_zooming'* = *'true'*) and highly accurate floating point arithmetics (*'int_zooming'* = *'false'*). Especially for Interpolation = *'bilinear'*, however, the faster calculation can lead to minor gray value deviations since the faster algorithm is less accurate and only has an accuracy around 10^{-7} times the size of the image. Therefore, when applying large scales *'int_zooming'* = *'false'* is recommended.

Attention

The used coordinate system is the same as in affine_trans_pixel. This means that in fact not HomMat2D is applied but a modified version. Therefore, applying projective_trans_image corresponds to the following chain of transformations, which is applied to each point (Row_i, Col_i) of the image (input and output pixels as homogeneous vectors):

$$\begin{pmatrix} RowTrans_i \\ ColTrans_i \\ 1 \end{pmatrix} = \begin{bmatrix} 1 & 0 & -0.5 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D} \cdot \begin{bmatrix} 1 & 0 & +0.5 \\ 0 & 1 & +0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} Row_i \\ Col_i \\ 1 \end{pmatrix}$$

As an effect, you might get unexpected results when creating projective transformations based on coordinates that are derived from the image, e.g., by operators like area_center_gray. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric image and then rotate the image around this point using hom_mat2d_rotate, the resulting image will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to HomMat2D before using it in projective_trans_image:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
projective_trans_image(Image, TransImage, HomMat2DAdapted,
'bilinear', 'false', 'false')
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

projective_trans_image can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device and the parameter TransformDomain is set to *'false'*. The result can diverge slightly from that calculated on the CPU.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **TransImage** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
  Homogeneous projective transformation matrix.
- ▷ **Interpolation** (input_control) ..... string ⇝ *string*
  Interpolation method for the transformation.
  Default: 'bilinear'
  List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear'}

▷ **AdaptImageSize** (input_control) ..... string ⇝ *string*
Adapt the size of the output image automatically?
Default: 'false'
List of values: AdaptImageSize ∈ {'true', 'false'}

▷ **TransformDomain** (input_control) ..... string ⇝ *string*
Should the domain of the input image also be transformed?
Default: 'false'
List of values: TransformDomain ∈ {'true', 'false'}

Module

Foundation

projective_trans_image_size (Image : TransImage : HomMat2D, Interpolation, Width, Height, TransformDomain :)

Apply a projective transformation to an image and specify the output image size.

projective_trans_image_size applies the projective transformation (homography) determined by the homogeneous transformation matrix HomMat2D on the input image Image and stores the result into the output image TransImage.

TransImage will be clipped at the output dimensions Height×Width. Apart from this, projective_trans_image_size is identical to its alternative version projective_trans_image.

Attention

The used coordinate system is the same as in affine_trans_pixel. This means that in fact not HomMat2D is applied but a modified version. Therefore, applying projective_trans_image_size corresponds to the following chain of transformations, which is applied to each point (Row_i, Col_i) of the image (input and output pixels as homogeneous vectors):

$$\begin{pmatrix} RowTrans_i \\ ColTrans_i \\ 1 \end{pmatrix} = \begin{bmatrix} 1 & 0 & -0.5 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \text{HomMat2D} \cdot \begin{bmatrix} 1 & 0 & +0.5 \\ 0 & 1 & +0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} Row_i \\ Col_i \\ 1 \end{pmatrix}$$

As an effect, you might get unexpected results when creating projective transformations based on coordinates that are derived from the image, e.g., by operators like area_center_gray. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric image and then rotate the image around this point using hom_mat2d_rotate, the resulting image will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to HomMat2D before using it in projective_trans_image_size:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
projective_trans_image_size(Image, TransImage, HomMat2DAdapted,
'bilinear', Width, Height, 'false')
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

projective_trans_image_size can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device and the parameter TransformDomain is set to *'false'*. The result can diverge slightly from that calculated on the CPU.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **TransImage** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
  Homogeneous projective transformation matrix.
- ▷ **Interpolation** (input_control) ..... string ⇝ *string*
  Interpolation method for the transformation.
  Default: 'bilinear'
  List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear'}
- ▷ **Width** (input_control) ..... extent.x ⇝ *integer*
  Output image width.
- ▷ **Height** (input_control) ..... extent.y ⇝ *integer*
  Output image height.
- ▷ **TransformDomain** (input_control) ..... string ⇝ *string*
  Should the domain of the input image also be transformed?
  Default: 'false'
  List of values: TransformDomain ∈ {'true', 'false'}

Execution Information

rotate_image (Image : ImageRotate : Phi, Interpolation :)

Rotate an image about its center.

rotate_image rotates the Image counterclockwise by Phi degrees about its center and stores the result in the output image ImageRotate. The output image has the same size as the input image. The only exception are rotations by 90 and 270 degrees where width and height will be exchanged. The domain of the input image is ignored, i.e., assumed to be the full rectangle of the image. The domain of the output image is the intersection of the transformed rectangle and the rectangle of the output image.

If Phi is a multiple of 90 degrees, this operator is much faster, especially than the general operator affine_trans_image. The effect of the parameter Interpolation is the same as in affine_trans_image. It is ignored for rotations by 90, 180, and 270 degrees. If it is necessary to rotate the domain, too, the operator projective_trans_image must be used.

Additionally, for images of type byte, int2 or uint2 the system parameter *'int_zooming'* selects between fast calculation in fixed point arithmetics (*'int_zooming'* = *'true'*) and highly accurate calculation in floating point arithmetics (*'int_zooming'* = *'false'*). Except for rotations by 90, 180, or 270 degrees, fixed point calculation can lead to minor gray value deviations. Furthermore, the domain of resulting images can differ as well.

Attention

The domain of the input image is ignored, i.e., assumed to be the full rectangle of the image. The domain of the output image is the intersection of the transformed rectangle and the rectangle of the output image. The angle Phi is given in degrees, not in radians. For rotations by 90, 180, and 270 degrees rotate_image is not parallelized internally.

rotate_image can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device. Due to numerical reasons, there can be slight differences in the output compared to the execution on the CPU.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Input image.
- ▷ **ImageRotate** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Rotated image.
- ▷ **Phi** (input_control) ..... angle.deg ⇝ *real* / integer
  Rotation angle.
  Default: 90
  Suggested values: Phi ∈ {90, 180, 270}
  Value range: 0 ≤ Phi ≤ 360
  Minimum increment: 0.001
  Recommended increment: 0.2
- ▷ **Interpolation** (input_control) ..... string ⇝ *string*
  Type of interpolation.
  Default: 'constant'
  List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

Example

```
read_image(Image,'monkey')
dev_display (Image)
rotate_image(Image,RotImage,270,'constant')
dev_display (RotImage)
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Alternatives

hom_mat2d_rotate, affine_trans_image

See also

mirror_image

Module

Foundation

zoom_image_factor (Image : ImageZoomed : ScaleWidth, ScaleHeight, Interpolation :)

Zoom an image by a given factor.

zoom_image_factor scales the image Image by a factor of ScaleWidth in width and a factor ScaleHeight in height. The parameter Interpolation determines the type of interpolation used (see affine_trans_image). The domain of the input image is ignored, i.e., assumed to be the full rectangle of the image.

Attention

If the system parameter *'int_zooming'* is set to *'true'*, the internally used integer arithmetic may lead to errors in the following three cases: First, if zoom_image_factor is used on an uint2 or int2 image with high dynamics (i.e. images containing values close to the respective limits) in combination with scale factors smaller than 0.5, then the gray values of the output image may be erroneous. Second, if Interpolation is set to a value other than *'nearest_neighbor'*, a large scale factor is applied, and a large output image is obtained, then undefined gray values at the lower and at the right image border may result. The maximum width B_{max} of this border of undefined gray values can be estimated as $B_{max} = 0.5 \cdot S \cdot I/2^{15}$, where S is the scale factor in one dimension and I is the size of the output image in the corresponding dimension. Third, for real images undefined gray values can occur on all image borders, if Interpolation is set to *'nearest_neighbor'*, and if both the input and output image is large. In all cases, it is recommended to set *'int_zooming'* to *'false'* via the operator set_system.

If *'nearest_neighbor'* is set as interpolation method the results can differ slightly for different image types. This is due to the usage of image type specific optimizations of the applied interpolation algorithm.

zoom_image_factor is not parallelized internally if ScaleWidth = 0.5 and ScaleHeight = 0.5. Further zoom_image_factor is not parallelized internally with Interpolation='*nearest_neighbor*'.

zoom_image_factor can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device. Due to numerical reasons, there can be slight differences in the output compared to the execution on the CPU.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Input image.

▷ **ImageZoomed** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Scaled image.

▷ **ScaleWidth** (input_control) ..... extent.x ⇝ *real*
Scale factor for the width of the image.
Default: 0.5
Suggested values: ScaleWidth ∈ {0.25, 0.5, 1.5, 2.0}
Value range: 0.001 ≤ ScaleWidth ≤ 10.0
Minimum increment: 0.001
Recommended increment: 0.1

▷ **ScaleHeight** (input_control) ..... extent.y ⇝ *real*
Scale factor for the height of the image.
Default: 0.5
Suggested values: ScaleHeight ∈ {0.25, 0.5, 1.5, 2.0}
Value range: 0.001 ≤ ScaleHeight ≤ 10.0
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Type of interpolation.
Default: 'constant'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

Example

```
read_image(Image,'monkey')
dev_display (Image)
zoom_image_factor (Image, ZoomImage, 0.25, 0.25, 'constant')
dev_display (ZoomImage)
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

zoom_image_size (Image : ImageZoom : Width, Height, Interpolation :)

Zoom an image to a given size.

zoom_image_size scales the image Image to the size given by Width and Height. The parameter Interpolation determines the type of interpolation used (see affine_trans_image). The domain of the input image is ignored, i.e., assumed to be the full rectangle of the image.

Attention

If the system parameter *'int_zooming'* is set to *'true'*, the internally used integer arithmetic may lead to errors in the following three cases: First, if zoom_image_size is used on an uint2 or int2 image with high dynamics (i.e. images containing values close to the respective limits) in combination with scale factors (ratio of output to input image size) smaller than 0.5, then the gray values of the output image may be erroneous. Second, if Interpolation is set to a value other than *'nearest_neighbor'*, a large scale factor is applied, and a large output image is obtained, then undefined gray values at the lower and at the right image border may result. The maximum width B_{max} of this border of undefined gray values can be estimated as $B_{max} = 0.5 \cdot S \cdot I/2^{15}$, where S is the scale factor in one dimension and I is the size of the output image in the corresponding dimension. Third, for real images undefined gray values can occur on all image borders, if Interpolation is set to *'nearest_neighbor'*, and if both the input and output image is large. In all cases, it is recommended to set *'int_zooming'* to *'false'* via the operator set_system.

If *'nearest_neighbor'* is set as interpolation method the results can differ slightly for different image types. This is due to the usage of image type specific optimizations of the applied interpolation algorithm.

zoom_image_size is not parallelized internally if Width and Height correspond to half the dimensions of Image. Further zoom_image_size is not parallelized internally with Interpolation='*nearest_neighbor*'.

zoom_image_size can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device. Due to numerical reasons, there can be slight differences in the output compared to the execution on the CPU.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Input image.

▷ **ImageZoom** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Scaled image.

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the resulting image.
Default: 512
Suggested values: `Width` ∈ {128, 256, 512}
Value range: 2 ≤ `Width` ≤ 512
Minimum increment: 1
Recommended increment: 10

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the resulting image.
Default: 512
Suggested values: `Height` ∈ {128, 256, 512}
Value range: 2 ≤ `Height` ≤ 512
Minimum increment: 1
Recommended increment: 10

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Type of interpolation.
Default: 'constant'
List of values: `Interpolation` ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

Example

```
read_image(Image,'monkey')
dev_display (Image)
zoom_image_size(Image,ZoomImage,200,200,'constant')
dev_display (ZoomImage)
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

12.8 Inpainting

```
harmonic_interpolation ( Image,
    Region :  InpaintedImage :  Precision :  )
```

Perform a harmonic interpolation on an image region.

The operator harmonic_interpolation reconstructs the destroyed image data of Image inside the region Region by solving the discrete Laplace equation $u_{xx} + u_{yy} = 0$ for the corresponding gray value function u. The unique solution, which exists under Dirichlet boundary conditions given by Image outside of Region, is returned in InpaintedImage.

This technique is called harmonic interpolation since in function theory the solutions of the Laplace equation are referred to as harmonic functions.

If Region touches the border of the gray value matrix of Image and thus some Dirichlet boundary values do not exist, von Neumann boundary conditions are used instead. This means that the gray values are mirrored at the border of Image. If no Dirichlet boundary values exist at all, a constant image with gray value *0* is returned.

The spatial derivatives are discretized as $u_{xx}(x,y) = u(x-1,y) - 2u(x,y) + u(x+1,y)$ and $u_{yy}(x,y) = u(x,y-1) - 2u(x,y) + u(x,y+1)$. The equation is solved by an iterative conjugate gradient solver, which iteratively improves the computational error until the maximum norm of its update step becomes a smaller fraction than Precision of the norm of the input data or a maximum of *1000* iterations is reached. $\texttt{Precision} = 0.01$ thus means a relative computational accuracy of 1%.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **Region** (input_object) ..... region ⇝ *object*
  Inpainting region.
- ▷ **InpaintedImage** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **Precision** (input_control) ..... real ⇝ *real*
  Computational accuracy.
  Default: 0.001
  Suggested values: Precision ∈ {0.0, 0.0001, 0.001, 0.01}
  Restriction: Precision >= 0.0

Execution Information

inpainting_aniso (Image, Region : InpaintedImage : Mode, Contrast, Theta, Iterations, Rho :)

Perform an inpainting by anisotropic diffusion.

The operator inpainting_aniso uses the anisotropic diffusion according to the model of Perona and Malik, to continue image edges that cross the border of the region Region and to connect them inside of Region.

With this, the structure of the edges in Region will be made consistent with the surrounding image matrix, so that an occlusion of errors or unwanted objects in the input image, a so called inpainting, is less visible to the human beholder, since there remain no obvious artifacts or smudges.

Considering the image as a gray value function u, the algorithm is a discretization of the partial differential equation

$$u_t = div(g(|\nabla u|^2, c)\nabla u)$$

with the initial value $u = u_0$ defined by Image at a time $t_0 = 0$. The equation is iterated Iterations times in time steps of length Theta, so that the output image InpaintedImage contains the gray value function at the time Iterations $\cdot$ Theta.

The primary goal of the anisotropic diffusion, which is also referred to as nonlinear isotropic diffusion, is the elimination of image noise in constant image patches while preserving the edges in the image. The distinction between edges and constant patches is achieved using the threshold Contrast on the magnitude of the gray value differences between adjacent pixels. Contrast is referred to as the contrast parameter and is abbreviated with the letter c. If the edge information is distributed in an environment of the already existing edges by smoothing the edge amplitude matrix, it is furthermore possible to continue edges into the computation area Region. The standard deviation of this smoothing process is determined by the parameter Rho.

The algorithm used is basically the same as in the anisotropic diffusion filter anisotropic_diffusion, except that here, border treatment is not done by mirroring the gray values at the border of Region. Instead, this procedure is only applicable on regions that keep a distance of at least 3 pixels to the border of the image matrix of Image, since the gray values on this band around Region are used to define the boundary conditions for the respective differential equation and thus assure consistency with the neighborhood of Region. Please note that the inpainting progress is restricted to those pixels that are included in the ROI of the input image Image. If the ROI does not include the entire region Region, a band around the intersection of Region and the ROI is used to define the boundary values.

The result of the diffusion process depends on the gray values in the computation area of the input image Image. It must be pointed out that already existing image edges are preserved within Region. In particular, this holds for gray value jumps at the border of Region, which can result for example from a previous inpainting with constant gray value. If the procedure is to be used for inpainting, it is recommended to apply the operator harmonic_interpolation first to remove all unwanted edges inside the computation area and to minimize the gray value difference between adjacent pixels, unless the input image already contains information inside Region that should be preserved.

The variable diffusion coefficient g can be chosen to follow different monotonically decreasing functions with values between *0* and *1* and determines the response of the diffusion process to an edge. With the parameter Mode, the following functions can be selected:

$$g_1(x, c) = \frac{1}{\sqrt{1 + 2\frac{x}{c^2}}}$$

Choosing the function g_1 by setting Mode to *'parabolic'* guarantees that the associated differential equation is parabolic, so that a well-posedness theory exists for the problem and the procedure is stable for an arbitrary step size Theta. In this case however, there remains a slight diffusion even across edges of an amplitude larger than c.

$$g_2(x, c) = \frac{1}{1 + \frac{x}{c^2}}$$

The choice of *'perona-malik'* for Mode, as used in the publication of Perona and Malik, does not possess the theoretical properties of g_1, but in practice it has proved to be sufficiently stable and is thus widely used. The theoretical instability results in a slight sharpening of strong edges.

$$g_3(x, c) = 1 - \exp(-C\frac{c^8}{x^4})$$

The function g_3 with the constant $C = 3.31488$, proposed by Weickert, and selectable by setting Mode to *'weickert'* is an improvement of g_2 with respect to edge sharpening. The transition between smoothing and sharpening happens very abruptly at $x = c^2$.

Furthermore, the choice of the value *'shock'* is possible for `Mode` to select a contrast invariant modification of the anisotropic diffusion. In this variant, the generation of edges is not achieved by variation of the diffusion coefficient g, but the constant coefficient $g = 1$ and thus isotropic diffusion is used. Additionally, a shock filter of type

$$u_t = -sgn(\nabla|\nabla u|)|\nabla u|$$

is applied, which, just like a negative diffusion coefficient, causes a sharpening of the edges, but works independent of the absolute value of $|\nabla u|$. In this mode, `Contrast` does not have the meaning of a contrast parameter, but specifies the ratio between the diffusion and the shock filter part applied at each iteration step. Hence, the value *0* would correspond to pure isotropic diffusion, as used in the operator `isotropic_diffusion`. The parameter is scaled in such a way that diffusion and sharpening cancel each other out for `Contrast` = *1*. A value `Contrast` > *1* should not be used, since it would make the algorithm unstable.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **`Region`** (input_object) ..... region ⇝ *object*
  Inpainting region.
- ▷ **`InpaintedImage`** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **`Mode`** (input_control) ..... string ⇝ *string*
  Type of edge sharpening algorithm.
  Default: 'weickert'
  List of values: `Mode` ∈ {'weickert', 'perona-malik', 'parabolic', 'shock'}
- ▷ **`Contrast`** (input_control) ..... real ⇝ *real*
  Contrast parameter.
  Default: 5.0
  Suggested values: `Contrast` ∈ {0.5, 2.0, 5.0, 10.0, 20.0, 50.0, 100.0}
  Restriction: Contrast > 0
- ▷ **`Theta`** (input_control) ..... real ⇝ *real*
  Step size.
  Default: 0.5
  Suggested values: `Theta` ∈ {0.5, 1.0, 5.0, 10.0, 30.0, 100.0}
  Restriction: Theta > 0
- ▷ **`Iterations`** (input_control) ..... integer ⇝ *integer*
  Number of iterations.
  Default: 10
  Suggested values: `Iterations` ∈ {1, 3, 10, 100, 500}
  Restriction: Iterations >= 1
- ▷ **`Rho`** (input_control) ..... real ⇝ *real*
  Smoothing coefficient for edge information.
  Default: 3.0
  Suggested values: `Rho` ∈ {0.0, 0.1, 0.5, 1.0, 3.0, 10.0}
  Restriction: Rho >= 0

Example

```
read_image (Image, 'fabrik')
gen_rectangle1 (Rectangle, 270, 180, 320, 230)
harmonic_interpolation (Image, Rectangle, InpaintedImage, 0.01)
inpainting_aniso (InpaintedImage, Rectangle, InpaintedImage2, \
                  'perona-malik', 5.0, 100, 50, 0.5)
dev_display(InpaintedImage2)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

inpainting_ced (Image, Region : InpaintedImage : Sigma, Rho, Theta, Iterations :)

Perform an inpainting by coherence enhancing diffusion.

The operator inpainting_ced performs an anisotropic diffusion process on the region Region of the input image Image with the objective of completing discontinuous image edges diffusively by increasing the coherence of the image structures contained in Image and without smoothing these edges perpendicular to their dominating direction. The mechanism is the same as in the operator coherence_enhancing_diff, which is based on a discretization of the anisotropic diffusion equation

$$u_t = div(G(u)\nabla u)$$

formulated by Weickert. With a 2×2 coefficient matrix G that depends on the gray values in Image, this is an enhancement of the mean curvature flow or intrinsic heat equation

$$u_t = div(\frac{\nabla u}{|\nabla u|})|\nabla u| = curv(u)|\nabla u|$$

on the gray value function u defined by the input image Image at a time $t_0 = 0$. The smoothing operator mean_curvature_flow is a direct application of the mean curvature flow equation. With the operator inpainting_mcf, it can also be used for image inpainting. The discrete diffusion equation is solved in Iterations time steps of length Theta, so that the output image InpaintedImage contains the gray value function at the time Iterations $\cdot$ Theta.

To detect the image direction more robustly, in particular on noisy input data, an additional isotropic smoothing step can precede the computation of the gray value gradients. The parameter Sigma determines the magnitude of the smoothing by means of the standard deviation of a corresponding Gaussian convolution kernel, as used in the operator isotropic_diffusion for isotropic image smoothing.

Similar to the operator inpainting_mcf, the structure of the image data in Region is simplified by smoothing the level lines of Image. By this, image errors and unwanted objects can be removed from the image, while the edges in the neighborhood are extended continuously. This procedure is called image inpainting. The objective is to introduce a minimum amount of artifacts or smoothing effects, so that the image manipulation is least visible to a human beholder.

While the matrix G is given by

$$G_{MCF}(u) = I - \frac{1}{|\nabla u|^2}\nabla u(\nabla u)^T,$$

in the case of the operator inpainting_mcf, where I denotes the unit matrix, G_{MCF} is again smoothed componentwise by a Gaussian filter of standard deviation Rho for coherence_enhancing_diff. Then, the final coefficient matrix

$$G_{CED} = g_1\left((\lambda_1 - \lambda_2)^2\right) w_1 (w_1)^T + g_2\left((\lambda_1 - \lambda_2)^2\right) w_2 (w_2)^T$$

is constructed from the eigenvalues λ_1, λ_2 and eigenvectors w_1, w_2 of the resulting intermediate matrix, where the functions

$$\begin{aligned} g_1(p) &= 0.001 \\ g_2(p) &= 0.001 + 0.999 \exp\left(\frac{-1}{p}\right) \end{aligned}$$

were determined empirically and taken from the publication of Weickert.

Hence, the diffusion direction in mean_curvature_flow is only determined by the local direction of the gray value gradient, while G_{CED} considers the macroscopic structure of the image objects on the scale Rho and the magnitude of the diffusion in coherence_enhancing_diff depends on how well this structure is defined.

To achieve the highest possible consistency of the newly created edges with the image data from the neighborhood, the gray values are not mirrored at the border of Region to compute the convolution with the smoothing filter mask of scale Rho on the pixels close to the border, although this would be the common approach for filter operators. Instead, the existence of gray values on a band of width $ceil(3.1 * Rho) + 2$ pixels around Region is presumed and these values are used in the convolution. This means that Region must keep this much distance to the border of the image matrix Image. By involving the gray values and directional information from this extended area, it can be achieved that the continuation of the edges is not only continuous, but also smooth, which means without kinks. Please note that the inpainting progress is restricted to those pixels that are included in the ROI of the input image Image. If the ROI does not include the entire region Region, a band around the intersection of Region and the ROI is used to define the boundary values.

To decrease the number of iterations required for attaining a satisfactory result, it may be useful to initialize the gray value matrix in Region with the harmonic interpolant, a continuous function of minimal curvature, by applying the operator harmonic_interpolation to Image before calling inpainting_ced.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **Region** (input_object) ..... region ⇝ *object*
  Inpainting region.
- ▷ **InpaintedImage** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **Sigma** (input_control) ..... real ⇝ *real*
  Smoothing for derivative operator.
  Default: 0.5
  Suggested values: Sigma ∈ {0.0, 0.1, 0.5, 1.0}
  Restriction: Sigma >= 0
- ▷ **Rho** (input_control) ..... real ⇝ *real*
  Smoothing for diffusion coefficients.
  Default: 3.0
  Suggested values: Rho ∈ {0.0, 1.0, 3.0, 5.0, 10.0, 30.0}
  Restriction: Rho >= 0
- ▷ **Theta** (input_control) ..... real ⇝ *real*
  Time step.
  Default: 0.5
  Suggested values: Theta ∈ {0.1, 0.2, 0.3, 0.4, 0.5}
  Restriction: 0 < Theta <= 0.5

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 10
Suggested values: Iterations ∈ {1, 5, 10, 20, 50, 100, 500}
Restriction: Iterations >= 1

Example

```
read_image (Image, 'fabrik')
gen_rectangle1 (Rectangle, 270, 180, 320, 230)

inpainting_ct (Image, Region : InpaintedImage : Epsilon, Kappa, Sigma, Rho, ChannelCoefficients :)

Perform an inpainting by coherence transport.

The operator inpainting_ct inpaints a missing region Region of an image Image by transporting image information from the region's boundary along the coherence direction into this region.

Since this operator's basic concept is inpainting by continuing broken contour lines, the image content and inpainting region must be such that this idea makes sense. That is, if a contour line hits the region to inpaint at a pixel p, there should be some opposite point q where this contour line continues so that the continuation of contour lines from two opposite sides can succeed. In cases where there is less geometry in the image, a diffusion-based inpainter, e.g., harmonic_interpolation may yield better results. Alternatively, Kappa can be set to *0*. An extreme situation with little global geometries are pure textures. Then the idea behind this operator will fail to produce good results (think of a checkerboard with a big region to inpaint relative to the checker fields). For these kinds of images, a texture-based inpainting, e.g., inpainting_texture, can be used instead.

The operator uses a so-called upwind scheme to assign gray values to the missing pixels, i.e.,:

- The order of the pixels to process is given by their Euclidean distance to the boundary of the region to inpaint.
- A new value u_i is computed as a weighted average of already known values u_j within a disc of radius Epsilon around the current pixel. The disc is restricted to already known pixels.
- The size of this scheme's mask depends on Epsilon.

The initially used image data comes from a stripe of thickness Epsilon around the region to inpaint. Thus, Epsilon must be at least 1 for the scheme to work, but should be greater. The maximum value for Epsilon depends on the gray values that should be transported into the region. Choosing Epsilon = *5* can be used in many cases.

Since the goal is to close broken contour lines, the direction of the level lines must be estimated and used in the weight. This estimated direction is called the coherence direction, and is computed by means of the structure tensor S.

$$S = G_\rho * DvDv^T$$

and

$$v = G_\sigma * u$$

where $*$ denotes the convolution, u denotes the gray value image, D the derivative and G Gaussian kernels with standard deviation σ and ρ. These standard deviations are defined by the operator's parameters Sigma and Rho. Sigma should have the size of the noise or unimportant little objects, which are then not considered in the estimation step by the pre-smoothing. Rho gives the size of the window around a pixel that will be used for direction estimation. The coherence direction c then is given by the eigendirection of S with respect to the minimal eigenvalue λ, i.e.

$$Sc = \lambda c, |c| = 1$$

For multichannel or color images, the scheme above is applied to each channel separately, but the weights must be the same for all channels to propagate information in the same direction. Since the weight depends on the coherence direction, the common direction is given by the eigendirection of a composite structure tensor. If $u_1, ..., u_n$ denote the n channels of the image, the channel structure tensors $S_1, ..., S_n$ are computed and then combined to the composite structure tensor S.

$$S = \sum_{i=1}^{n} a_i S_i$$

The coefficients a_i are passed in ChannelCoefficients, which is a tuple of length n or length 1. If the tuple length is 1, the arithmetic mean is used, i.e., $a_i = 1/n$. If the length of ChannelCoefficients matches the number of channels, the a_i are set to

$$a_i = \frac{\texttt{ChannelCoefficients}_i}{\sum_{i=1}^{n} \texttt{ChannelCoefficients}_i}$$

in order to get a well-defined convex combination. Hence, the ChannelCoefficients must be greater than or equal to zero and their sum must be greater than zero. If the tuple length is neither 1 nor the number of channels or the requirement above is not satisfied, the operator returns an error message.

The purpose of using other ChannelCoefficients than the arithmetic mean is to adapt to different color codes. The coherence direction is a geometrical information of the composite image, which is given by high contrasts such as edges. Thus the more contrast a channel has, the more geometrical information it contains, and consequently the greater its coefficient should be chosen (relative to the others). For RGB images, *[0.299, 0.587, 0.114]* is a good choice.

The weight in the scheme is the product of a directional component and a distance component. If p is the 2D coordinate vector of the current pixel to be inpainted and q the 2D coordinate of a pixel in the neighborhood (the disc restricted to already known pixels), the directional component measures the deviation of the vector $p - q$ from the coherence direction. If the deviation exponentially scaled by β is large, a low directional component is assigned, whereas if it is small, a large directional component is assigned. β is controlled by Kappa (in percent):

$$\beta = 20 * \texttt{Epsilon} * \texttt{Kappa}/100$$

Kappa defines how important it is to propagate information along the coherence direction, so a large Kappa yields sharp edges, while a low Kappa allows for more diffusion.

A special case is when Kappa is zero: In this case the directional component of the weight is constant (one). The direction estimation step is then skipped to save computational costs and the parameters Sigma, Rho, ChannelCoefficients become meaningless, i.e, the propagation of information is not based on the structures visible in the image.

The distance component is $1/|p-q|$. Consequently, if q is far away from p, a low distance component is assigned, whereas if it is near to p, a high distance component is assigned.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **Region** (input_object) ..... region ⇝ *object*
  Inpainting region.
- ▷ **InpaintedImage** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **Epsilon** (input_control) ..... number ⇝ *real*
  Radius of the pixel neighborhood.
  Default: 5.0
  Value range: $1.0 \leq$ Epsilon ≤ 20.0
  Minimum increment: 1.0
  Recommended increment: 1.0
- ▷ **Kappa** (input_control) ..... number ⇝ *real*
  Sharpness parameter in percent.
  Default: 25.0
  Value range: $0.0 \leq$ Kappa ≤ 100.0
  Minimum increment: 1.0
  Recommended increment: 1.0
- ▷ **Sigma** (input_control) ..... number ⇝ *real*
  Pre-smoothing parameter.
  Default: 1.41
  Value range: $0.0 \leq$ Sigma ≤ 20.0
  Minimum increment: 0.001
  Recommended increment: 0.01
- ▷ **Rho** (input_control) ..... number ⇝ *real*
  Smoothing parameter for the direction estimation.
  Default: 4.0
  Value range: $0.001 \leq$ Rho ≤ 20.0
  Minimum increment: 0.001
  Recommended increment: 0.01
- ▷ **ChannelCoefficients** (input_control) ..... number(-array) ⇝ *real*
  Channel weights.
  Default: 1

Example

```
read_image (Image, 'claudia')
gen_circle (Circle, 333, 164, 35)
inpainting_ct (Image, Circle, InpaintedImage, 15, 25, 1.5, 3,1.0)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

inpainting_mcf (Image, Region : InpaintedImage : Sigma, Theta, Iterations :)

Perform an inpainting by smoothing of level lines.

The operator inpainting_mcf extends the image edges that adjoin the region Region of the input image Image into the interior of Region and connects their ends by smoothing the level lines of the gray value function of Image.

This happens through the application of the mean curvature flow or intrinsic heat equation

$$u_t = div(\frac{\nabla u}{|\nabla u|})|\nabla u| = curv(u)|\nabla u|$$

on the gray value function u defined in the region Region by the input image Image at a time $t_0 = 0$. The discretized equation is solved in Iterations time steps of length Theta, so that the output image InpaintedImage contains the gray value function at the time Iterations · Theta.

A stationary state of the mean curvature flow equation, which is also the basis of the operator mean_curvature_flow, has the special property that the level lines of u all have the curvature *0*. This means that after sufficiently many iterations there are only straight edges left inside the computation area of the output image InpaintedImage. By this, the structure of objects inside of Region can be simplified, while the remaining edges are continuously connected to those of the surrounding image matrix. This allows for a removal of image errors and unwanted objects in the input image, a so called image inpainting, which is only weakly visible to a human beholder since there remain no obvious artifacts or smudges.

To detect the image direction more robustly, in particular on noisy input data, an additional isotropic smoothing step can precede the computation of the gray value gradients. The parameter Sigma determines the magnitude of the smoothing by means of the standard deviation of a corresponding Gaussian convolution kernel, as used in the operator isotropic_diffusion for isotropic image smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **Region** (input_object) ..... region ⇝ *object*
  Inpainting region.
- ▷ **InpaintedImage** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **Sigma** (input_control) ..... real ⇝ *real*
  Smoothing for derivative operator.
  Default: 0.5
  Suggested values: Sigma ∈ {0.0, 0.1, 0.5, 1.0}
  Restriction: Sigma >= 0
- ▷ **Theta** (input_control) ..... real ⇝ *real*
  Time step.
  Default: 0.5
  Suggested values: Theta ∈ {0.1, 0.2, 0.3, 0.4, 0.5}
  Restriction: 0 < Theta <= 0.5

▷ **Iterations** (input_control) . . . . . integer ⇝ *integer*
Number of iterations.
Default: 10
Suggested values: Iterations ∈ {1, 5, 10, 20, 50, 100, 500}
Restriction: Iterations >= 1

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

inpainting_texture (Image, Region : InpaintedImage : MaskSize, SearchSize, Anisotropy, PostIteration, Smoothness :)

Perform an inpainting by texture propagation.

The operator inpainting_texture is used for removing large objects and image errors from the region Region of the input image Image. Image blocks of side length MaskSize are copied from the intact part of the image to the border of the computation area, until that area has been filled up with new gray values. This process is called image inpainting. Hence, the computation area is also referred to as the inpainting area and is reduced with every inserted rectangle, starting with Region. Let the center of the current block be at the point x. Since x is always chosen from the border of the inpainting area the current block overlaps with the known or already filled-in gray values. The gray value correlation with the overlapping part of this block is used to determine which other image block fits at the position x. As the correlation function, the sum of the squared gray value differences is used. The image blocks that are taken into account for the correlation, and hence as candidates for the data source of the next inpainting step, are called comparison blocks. The search area for suitable gray value patterns in which the centers of the comparison blocks is searched is limited to a square of side length $2 \cdot$ SearchSize around the point x.

On the one hand, the order in which the pixels of Region are filled in depends on the size of the overlapping area and thus the number of pixels available for the correlation. On the other hand, the absolute value of the derivative of the gray value function tangential to the border of the computation area is also considered. The larger the value of the parameter Anisotropy is, the more the points in which the derivative is large are preferred. This way it can be achieved that, e.g., straight lines which are represented by large gradients, are continued through the entire computation area without being interrupted by the inpainting of image structures from other parts of the border when the size of the inpainting area becomes small. On the other hand, a large value of Anisotropy also means that possible phantom edges, i.e., unwanted random structures that have developed during the inpainting process, are also propagated and the magnitude of those image disturbances is increased.

To confine the formation of such artifacts, the original algorithm can be extended by a post-iteration step that selects smooth and inconspicuous image patches as data sources for the inpainting. If the parameter PostIteration is set to *'min_grad'* the sum of the squares of the gray value gradients is minimized on the comparison blocks. With the value *'min_range_extension'*, the growth of the gray value interval of the comparison blocks with respect to the reference block around the point x is minimized. If PostIteration has the value *'none'* no post-iteration is performed. The choice of feasible blocks for this minimization process is determined by the parameter

Smoothness, which is an upper limit to the permitted increase of the mean absolute gray value difference between the comparison blocks and the reference block with respect to the block that was selected by the original algorithm. With increasing value of Smoothness, the inpainting result becomes smoother and loses structure. The matching accuracy of the selected comparison blocks decreases. If Smoothness is set to *0*, the post-iteration only considers comparison blocks with an equally high correlation to the reference block.

If the inpainting process cannot be completed because there are points x, for which no complete block of intact gray value information is contained in the search area of size SearchSize, the remaining pixels keep their initial gray value and the ROI of the output image InpaintedImage is reduced by the region that could not be processed. If the structure size of the ROI of Image or of the computation area Region is smaller than MaskSize, the execution time of the algorithm can increase extremely. Hence, it is recommended to only use clearly structured input regions.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **Region** (input_object) ..... region ⇝ *object*
  Inpainting region.
- ▷ **InpaintedImage** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **MaskSize** (input_control) ..... integer ⇝ *integer*
  Size of the inpainting blocks.
  Default: 9
  Suggested values: MaskSize ∈ {7, 9, 11, 15, 21}
  Restriction: MaskSize >= 3 && odd(MaskSize)
- ▷ **SearchSize** (input_control) ..... integer ⇝ *integer*
  Size of the search window.
  Default: 30
  Suggested values: SearchSize ∈ {15, 30, 50, 100, 1000}
  Restriction: 2 * SearchSize > MaskSize
- ▷ **Anisotropy** (input_control) ..... real ⇝ *real*
  Influence of the edge amplitude on the inpainting order.
  Default: 1.0
  Suggested values: Anisotropy ∈ {0.0, 0.01, 0.1, 0.5, 1.0, 10.0}
  Restriction: Anisotropy >= 0
- ▷ **PostIteration** (input_control) ..... string ⇝ *string*
  Post-iteration for artifact reduction.
  Default: 'none'
  List of values: PostIteration ∈ {'none', 'min_grad', 'min_range_extension'}
- ▷ **Smoothness** (input_control) ..... real ⇝ *real*
  Gray value tolerance for post-iteration.
  Default: 1.0
  Suggested values: Smoothness ∈ {0.0, 0.1, 0.2, 0.5, 1.0}
  Restriction: Smoothness >= 0

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

12.9 Lines

bandpass_image (Image : ImageBandpass : FilterType :)

Edge extraction using bandpass filters.

bandpass_image serves as an edge filter. It applies a linear filter with the following convolution mask to Image:

FilterType: *'lines'*
In contrast to the edge operator sobel_amp this filter detects lines instead of edges, i.e., two closely adjacent edges.

$$\begin{array}{rrrrr} 0 & -2 & -2 & -2 & 0 \\ -2 & 0 & 3 & 0 & -2 \\ -2 & 3 & 12 & 3 & -2 \\ -2 & 0 & 3 & 0 & -2 \\ 0 & -2 & -2 & -2 & 0 \end{array}$$

At the border of the image the gray values are mirrored. Over- and underflows of gray values are clipped. The resulting images are returned in ImageBandpass.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2
  Input images.
- ▷ **ImageBandpass** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2
  Bandpass-filtered images.
- ▷ **FilterType** (input_control) ..... string ⇝ *string*
  Filter type: currently only 'lines' is supported.
  Default: 'lines'
  List of values: FilterType ∈ {'lines'}

Example

```
bandpass_image(Image,&LineImage,"lines");
threshold(LineImage,&Lines,60.0,255.0);
skeleton(Lines,&ThinLines);
```

Result

bandpass_image returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

lines_color (Image : Lines : Sigma, Low, High, ExtractWidth, CompleteJunctions :)

Detect color lines and their width.

lines_color extracts color lines from the input image Image and returns the extracted lines as subpixel precise XLD-contours in Lines. Color lines are defined as dark lines in the amplitude image of the color edge filter (see edges_color). lines_color always uses the Canny color edge filter. Hence, the required partial derivatives of the image are always computed by convolution with the respective partial derivatives of the Gaussian smoothing masks (see derivate_gauss). The corresponding smoothing is determined by the parameter Sigma.

By defining color lines as dark lines in the amplitude image, in contrast to lines_gauss, for single-channel images no distinction is made whether the lines are darker or brighter than their surroundings. Furthermore, lines_color also returns staircase lines, i.e., lines for which the gray value of the lines lies between the gray values in the surrounding area to the left and right sides of the line. In multi-channel images, the above definition allows each channel to have a different line type. For example, in a three-channel image the first channel may have a dark line, the second channel a bright line, and the third channel a staircase line at the same position.

If ExtractWidth is set to *'true'* the line width is extracted for each line point. Because the line extractor is unable to extract certain junctions because of differential geometric reasons, it tries to extract these by different means if CompleteJunctions is set to *'true'*.

lines_color links the line points into lines by using an algorithm similar to a hysteresis threshold operation, which is also used in lines_gauss and edges_color_sub_pix. Points with an amplitude larger than High are immediately accepted as belonging to a line, while points with an amplitude smaller than Low are rejected. All other points are accepted as lines if they are connected to accepted line points (see also lines_gauss). Here, amplitude means the line amplitude of the dark line (see lines_gauss and lines_facet). This value corresponds to the third directional derivative of the smoothed input image in the direction perpendicular to the line.

For the choice of the thresholds High and Low one has to keep in mind that the third directional derivative depends on the amplitude and width of the line as well as the choice of Sigma. The value of the third derivative depends linearly on the amplitude, i.e., the larger the amplitude, the larger the response. For the width of the line there is an inverse dependence: The wider the line is, the smaller the response gets. This holds analogously for the dependence on Sigma: The larger Sigma is chosen, the smaller the second derivative will be. This means that for larger smoothing correspondingly smaller values for High and Low should be chosen.

The extracted lines are returned in a topologically sound data structure in Lines. This means that lines are correctly split at junction points.

lines_color defines the following attributes for each line point if ExtractWidth was set to *'false'*:

- *'angle'* The angle of the direction perpendicular to the line (oriented such that the normal vectors point to the right side of the line as the line is traversed from start to end point; the angles are given with respect to the row axis of the image.)
- *'response'*: The magnitude of the second derivative

If ExtractWidth was set to *'true'*, additionally the following attributes are defined:

- *'width_left'*: The line width to the left of the line
- *'width_right'*: The line width to the right of the line

Use get_contour_attrib_xld to obtain attribute values. See the operator reference of get_contour_attrib_xld for further information about contour attributes.

Attention

In general, but in particular if the line width is to be extracted, Sigma $\geq w/\sqrt{3}$ should be selected, where w is the width (half the diameter) of the lines in the image. As the lowest allowable value Sigma $\geq w/2.5$ *must* be

selected. If, for example, lines with a width of 4 pixels (diameter 8 pixels) are to be extracted, Sigma $\geq$ 2.3 should be selected. If it is expected that staircase lines are present in at least one channel, and if such lines should be extracted, in addition to the above restriction, Sigma $\leq w$ should be selected. This is necessary because staircase lines turn into normal step edges for large amounts of smoothing, and therefore no longer appear as dark lines in the amplitude image of the color edge filter.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2
  Input image.
- ▷ **Lines** (output_object) . . . . . xld_cont-array ⇝ *object*
  Extracted lines.
- ▷ **Sigma** (input_control) . . . . . number ⇝ *real* / integer
  Amount of Gaussian smoothing to be applied.
  Default: 1.5
  Suggested values: Sigma ∈ {1, 1.2, 1.5, 1.8, 2, 2.5, 3, 4, 5}
  Recommended increment: 0.1
  Restriction: Sigma > 0.0
- ▷ **Low** (input_control) . . . . . number ⇝ *real* / integer
  Lower threshold for the hysteresis threshold operation.
  Default: 3
  Suggested values: Low ∈ {0, 0.5, 1, 2, 3, 4, 5, 8, 10}
  Value range: 0 ≤ Low
  Recommended increment: 0.5
- ▷ **High** (input_control) . . . . . number ⇝ *real* / integer
  Upper threshold for the hysteresis threshold operation.
  Default: 8
  Suggested values: High ∈ {0, 0.5, 1, 2, 3, 4, 5, 8, 10, 12, 15, 18, 20, 25}
  Value range: 0 ≤ High
  Recommended increment: 0.5
  Restriction: High >= Low
- ▷ **ExtractWidth** (input_control) . . . . . string ⇝ *string*
  Should the line width be extracted?
  Default: 'true'
  List of values: ExtractWidth ∈ {'true', 'false'}
- ▷ **CompleteJunctions** (input_control) . . . . . string ⇝ *string*
  Should junctions be added where they cannot be extracted?
  Default: 'true'
  List of values: CompleteJunctions ∈ {'true', 'false'}

Complexity

The amount of temporary memory required is dependent on the height H of the domain of Image.

Result

lines_color returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

lines_facet (Image : Lines : MaskSize, Low, High, LightDark :)

Detection of lines using the facet model.

The operator lines_facet can be used to extract lines (curvilinear structures) from the image Image. The extracted lines are returned in Lines as subpixel precise XLD-contours. The parameter LightDark determines, whether bright or dark lines are extracted.

The extraction is done by using the facet model, i.e., a least squares fit, to determine the parameters of a quadratic polynomial in x and y for each point of the image. The parameter MaskSize determines the size of the window used for the least squares fit. Larger values of MaskSize lead to a larger smoothing of the image, but can lead to worse localization of the line. The parameters of the polynomial are used to calculate the line direction for each pixel. Pixels which exhibit a local maximum in the second directional derivative perpendicular to the line direction are marked as line points. The line points found in this manner are then linked to contours. This is done by immediately accepting line points that have a second derivative larger than High. Points that have a second derivative smaller than Low are rejected. All other line points are accepted if they are connected to accepted points by a connected path. This is similar to a hysteresis threshold operation with infinite path length (see hysteresis_threshold). However, this function is not used internally since it does not allow the extraction of subpixel precise contours.

The gist of how to select the thresholds in the description of lines_gauss also holds for this operator. A value of Sigma = 1.5 there roughly corresponds to a MaskSize of 5 here.

The extracted lines are returned in a topologically sound data structure in Lines. This means that lines are correctly split at junction points.

lines_facet defines the following attributes for each line point:

'angle': The angle of the direction perpendicular to the line

'response': The magnitude of the second derivative

Use get_contour_attrib_xld to obtain attribute values. See the operator reference of get_contour_attrib_xld for further information about contour attributes.

Attention

The smaller the filter size MaskSize is chosen, the more short, fragmented lines will be extracted. This can lead to considerably longer execution times.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
  Input image.
- ▷ **Lines** (output_object) ..... xld_cont-array ⇝ *object*
  Extracted lines.

▷ **MaskSize** (input_control) . . . . . integer ⇝ *integer*
Size of the facet model mask.
Default: 5
List of values: MaskSize ∈ {3, 5, 7, 9, 11}

▷ **Low** (input_control) . . . . . number ⇝ *real* / integer
Lower threshold for the hysteresis threshold operation.
Default: 3
Suggested values: Low ∈ {0, 0.5, 1, 2, 3, 4, 5, 8, 10}
Value range: 0 ≤ Low
Recommended increment: 0.5

▷ **High** (input_control) . . . . . number ⇝ *real* / integer
Upper threshold for the hysteresis threshold operation.
Default: 8
Suggested values: High ∈ {0, 0.5, 1, 2, 3, 4, 5, 8, 10, 12, 15, 18, 20, 25}
Value range: 0 ≤ High
Recommended increment: 0.5
Restriction: High >= Low

▷ **LightDark** (input_control) . . . . . string ⇝ *string*
Extract bright or dark lines.
Default: 'light'
List of values: LightDark ∈ {'dark', 'light'}

Example

```
* Detection of lines in an aerial image
read_image(Image,'mreut4_3')
lines_facet(Image,Lines,5,3,8,'light')
dev_display(Lines)
```

Complexity

Let A be the number of pixels in the domain of Image. Then the runtime complexity is $O(A * \texttt{MaskSize})$.

The amount of temporary memory required is dependent on the height H of the domain of Image and the width W of Image. Let $S = W * H$, then lines_facet requires at least $55 * S$ bytes of temporary memory during execution.

Result

lines_facet returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

2D Metrology

lines_gauss (Image : Lines : Sigma, Low, High, LightDark, ExtractWidth, LineModel, CompleteJunctions :)

Detect lines and their width.

The operator lines_gauss can be used to extract lines (curvilinear structures) from the image Image. The extracted lines are returned in Lines as subpixel precise XLD-contours.

The parameter LightDark determines, whether bright (*'light'*) or dark (*'dark'*) lines are extracted.

If ExtractWidth is set to *'true'* the line width is extracted for each line point.

LineModel determines if and how the position and width of asymmetric lines (lines having different contrast on each side of the line) should be compensated. The following values can be set for LineModel:

'bar-shaped': Bar-shaped line model. Covers most use cases.

'parabolic': Parabolic line model. Can be used for the extraction of backlit tubular objects (e.g., blood vessels in X-ray images) where the lines appear very sharp.

'gaussian': Gaussian line model. Can be used for the extraction of backlit tubular objects (e.g., blood vessels in X-ray images) where the lines appear less sharp.

'none': The effects of asymmetric lines are not compensated.

The parameter LineModel is only effective if ExtractWidth=*'true'*.

Because the line extractor is unable to extract certain junctions because of differential geometric reasons, it tries to extract these by different means if CompleteJunctions is set to *'true'*.

The extraction is done by using partial derivatives of a Gaussian smoothing kernel to determine the parameters of a quadratic polynomial in x and y for each point of the image. The parameter Sigma determines the amount of smoothing to be performed. Larger values of Sigma lead to a larger smoothing of the image, but can lead to worse localization of the line. Generally, the localization will be much better than that of lines returned by lines_facet with comparable parameters. The parameters of the polynomial are used to calculate the line direction for each pixel. Pixels which exhibit a local maximum in the second directional derivative perpendicular to the line direction are marked as line points. The line points found in this manner are then linked to contours. This is done by immediately accepting line points that have a second derivative larger than High. Points that have a second derivative smaller than Low are rejected. All other line points are accepted if they are connected to accepted points by a connected path. This is similar to a hysteresis threshold operation with infinite path length (see hysteresis_threshold), here, however contours are extracted with subpixel precision.

For the choice of the thresholds High and Low one has to keep in mind that the second directional derivative depends on the amplitude and width of the line as well as the choice of Sigma. The value of the second derivative depends linearly on the amplitude, i.e., the larger the amplitude, the larger the response. For the width of the line there is an approximately inverse exponential dependence: The wider the line is, the smaller the response gets. This holds analogously for the dependence on Sigma: The larger Sigma is chosen, the smaller the second derivative will be. This means that for larger smoothing correspondingly smaller values for High and Low have to be chosen. Two examples help to illustrate this: If 5 pixel wide lines with an amplitude larger than 100 are to be extracted from an image with a smoothing of Sigma = 1.5, High should be chosen larger than 14. If, on the other hand, 10 pixel wide lines with an amplitude larger than 100 and a Sigma = 3 are to be detected, High should be chosen larger than 3.5. For the choice of Low values between 0.25 High and 0.5 High are appropriate.

The parameters Low and High can be calculated from the respective gray value contrast of the lines to be extracted ($ContrastLow$ and $ContrastHigh$) and from the chosen value for Sigma with the following formula:

$$\begin{pmatrix} \texttt{Low} \\ \texttt{High} \end{pmatrix} = \left| -2 \cdot \begin{pmatrix} ContrastLow \\ ContrastHigh \end{pmatrix} \cdot \frac{w}{\sqrt{2\pi} \cdot \texttt{Sigma}^3} \cdot e^{-\frac{w^2}{2 \cdot \texttt{Sigma}^2}} \right|$$

where w is the width (half the diameter) of the lines in the image. $ContrastLow$ and $ContrastHigh$ determine the gray value range the lines are expected to differ from the background. Suitable values for Low and High can be calculated using the procedure calculate_lines_gauss_parameters.

The extracted lines are returned in a topologically sound data structure in Lines. This means that lines are correctly split at junction points.

lines_gauss defines the following attributes for each line point if ExtractWidth was set to *'false'*:

'angle': The angle of the direction perpendicular to the line
'response': The magnitude of the second derivative

If `ExtractWidth` was set to *'true'*, the following attributes are defined in addition to *'angle'* and *'response'*:

'width_left': The line width to the left of the line
'width_right': The line width to the right of the line

If `ExtractWidth` was set to *'true'* and `LineModel` to a value different from *'none'*, the following attributes are defined in addition to *'angle'*, *'response'*, *'width_left'*, and *'width_right'*:

'asymmetry': The asymmetry of the line point
'contrast': The contrast of the line point

Here, the asymmetry is positive if the asymmetric part, i.e., the part with the weaker gradient, is on the right side of the line, while it is negative if the asymmetric part is on the left side of the line.

The contrast results from the difference between the gray value of the line and the gray value of the background. The contrast is positive if bright lines are extracted, while it is negative if dark lines are extracted. The returned contrast may be larger than the maximum gray value the input image type is able to represent, especially if the line model specified by `LineModel` is not present in the image. For example, for byte images, the contrast may be greater than 255.

Use `get_contour_attrib_xld` to obtain attribute values. See the operator reference of `get_contour_attrib_xld` for further information about contour attributes.

`lines_gauss` can be executed on OpenCL devices.

Attention

In general, but in particular if the line width is to be extracted, `Sigma` $\geq w/\sqrt{3}$ should be selected, where w is the width (half the diameter) of the lines in the image. As the lowest allowable value `Sigma` $\geq w/2.5$ must be selected. If, for example, lines with a width of 4 pixels (diameter 8 pixels) are to be extracted, `Sigma` ≥ 2.3 should be selected. Note that the attributes *'width_left'*, *'width_right'*, *'asymmetry'*, and *'contrast'* are set to zero if `Sigma` is set too low.

`lines_gauss` uses a special implementation that is optimized using SSE2 or AVX2 instructions, if the system parameters *'sse2_enable'* or *'avx2_enable'* are set to *'true'* (see `set_system`). These implementations are slightly inaccurate compared to the pure C version due to numerical issues. If you prefer accuracy over performance you can set the respective system parameter to *'false'* (using `set_system`) before you call `lines_gauss`. This way `lines_gauss` does not use SSE2 or AVX2 accelerations. Don't forget to set *'sse2_enable'* or *'avx2_enable'* back to *'true'* afterwards.

When `lines_gauss` is run on OpenCL devices, the same limitations apply as for `derivate_gauss`: `Sigma` must be chosen so that the required filter mask is smaller than 129 pixels. Also note that the results can vary compared to the CPU implementation.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **`Image`** (input_object) ..... singlechannelimage ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
  Input image.
- ▷ **`Lines`** (output_object) ..... xld_cont-array ⇝ *object*
  Extracted lines.
- ▷ **`Sigma`** (input_control) ..... number ⇝ *real* / integer
  Amount of Gaussian smoothing to be applied.
  Default: 1.5
  Suggested values: `Sigma` ∈ {1, 1.2, 1.5, 1.8, 2, 2.5, 3, 4, 5}
  Value range: 0 ≤ Sigma
  Recommended increment: 0.1
- ▷ **`Low`** (input_control) ..... number ⇝ *real* / integer
  Lower threshold for the hysteresis threshold operation.
  Default: 3
  Suggested values: `Low` ∈ {0, 0.5, 1, 2, 3, 4, 5, 8, 10}
  Value range: 0 ≤ Low
  Recommended increment: 0.5

▷ **High** (input_control) . . . . . number ⇝ *real* / integer
Upper threshold for the hysteresis threshold operation.
Default: 8
Suggested values: High ∈ {0, 0.5, 1, 2, 3, 4, 5, 8, 10, 12, 15, 18, 20, 25}
Value range: 0 ≤ High
Recommended increment: 0.5
Restriction: High >= Low

▷ **LightDark** (input_control) . . . . . string ⇝ *string*
Extract bright or dark lines.
Default: 'light'
List of values: LightDark ∈ {'dark', 'light'}

▷ **ExtractWidth** (input_control) . . . . . string ⇝ *string*
Should the line width be extracted?
Default: 'true'
List of values: ExtractWidth ∈ {'true', 'false'}

▷ **LineModel** (input_control) . . . . . string ⇝ *string*
Line model used to correct the line position and width.
Default: 'bar-shaped'
List of values: LineModel ∈ {'none', 'bar-shaped', 'parabolic', 'gaussian'}

▷ **CompleteJunctions** (input_control) . . . . . string ⇝ *string*
Should junctions be added where they cannot be extracted?
Default: 'true'
List of values: CompleteJunctions ∈ {'true', 'false'}

Example

```
* Detection of lines in an aerial image
read_image(Image,'mreut4_3')
lines_gauss(Image,Lines,1.5,3,8,'light','true','bar-shaped','true')
dev_display(Lines)
```

Complexity

Let A be the number of pixels in the domain of Image. Then the runtime complexity is $O(A * \text{Sigma})$.

The amount of temporary memory required is dependent on the height H of the domain of Image and the width W of Image. Let $S = W * H$, then lines_gauss requires at least $55 * S$ bytes of temporary memory during execution.

Result

lines_gauss returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

12.10 Match

exhaustive_match (Image, RegionOfInterest, ImageTemplate : ImageMatch : Mode :)

Matching of a template and an image.

The operator exhaustive_match matches ImageTemplate and Image within the region of interest RegionOfInterest. Hereby the ImageTemplate will be moved over all points of Image which lie within the RegionOfInterest. With regard to the parameter Mode, a matching criterion will be calculated. The result values will be stored in ImageMatch.

The following matching criteria (Mode) are available:

'norm_correlation'

$$\texttt{ImageMatch}[i][j] = 255 \cdot \frac{\sum_{u,v} (\texttt{Image}[i-u][j-v] \cdot \texttt{ImageTemplate}[l-u][c-v])}{\sqrt{\sum_{u,v} (\texttt{Image}[i-u][j-v]^2) \cdot \sum_{u,v} (\texttt{ImageTemplate}[l-u][c-v]^2)}}$$

whereby $X[i][j]$ indicates the gray value in the i-th column and j-th row of the image X. (l, c) is the center of the region of ImageTemplate. u and v are chosen so that all points of the template will be reached, i, j run across the RegionOfInterest. At the image frame only those parts of ImageTemplate will be considered which lie inside the image (i.e. u and v will be restricted correspondingly). Higher values returned in ImageMatch, represent better matches.

Range of values: [*0 ... 255* (best fit)].

'dfd' Calculating the average "displaced frame difference":

$$\texttt{ImageMatch}[i][j] = \frac{\sum_{u,v} |\texttt{Image}[i-u][j-v] - \texttt{ImageTemplate}[l-u][c-v]|}{AREA(ImageTemplate)}$$

The terms are the same as in *'norm_correlation'*. $AREA(X)$ means the area of the region X. Lower values returned in ImageMatch, represent better matches.

Range of values: [*0* (best fit) *... 255*].

To calculate the normalized correlation as well as the "displaced frame difference" is (with regard to the area of ImageTemplate) very time consuming. Therefore it is important to restrict the input region (RegionOfInterest if possible, i.e. to apply the filter only in a very confined "region of interest".

As far as quality is concerned, both modes return comparable results, whereby the mode *'dfd'* is faster by a factor of about 3.5.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
Input image.

▷ **RegionOfInterest** (input_object) ..... region ⇝ *object*
Area to be searched in the input image.

▷ **ImageTemplate** (input_object) . . . . . singlechannelimage ⇝ *object :* byte
This area will be "matched" by Image within the RegionOfInterest.

▷ **ImageMatch** (output_object) . . . . . image(-array) ⇝ *object :* byte
Result image: values of the matching criterion.

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Desired matching criterion.
Default: 'dfd'
List of values: Mode ∈ {'norm_correlation', 'dfd'}

Example

```
read_image(Image,'monkey')
dev_display(Image)
draw_rectangle2(WindowHandle,Row,Column,Phi,Length1,Length2)
gen_rectangle2(Rectangle,Row,Column,Phi,Length1,Length2)
reduce_domain(Image,Rectangle,Template)
exhaustive_match(Image,Image,Template,ImageMatch,'dfd')
invert_image(ImageMatch,ImageInvert)
local_max(Image,Maxima)
union1(Maxima,AllMaxima)
add_channels(AllMaxima,ImageInvert,FitMaxima)
threshold(FitMaxima,BestFit,230.0,255.0)
dev_display(BestFit)
```

Result

If the parameter values are correct, the operator exhaustive_match returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

exhaustive_match_mg

Module

Foundation

exhaustive_match_mg (Image, ImageTemplate : ImageMatch : Mode, Level, Threshold :)

Matching a template and an image in a resolution pyramid.

The operator exhaustive_match_mg is an additional option for the operator exhaustive_match performing a matching of the image Image and the template ImageTemplate. Hereby ImageTemplate will be moved over all points of the region of Image, a matching criterion will be calculated with regard to the parameter Mode and the result values will be stored in ImageMatch.

Of images having been filtered this way, normally only those areas with good matching results are of interest. The size of the area to be searched, i.e. the region of the input image Image, determines decisively the runtime of

the matching filter. Therefore it is recommendable to use at first exhaustive_match_mg with reduced image resolution in order to determine a "region of interest" in which good matching results can be expected; then in this restricted area only the real matching (see also exhaustive_match) will be executed with normal resolution.

Hereby the Gauss-pyramids of Image and ImageTemplate will be composed (in particular the corresponding regions will be transformed as well). Then on each level of the resolution pyramids - starting with the startlevel Level - the matching inside the current "region of interest" will be executed. Whereby the "region of interest" on the startlevel is equivalent to the region of the input image Image. After the filtering, a new "region of interest" is determined with the help of a threshold operation and will be transformed on the next resolution level:

threshold(..0,Threshold..), if Mode = 'dfd'
threshold(..Threshold,255..), if Mode = 'norm_correlation'

The final matching in the determined "region of interest" will then be calculated with the highest resolution (Level 0). The output image ImageMatch includes the corresponding filter result and the final "region of interest", which is determined on the result image with the help of a threshold operation.

The operator exhaustive_match_mg therefore is not simply a filter, but can also be considered as a member of the class of region transformations.

Parameters

- ▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte
  Input image.
- ▷ **ImageTemplate** (input_object) . . . . . singlechannelimage ⇝ *object :* byte
  The domain of this image will be matched with Image.
- ▷ **ImageMatch** (output_object) . . . . . image(-array) ⇝ *object :* byte
  Result image and result region: values of the matching criterion within the determined "region of interest".
  Number of elements: ImageMatch == Image
- ▷ **Mode** (input_control) . . . . . string ⇝ *string*
  Desired matching criterion.
  Default: 'dfd'
  List of values: Mode ∈ {'norm_correlation', 'dfd'}
- ▷ **Level** (input_control) . . . . . integer ⇝ *integer*
  Startlevel in the resolution pyramid (highest resolution: Level 0).
  Default: 1
  Suggested values: Level ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8}
  Restriction: Level <= ld(width(Image)) && Level <= ld(height(Image)) && Level <= ld(width(ImageTemplate)) && Level <= ld(height(ImageTemplate))
- ▷ **Threshold** (input_control) . . . . . integer ⇝ *integer*
  Threshold to determine the "region of interest".
  Default: 30
  Suggested values: Threshold ∈ {5, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 105, 110, 115, 120, 125, 130, 135, 140, 145, 150, 155, 160, 165, 170, 175, 180, 185, 190, 195, 200, 205, 210, 215, 220, 225, 230, 235, 240, 245, 250}
  Value range: 0 ≤ Threshold ≤ 255
  Minimum increment: 1
  Recommended increment: 5

Example

```
read_image(&Image,"monkey");
disp_image(Image,WindowHandle);
draw_rectangle2(WindowHandle,&Row,&Column,&Phi,&Length1,&Length2);
gen_rectangle2(&Rectangle,Row,Column,Phi,Length1,Length2);
reduce_domain(Image,Rectangle,&Template);
exhaustive_match_mg(Image,Template,&ImageMatch,'dfd'1,30);
invert_image(ImageMatch,&ImageInvert);
local_max(ImageInvert,&BestFit);
disp_region(BestFit,WindowHandle);
```

Result

If the parameter values are correct, the operator exhaustive_match_mg returns the value 2 (H_MSG_TRUE).

If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

gen_gauss_pyramid

Module

Foundation

gen_gauss_pyramid (Image : ImagePyramid : Mode, Scale :)

Calculating a Gauss pyramid.

The operator gen_gauss_pyramid calculates a pyramid of scaled down images. The scale by which the next image will be reduced is determined by the parameter Scale. For instance, a value of 0.5 for Scale will shorten the edge length of Image by 50%. This is exactly equivalent to the "normal" pyramid.

The parameter Mode determines the way of averaging. For a more detailed description concerning this parameter see also affine_trans_image. In the case that Scale is equal 0.5 there are the additional modes *'min'* and *'max'* available. In this case the minimum or the maximum of the four neighboring pixels is selected.

Please note that each level will be returned as an individual image, i.e., as one iconic object, with one matrix and its own domain. Single or multiple levels can be selected by using select_obj or copy_obj, respectively.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2 / real
Input image.

▷ **ImagePyramid** (output_object) . . . . . (multichannel-)image-array ⇝ *object :* byte / uint2 / real
Output images.
Number of elements: ImagePyramid > Image

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Kind of filter mask.
Default: 'weighted'
List of values: Mode ∈ {'nearest_neighbor', 'constant', 'weighted', 'min', 'max'}

▷ **Scale** (input_control) . . . . . real ⇝ *real*
Factor for scaling down.
Default: 0.5
Suggested values: Scale ∈ {0.2, 0.3, 0.4, 0.5, 0.6}
Value range: 0.001 ≤ Scale ≤ 0.9
Recommended increment: 0.1

Example

```
gen_gauss_pyramid(Image,Pyramid,"weighted",0.5);
count_obj(Pyramid,&num);
for (i=1; i<=num; i++)
```

```
{
  select_obj(Pyramid,&Single,i);
  disp_image(Single,WindowHandle);
  clear(Single);
}
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on channel level.

affine_trans_image

Module

Foundation

monotony (Image : ImageMonotony : :)

Calculating the monotony operation.

The operator monotony calculates the monotony operator. Thereby the points which are strictly smaller than the current gray value will be counted in the 8 neighborhood. This number will be entered into the output imaged.

If there is a strict maximum, the value 8 is returned; in case of a minimum or a plateau, the value 0 will be returned. A ridge or a slope will return the corresponding intermediate values.

The monotony operator is often used to prepare matching operations as it is invariant with regard to lightness modifications.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Input image.

▷ **ImageMonotony** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
Result of the monotony operator.
Number of elements: ImageMonotony == Image

Example

```
/* searching the strict maximums */
gauss_filter(Image,&Gauss,5);
monotony(Gauss,&Monotony);
threshold(Monotony,Maxima,8.0,8.0);
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

12.11 Misc

convol_image (Image : ImageResult : FilterMask, Margin :)

Calculate the correlation between an image and an arbitrary filter mask

convol_image calculates the correlation between the input image Image and an arbitrary linear filter mask. The used filter mask, which is given in FilterMask, can be either loaded from a file or passed as a tuple. Several options for the treatment at the image's borders can be chosen (Margin):

gray value Pixels outside of the image border are assumed to be constant (with the indicated gray value).

'continued' Continuation of the gray values at the image border.

'cyclic' Cyclic continuation at the image borders.

'mirrored' Reflection of pixels at the image borders.

At all image positions, the correlation between the image and the filter mask is calculated. If an overflow or underflow occurs, the resulting gray value is clipped. Hence, if filters that result in negative output values are used (e.g., derivative filters), the input image should be of type int2 or real.

The reference pixel of the mask, i.e., the pixel that lies at the current image position for which the correlation is calculated, is determined as follows: First, the region of all mask pixels with a weight other than 0 is computed. Then, the center of this region is computed and rounded. This is the reference point of the mask.

If a file name is given in FilterMask, the filter mask is read from a text file with the following structure:

⟨Mask size⟩
⟨Inverse weight of the mask⟩
⟨Matrix⟩

The first line contains the size of the filter mask, given as two numbers separated by white space (e.g., 3 3 for 3×3). Here, the first number defines the height (rows) of the filter mask, while the second number defines its width (columns). The next line contains the inverse weight of the mask, i.e., the number by which the correlation at a particular image position is divided. The remaining lines contain the filter mask as integer or floating point numbers (separated by white space), one line of the mask per line in the file. The default HALCON file extension for the filter mask is 'fil'. It is not necessary to pass this extension to the operator. If the filter mask is to be computed from a tuple, the tuple given in FilterMask must also satisfy the structure described above. However, in this case the line feed is omitted.

For example, lets assume we want to use the following filter mask:

$$\frac{1}{16}\begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}$$

If the filter mask should be generated from a file, then the file should look like this:

3 3
16
1 2 1

2 4 2
1 2 1

In contrast, if the filter mask should be generated from a tuple, then the following tuple must be passed in `FilterMask`:

[3,3,16,1,2,1,2,4,2,1,2,1]

For convenience, it is possible to pass two vectors instead of a matrix in `FilterMask`:

[MaskHeight,MaskWidth,Weight,V1,V2]

The outer product of those two vectors forms the filter matrix:

$Mask := V1 * V1^T$

E.g., the matrix above can also be passed as:

[3,3,16,1,2,1,1,2,1]

If `FilterMask` is separable (which is detected automatically), `convol_image` uses a special implementation that is significantly faster than the filtering with non separable masks.

If *'sse2_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations for `byte` and `real` images are performed using SIMD technology. If *'sse41_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations for `int2` and `uint2` images are performed using SIMD technology. If *'avx_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations for `real` images are performed using AVX SIMD technology.

Attention

Note that `convol_image` does not compute a convolution of the image with the given filter mask but a correlation, i.e., it uses the given filter mask directly, not a mirrored version of the filter mask.

When using a 3x3 or 5x5 rectangular filter mask and the border treatment *'mirrored'*, `convol_image` can be executed on OpenCL devices.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Images for which the correlation will be calculated.
- ▷ **`ImageResult`** (output_object) ..... multichannel-image(-array) ⇝ *object :* byte / int2 / uint2 / real
  Result of the correlation.
- ▷ **`FilterMask`** (input_control) ..... filename.read(-array) ⇝ *string* / integer / real
  Filter mask as file name or tuple.
  Default: 'sobel'
  Suggested values: `FilterMask` ∈ {'sobel', 'laplace4', 'lowpas_3_3'}
  File extension: `.fil`
- ▷ **`Margin`** (input_control) ..... string ⇝ *string* / integer / real
  Border treatment.
  Default: 'mirrored'
  Suggested values: `Margin` ∈ {'mirrored', 'cyclic', 'continued', 0, 30, 60, 90, 120, 150, 180, 210, 240, 255}

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Module

Foundation

deviation_n (Image : ImageDeviation : :)

Calculate standard deviation over several channels.

deviation_n generates the pixel-by-pixel standard deviation of a multichannel gray value image. For each coordinate point p the expected value is defined as the arithmetic mean:

$$E = \frac{\sum g_c(p)}{n}$$

where $g\_c(p)$ denominates the gray value at p on channel c. n is the number of channels in the image.

The standard deviation itself is then calculated as:

$$s = 2 \cdot \sqrt{\frac{1}{n-1} \cdot \sum (g_c(p) - E)^2}$$

Note that this formula produces the *sample* standard deviation. The factor 2 is used to make better use of the range of values of the output image format. The output image has one channel.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Multichannel gray image.

▷ **ImageDeviation** (output_object) . . . . . image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Result of calculation.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on domain level.
- Automatically parallelized on tuple level.

expand_domain_gray (
InputImage : ExpandedImage : ExpansionRange :)

Expand the domain of an image and set the gray values in the expanded domain.

expand_domain_gray expands the border gray values of the domain outwards. The width of the expansion is set by the parameter ExpansionRange, which describes the expansion radius in pixels. All filters in HALCON which are applied to the image domain also include the gray values of a certain number of pixels, depending on the filter size, outside of the image domain in their calculation. This may lead to undesirable side effects especially in the border region of the domain. For example, if the foreground (domain) and the background of the image differ strongly in brightness, the result of a filter operation may lead to undesired darkening or brightening at the border of the domain. In order to avoid this drawback, the domain is artificially expanded by expand_domain_gray in a preliminary stage, copying the gray values of the border pixels to the outside of the domain. In addition, the domain itself is also expanded to reflect the newly set pixels. Therefore, in many cases it is reasonable to reduce the domain again (reduce_domain or change_domain) after using expand_domain_gray and call the filter operation afterwards. ExpansionRange should be set to a value high enough to make sure the whole region

including its dilatation through the filter mask has initialized values. Usually this leads to ExpansionRange values of half the filter length or greater. In combination with the filter mean_image on images of type real we recommend to determine the value for ExpansionRange as shown in the example below. For speed reasons this filter uses the values from pixels within the smallest rectangle around the dilated region.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **InputImage** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
Input image with domain to be expanded.

▷ **ExpandedImage** (output_object) .....image(-array) ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
Output image with new gray values in the expanded domain.

▷ **ExpansionRange** (input_control) ..... integer ⇝ *integer*
Radius of the gray value expansion, measured in pixels.
Default: 2
Suggested values: ExpansionRange ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 14, 16}
Restriction: ExpansionRange >= 1

Example

```
read_image(Fabrik, 'fabrik')
gen_rectangle2(Rectangle_Label,243,320,-1.55,62,28)
reduce_domain(Fabrik, Rectangle_Label, Fabrik_Label)
* Character extraction without gray value expansion:
MaskSize := 31
mean_image(Fabrik_Label,Label_Mean_normal,MaskSize, MaskSize)
dyn_threshold(Fabrik_Label,Label_Mean_normal,Characters_normal,10,'dark')
dev_display(Fabrik)
dev_display(Characters_normal)
* The characters in the border region are not extracted !
stop()
* Character extraction with gray value expansion:
get_domain (Fabrik_Label, Domain)
expand_domain_gray (Fabrik_Label, Expanded_Fabrik_Label, MaskSize)
get_domain (Expanded_Fabrik_Label, Expanded_Domain)
shape_trans (Expanded_Domain, RegionRect, 'rectangle1')
difference (RegionRect, Expanded_Domain, Region_Difference)
overpaint_region (Expanded_Fabrik_Label, Region_Difference, 0, 'fill')
reduce_domain (Expanded_Fabrik_Label, Domain, Reduced_Expanded_Fabrik_Label)
mean_image (Reduced_Expanded_Fabrik_Label, Label_Mean_Expanded,\
MaskSize, MaskSize)
dyn_threshold(Fabrik_Label,Label_Mean_Expanded,\
Characters_expanded,10,'dark')
dev_display(Fabrik)
dev_display(Characters_expanded)
```

Complexity

Let L the perimeter of the domain. Then the runtime complexity is approximately $O(L) * \text{ExpansionRange}$.

Result

expand_domain_gray returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on tuple level.

Module

Foundation

gray_inside (Image : ImageDist : :)

Calculate the lowest possible gray value on an arbitrary path to the image border for each point in the image.

gray_inside determines the "cheapest" path to the image border for each point in the image, i.e., the path on which the lowest gray values have to be overcome. The resulting image contains the difference of the gray value of the particular point and the maximum gray value on the path. Bright areas in the result image therefore signify that these areas (which are typically dark in the original image) are surrounded by bright areas. Dark areas in the result image signify that there are only small gray value differences between them and the image border (which doesn't mean that they are surrounded by dark areas; a small "gap" of dark values suffices). The value 0 (black) in the result image signifies that only darker or equally bright pixels exist on the path to the image border.

The operator is implemented by first segmenting into basins and watersheds the image using the watersheds operator. If the image is regarded as a gray value mountain range, basins are the places where water accumulates and the mountain ridges are the watersheds. Then, the watersheds are distributed to adjacent basins, thus leaving only basins. The border of the domain (region) of the original image is now searched for the lowest gray value, and the region in which it resides is given its result values. If the lowest gray value resides on the image border, all result values can be calculated immediately using the gray value differences to the darkest point. If the smallest found gray value lies in the interior of a basin, the lowest possible gray value has to be determined from the already processed adjacent basins in order to compute the new values. An 8-neighborhood is used to determine adjacency. The found region is subtracted from the regions yet to process, and the whole process is repeated. Thus, the image is "stripped" form the outside.

Analogously to watersheds, it is advisable to apply a smoothing operation before calling watersheds, e.g., binomial_filter or gauss_filter, in order to reduce the amount of regions that result from the watershed algorithm, and thus to speed up the processing time.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Image being processed.

▷ **ImageDist** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* int2
Result image.

Example

```
read_image(Image,'fabrik')
gauss_filter (Image,GaussImage,11)
gray_inside(GaussImage,ImageOut)
dev_display(ImageOut)
```

Result

gray_inside always returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Possible Predecessors

binomial_filter, gauss_filter, smooth_image, mean_image, median_image

Possible Successors

watersheds

Module

Foundation

gray_skeleton (Image : GraySkeleton : :)

Thinning of gray value images.

gray_skeleton applies a gray value thinning operation to the input image Image. Figuratively, the gray value "mountain range" is reduced to its ridge lines by setting the gray value of "hillsides" to the gray value at the corresponding valley bottom. The resulting ridge lines are at most two pixels wide. This operator is especially useful for thinning edge images, and is thus an alternative to nonmax_suppression_amp. In contrast to nonmax_suppression_amp, gray_skeleton preserves contours, but is much slower. In contrast to skeleton, this operator changes the gray values of an image while leaving its region unchanged.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2
Image to be thinned.

▷ **GraySkeleton** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2
Thinned image.

Example

```
* Seeking leafs of a beech tree in an aerial picture:
read_image(Image,'forest')
gray_skeleton(Image,Skelett)
mean_image(Skelett,MeanSkelett,7,7)
dyn_threshold(Skelett,MeanSkelett,Leafs,3,'light')
```

Result

gray_skeleton returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Possible Successors

mean_image

Alternatives

nonmax_suppression_amp, nonmax_suppression_dir, local_max

lut_trans (Image : ImageResult : Lut :)

Transform an image with a gray-value look-up-table

lut_trans transforms an image Image by using a gray value look-up-table Lut. This table acts as a transformation function. In the case of byte-images, Lut has to be a tuple of length 256. In the case of int2-images, Lut has to be a tuple of length 256 <= length <= 65536. If the length of the Lut is <= 32768, the transformation is applied to the positive gray values only, i.e., the first element of the Lut specifies the new gray value for the gray value 0. If the Lut is longer than 32768, exactly 65536 must be passed. In this case, the positive and negative gray values are transformed. In this case, the first element indicates the new gray value for the gray value -32768 of the input image, while the last element of the tuple indicates the new gray value for the gray value 32767. In all cases, the gray values of values outside the range of Lut are set to 0. In the case of uint2-images, Lut has to be a tuple of length 256 <= length <= 65536. Gray values outside the range of Lut are set to 0.

Attention

lut_trans can be executed on OpenCL devices.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Image whose gray values are to be transformed.
- ▷ **ImageResult** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Transformed image.
- ▷ **Lut** (input_control) ..... integer-array ⇝ *integer*
  Table containing the transformation.

Example

```
* Apply a gamma correction to an image.
Gamma := 2.2
GammaLUT := []
for G := 0 to 255 by 1
    GammaLUT := [GammaLUT,round(255.0*pow(G/255.0,1.0/Gamma))]
endfor
read_image (Image, 'mreut')
lut_trans (Image, ImageGamma, GammaLUT)
```

Result

The operator lut_trans returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

- Automatically parallelized on domain level.

Module

Foundation

symmetry (Image : ImageSymmetry : MaskSize, Direction, Exponent :)

Symmetry of gray values along a row.

symmetry calculates the symmetry along a line. For each pixel the gray values of both sides of the line are compared: The absolute value of the differences of gray values with same distance to the pixel is computed. Each of these differences is weighted by the exponent (after division by 255) and then summed up.

$$sym := 255 - \frac{255}{\texttt{MaskSize}} \sum_{i=1}^{\texttt{MaskSize}} \left(\frac{|g(i) - g(-i)|}{255} \right)^{\texttt{Exponent}}$$

Pixels with a high symmetry have large gray values.

Attention

Currently only horizontal search lines are implemented. Note that the parameter Direction exists for future extensions and can currently only have the value 0.0.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Input image.

▷ **ImageSymmetry** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Symmetry image.

▷ **MaskSize** (input_control) ..... number ⇝ *integer*
Extension of search area.
Default: 40
Suggested values: MaskSize ∈ {3, 5, 7, 10, 15, 20, 25, 30, 40, 50, 60, 70, 80, 100, 120, 140, 180}
Value range: 3 ≤ MaskSize ≤ 1000
Minimum increment: 1
Recommended increment: 2

▷ **Direction** (input_control) ..... number ⇝ *real*
Angle of test direction.
Default: 0.0
Suggested values: Direction ∈ {0.0}
Value range: 0.0 ≤ Direction ≤ 0.0

▷ **Exponent** (input_control) ..... number ⇝ *real*
Exponent for weighting.
Default: 0.5
Suggested values: Exponent ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.7, 0.8, 0.9, 1.0}
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: 0 < Exponent && Exponent <= 100

Example

```
read_image(Image,'monkey')
symmetry(Image,ImageSymmetry,70,0.0,0.5)
threshold(ImageSymmetry,SymmPoints,170,255)
```

Result

If the parameter values are correct the operator symmetry returns the value 2 (H_MSG_TRUE) The behavior in case of empty input (no input images available) is set via the operator set_system(::'no_object_result',<Result>:). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

`threshold`

Module

Foundation

topographic_sketch (Image : Sketch : :)

Compute the topographic primal sketch of an image.

`topographic_sketch` computes the topographic primal sketch of the input image `Image`. This is done by approximating the image locally by a bicubic polynomial ("facet model"). It serves to calculate the first and second partial derivatives of the image, and thus to classify the image into 11 classes. These classes are coded in the output image `Sketch` as numbers from 1 to 11. The classes are as follows:

Peak	1
Pit	2
Ridge	3
Ravine	4
Saddle	5
Flat	6
Hillside Slope	7
Hillside Convex	8
Hillside Concave	9
Hillside Saddle	10
Hillside Inflection	11

In order to obtain the separate classes as regions, a threshold operation has to be applied to the result image with the appropriate thresholds.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Image for which the topographic primal sketch is to be computed.

▷ **Sketch** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Label image containing the 11 classes.

Example

```
* To extract the Ridges from a Image
read_image(Image,'sinus')
topographic_sketch(Image,Sketch)
threshold(Sketch,Ridges,3,3)
```

Complexity

Let n be the number of pixels in the image. Then $O(n)$ operations are performed.

Result

`topographic_sketch` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Possible Successors

12.12 Noise

add_noise_distribution (Image : ImageNoise : Distribution :)

Add noise to an image.

`add_noise_distribution` adds noise distributed according to `Distribution` to the `Image`. The resulting gray values are clipped to the range of the corresponding pixel type.

The `Distribution` is stored in a tuple of length 513. The individual values of this tuple define the frequency of noise with a specific amplitude defined by the position within the tuple. The central value, i.e., the value at the position 256 in the tuple defines the frequency of pixels that are not changed. The value at the position 255 defines the frequency of pixels for which the grayvalue is decreased by 1. The value at the position 254 defines the respective frequency for a grayvalue decrease of 2, and so on. Analogously, the value at position 257 defines the frequency of pixels for which the grayvalue is increased by 1.

The `Distribution` represents salt and pepper noise if at most one value at a position smaller than 256 is not equal to zero and at most one value at a position larger than 256 is not equal to zero. In case of salt and pepper noise, the added noisy pixels are set to the minimum (pepper) and maximum (salt) values that can be represented by `ImageNoise` if the amount of pepper is indicated by the value at position 0 and the amount of salt is indicated by the value at position 512 in the tuple.

The random noise is generated using the C function "drand48()". See the parameter *'seed_rand'* of `set_system` for information on the used random seed.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2
Input image.

▷ **ImageNoise** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2
Noisy image.
Number of elements: ImageNoise == Image

▷ **Distribution** (input_control) . . . . . distribution.values-array ⇝ *real*
Noise distribution.
Number of elements: 513

Example

```
read_image(Image,'mreut')
dev_display (Image)
sp_distribution(30,30,Dist)
add_noise_distribution(Image,ImageNoise,Dist)
dev_display (ImageNoise)
```

Result

`add_noise_distribution` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Possible Predecessors

Alternatives

`add_noise_white`

See also

`sp_distribution`, `gauss_distribution`, `noise_distribution_mean`, `add_noise_white`

Module

Foundation

add_noise_white (Image : ImageNoise : Amp :)

Add noise to an image.

`add_noise_white` adds noise to the image `Image`. The noise is white noise, equally distributed in the interval [-`Amp`,`Amp`]. The resulting gray values are clipped to the range of the corresponding pixel type.

The random noise is generated using the C function “drand48”. See the parameter *’seed_rand’* of `set_system` for information on the used random seed.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Input image.

▷ **ImageNoise** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / real
Noisy image.
Number of elements: ImageNoise == Image

▷ **Amp** (input_control) . . . . . real ⇝ *real*
Maximum noise amplitude.
Default: 60.0
Suggested values: Amp ∈ {1.0, 2.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Amp
Minimum increment: 0.001
Recommended increment: 10.0

Example

```
read_image(Image,'fabrik')
dev_display (Image)
add_noise_white(Image,ImageNoise,90)
dev_display (ImageNoise)
```

Result

add_noise_white returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Module

Foundation

gauss_distribution (: : Sigma : Distribution)

Generate a Gaussian noise distribution.

gauss_distribution generates a Gaussian noise distribution. The parameter Sigma determines the noise's standard deviation. Usually, the result Distribution is used as input for the operator add_noise_distribution.

Parameters

▷ **Sigma** (input_control) ..... real ⇝ *real*
Standard deviation of the Gaussian noise distribution.
Default: 2.0
Suggested values: Sigma ∈ {1.5, 2.0, 3.0, 5.0, 10.0}
Value range: 0.0 ≤ Sigma ≤ 100.0
Minimum increment: 0.1
Recommended increment: 1.0

▷ **Distribution** (output_control) ..... distribution.values-array ⇝ *real*
Resulting Gaussian noise distribution.
Number of elements: 513

Example

```
read_image(Image,'fabrik')
dev_display (Image)
gauss_distribution(30,Dist)
add_noise_distribution(Image,ImageNoise,Dist)
dev_display (ImageNoise)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Successors

add_noise_distribution

Alternatives

sp_distribution, noise_distribution_mean

sp_distribution, add_noise_white, noise_distribution_mean

Module

Foundation

noise_distribution_mean (ConstRegion, Image : : FilterSize : Distribution)

Determine the noise distribution of an image.

noise_distribution_mean calculates the noise distribution in a region of the image Image. The parameter ConstRegion determines a region of the image with approximately constant gray values. Ideally, the changes in gray values should only be caused by noise in this region. From this region the noise distribution is determined by using the mean_image operator to smooth the image, and to use the gray value differences in this area as an estimate for the noise distribution, which is returned in Distribution.

Attention

It is important to ensure that the region ConstRegion is not too close to a large gradient in the image, because the gradient values are then used for calculating the mean. This means the distance of ConstRegion must be at least as large as the filter size FilterSize used for calculating the mean.

Parameters

▷ **ConstRegion** (input_object) . . . . . region(-array) ⇝ *object*
Region from which the noise distribution is to be estimated.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte
Corresponding image.

▷ **FilterSize** (input_control) . . . . . integer ⇝ *integer*
Size of the mean filter.
Default: 21
Suggested values: FilterSize ∈ {5, 11, 15, 21, 31, 51, 101}
Value range: 3 ≤ FilterSize ≤ 501 (lin)
Minimum increment: 2
Recommended increment: 2

▷ **Distribution** (output_control) . . . . . distribution.values-array ⇝ *real*
Noise distribution of all input regions.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

sp_distribution (: : PercentSalt, PercentPepper : Distribution)

Generate a salt-and-pepper noise distribution.

sp_distribution generates a noise distribution with the values 0 and 255. The parameters PercentSalt and PercentPepper determine the percentage of white and black noise pixels, respectively. The sum of these parameters must be smaller than 100. Usually, the result Distribution is used as input for the operator add_noise_distribution.

Parameters

▷ **PercentSalt** (input_control) . . . . . number ⇝ *real* / integer
Percentage of salt (white noise pixels).
Default: 5.0
Suggested values: PercentSalt ∈ {1.0, 2.0, 5.0, 7.0, 10.0, 15.0, 20.0, 30.0}
Value range: 0.0 ≤ PercentSalt ≤ 100.0
Minimum increment: 0.1
Recommended increment: 1.0
Restriction: PercentSalt + PercentPepper <= 100

▷ **PercentPepper** (input_control) . . . . . number ⇝ *real* / integer
Percentage of pepper (black noise pixels).
Default: 5.0
Suggested values: PercentPepper ∈ {1.0, 2.0, 5.0, 7.0, 10.0, 15.0, 20.0, 30.0}
Value range: 0.0 ≤ PercentPepper ≤ 100.0
Minimum increment: 0.1
Recommended increment: 1.0
Restriction: PercentSalt + PercentPepper <= 100

▷ **Distribution** (output_control) . . . . . distribution.values-array ⇝ *real*
Resulting noise distribution.
Number of elements: 513

Example

```
read_image(Image,'fabrik')
dev_display (Image)
sp_distribution(30,30,Dist)
add_noise_distribution(Image,ImageNoise,Dist)
dev_display (ImageNoise)
```

Execution Information

12.13 Optical Flow

derivate_vector_field (VectorField : Result : Sigma, Component :)

Convolve a vector field with derivatives of the Gaussian.

derivate_vector_field convolves the components of a vector field with the derivatives of a Gaussian and calculates various features derived therefrom. derivate_vector_field only accepts vector fields of the semantic type vector_field_relative. The VectorField $F(r,c) = (u(r,c), v(r,c))$ is defined as in optical_flow_mg. Sigma is the parameter of the Gaussian (i.e., the amount of smoothing). If a single value is passed in Sigma, the amount of smoothing in the column and row direction is identical. If two values are passed in Sigma, the first value specifies the amount of smoothing in the column direction, while the second value specifies the amount of smoothing in the row direction. The possible values for Component are:

'curl': The curl of the vector field. One application of using *'curl'* is to analyse optical flow fields. Metaphorically speaking, the curl is how much a small boat would rotate if the vector field was a fluid.

$$curl = \frac{\partial u(r,c)}{\partial c} - \frac{\partial v(r,c)}{\partial r}$$

'divergence': The divergence of the vector field. One application of using *'divergence'* is to analyze optical flow fields. Metaphorically speaking, the divergence is where the source and sink would be if the vector field was a fluid.

$$div = \frac{\partial u(r,c)}{\partial r} + \frac{\partial v(r,c)}{\partial c}$$

When used in context of photometric stereo, the operator derivate_vector_field offers two more parameters, which are especially designed to process the gradient field that is returned by photometric_stereo. In this case, we interpret the input vector field as gradient of the underlying surface.

In the following formulas, the input vector field is therefore noted as $G(r,c) = \nabla f = (\frac{\partial f(r,c)}{\partial r}, \frac{\partial f(r,c)}{\partial c})$

where the first and second component of the input is the gradient field of the surface $f(r,c)$. In the formulas below f_rc denotes the first derivative in column direction of the first component of the gradient field.

'mean_curvature': Mean curvature H of the underlying surface when the input vector field VectorField is interpreted as gradient field. One application of using *'mean_curvature'* is to process the vector field that is returned by photometric_stereo. After filtering the vector field, even tiny scratches or bumps can be segmented.

$$\begin{aligned}
A &= (1 + \frac{\partial f(r,c)^2}{\partial r}) \frac{\partial^2 f(r,c)}{\partial c^2} \\
B &= \frac{\partial f(r,c)}{\partial r} \frac{\partial f(r,c)}{\partial c} (\frac{\partial^2 f(r,c)}{\partial r \partial c} + \frac{\partial^2 f(r,c)}{\partial c \partial r}) \\
C &= (1 + \frac{\partial f(r,c)^2}{\partial c}) \frac{\partial^2 f(r,c)}{\partial r^2} \\
D &= (1 + \frac{\partial f(r,c)^2}{\partial r} + \frac{\partial f(r,c)^2}{\partial c})^{\frac{3}{2}} \\
H &= \frac{A - B + C}{D}
\end{aligned}$$

'gauss_curvature': Gaussian curvature K of the underlying surface when the input vector field VectorField is interpreted as gradient field. One application of using *'gauss_curvature'* is to process the vector field that is returned by photometric_stereo. After filtering the vector field, even tiny scratches or bumps can be segmented. If the underlying surface of the vector field is developable, the Gaussian curvature is zero.

$$K = \frac{\frac{\partial f(r,c)^2}{\partial r \partial r} * \frac{\partial f(r,c)^2}{\partial c \partial c} - \frac{\partial f(r,c)^2}{\partial r \partial c} * \frac{\partial f(r,c)^2}{\partial c \partial r}}{(1 + \frac{\partial f(r,c)^2}{\partial r} + \frac{\partial f(r,c)^2}{\partial c})^2}$$

Parameters

▷ **VectorField** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* vector_field
Input vector field.

▷ **Result** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* real
Filtered result images.

▷ **Sigma** (input_control) . . . . . real(-array) ⇝ *real*
Sigma of the Gaussian.
Default: 1.0
Suggested values: Sigma ∈ {0.7, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0}
Value range: 0.01 ≤ Sigma ≤ 50.0

▷ **Component** (input_control) . . . . . string ⇝ *string*
Component to be calculated.
Default: 'mean_curvature'
List of values: Component ∈ {'curl', 'divergence', 'mean_curvature', 'gauss_curvature'}

Result

If the parameters are valid, the operator derivate_vector_field returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on domain level.
- Automatically parallelized on tuple level.

optical_flow_mg (ImageT1, ImageT2 : VectorField : Algorithm, SmoothingSigma, IntegrationSigma, FlowSmoothness, GradientConstancy, MGParamName, MGParamValue :)

Compute the optical flow between two images.

optical_flow_mg computes the optical flow between two images. The optical flow represents information about the movement between two consecutive images of a monocular image sequence. The movement in the images can be caused by objects that move in the world or by a movement of the camera (or both) between the acquisition of the two images. The projection of these 3D movements into the 2D image plane is called the optical flow.

The two consecutive images of the image sequence are passed in ImageT1 and ImageT2. The computed optical flow is returned in VectorField. The vectors in the vector field VectorField represent the movement in the image plane between ImageT1 and ImageT2. The point in ImageT2 that corresponds to the point (r, c) in ImageT1 is given by $(r', c') = (r + u(r, c), c + v(r, c))$, where $u(r, c)$ and $v(r, c)$ denote the value of the row and column components of the vector field image VectorField at the point (r, c).

The parameter Algorithm allows the selection of three different algorithms for computing the optical flow. All three algorithms are implemented by using multigrid solvers to ensure an efficient solution of the underlying partial differential equations.

For Algorithm = *'fdrig'*, the method proposed by Brox, Bruhn, Papenberg, and Weickert is used. This approach is **f**low-**d**riven, **r**obust, **i**sotropic, and uses a **g**radient constancy term.

For Algorithm = *'ddraw'*, a robust variant of the method proposed by Nagel and Enkelmann is used. This approach is **d**ata-**d**riven, **r**obust, **a**nisotropic, and uses **w**arping (in contrast to the original approach).

For Algorithm = *'clg'* the **c**ombined **l**ocal-**g**lobal method proposed by Bruhn, Weickert, Feddern, Kohlberger, and Schnörr is used.

In all three algorithms, the input images can first be smoothed by a Gaussian filter with a standard deviation of SmoothingSigma (see derivate_gauss).

All three approaches are variational approaches that compute the optical flow as the minimizer of a suitable energy functional. In general, the energy functionals have the following form:

$$E(\mathbf{w}) = E_{\mathrm{D}}(\mathbf{w}) + \alpha E_{\mathrm{S}}(\mathbf{w}),$$

where $\mathbf{w} = (u, v, 1)$ is the optical flow vector field to be determined (with a time step of 1 in the third coordinate). The image sequence is regarded as a continuous function $f(\mathbf{x})$, where $\mathbf{x} = (r, c, t)$ and (r, c) denotes the position and t the time. Furthermore, $E_{\mathrm{D}}(\mathbf{w})$ denotes the data term, while $E_{\mathrm{S}}(\mathbf{w})$ denotes the smoothness term, and α is a regularization parameter that determines the smoothness of the solution. The regularization parameter α is passed in FlowSmoothness. While the data term encodes assumptions about the constancy of the object features in consecutive images, e.g., the constancy of the gray values or the constancy of the first spatial derivative of the gray values, the smoothness term encodes assumptions about the (piecewise) smoothness of the solution, i.e., the smoothness of the vector field to be determined.

The **FDRIG algorithm** is based on the minimization of an energy functional that contains the following assumptions:

Constancy of the gray values: It is assumed that corresponding pixels in consecutive images of an image sequence have the same gray value, i.e., that $f(r + u, c + v, t + 1) = f(r, c, t)$. This can be written more compactly as $f(\mathbf{x} + \mathbf{w}) = f(\mathbf{x})$ using vector notation.

Constancy of the spatial gray value derivatives: It is assumed that corresponding pixels in consecutive images of an image sequence additionally have have the same spatial gray value derivatives, i.e, that $\nabla_2 f(x+u, y+v, t+1) = \nabla_2 f(x, y, t)$ also holds, where $\nabla_2 f = (\partial_x f, \partial_y f)$. This can be written more compactly as $\nabla_2 f(\mathbf{x}+\mathbf{w}) = \nabla_2 f(\mathbf{x})$. In contrast to the gray value constancy, the gradient constancy has the advantage that it is invariant to additive global illumination changes.

Large displacements: It is assumed that large displacements, i.e., displacements larger than one pixel, occur. Under this assumption, it makes sense to consciously abstain from using the linearization of the constancy assumptions in the model that is typically proposed in the literature.

Statistical robustness in the data term: To reduce the influence of outliers, i.e., points that violate the constancy assumptions, they are penalized in a statistically robust manner, i.e., the customary non-robust square penalization $\Psi_{\mathrm{D}}(s^2) = s^2$ is replaced by a linear penalization via $\Psi_{\mathrm{S}}(s^2) = \sqrt{s^2 + \epsilon^2}$, where $\epsilon = 0.001$ is a fixed regularization constant.

Preservation of discontinuities in the flow field I: The solution is assumed to be piecewise smooth. While the actual smoothness is achieved by penalizing the first derivatives of the flow $|\nabla_2 u|^2 + |\nabla_2 v|^2$, the use of a statistically robust (linear) penalty function $\Psi_{\mathrm{S}}(s^2) = \sqrt{s^2 + \epsilon^2}$ with $\epsilon = 0.001$ provides the desired preservation of edges in the movement in the flow field to be determined. This type of smoothness term is called flow-driven and isotropic.

Taking into account all of the above assumptions, the energy functional of the FDRIG algorithm can be written as

$$\begin{aligned} E_{\mathrm{FDRIG}}(\mathbf{w}) \;=\; & \int \Psi_{\mathrm{S}}\Big(\underbrace{|f(\mathbf{x}+\mathbf{w}) - f(\mathbf{x})|^2}_{\text{gray value constancy}} + \gamma \underbrace{|\nabla_2 f(\mathbf{x}+\mathbf{w}) - \nabla_2 f(\mathbf{x})|^2}_{\text{gradient constancy}} \Big) dr dc \\ & + \alpha \int \Psi_{\mathrm{S}} \Big(\underbrace{|\nabla_2 u(\mathbf{x})|^2 + |\nabla_2 v(\mathbf{x})|^2}_{\text{smoothness assumption}} \Big) dr dc \end{aligned}$$

Here, α is the regularization parameter passed in FlowSmoothness, while γ is the gradient constancy weight passed in GradientConstancy. These two parameters, which constitute the model parameters of the FDRIG algorithm, are described in more detail below.

The **DDRAW algorithm** is based on the minimization of an energy functional that contains the following assumptions:

Constancy of the gray values: It is assumed that corresponding pixels in consecutive images of an image sequence have the same gray value, i.e., that $f(\mathbf{x}+\mathbf{w}) = f(\mathbf{x})$.

Large displacements: It is assumed that large displacements, i.e., displacements larger than one pixel, occur. Under this assumption, it makes sense to consciously abstain from using the linearization of the constancy assumptions in the model that is typically proposed in the literature.

Statistical robustness in the data term: To reduce the influence of outliers, i.e., points that violate the constancy assumptions, they are penalized in a statistically robust manner, i.e., the customary non-robust square penalization $\Psi_{\mathrm{D}}(s^2) = s^2$ is replaced by a linear penalization via $\Psi_{\mathrm{S}}(s^2) = \sqrt{s^2+\epsilon^2}$, where $\epsilon = 0.001$ is a fixed regularization constant.

Preservation of discontinuities in the flow field II: The solution is assumed to be piecewise smooth. In contrast to the FDRIG algorithm, which allows discontinuities everywhere, the DDRAW algorithm only allows discontinuities at the edges in the original image. Here, the local smoothness is controlled in such a way that the flow field is sharp across image edges, while it is smooth along the image edges. This type of smoothness term is called data-driven and anisotropic.

All assumptions of the DDRAW algorithm can be combined into the following energy functional:

$$\begin{aligned} E_{\mathrm{DDRAW}}(\mathbf{w}) \;=\; & \int \Psi_{\mathrm{S}}\Big(\underbrace{|f(\mathbf{x}+\mathbf{w}) - f(\mathbf{x})|^2}_{\text{gray value constancy}} \Big) dr dc \\ & + \alpha \int \big(\underbrace{\nabla_2 u(\mathbf{x})^\top P_{\mathrm{NE}}(\nabla_2 f(\mathbf{x}))\, \nabla_2 u(\mathbf{x}) + \nabla_2 v(\mathbf{x})^\top P_{\mathrm{NE}}(\nabla_2 f(\mathbf{x}))\, \nabla_2 v(\mathbf{x})}_{\text{smoothness assumption}} \big) dr dc\,, \end{aligned}$$

where $P_{\mathrm{NE}}(\nabla_2 f(\mathbf{x}))$ is a normalized projection matrix orthogonal to $\nabla_2 f(\mathbf{x})$, for which

$$P_{\mathrm{NE}}(\nabla_2 f(\mathbf{x})) = \frac{1}{|\nabla_2 f(\mathbf{x})|^2 + 2\epsilon_{\mathrm{S}}^2} \begin{pmatrix} f_c^2(\mathbf{x}) + \epsilon_{\mathrm{S}}^2 & -f_r(\mathbf{x}) f_c(\mathbf{x}) \\ -f_r(\mathbf{x}) f_c(\mathbf{x}) & f_r^2(\mathbf{x}) + \epsilon_{\mathrm{S}}^2 \end{pmatrix} .$$

holds. This matrix ensures that the smoothness of the flow field is only assumed along the image edges. In contrast, no assumption is made with respect to the smoothness across the image edges, resulting in the fact that discontinuities in the solution may occur across the image edges. In this respect, $\epsilon_{\mathrm{S}} = 0.001$ serves as a regularization parameter that prevents the projection matrix $P_{\mathrm{NE}}(\nabla_2 f(\mathbf{x}))$ from becoming singular. In contrast to the FDRIG algorithm, there is only one model parameter for the DDRAW algorithm: the regularization parameter α. As mentioned above, α is described in more detail below.

As for the two approaches described above, the **CLG algorithm** uses certain assumptions:

Constancy of the gray values: It is assumed that corresponding pixels in consecutive images of an image sequence have the same gray value, i.e., that $f(\mathbf{x}+\mathbf{w}) = f(\mathbf{x})$.

Small displacements: In contrast to the two approaches above, it is assumed that only small displacements can occur, i.e., displacements in the order of a few pixels. This facilitates a linearization of the constancy assumptions in the model, and leads to the approximation $f(\mathbf{x}) + \nabla_3 f(\mathbf{x})^\top \mathbf{w}(\mathbf{x}) = f(\mathbf{x})$, i.e., $\nabla_3 f(\mathbf{x})^\top \mathbf{w}(\mathbf{x}) = 0$ should hold. Here, $\nabla_3 f(\mathbf{x})$ denotes the gradient in the spatial as well as the temporal domain.

Local constancy of the solution: Furthermore, it is assumed that the flow field to be computed is locally constant. This facilitates the integration of the image data in the data term over the respective neighborhood of each pixel. This, in turn, increases the robustness of the algorithm against noise. Mathematically, this can be achieved by reformulating the quadratic data term as $(\nabla_3 f(\mathbf{x})^\top \mathbf{w}(\mathbf{x}))^2 = \mathbf{w}(\mathbf{x})^\top \nabla_3 f(\mathbf{x}) \nabla_3 f(\mathbf{x})^\top \mathbf{w}(\mathbf{x})$. By performing a local Gaussian-weighted integration over a neighborhood specified by the ρ (passed in `IntegrationSigma`), the following data term is obtained: $\mathbf{w}(\mathbf{x})^\top G_\rho * (\nabla_3 f(\mathbf{x}) \nabla_3 f(\mathbf{x})^\top)\, \mathbf{w}(\mathbf{x})$. Here, $G_\rho * \ldots$ denotes a convolution of the 3×3 matrix $\nabla_3 f(\mathbf{x}) \nabla_3 f(\mathbf{x})^\top$ with a Gaussian filter with a standard deviation of ρ (see `derivate_gauss`).

General smoothness of the flow field: Finally, the solution is assumed to be smooth everywhere in the image. This particular type of smoothness term is called homogeneous.

All of the above assumptions can be combined into the following energy functional:

$$E_{\mathrm{CLG}}(\mathbf{w}) = \int \underbrace{\big(\mathbf{w}(\mathbf{x})^\top G_\rho * (\nabla_3 f(\mathbf{x}) \nabla_3 f(\mathbf{x})^\top)\, \mathbf{w}(\mathbf{x})\big)}_{\text{gray value constancy}} dr dc + \alpha \int \big(\underbrace{|\nabla_2 u(\mathbf{x})|^2 + |\nabla_2 v(\mathbf{x})|^2}_{\text{smoothness assumption}} \big) dr dc\,,$$

The corresponding model parameters are the regularization parameter α as well as the integration scale ρ (passed in `IntegrationSigma`), which determines the size of the neighborhood over which to integrate the data term. These two parameters are described in more detail below.

To compute the optical flow vector field for two consecutive images of an image sequence with the FDRIG, DDRAW, or CLG algorithm, the solution that best fulfills the assumptions of the respective algorithm must be determined. From a mathematical point of view, this means that a minimization of the above energy functionals should be performed. For the FDRIG and DDRAW algorithms, so called coarse-to-fine warping strategies play an important role in this minimization, because they enable the calculation of large displacements. Thus, they are a suitable means to handle the omission of the linearization of the constancy assumptions numerically in these two approaches.

To calculate large displacements, coarse-to-fine warping strategies use two concepts that are closely interlocked: The successive refinement of the problem (coarse-to-fine) and the successive compensation of the current image pair by already computed displacements (warping). Algorithmically, such coarse-to-fine warping strategies can be described as follows:

1. First, both images of the current image pair are zoomed down to a very coarse resolution level.

2. Then, the optical flow vector field is computed on this coarse resolution.

3. The vector field is required on the next resolution level: It is applied there to the second image of the image sequence, i.e., the problem on the finer resolution level is compensated by the already computed optical flow field. This step is also known as warping.

4. The modified problem (difference problem) is now solved on the finer resolution level, i.e., the optical flow vector field is computed there.

5. The steps 3-4 are repeated until the finest resolution level is reached.

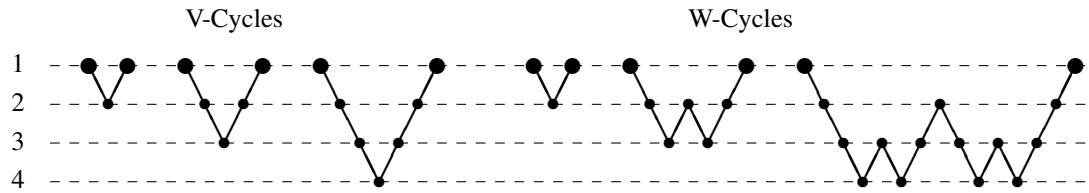
6. The final result is computed by adding up the vector fields from all resolution levels.

This incremental computation of the optical flow vector field has the following advantage: While the coarse-to-fine strategy ensures that the displacements on the finest resolution level are very small, the warping strategy ensures that the displacements remain small for the incremental displacements (optical flow vector fields of the difference problems). Since small displacements can be computed much more accurately than larger displacements, the accuracy of the results typically increases significantly by using such a coarse-to-fine warping strategy. However, instead of having to solve a single correspondence problem, an entire hierarchy of these problems must now be solved. For the CLG algorithm, such a coarse-to-fine warping strategy is unnecessary since the model already assumes small displacements.

The maximum number of resolution levels (warping levels), the resolution ratio between two consecutive resolution levels, as well as the finest resolution level can be specified for the FDRIG as well as the DDRAW algorithm. Details can be found below.

The minimization of functionals is mathematically very closely related to the minimization of functions: Like the fact that the zero crossing of the first derivative is a necessary condition for the minimum of a function, the fulfillment of the so called Euler-Lagrange equations is a necessary condition for the minimizing function of a functional (the minimizing function corresponds to the desired optical flow vector field in this case). The Euler-Lagrange equations are partial differential equations. By discretizing these Euler-Lagrange equations using finite differences, large sparse nonlinear equation systems result for the FDRIG and DDRAW algorithms. Because coarse-to-fine warping strategies are used, such an equation system must be solved for each resolution level, i.e., for each warping level. For the CLG algorithm, a single sparse linear equation system must be solved.

To ensure that the above nonlinear equation systems can be solved efficiently, the FDRIG and DDRAW use bidirectional multigrid methods. From a numerical point of view, these strategies are among the fastest methods for solving large linear and nonlinear equation systems. In contrast to conventional non-hierarchical iterative methods, e.g., the different linear and nonlinear Gauss-Seidel variants, the multigrid methods have the advantage that corrections to the solution can be determined efficiently on coarser resolution levels. This, in turn, leads to a significantly faster convergence. The basic idea of multigrid methods additionally consists of hierarchically computing these correction steps, i.e., the computation of the error on a coarser resolution level itself uses the same strategy and efficiently computes its error (i.e., the error of the error) by correction steps on an even coarser resolution level. Depending on whether one or two error correction steps are performed per cycle, a so called V or W cycle is obtained. The corresponding strategies for stepping through the resolution hierarchy are as follows for two to four resolution levels (where 1 is a fine and 4 is a coarse resolution level):



Here, iterations on the original problem are denoted by large markers, while small markers denote iterations on error correction problems.

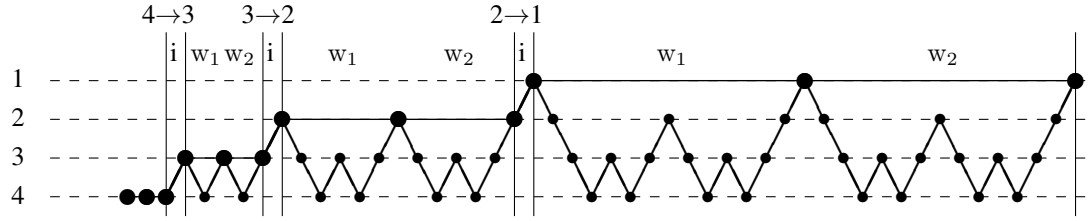
Algorithmically, a correction cycle can be described as follows:

1. In the first step, several (few) iterations using an interactive linear or nonlinear basic solver are performed (e.g., a variant of the Gauss-Seidel solver). This step is called pre-relaxation step.

2. In the second step, the current error is computed to correct the current solution (the solution after step 1). For efficiency reasons, the error is calculated on a coarser resolution level. This step, which can be performed iteratively several times, is called coarse grid correction step.

3. In a final step, again several (few) iterations using the interactive linear or nonlinear basic solver of step 1 are performed. This step is called post-relaxation step.

In addition, the solution can be initialized in a hierarchical manner. Starting from a very coarse variant of the original (non)linear equation system (level 4), the solution is successively refined. To do so, interpolated solutions of coarser variants of the equation system are used as the initialization of the next finer variant. On each resolution level itself, the V or W cycles described above are used to efficiently solve the (non)linear equation system on that resolution level. The corresponding multigrid methods are called full multigrid methods in the literature. The full multigrid algorithm can be visualized as follows:



This example represents a full multigrid algorithm that uses two W correction cycles per resolution level of the hierarchical initialization. The interpolation steps of the solution from one resolution level to the next are denoted by i and the two W correction cycles by w_1 and w_2. Iterations on the original problem are denoted by large markers, while small markers denote iterations on error correction problems.

In the multigrid implementation of the FDRIG, DDRAW, and CLG algorithm, the following parameters can be set: whether a hierarchical initialization is performed; the number of coarse grid correction steps; the maximum number of correction levels (resolution levels); the number of pre-relaxation steps; the number of post-relaxation steps. These parameters are described in more detail below.

The basic solver for the FDRIG algorithm is a point-coupled fixed-point variant of the linear Gauss-Seidel algorithm. The basic solver for the DDRAW algorithm is an alternating line-coupled fixed-point variant of the same type. The number of fixed-point steps can be specified for both algorithms with a further parameter. The basic solver for the CLG algorithm is a point-coupled linear Gauss-Seidel algorithm. The transfer of the data between the different resolution levels is performed by area-based interpolation and area-based averaging, respectively.

After the algorithms have been described, the effects of the individual parameters are discussed in the following.

The input images, along with their domains (regions of interest) are passed in `ImageT1` and `ImageT2`. The computation of the optical flow vector field `VectorField` is performed on the smallest surrounding rectangle

of the intersection of the domains of ImageT1 and ImageT2. The domain of VectorField is the intersection of the two domains. Hence, by specifying reduced domains for ImageT1 and ImageT2, the processing can be focused and runtime can potentially be saved. It should be noted, however, that all methods compute a global solution of the optical flow. In particular, it follows that the solution on a reduced domain need not (and cannot) be identical to the resolution on the full domain restricted to the reduced domain.

SmoothingSigma specifies the standard deviation of the Gaussian kernel that is used to smooth both input images. The larger the value of SmoothingSigma, the larger the low-pass effect of the Gaussian kernel, i.e., the smoother the preprocessed image. Usually, SmoothingSigma = 0.8 is a suitable choice. However, other values in the interval $[0, 2]$ are also possible. Larger standard deviations should only be considered if the input images are very noisy. It should be noted that larger values of SmoothingSigma lead to slightly longer execution times.

IntegrationSigma specifies the standard deviation ρ of the Gaussian kernel G_ρ that is used for the local integration of the neighborhood information of the data term. This parameter is used only in the CLG algorithm and has no effect on the other two algorithms. Usually, IntegrationSigma = 1.0 is a suitable choice. However, other values in the interval $[0, 3]$ are also possible. Larger standard deviations should only be considered if the input images are very noisy. It should be noted that larger values of IntegrationSigma lead to slightly longer execution times.

FlowSmoothness specifies the weight α of the smoothness term with respect to the data term. The larger the value of FlowSmoothness, the smoother the computed optical flow field. It should be noted that choosing FlowSmoothness too small can lead to unusable results, even though statistically robust penalty functions are used, in particular if the warping strategy needs to predict too much information outside of the image. For byte images with a gray value range of $[0, 255]$, values of FlowSmoothness around 20 for the flow-driven FDRIG algorithm and around 1000 for the data-driven DDRAW algorithm and the homogeneous CLG algorithm typically yield good results.

GradientConstancy specifies the weight γ of the gradient constancy with respect to the gray value constancy. This parameter is used only in the FDRIG algorithm. For the other two algorithms, it does not influence the results. For byte images with a gray value range of $[0, 255]$, a value of GradientConstancy = 5 is typically a good choice, since then both constancy assumptions are used to the same extent. For large changes in illumination, however, significantly larger values of GradientConstancy may be necessary to achieve good results. It should be noted that for large values of the gradient constancy weight the smoothness parameter FlowSmoothness must also be chosen larger.

The parameters of the multigrid solver and for the coarse-to-fine warping strategy can be specified with the generic parameters MGParamName and MGParamValue. Usually, it suffices to use one of the four default parameter sets via MGParamName = *'default_parameters'* and MGParamValue = *'very_accurate'*, *'accurate'*, *'fast_accurate'*, or *'fast'*. The default parameter sets are described below. If the parameters should be specified individually, MGParamName and MGParamValue must be set to tuples of the same length. The values corresponding to the parameters specified in MGParamName must be specified at the corresponding position in MGParamValue.

MGParamName = *'warp_zoom_factor'* can be used to specify the resolution ratio between two consecutive warping levels in the coarse-to-fine warping hierarchy. *'warp_zoom_factor'* must be selected from the open interval $(0, 1)$. For performance reasons, *'warp_zoom_factor'* is typically set to 0.5, i.e., the number of pixels is halved in each direction for each coarser warping level. This leads to an increase of 33% in the calculations that need to be performed with respect to an algorithm that does not use warping. Values for *'warp_zoom_factor'* close to 1 can lead to slightly better results. However, they require a disproportionately larger computation time, e.g., 426% for *'warp_zoom_factor'* = 0.9.

MGParamName = *'warp_levels'* can be used to restrict the warping hierarchy to a maximum number of levels. For *'warp_levels'* = 0, the largest possible number of levels is used. If the image size does not allow to use the specified number of levels (taking the resolution ratio *'warp_zoom_factor'* into account), the largest possible number of levels is used. Usually, *'warp_levels'* should be set to 0.

MGParamName = *'warp_last_level'* can be used to specify the number of warping levels for which the flow increment should *no longer* be computed. Usually, *'warp_last_level'* is set to 1 or 2, i.e., a flow increment is computed for each warping level, or the finest warping level is skipped in the computation. Since in the latter case the computation is performed on an image of half the resolution of the original image, the gained computation time can be used to compute a more accurate solution, e.g., by using a full multigrid algorithm with additional iterations. The more accurate solution is then interpolated to the full resolution.

The three parameters that specify the coarse-to-fine warping strategy are only used in the FDRIG and DDRAW algorithms. They are ignored for the CLG algorithm.

MGParamName = *'mg_solver'* can be used to specify the general multigrid strategy for solving the (non)linear equation system (in each warping level). For *'mg_solver'* = *'multigrid'*, a normal multigrid algorithm (*without* coarse-to-fine initialization) is used, while for *'mg_solver'* = *'full_multigrid'* a full multigrid algorithm (*with* coarse-to-fine initialization) is used. Since a resolution reduction of 0.5 is used between two consecutive levels of the coarse-to-fine initialization (in contrast to the resolution reduction in the warping strategy, this value is hard-coded into the algorithm), the use of a full multigrid algorithm results in an increase of the computation time by approximately 33% with respect to the normal multigrid algorithm. Using *'mg_solver'* to *'full_multigrid'* typically yields numerically more accurate results than *'mg_solver'* = *'multigrid'*.

MGParamName = *'mg_cycle_type'* can be used to specify whether a V or W correction cycle is used per multigrid level. Since a resolution reduction of 0.5 is used between two consecutive levels of the respective correction cycle, using a W cycle instead of a V cycle increases the computation time by approximately 50%. Using *'mg_cycle_type'* = *'w'* typically yields numerically more accurate results than *'mg_cycle_type'* = *'v'*.

MGParamName = *'mg_levels'* can be used to restrict the multigrid hierarchy for the coarse-to-fine initialization as well as for the actual V or W correction cycles. For *'mg_levels'* = 0, the largest possible number of levels is used. If the image size does not allow to use the specified number of levels, the largest possible number of levels is used. Usually, *'mg_levels'* should be set to 0.

MGParamName = *'mg_cycles'* can be used to specify the total number of V or W correction cycles that are being performed. If a full multigrid algorithm is used, *'mg_cycles'* refers to *each* level of the coarse-to-fine initialization. Usually, one or two cycles are sufficient to yield a sufficiently accurate solution of the equation system. Typically, the larger *'mg_cycles'*, the more accurate the numerical results. This parameter enters almost linearly into the computation time, i.e., doubling the number of cycles leads approximately to twice the computation time.

MGParamName = *'mg_pre_relax'* can be used to specify the number of iterations that are performed on each level of the V or W correction cycles using the iterative basic solver *before* the actual error correction is performed. Usually, one or two pre-relaxation steps are sufficient. Typically, the larger *'mg_pre_relax'*, the more accurate the numerical results.

MGParamName = *'mg_post_relax'* can be used to specify the number of iterations that are performed on each level of the V or W correction cycles using the iterative basic solver *after* the actual error correction is performed. Usually, one or two post-relaxation steps are sufficient. Typically, the larger *'mg_post_relax'*, the more accurate the numerical results.

Like when increasing the number of correction cycles, increasing the number of pre- and post-relaxation steps increases the computation time asymptotically linearly. However, no additional restriction and prolongation operations (zooming down and up of the error correction images) are performed. Consequently, a moderate increase in the number of relaxation steps only leads to a slight increase in the computation times.

MGParamName = *'mg_inner_iter'* can be used to specify the number of iterations to solve the linear equation systems in each fixed-point iteration of the nonlinear basic solver. Usually, one iteration is sufficient to achieve a sufficient convergence speed of the multigrid algorithm. The increase in computation time is slightly smaller than for the increase in the relaxation steps. This parameter only influences the FDRIG and DDRAW algorithms since for the CLG algorithm no nonlinear equation system needs to be solved.

MGParamName = *'parallel_solver'* can be used to enable a parallel processing of the FDRIG algorithm. This changes the results of the operator slightly, but can allow for a faster processing. The value can be set to *'true'* or *'false'* (default).

As described above, usually it is sufficient to use one of the default parameter sets for the parameters described above by using MGParamName = *'default_parameters'* and MGParamValue = *'very_accurate'*, *'accurate'*, *'fast_accurate'*, or *'fast'*. If necessary, individual parameters can be modified after the default parameter set has been chosen by specifying a subset of the above parameters and corresponding values after *'default_parameters'* in MGParamName and MGParamValue (e.g., MGParamName = *['default_parameters','warp_zoom_factor']* and MGParamValue = *['accurate',0.6]*).

The default parameter sets use the following values for the above parameters:

'default_parameters' = *'very_accurate'*: *'warp_zoom_factor'* = 0.5, *'warp_levels'* = 0, *'warp_last_level'* = 1, *'mg_solver'* = *'full_multigrid'*, *'mg_cycle_type'* = *'w'*, *'mg_levels'* = 0, *'mg_cycles'* = 1, *'mg_pre_relax'* = 2, *'mg_post_relax'* = 2, *'mg_inner_iter'* = 1.

'default_parameters' = *'accurate'*: *'warp_zoom_factor'* = 0.5, *'warp_levels'* = 0, *'warp_last_level'* = 1, *'mg_solver'* = *'multigrid'*, *'mg_cycle_type'* = *'v'*, *'mg_levels'* = 0, *'mg_cycles'* = 1, *'mg_pre_relax'* = 1, *'mg_post_relax'* = 1, *'mg_inner_iter'* = 1.

'default_parameters' = 'fast_accurate': *'warp_zoom_factor'* = 0.5, *'warp_levels'* = 0, *'warp_last_level'* = 2, *'mg_solver' = 'full_multigrid'*, *'mg_cycle_type' = 'w'*, *'mg_levels'* = 0, *'mg_cycles'* = 1, *'mg_pre_relax'* = 2, *'mg_post_relax'* = 2, *'mg_inner_iter'* = 1.

'default_parameters' = 'fast': *'warp_zoom_factor'* = 0.5, *'warp_levels'* = 0, *'warp_last_level'* = 2, *'mg_solver' = 'multigrid'*, *'mg_cycle_type' = 'v'*, *'mg_levels'* = 0, *'mg_cycles'* = 1, *'mg_pre_relax'* = 1, *'mg_post_relax'* = 1, *'mg_inner_iter'* = 1.

It should be noted that for the CLG algorithm the two modes *'fast_accurate'* and *'fast'* are identical to the modes *'very_accurate'* and *'accurate'* since the CLG algorithm does not use a coarse-to-fine warping strategy.

Parameters

- ▷ **ImageT1** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Input image 1.
- ▷ **ImageT2** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Input image 2.
- ▷ **VectorField** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* vector_field
  Optical flow.
- ▷ **Algorithm** (input_control) . . . . . string ⇝ *string*
  Algorithm for computing the optical flow.
  Default: 'fdrig'
  List of values: `Algorithm` ∈ {'fdrig', 'ddraw', 'clg'}
- ▷ **SmoothingSigma** (input_control) . . . . . real ⇝ *real*
  Standard deviation for initial Gaussian smoothing.
  Default: 0.8
  Suggested values: `SmoothingSigma` ∈ {0.0, 0.2, 0.4, 0.6, 0.8, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0}
  Restriction: SmoothingSigma >= 0.0
- ▷ **IntegrationSigma** (input_control) . . . . . real ⇝ *real*
  Standard deviation of the integration filter.
  Default: 1.0
  Suggested values: `IntegrationSigma` ∈ {0.0, 0.2, 0.4, 0.6, 0.8, 1.0, 1.2, 1.4, 1.6, 1.8, 2.0, 2.2, 2.4, 2.6, 2.8, 3.0}
  Restriction: IntegrationSigma >= 0.0
- ▷ **FlowSmoothness** (input_control) . . . . . real ⇝ *real*
  Weight of the smoothing term relative to the data term.
  Default: 20.0
  Suggested values: `FlowSmoothness` ∈ {10.0, 20.0, 30.0, 50.0, 70.0, 100.0, 200.0, 300.0, 500.0, 700.0, 1000.0, 1500.0, 2000.0}
  Restriction: FlowSmoothness >= 0.0
- ▷ **GradientConstancy** (input_control) . . . . . real ⇝ *real*
  Weight of the gradient constancy relative to the gray value constancy.
  Default: 5.0
  Suggested values: `GradientConstancy` ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 15.0, 20.0, 30.0, 40.0, 50.0, 70.0, 100.0}
  Restriction: GradientConstancy >= 0.0
- ▷ **MGParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
  Parameter name(s) for the multigrid algorithm.
  Default: 'default_parameters'
  List of values: `MGParamName` ∈ {'default_parameters', 'mg_solver', 'mg_cycle_type', 'mg_levels', 'mg_cycles', 'mg_pre_relax', 'mg_post_relax', 'mg_inner_iter', 'warp_levels', 'warp_zoom_factor', 'warp_last_level', 'parallel_solver'}
- ▷ **MGParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
  Parameter value(s) for the multigrid algorithm.
  Default: 'accurate'
  Suggested values: `MGParamValue` ∈ {'very_accurate', 'accurate', 'fast_accurate', 'fast', 'multigrid', 'full_multigrid', 'v', 'w', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 'true', 'false'}

Example

```
grab_image (ImageT1, AcqHandle)
while (true)
  grab_image (ImageT2, AcqHandle)
  optical_flow_mg (ImageT1, ImageT2, VectorField, 'fdrig', 0.8, 1, 10, \
                   5, 'default_parameters', 'accurate')
  threshold (VectorField, Region, 1, 10000)
  copy_obj (ImageT2, ImageT1, 1, 1)
endwhile
```

Result

If the parameter values are correct, the operator `optical_flow_mg` returns the value `2` (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

unwarp_image_vector_field (Image, VectorField : ImageUnwarped : :)

Unwarp an image using a vector field.

`unwarp_image_vector_field` unwarps the image `Image` using the vector field `VectorField` and returns the unwarped image in `ImageUnwarped`. The vector field must be of the semantic type `vector_field_relative` and is typically determined with `optical_flow_mg`. Hence, `unwarp_image_vector_field` can be used to unwarp the second input image of `optical_flow_mg` to the first input image. It should be noted that because of the above semantics the vector field image represents an inverse transformation from the destination image of the vector field to the source image.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **VectorField** (input_object) ..... singlechannelimage(-array) ⇝ *object :* vector_field
  Input vector field.
- ▷ **ImageUnwarped** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Unwarped image.

Example

```
optical_flow_mg (Image1, Image2, VectorField, 'fdrig', 0.8, 1, 20, \
                 5, 'default_parameters', 'accurate')
unwarp_image_vector_field (Image2, VectorField, ImageUnwarped)
```

Result

If the parameter values are correct, the operator `unwarp_image_vector_field` returns the value `2` (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on domain level.
- Automatically parallelized on tuple level.

vector_field_length (VectorField : Length : Mode :)

Compute the length of the vectors of a vector field.

`vector_field_length` compute the length of the vectors of the vector field `VectorField` and returns them in `Length`. `vector_field_length` only accepts vector fields of the semantic type `vector_field_relative`. The parameter `Mode` can be used to specify how the lengths are computed. For `Mode` = *'length'*, the Euclidean length of the vectors is computed. For `Mode` = *'squared_length'*, the square of the length of the vectors is computed. This avoids having to compute a square root internally, which is a costly operation on many processors, and hence saves runtime on these processors. Note that the `VectorField` must be in relative coordinates as returned by `optical_flow_mg`.

Parameters

▷ **VectorField** (input_object) ..... singlechannelimage(-array) ⇝ *object :* vector_field
Input vector field

▷ **Length** (output_object) ..... singlechannelimage(-array) ⇝ *object :* real
Length of the vectors of the vector field.

▷ **Mode** (input_control) ..... string ⇝ *string*
Mode for computing the length of the vectors.
Default: 'length'
List of values: `Mode` ∈ {'length', 'squared_length'}

Result

If the parameter values are correct, the operator `vector_field_length` returns the value `2` (`H_MSG_TRUE`). If the input is empty (no input images are available) the behavior can be set via `set_system ('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on domain level.
- Automatically parallelized on tuple level.

12.14 Points

corner_response (Image : ImageCorner : Size, Weight :)

Searching corners in images.

The operator corner_response extracts gray value corners in an image. The formula for the calculation of the response is:

$$\begin{aligned} R(x,y) &= A(x,y) \cdot B(x,y) - C^2(x,y) - Weight \cdot (A(x,y) + B(x,y))^2 \\ A(x,y) &= W(u,v) * (\nabla_x I(x,y))^2 \\ B(x,y) &= W(u,v) * (\nabla_y I(x,y))^2 \\ C(c,y) &= W(u,v) * (\nabla_x I(x,y) \nabla_y I(x,y)) \end{aligned}$$

with I: input image, R: output image of the filter, A, and B: smoothed directional derivatives, C: smoothing of the products of the directional derivatives. The operator gauss_image is used for smoothing (W), the operator sobel_amp is used for calculating the derivative (∇).

The corner response function is invariant with regard to rotation. In order to achieve a suitable dependency of the function $R(x,y)$ on the local gradient, the parameter Weight must be set to 0.04. With this, only gray value corners will return positive values for $R(x,y)$, while straight edges will receive negative values. The output image type is identical to the input image type. Therefore, the negative output values are set to 0 if byte images are used as input images. If this is not desired, the input image should be converted into a real or int2 image with convert_image_type.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / int2 / real
  Input image.
- ▷ **ImageCorner** (output_object) ..... multichannel-image(-array) ⇝ *object :* byte / uint2 / int2 / real
  Result of the filtering.
  Number of elements: ImageCorner == Image
- ▷ **Size** (input_control) ..... integer ⇝ *integer*
  Desired filtersize of the graymask.
  Default: 3
  Suggested values: Size ∈ {3, 5, 7, 9, 11}
- ▷ **Weight** (input_control) ..... real ⇝ *real*
  Weighting.
  Default: 0.04
  Value range: 0.0 ≤ Weight ≤ 0.3
  Minimum increment: 0.001
  Recommended increment: 0.01

Example

```
read_image(&Fabrik,"fabrik");
```

```
corner_response(Fabrik,&CornerResponse,3,0.04);
local_max(CornerResponse,&LocalMax);
disp_image(Fabrik,WindowHandle);
set_color(WindowHandle,"red");
disp_region(LocalMax,WindowHandle);
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

dots_image (Image : DotImage : Diameter, FilterType, PixelShift :)

Enhance circular dots in an image.

dots_image enhances circular dots of diameter Diameter in the input image Image. Hence, dots_image is especially suited for the segmentation of dot prints, e.g., in OCR applications. The enhancement is performed by using matched filters with filter masks that are tuned for a particular dot size. For example, for Diameter $= 5$ the filter mask is given by:

$$\frac{1}{336}\begin{pmatrix} & & -21 & -21 & -21 & & \\ & -21 & 16 & 16 & 16 & -21 & \\ -21 & 16 & 16 & 16 & 16 & 16 & -21 \\ -21 & 16 & 16 & 16 & 16 & 16 & -21 \\ -21 & 16 & 16 & 16 & 16 & 16 & -21 \\ & -21 & 16 & 16 & 16 & -21 & \\ & & -21 & -21 & -21 & & \end{pmatrix}$$

The parameter FilterType selects whether *'dark'*, *'light'*, or *'all'* dots in the image should be enhanced. The PixelShift can be used either to increase the contrast of the output image (PixelShift > 0) or to dampen the values in extremely bright areas that would be cut off otherwise (PixelShift $= -1$).

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Input image.

▷ **DotImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Output image.

▷ **Diameter** (input_control) . . . . . integer ⇝ *integer*
Diameter of the dots to be enhanced.
Default: 5
List of values: `Diameter` ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23}

▷ **FilterType** (input_control) . . . . . string ⇝ *string*
Enhance dark, light, or all dots.
Default: 'light'
List of values: `FilterType` ∈ {'dark', 'light', 'all'}

▷ **PixelShift** (input_control) . . . . . integer ⇝ *integer*
Shift of the filter response.
Default: 0
List of values: `PixelShift` ∈ {-1, 0, 1, 2}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

points_foerstner (Image : : SigmaGrad, SigmaInt, SigmaPoints, ThreshInhom, ThreshShape, Smoothing, EliminateDoublets : RowJunctions, ColumnJunctions, CoRRJunctions, CoRCJunctions, CoCCJunctions, RowArea, ColumnArea, CoRRArea, CoRCArea, CoCCArea)

Detect points of interest using the Förstner operator.

`points_foerstner` extracts significant points from an image. Significant points are points that differ from their neighborhood, i.e., points where the image function changes in two dimensions. These changes occur on the one hand at the intersection of image edges (called junction points), and on the other hand at places where color or brightness differs from the surrounding neighborhood (called area points).

The point extraction takes place in two steps: In the first step the point regions, i.e., the inhomogeneous, isotropic regions, are extracted from the image. To do so, the smoothed matrix

$$M = S * \begin{pmatrix} \sum_{c=1}^{n} I_{x,c}^2 & \sum_{c=1}^{n} I_{x,c} I_{y,c} \\ \sum_{c=1}^{n} I_{x,c} I_{y,c} & \sum_{c=1}^{n} I_{y,c}^2 \end{pmatrix}$$

is calculated, where $I_{x,c}$ and $I_{y,c}$ are the first derivatives of each image channel and S stands for a smoothing. If `Smoothing` is *'gauss'*, the derivatives are computed with Gaussian derivatives of size `SigmaGrad` and the

smoothing is performed by a Gaussian of size SigmaInt. If Smoothing is *'mean'*, the derivatives are computed with a 3×3 Sobel filter (and hence SigmaGrad is ignored) and the smoothing is performed by a SigmaInt $\times$ SigmaInt mean filter. Then

$$\textit{inhomogeneity} = \mathrm{Trace}M$$

is the degree of inhomogeneity in the image and

$$\textit{isotropy} = 4 \cdot \frac{\mathrm{Det}M}{(\mathrm{Trace}M)^2}$$

is the degree of the isotropy of the texture in the image. Image points that have an inhomogeneity greater or equal to ThreshInhom and at the same time an isotropy greater or equal to ThreshShape are subsequently examined further.

In the second step, two optimization functions are calculated for the resulting points. Essentially, these optimization functions average for each point the distances to the edge directions (for junction points) and the gradient directions (for area points) within an observation window around the point. If Smoothing is *'gauss'*, the averaging is performed by a Gaussian of size SigmaPoints, if Smoothing is *'mean'*, the averaging is performed by a SigmaPoints $\times$ SigmaPoints mean filter. The local minima of the optimization functions determine the extracted points. Their subpixel precise position is returned in (RowJunctions, ColumnJunctions) and (RowArea, ColumnArea).

In addition to their position, for each extracted point the elements CoRRJunctions, CoRCJunctions, and CoCCJunctions (and CoRRArea, CoRCArea, and CoCCArea, respectively) of the corresponding covariance matrix are returned. This matrix facilitates conclusions about the precision of the calculated point position. To obtain the actual values, it is necessary to estimate the amount of noise in the input image and to multiply all components of the covariance matrix with the variance of the noise. (To estimate the amount of noise, apply intensity to homogeneous image regions or plane_deviation to image regions, where the gray values form a plane. In both cases the amount of noise is returned in the parameter Deviation.) This is illustrated by the example program points_foerstner_ellipses.hdev.

It lies in the nature of this operator that corners often result in two distinct points: One junction point, where the edges of the corner actually meet, and one area point inside the corner. Such doublets will be eliminated automatically, if EliminateDoublets is *'true'*. To do so, each pair of one junction point and one area point is examined. If the points lie within each others' observation window of the optimization function, for both points the precision of the point position is calculated and the point with the lower precision is rejected. If EliminateDoublets is *'false'*, every detected point is returned.

Attention

Note that only odd values for SigmaInt and SigmaPoints are allowed, if Smoothing is *'mean'*. Even values automatically will be replaced by the next larger odd value.

points_foerstner with Smoothing = *'gauss'* uses a special implementation that is optimized using SSE2 instructions if the system parameter *'sse2_enable'* is set to *'true'* (which is default if SSE2 is available on your machine). This implementation is slightly inaccurate compared to the pure C version due to numerical issues (for 'byte' images the difference in RowJunctions and ColumnJunctions is in order of magnitude of $1.0e-5$). If you prefer accuracy over performance you can set *'sse2_enable'* to *'false'* (using set_system) before you call points_foerstner. This way points_foerstner does not use SSE2 accelerations. Don't forget to set *'sse2_enable'* back to *'true'* afterwards.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / uint2 / real
Input image.

▷ **SigmaGrad** (input_control) ..... number ⇝ *real* / integer
Amount of smoothing used for the calculation of the gradient. If Smoothing is 'mean', SigmaGrad is ignored.
Default: 1.0
Suggested values: SigmaGrad ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
Value range: 0.0 ≤ SigmaGrad
Recommended increment: 0.1

▷ **SigmaInt** (input_control) . . . . . number ⇝ *real* / integer
Amount of smoothing used for the integration of the gradients.
Default: 2.0
Suggested values: SigmaInt ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
Recommended increment: 0.1
Restriction: SigmaInt > 0

▷ **SigmaPoints** (input_control) . . . . . number ⇝ *real* / integer
Amount of smoothing used in the optimization functions.
Default: 3.0
Suggested values: SigmaPoints ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
Recommended increment: 0.1
Restriction: SigmaPoints >= SigmaInt && SigmaPoints > 0.6

▷ **ThreshInhom** (input_control) . . . . . number ⇝ *real* / integer
Threshold for the segmentation of inhomogeneous image areas.
Default: 200
Suggested values: ThreshInhom ∈ {50, 100, 200, 500, 1000}
Value range: 0.0 ≤ ThreshInhom

▷ **ThreshShape** (input_control) . . . . . real ⇝ *real*
Threshold for the segmentation of point areas.
Default: 0.3
Suggested values: ThreshShape ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.7}
Value range: 0.01 ≤ ThreshShape ≤ 1
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Smoothing** (input_control) . . . . . string ⇝ *string*
Used smoothing method.
Default: 'gauss'
List of values: Smoothing ∈ {'gauss', 'mean'}

▷ **EliminateDoublets** (input_control) . . . . . string ⇝ *string*
Elimination of multiply detected points.
Default: 'false'
List of values: EliminateDoublets ∈ {'false', 'true'}

▷ **RowJunctions** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinates of the detected junction points.

▷ **ColumnJunctions** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinates of the detected junction points.

▷ **CoRRJunctions** (output_control) . . . . . number-array ⇝ *real*
Row part of the covariance matrix of the detected junction points.

▷ **CoRCJunctions** (output_control) . . . . . number-array ⇝ *real*
Mixed part of the covariance matrix of the detected junction points.

▷ **CoCCJunctions** (output_control) . . . . . number-array ⇝ *real*
Column part of the covariance matrix of the detected junction points.

▷ **RowArea** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinates of the detected area points.

▷ **ColumnArea** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinates of the detected area points.

▷ **CoRRArea** (output_control) . . . . . number-array ⇝ *real*
Row part of the covariance matrix of the detected area points.

▷ **CoRCArea** (output_control) . . . . . number-array ⇝ *real*
Mixed part of the covariance matrix of the detected area points.

▷ **CoCCArea** (output_control) . . . . . number-array ⇝ *real*
Column part of the covariance matrix of the detected area points.

Result

points_foerstner returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during the execution. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

points_harris (Image : : SigmaGrad, SigmaSmooth, Alpha, Threshold : Row, Column)

Detect points of interest using the Harris operator.

points_harris extracts points of interest from an image. The Harris operator is based upon the smoothed matrix

$$M = G_\sigma * \begin{pmatrix} \sum_{c=1}^{n} I_{x,c}^2 & \sum_{c=1}^{n} I_{x,c} I_{y,c} \\ \sum_{c=1}^{n} I_{x,c} I_{y,c} & \sum_{c=1}^{n} I_{y,c}^2 \end{pmatrix},$$

where G_σ stands for a Gaussian smoothing of size SigmaSmooth and $I_{x,c}$ and $I_{y,c}$ are the first derivatives of each image channel, computed with Gaussian derivatives of size SigmaGrad. The resulting points are the positive local extrema of

$$\mathrm{Det}M - \mathtt{Alpha} * (\mathrm{Trace}M)^2.$$

If necessary, they can be restricted to points with a minimum filter response of Threshold. The coordinates of the points are calculated with subpixel accuracy.

Attention

points_harris uses a special implementation that is optimized using SSE2 instructions if the system parameter *'sse2_enable'* is set to *'true'* (which is default if SSE2 is available on your machine). This implementation is slightly inaccurate compared to the pure C version due to numerical issues (for 'byte' images the difference in Row and Column is in order of magnitude of $1.0e-5$). If you prefer accuracy over performance you can set *'sse2_enable'* to *'false'* (using set_system) before you call points_harris. This way points_harris does not use SSE2 accelerations. Don't forget to set *'sse2_enable'* back to *'true'* afterwards.

points_harris can be executed on an OpenCL device if both SigmaGrad and SigmaSmooth induce a filter size of no more than 129 pixels. This corresponds to a value of less than 20.7 for both parameters. As with

the SSE2 version, the results of the OpenCL implementation may diverge slightly from that of pure C version due to numerical issues.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2 / real
Input image.

▷ **SigmaGrad** (input_control) . . . . . real ⇝ *real*
Amount of smoothing used for the calculation of the gradient.
Default: 0.7
Suggested values: SigmaGrad ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
Recommended increment: 0.1
Restriction: SigmaGrad > 0.0

▷ **SigmaSmooth** (input_control) . . . . . real ⇝ *real*
Amount of smoothing used for the integration of the gradients.
Default: 2.0
Suggested values: SigmaSmooth ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
Recommended increment: 0.1
Restriction: SigmaSmooth > 0.0

▷ **Alpha** (input_control) . . . . . real ⇝ *real*
Weight of the squared trace of the squared gradient matrix.
Default: 0.08
Suggested values: Alpha ∈ {0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08}
Value range: 0.0 ≤ Alpha
Minimum increment: 0.001
Recommended increment: 0.01

▷ **Threshold** (input_control) . . . . . number ⇝ *real* / integer
Minimum filter response for the points.
Default: 1000.0
Restriction: Threshold >= 0.0

▷ **Row** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinates of the detected points.

▷ **Column** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinates of the detected points.

Result

points_harris returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during the execution. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

points_harris_binomial (Image : : MaskSizeGrad, MaskSizeSmooth, Alpha, Threshold, Subpix : Row, Column)

Detect points of interest using the binomial approximation of the Harris operator.

points_harris extracts points of interest from an image Image. The Harris operator is based upon the smoothed matrix

$$M = G_\sigma * \begin{pmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{pmatrix} ,$$

where G_σ stands for a Binomial smoothing of size MaskSizeSmooth and I_x and I_y are the first derivatives of the image, computed with a Sobel filter of size MaskSizeGrad. The resulting points are the positive local extrema of

$$\mathrm{Det}M - \texttt{Alpha} * (\mathrm{Trace}M)^2.$$

If necessary, they can be restricted to points with a minimum filter response of Threshold. By default the coordinates of the points are calculated with subpixel accuracy. This can be turned off by setting the parameter Subpix to 'off'.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2
Input image.

▷ **MaskSizeGrad** (input_control) . . . . . integer ⇝ *integer*
Amount of binomial smoothing used for the calculation of the gradient.
Default: 5
Suggested values: MaskSizeGrad ∈ {3, 5, 7, 9, 11, 15, 21, 31}
Value range: 1 ≤ MaskSizeGrad
Recommended increment: 2

▷ **MaskSizeSmooth** (input_control) . . . . . integer ⇝ *integer*
Amount of smoothing used for the integration of the gradients.
Default: 15
Suggested values: MaskSizeSmooth ∈ {3, 5, 7, 9, 11, 15, 21, 31}
Value range: 1 ≤ MaskSizeSmooth
Recommended increment: 2

▷ **Alpha** (input_control) . . . . . real ⇝ *real*
Weight of the squared trace of the squared gradient matrix.
Default: 0.08
Suggested values: Alpha ∈ {0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08}
Value range: 0.0 ≤ Alpha
Minimum increment: 0.001
Recommended increment: 0.01

▷ **Threshold** (input_control) . . . . . number ⇝ *real* / integer
Minimum filter response for the points.
Default: 1000.0
Value range: 0.0 ≤ Threshold

▷ **Subpix** (input_control) . . . . . string ⇝ *string*
Turn on or off subpixel refinement.
Default: 'on'
List of values: Subpix ∈ {'on', 'off'}

▷ **Row** (output_control) ..... point.y-array ⇝ *real*
Row coordinates of the detected points.

▷ **Column** (output_control) ..... point.x-array ⇝ *real*
Column coordinates of the detected points.

Result

points_harris returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during the execution. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

points_lepetit (Image : : Radius, CheckNeighbor, MinCheckNeighborDiff, MinScore, Subpix : Row, Column)

Detect points of interest using the Lepetit operator.

points_lepetit extracts points of interest like corners or blob-like structures from Image. The Image is first smoothed with a median of size 3x3. Then, all the gray values on a circle with radius Radius around an interest point candidate (*m*) are examined. The absolute differences of two diagonally opposed gray values (*m1*,*m2*) on the circle to the central pixel *m* is computed. At least one of these differences has to be larger than MinCheckNeighborDiff. All diagonally opposed pixels on the circle must fulfill that condition. To suppress detection of points at edges that have a small curvature (aliasing), it is possible to compute CheckNeighbor further differences of circle point neighbors of *m1* and *m2* to the center, that as well fulfill the above criteria. By computing all gray value differences of the circle points to the center, a mean gray value difference is determined. That value has to be larger than MinScore and allows to restrict the results to points with high contrast. By computing the score of all eight neighbors of m, it is possible to fit a quadratic equation to that. The maxima of that equation determines a subpixel accurate interest point position. By setting the parameter Subpix to 'interpolation' (default) or 'none', it is possible to turn that refinement step on or off. The resulting points are returned in Row and Column. The operator points_lepetit can especially be used for very fast interest point extraction. The results are however less robust than points extracted by points_harris for example.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
Input image.

▷ **Radius** (input_control) ..... integer ⇝ *integer*
Radius of the circle.
Default: 3
Suggested values: Radius ∈ {3, 5, 6, 7, 8, 9, 10, 15}

▷ **CheckNeighbor** (input_control) ..... integer ⇝ *integer*
Number of checked neighbors on the circle.
Default: 1
Suggested values: CheckNeighbor ∈ {1, 2, 3, 5}

▷ **MinCheckNeighborDiff** (input_control) ..... integer ⇝ *integer*
Threshold of gray value difference to each circle point.
Default: 15
Suggested values: MinCheckNeighborDiff ∈ {10, 15, 20, 25, 30, 35, 40, 45, 60, 80}

▷ **MinScore** (input_control) ..... integer ⇝ *integer*
Threshold of gray value difference to all circle points.
Default: 30
Suggested values: MinScore ∈ {5, 10, 15, 20, 25, 30}

▷ **Subpix** (input_control) ..... string ⇝ *string*
Subpixel accuracy of point coordinates.
Default: 'interpolation'
List of values: Subpix ∈ {'none', 'interpolation'}

▷ **Row** (output_control) ..... point.y-array ⇝ *integer* / real
Row-coordinates of the detected points.

▷ **Column** (output_control) ..... point.x-array ⇝ *integer* / real
Column-coordinates of the detected points.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

points_sojka (Image : : MaskSize, SigmaW, SigmaD, MinGrad, MinApparentness, MinAngle, Subpix : Row, Column)

Find corners using the Sojka operator.

points_sojka defines a corner as the point of intersection of two straight, non-collinear gray value edges. To decide whether a point of the input image Image is a corner or not, a neighborhood of MaskSize × MaskSize points is inspected. Only those image regions that are relevant for the decision are considered. Pixels with a magnitude of the gradient of less than MinGrad are ignored from the outset.

Furthermore, only those of the remaining points are used that belong to one of the two gray value edges that form the corner. For this, the so called *Apparentness* is calculated, which is an indicator of the probability that the examined point actually is a corner point. Essentially, it is determined by the number of relevant points and their gradients. A point can only be accepted as a corner when its *Apparentness* is at least MinApparentness. Typical values of MinApparentness should range in the region of a few multiples of MinGrad.

To calculate the *Apparentness*, each mask point is weighted according to two criteria: First, the influence of a mask point is weighted with a Gaussian of size SigmaW according to its distance from the possible corner point. SigmaW should be roughly between quarter and half of MaskSize to obtain a reasonable proportion of the size of the weighting function to the mask size. Secondly, the distance of the point from the (assumed) ideal gray value edge is estimated and the point is weighted with a Gaussian of size SigmaD according to that distance. I.e., pixels that (due to the discretization of the input image) lie farther from the ideal gray value edge have less influence on the result than pixels with a smaller distance. Typically, it is not necessary to modify the default value *0.75* of SigmaD .

As a further criterion, the angle is calculated, by which the gray value edges change their direction in the corner point. A point can only be accepted as a corner when this angle is greater than MinAngle.

The position of the detected corner points is returned in (Row, Column). Row and Column are calculated with subpixel accuracy if Subpix is *'true'*. They are calculated only with pixel accuracy if Subpix is *'false'*.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
  Input image.
- ▷ **MaskSize** (input_control) ..... integer ⇝ *integer*
  Required filter size.
  Default: 9
  List of values: MaskSize ∈ {5, 7, 9, 11, 13}
- ▷ **SigmaW** (input_control) ..... number ⇝ *real* / integer
  Sigma of the weight function according to the distance to the corner candidate.
  Default: 2.5
  Suggested values: SigmaW ∈ {2.0, 2.2, 2.4, 2.5, 2.6, 2.8, 3.0}
  Restriction: 2.0 <= SigmaW && SigmaW <= 3.0
- ▷ **SigmaD** (input_control) ..... number ⇝ *real* / integer
  Sigma of the weight function for the distance to the ideal gray value edge.
  Default: 0.75
  Suggested values: SigmaD ∈ {0.6, 0.7, 0.75, 0.8, 0.9, 1.0}
  Restriction: 0.6 <= SigmaD && SigmaD <= 1.0
- ▷ **MinGrad** (input_control) ..... number ⇝ *real* / integer
  Threshold for the magnitude of the gradient.
  Default: 30.0
  Suggested values: MinGrad ∈ {20.0, 15.0, 30.0, 35.0, 40.0}
- ▷ **MinApparentness** (input_control) ..... number ⇝ *real* / integer
  Threshold for $Apparentness$.
  Default: 90.0
  Suggested values: MinApparentness ∈ {30.0, 60.0, 90.0, 150.0, 300.0, 600.0, 1500.0}
- ▷ **MinAngle** (input_control) ..... angle.rad ⇝ *real*
  Threshold for the direction change in a corner point (radians).
  Default: 0.5
  Restriction: 0.0 <= MinAngle && MinAngle <= pi
- ▷ **Subpix** (input_control) ..... string ⇝ *string*
  Subpixel precise calculation of the corner points.
  Default: 'false'
  List of values: Subpix ∈ {'false', 'true'}
- ▷ **Row** (output_control) ..... point.y-array ⇝ *real*
  Row coordinates of the detected corner points.
- ▷ **Column** (output_control) ..... point.x-array ⇝ *real*
  Column coordinates of the detected corner points.

Result

points_sojka returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during the execution. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

12.15 Scene Flow

```
scene_flow_calib ( ImageRect1T1, ImageRect2T1, ImageRect1T2,
    ImageRect2T2, Disparity : : SmoothingFlow, SmoothingDisparity,
    GenParamName, GenParamValue, CamParamRect1, CamParamRect2,
    RelPoseRect : ObjectModel3D )
```

Compute the calibrated scene flow between two stereo image pairs.

`scene_flow_calib` computes the calibrated scene flow between two consecutive rectified stereo image pairs. The scene flow is the three-dimensional position and motion of surface points in a dynamic scene. The movement in the images can be caused by objects that move in the world or by a movement of the camera (or both) between the acquisition of the two image pairs.

The scene flow is returned as the 3D object model `ObjectModel3D`. The 3D object model contains the coordinates of the reconstructed 3D points. Furthermore, the 3D flow is encoded in the 3D object model by the attributes *'&flow_x'*, *'&flow_y'*, and *'&flow_z'*.

The two consecutive stereo image pairs of the image sequence are passed in `ImageRect1T1`, `ImageRect2T1`, `ImageRect1T2`, and `ImageRect2T2`. Each stereo image pair must be rectified. Note that the images can be rectified by using the operators `calibrate_cameras`, `gen_binocular_rectification_map`, and `map_image`.

The camera geometry of the rectified binocular camera system is specified by its internal camera parameters `CamParamRect1` of the rectified camera 1 and `CamParamRect2` of the rectified camera 2, and the pose `RelPoseRect` that defines the pose of the rectified camera 2 in relation to the rectified camera 1. These camera parameters can be obtained from the operators `calibrate_cameras` and `gen_binocular_rectification_map`. The focal length and scale factor of the rectified camera system 1 and 2 must be equal.

Furthermore, a single-channel `Disparity` image is required, which specifies for each pixel $(r, c1)$ of the image `ImageRect1T1` a matching pixel $(r, c2)$ of `ImageRect2T1` according to the equation $c2 = c1 + d(r, c1)$, where $d(r, c)$ is the `Disparity` at pixel (r, c). The disparity image can be computed using `binocular_disparity` or `binocular_disparity_mg`.

To calculate the calibrated scene flow, internally `scene_flow_uncalib` is first executed. The results are then converted to 3D points and 3D flow vectors using the stereo camera geometry parameters described above.

For a description of the remaining parameters of `scene_flow_calib`, please refer to `scene_flow_uncalib`.

Parameters

- ▷ **ImageRect1T1** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Input image 1 at time t_1.
- ▷ **ImageRect2T1** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Input image 2 at time t_1.
- ▷ **ImageRect1T2** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Input image 1 at time t_2.
- ▷ **ImageRect2T2** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
  Input image 2 at time t_2.
- ▷ **Disparity** (input_object) ..... singlechannelimage(-array) ⇝ *object :* real
  Disparity between input images 1 and 2 at time t_1.

▷ **SmoothingFlow** (input_control) . . . . . number ⇝ *real* / integer
Weight of the regularization term relative to the data term (derivatives of the optical flow).
Default: 40.0
Suggested values: SmoothingFlow ∈ {10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 80.0, 90.0, 100.0}
Restriction: SmoothingFlow > 0.0

▷ **SmoothingDisparity** (input_control) . . . . . number ⇝ *real* / integer
Weight of the regularization term relative to the data term (derivatives of the disparity change).
Default: 40.0
Suggested values: SmoothingDisparity ∈ {10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 80.0, 90.0, 100.0}
Restriction: SmoothingDisparity > 0.0

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Parameter name(s) for the algorithm.
Default: 'default_parameters'
Suggested values: GenParamName ∈ {'default_parameters', 'warp_levels', 'warp_zoom_factor', 'warp_last_level', 'outer_iter', 'inner_iter', 'sor_iter', 'omega'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Parameter value(s) for the algorithm.
Default: 'accurate'
Suggested values: GenParamValue ∈ {'very_accurate', 'accurate', 'fast', 'very_fast', 0, 1, 2, 3, 4, 5, 6, 0.5, 0.6, 0.7, 0.75, 3, 5, 7, 2, 3, 1.9}

▷ **CamParamRect1** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters of the rectified camera 1.

▷ **CamParamRect2** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters of the rectified camera 2.

▷ **RelPoseRect** (input_control) . . . . . pose ⇝ *real* / integer
Pose of the rectified camera 2 in relation to the rectified camera 1.
Number of elements: 7

▷ **ObjectModel3D** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

Result

If the parameter values are correct, the operator scene_flow_calib returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

scene_flow_uncalib (ImageRect1T1, ImageRect2T1, ImageRect1T2, ImageRect2T2, Disparity : OpticalFlow, DisparityChange : SmoothingFlow, SmoothingDisparity, GenParamName, GenParamValue :)

Compute the uncalibrated scene flow between two stereo image pairs.

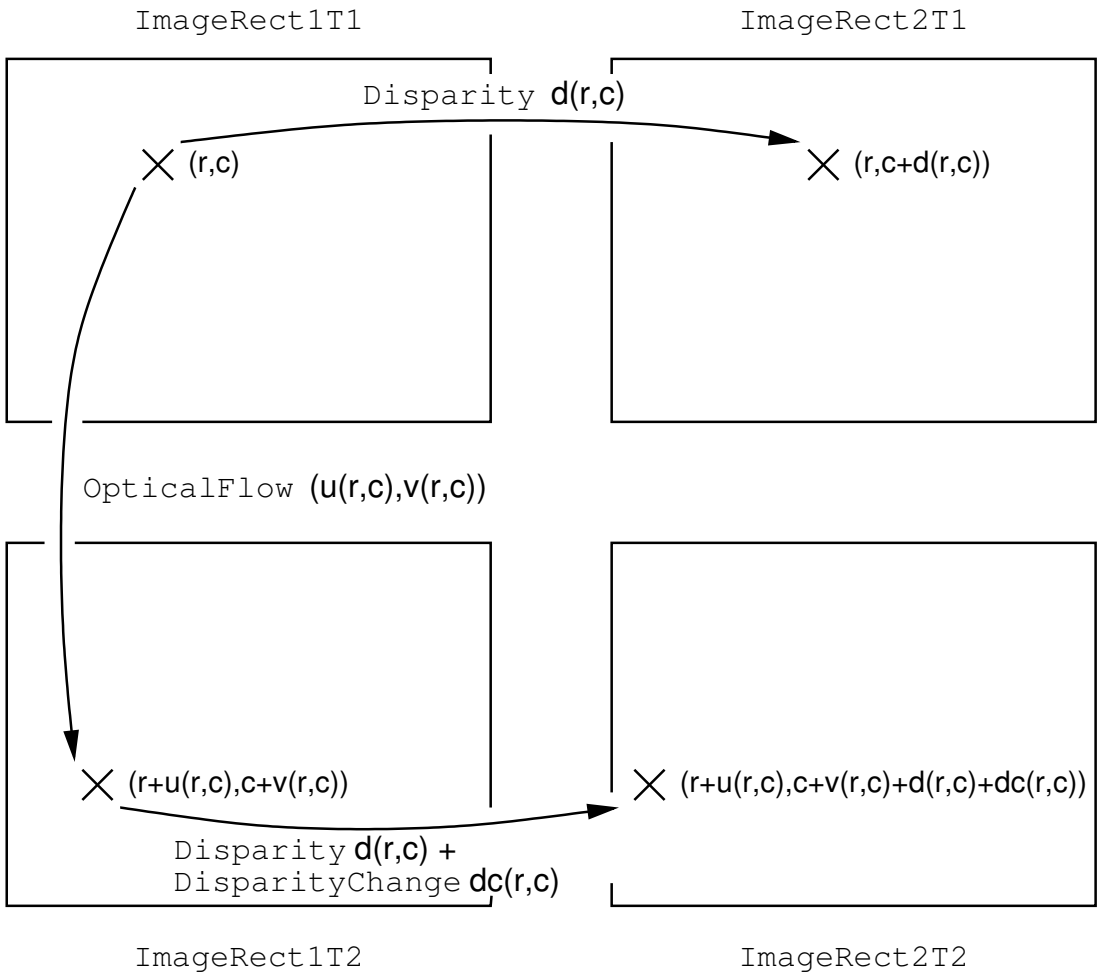
scene_flow_uncalib computes the uncalibrated scene flow between two consecutive rectified stereo image pairs. The scene flow is the three-dimensional position and motion of surface points in a dynamic scene. The movement in the images can be caused by objects that move in the world or by a movement of the camera (or both) between the acquisition of the two image pairs. To calculate the calibrated scene flow, scene_flow_calib can be used.

The two consecutive stereo image pairs of the image sequence are passed in ImageRect1T1, ImageRect2T1, ImageRect1T2, and ImageRect2T2. Each stereo image pair must be rectified. Note that the images can be rectified by using the operators calibrate_cameras, gen_binocular_rectification_map, and map_image. Furthermore, a single-channel Disparity image is required, which specifies for each pixel $(r, c1)$ of the image ImageRect1T1 a matching pixel $(r, c2)$ of ImageRect2T1 according to the equation $c2 = c1 + d(r, c1)$, where $d(r, c)$ is the Disparity at pixel (r, c). The disparity image can be computed using binocular_disparity or binocular_disparity_mg.

The computed uncalibrated scene flow is returned in OpticalFlow and DisparityChange. The vectors in the vector field OpticalFlow represent the movement in the image plane between ImageRect1T1 and ImageRect1T2. The single-channel image DisparityChange describes the change in disparity between ImageRect2T1 and ImageRect2T2. A world point is projected into ImageRect1T1 at position (r, c). The same point is projected into

- ImageRect2T1 at position $(r, c + d(r, c))$,
- ImageRect1T2 at position $(r + u(r, c), c + v(r, c))$,
- ImageRect2T2 at position $(r + u(r, c), c + v(r, c) + d(r, c) + dc(r, c))$,

where $u(r, c)$ and $v(r, c)$ denote the values of the row and column components of the vector field image OpticalFlow, $d(r, c)$ denotes the Disparity, and $dc(r, c)$ the DisparityChange at the pixel (r, c).



Relations between the four images and the optical flow as well as the disparities in the disparity images.

Parameter Description

The rectified input images are passed in `ImageRect1T1`, `ImageRect2T1`, `ImageRect1T2`, and `ImageRect2T2`. The computation of the scene flow is performed on the domain of `ImageRect1T1`, which is also the domain of the scene flow in `OpticalFlow` and `DisparityChange`. `Disparity` describes the disparity between the rectified images `ImageRect1T1` and `ImageRect2T1`.

`SmoothingFlow` and `SmoothingDisparity` specify the regularization weights λ and γ with respect to the data term. The larger the value of these parameters, the smoother the computed scene flow is. For byte images with a gray value range of $[0, 255]$, values around 40 typically yield good results.

The parameters of the iteration scheme and for the coarse-to-fine warping strategy can be specified with the generic parameters `GenParamName` and `GenParamValue`.

Usually, it is sufficient to use one of the default parameter sets for the parameters by using `GenParamName` = *'default_parameters'* and `GenParamValue` = *'very_accurate'*, *'accurate'*, *'fast'*, or *'very_fast'*. If necessary, individual parameters can be modified after the default parameter set has been chosen by specifying a subset of the parameters and corresponding values after *'default_parameters'* in `GenParamName` and `GenParamValue` (e.g., `GenParamName` = *['default_parameters','warp_zoom_factor']* and `GenParamValue` = *['accurate',0.6]*). The meaning of the individual parameters is described in detail below. The default parameter sets are given by:

'default_parameters'	*'very_accurate'*	*'accurate'*	*'fast'*	*'very_fast'*
'warp_zoom_factor'	0.75	0.5	0.5	0.5
'warp_levels'	0	0	0	0
'warp_last_level'	1	1	1	2
'outer_iter'	10	7	5	4
'inner_iter'	2	2	2	2
'sor_iter'	3	3	3	3
'omega'	1.9	1.9	1.9	1.9

If the parameters should be specified individually, `GenParamName` and `GenParamValue` must be set to tuples of the same length. The values corresponding to the parameters specified in `GenParamName` must be specified at the corresponding position in `GenParamValue`. For a deeper understanding of the following parameters, please refer to the section *Algorithm* below.

- `GenParamName` = *'warp_zoom_factor'* can be used to specify the resolution ratio between two consecutive warping levels in the coarse-to-fine warping hierarchy. *'warp_zoom_factor'* must be selected from the open interval $(0, 1)$. For performance reasons, *'warp_zoom_factor'* is typically set to 0.5, i.e., the number of pixels is halved in each direction for each coarser warping level. Values for *'warp_zoom_factor'* close to 1 can lead to slightly better results. However, they require a disproportionately larger computation time.
- `GenParamName` = *'warp_levels'* can be used to restrict the warping hierarchy to a maximum number of levels. For *'warp_levels'* = 0, the largest possible number of levels is used. If the image size does not allow to use the specified number of levels (taking the resolution ratio *'warp_zoom_factor'* into account), the largest possible number of levels is used. Usually, *'warp_levels'* should be set to 0.
- `GenParamName` = *'warp_last_level'* can be used to specify the number of warping levels for which the flow increment should no longer be computed. Usually, *'warp_last_level'* is set to 1 or 2, i.e., a flow increment is computed for each warping level, or the finest warping level is skipped in the computation. In the latter case, the computation is performed on an image of half the resolution of the original image and then interpolated to the full resolution.
- `GenParamName` = *'outer_iter'* can be used to specify the number of outer iterations in the minimization scheme. Typically, the larger *'outer_iter'*, the more accurate the numerical results are. Higher values for this parameter lead to an increase in the computation time. Typically, *'outer_iter'* is set to values between 5 and 10.
- `GenParamName` = *'inner_iter'* can be used to specify the number of inner iterations in the minimization scheme. Typically, the larger *'inner_iter'*, the more accurate the numerical results are. Higher values for this parameter lead to an increase in the computation time. Usually, two inner iterations are sufficient.
- `GenParamName` = *'sor_iter'* can be used to specify the number of SOR iterations for solving the linear system of equations. Typically, the larger *'sor_iter'*, the more accurate the numerical results are. Higher values for this parameter lead to an increase in the computation time. Usually, three SOR iterations are sufficient.
- `GenParamName` = *'omega'* can be used to specify the relaxation factor ω of the SOR method. *'omega'* must be selected from the open interval $(1, 2)$. Typically, *'omega'* is set to 1.9.

Algorithm

The scene flow is estimated by minimizing a suitable energy functional:

$$E(f) = \int E_D(f) + E_S(f)\,\mathrm{d}r\mathrm{d}c$$

where $f = (u, v, dc)$ is the optical flow field and the disparity change. $E_D(f)$ denotes the data term and $E_S(f)$ the smoothness (regularization) term. The algorithm is based on the following assumptions, which lead to the data and smoothness terms:

Brightness Constancy It is assumed that the gray value of a point remains constant in all four input images, resulting in the following four constraints:

$$
\begin{aligned}
C_{D1} &= I_{1,t1}(r,c) - I_{2,t1}(r, c + d(r,c)) = 0 \\
C_{F1} &= I_{1,t2}(r + u(r,c), c + v(r,c)) - I_{1,t1}(r,c) = 0 \\
C_{F2} &= I_{2,t2}(r + u(r,c), c + v(r,c) + d(r,c) + dc(r,c)) - I_{2,t1}(r, c + d(r,c)) = 0 \\
C_{D2} &= I_{2,t2}(r + u(r,c), c + v(r,c) + d(r,c) + dc(r,c)) - I_{1,t2}(r + u(r,c), c + v(r,c)) = 0
\end{aligned}
$$

Here, $I_{1,t1}$, $I_{2,t1}$, $I_{1,t2}$, and $I_{2,t2}$ denote `ImageRect1T1`, `ImageRect2T1`, `ImageRect1T2`, and `ImageRect2T2`, respectively.

Piecewise smoothness of the scene flow The solution is assumed to be piecewise smooth. This smoothness is achieved by penalizing the first derivatives of the flow $\nabla(u)^2, \nabla(v)^2, \nabla(dc)^2$. The use of a statistically robust (linear) penalty function $\Psi(s) = \sqrt{s^2 + \varepsilon}$ with $\varepsilon = 0.001$ provides the desired preservation of edges in the movement in the scene flow to be determined.

Because the disparity image d is given, the first constraint C_{D1} can be omitted. Taking into account all of the above assumptions, the energy functional can be written as

$$
E(f) = \int \Psi(C_{F1}^2) + \Psi(C_{F2}^2) + \Psi(C_{D2}^2) + \Psi(\lambda(\nabla(u)^2 + \nabla(v)^2) + \gamma \nabla(dc)^2) \, \mathrm{d}r\mathrm{d}c
$$

where λ and γ are the regularization parameters passed in `SmoothingFlow` and `SmoothingDisparity`.

To calculate large displacements, coarse-to-fine warping strategies use two concepts that are closely interlocked: The successive refinement of the problem (coarse-to-fine) and the successive compensation of the current image pair by already computed displacements (warping). Algorithmically, such coarse-to-fine warping strategies can be described as follows:

1. First, all images are zoomed down to a very coarse resolution level.
2. Then, the scene flow is computed on this coarse resolution.
3. The scene flow is required on the next resolution level: It is applied there to the second image pair of the image sequence, i.e., the problem on the finer resolution level is compensated by the already computed scene flow. This step is also known as warping.
4. The modified problem (difference problem) is now solved on the finer resolution level, i.e., the scene scene flow is computed there.
5. The steps 3-4 are repeated until the finest resolution level is reached.
6. The final result is computed by adding up the scene flow from all resolution levels.

This incremental computation of the scene flow has the following advantage: While the coarse-to-fine strategy ensures that the displacements on the finest resolution level are very small, the warping strategy ensures that the displacements remain small for the incremental displacements (scene flow of the difference problems). Since small displacements can be computed much more accurately than larger displacements, the accuracy of the results typically increases significantly by using such a coarse-to-fine warping strategy. However, instead of having to solve a single correspondence problem, an entire hierarchy of these problems must be solved.

The minimization of functionals is mathematically very closely related to the minimization of functions: Like the fact that the zero crossing of the first derivative is a necessary condition for the minimum of a function, the fulfillment of the so called Euler-Lagrange equations is a necessary condition for the minimizing function of a functional (the minimizing function corresponds to the desired scene flow in this case). The Euler-Lagrange equations are partial differential equations. By discretizing these Euler-Lagrange equations using finite differences, large sparse nonlinear equation systems have to be solved in this algorithm.

For each warping level a single equation system must be solved. The algorithm uses an iteration scheme consisting of two nested iterations (called the outer and inner iteration) and the SOR (Successive Over-Relaxation) method. The outer loop contains the linearization of the nonlinear terms resulting from the data constraints. The nonlinearity of Ψ' is removed by the inner fixed point iteration scheme. The resulting linear system of equations can be solved efficiently by the SOR method.

Parameters

▷ **ImageRect1T1** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Input image 1 at time t_1.

▷ **ImageRect2T1** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Input image 2 at time t_1.

▷ **ImageRect1T2** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Input image 1 at time t_2.

▷ **ImageRect2T2** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Input image 2 at time t_2.

▷ **Disparity** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* real
Disparity between input images 1 and 2 at time t_1.

▷ **OpticalFlow** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* vector_field
Estimated optical flow.

▷ **DisparityChange** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* real
Estimated change in disparity.

▷ **SmoothingFlow** (input_control) . . . . . number ⇝ *real* / integer
Weight of the regularization term relative to the data term (derivatives of the optical flow).
Default: 40.0
Suggested values: SmoothingFlow ∈ {10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 80.0, 90.0, 100.0}
Restriction: SmoothingFlow > 0.0

▷ **SmoothingDisparity** (input_control) . . . . . number ⇝ *real* / integer
Weight of the regularization term relative to the data term (derivatives of the disparity change).
Default: 40.0
Suggested values: SmoothingDisparity ∈ {10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 80.0, 90.0, 100.0}
Restriction: SmoothingDisparity > 0.0

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Parameter name(s) for the algorithm.
Default: 'default_parameters'
Suggested values: GenParamName ∈ {'default_parameters', 'warp_levels', 'warp_zoom_factor', 'warp_last_level', 'outer_iter', 'inner_iter', 'sor_iter', 'omega'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Parameter value(s) for the algorithm.
Default: 'accurate'
Suggested values: GenParamValue ∈ {'very_accurate', 'accurate', 'fast', 'very_fast', 0, 1, 2, 3, 4, 5, 6, 0.5, 0.6, 0.7, 0.75, 3, 5, 7, 2, 3, 1.9}

Result

If the parameter values are correct, the operator scene_flow_uncalib returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

binocular_disparity, binocular_disparity_mg

Possible Successors

12.16 Smoothing

This chapter contains operators for smoothing filters. Further information about filtering can be found at the introduction to the chapter Filters.

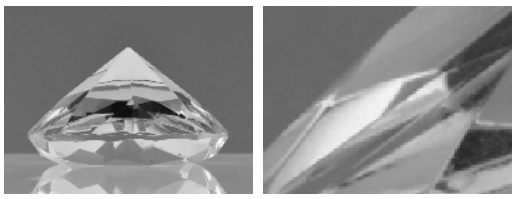
General information about smoothing filters

Smoothing operators are filters that help to suppress noise in an image. For this purpose it is assumed, that in the undisturbed or true image the gray value of a given data point does not completely differ from its surroundings, ideally even varies only little. Thus, to suppress noise, it can be useful to replace the measured gray value with an estimate based on surrounding data points. Such an estimate can be done in different ways, so HALCON provides different smoothing operators.

The operators differ in speed and suitability for different kinds of noise. Information like the complexity (runtime dependence on the image size) is, if available, given in the operator reference. While most operators treat a single image, some can process depending images (e.g., multichannel filters like `mean_n` and `rank_n`, or edge-preserving filters like `guided_filter` and `bilateral_filter`, which additionally use guidance images). Please note that some filters have both possibilities and more information is given in the specific operator reference.

Smoothing filters for single images with random noise

These smoothing filters apply their smoothing function on each channel of the input image separately and return a smoothed image with the same number of channels. In the following table we list implemented variants of smoothing filters for a single image with random noise and apply them for three different variants of random noise. The images in the table shall give an idea of the operators capability, but please note that the smoothed images highly depend on the input parameters and the individual image for every operator. For comparison, the different noisy images without filtering are given in the first row of the table. The undisturbed image without noise is shown in the following figure ((1) the full image as well as (2) its part by means of which possible effects on edges and remains from Salt & Pepper noise are visualized more clearly).



(1) (2)

(1) Undisturbed image, (2) part of the image chosen for the visualization of the filter capabilities

We marked filters recommended due to their special suitability concerning speed (S), edge-preservation (E), or a compromise between these two (C). The numbers in square brackets refer to further information that is given in a list below the table.

Further information related to the numbers in square brackets used in the table above:

1. The numbers in the column 'Time' are indications about the time the operator uses to process an image. The numbers are obtained from averaging over multiple runs on the three different noise images and given in arbitrary units. Note also that the runtime of an operator depends on many factors, not at least on the used parameters and the image size. For each filter, the first number is for an image of size 800x600, the second for an image of size 1497x1160. The shown images are parts of the smaller image with parameters reasonable to us (we do not claim to have found the parameters resulting neither necessarily in the best image smoothing nor the smallest runtime). Even if two filters have the same parameter name as input, we did not necessarily use the same parameter value for both of them. Therefore, these numbers are to be understood as an indicator only.
2. This operator can be used iteratively.
3. This operator uses a guidance image (which can be the Image itself).

Smoothing filters for single images with systematic noise

Video images composed of two half images can have systematic errors. In such a case, the operator fill_interlace can help.

Operators designed for smoothing over multiple channels

These smoothing filters take an image with multiple channels as input and return a single channel (gray value) image. In HALCON, the following filters of this group are implemented:

- mean_n
- rank_n

Further operators

In addition to the smoothing filters, this chapter contains the following operator: info_smooth, which returns information related to the different filters used by the operator smooth_image.

Glossary

In the following, the most important terms that are used in the context of smoothing filters are described:

smoothing Smoothing means to apply a filter function on the given data to capture the main data patterns while removing noise.

random noise Random noise is a stationary variation of brightness or color information by a small random amount for every pixel with an assumed mean of 0 over the total image.

systematic noise Systematic noise is predictable noise, caused, e.g., by the specific setup used to acquire the images.

anisotropic_diffusion (Image : ImageAniso : Mode, Contrast, Theta, Iterations :)

Perform an anisotropic diffusion of an image.

The operator anisotropic_diffusion performs an anisotropic diffusion on the input image Image according to the model of Perona and Malik. This procedure is also referred to as nonlinear isotropic diffusion. Considering the image as a gray value function u, the algorithm is a discretization of the partial differential equation

$$u_t = div(g(|\nabla u|^2, c)\nabla u)$$

with the initial value $u = u_0$ defined by Image at a time t_0. The equation is iterated Iterations times in time steps of length Theta, so that the output image ImageAniso contains the gray value function at the time $t_0 + \text{Iterations} \cdot \text{Theta}$.

The goal of the anisotropic diffusion is the elimination of image noise in constant image patches while preserving the edges in the image. The distinction between edges and constant patches is achieved using the threshold Contrast on the size of the gray value differences between adjacent pixels. Contrast is referred to as the contrast parameter and abbreviated with the letter c.

The variable diffusion coefficient g can be chosen to follow different monotonically decreasing functions with values between *0* and *1* and determines the response of the diffusion process to an edge. With the parameter Mode, the following functions can be selected:

$$g_1(x, c) = \frac{1}{\sqrt{1 + 2\frac{x}{c^2}}}$$

Choosing the function g_1 by setting Mode to *'parabolic'* guarantees that the associated differential equation is parabolic, so that a well-posedness theory exists for the problem and the procedure is stable for an arbitrary step size Theta. In this case however, there remains a slight diffusion even across edges of a height larger than c.

$$g_2(x, c) = \frac{1}{1 + \frac{x}{c^2}}$$

The choice of *'perona-malik'* for Mode, as used in the publication of Perona and Malik, does not possess the theoretical properties of g_1, but in practice it has proved to be sufficiently stable and is thus widely used. The theoretical instability results in a slight sharpening of strong edges.

$$g_3(x, c) = 1 - \exp(-C\frac{c^8}{x^4})$$

The function g_3 with the constant $C = 3.31488$, proposed by Weickert, and selectable by setting Mode to *'weickert'* is an improvement of g_2 with respect to edge sharpening. The transition between smoothing and sharpening happens very abruptly at $x = c^2$.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **ImageAniso** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
Output image.

▷ **Mode** (input_control) ..... string ⇝ *string*
Diffusion coefficient as a function of the edge amplitude.
Default: 'weickert'
List of values: `Mode` ∈ {'weickert', 'perona-malik', 'parabolic'}

▷ **Contrast** (input_control) ..... real ⇝ *real*
Contrast parameter.
Default: 5.0
Suggested values: `Contrast` ∈ {2.0, 5.0, 10.0, 20.0, 50.0, 100.0}
Restriction: Contrast > 0

▷ **Theta** (input_control) ..... real ⇝ *real*
Time step.
Default: 1.0
Suggested values: `Theta` ∈ {0.5, 1.0, 3.0}
Restriction: Theta > 0

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 10
Suggested values: `Iterations` ∈ {1, 3, 10, 100, 500}
Restriction: Iterations >= 1

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Alternatives

`bilateral_filter`, `guided_filter`

```
bilateral_filter ( Image,
    ImageJoint :  ImageBilateral :  SigmaSpatial,  SigmaRange,
    GenParamName,  GenParamValue :  )
```

bilateral filtering of an image.

`bilateral_filter` performs a joint bilateral filtering on the input `Image` using the guidance image `ImageJoint` and returns the result in `ImageBilateral`. `Image` and `ImageJoint` must be of the same size and type.

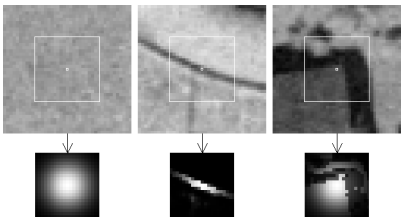
`SigmaSpatial` defines the size of the filter mask and corresponds to the standard deviation of a conventional Gauss filter. Bigger values increase the area of influence of the filter and less detail is preserved.

SigmaRange is used to modify the filter mask depending on the pixels of ImageJoint around the current pixel. Only pixels in areas with weak edges that have a contrast lower than SigmaRange contribute to the smoothing. Please note that the contrast in uint2 or real images may differ significantly from the default values of SigmaRange and adjust the parameter accordingly.

GenParamName and GenParamValue currently can be used to control the trade-off between accuracy and speed (see below).

Influence of the Joint Image

Each pixel of Image is filtered with a filter mask that depends on ImageJoint. The filter mask combines a Gaussian closeness function depending on SigmaSpatial and a Gaussian similarity function that weights gray value differences depending on SigmaRange.



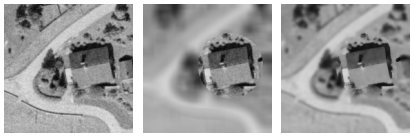
Examples for local filter masks depending on ImageJoint: Left: In homogeneous areas the filter mask is nearly Gaussian. Center: The filter mask follows the line. That means, only the dark pixels are smoothed and the edge is preserved. Right: The filter mask resembles the corner. Note that the filter mask extends across the shadow into areas with similar gray values.

If Image and ImageJoint are identical, bilateral_filter behaves like an edge-preserving smoothing where SigmaSpatial defines the size of the filter mask. Pixels at edges that have a contrast significantly greater than SigmaRange are preserved, while pixels in homogeneous areas are smoothed.

(1) (2) (3)

(1) Image and (2) ImageJoint are identical. That leads to edge-preserving smoothing in (3) ImageBilateral.

If Image and ImageJoint are different, each pixel of Image is smoothed with a filter mask that is influenced by ImageJoint. Pixels at positions where ImageJoint has strong edges with a contrast significantly greater than SigmaRange are smoothed less than pixels in homogeneous areas.



(1) (2) (3)

(1) Image and (2) ImageJoint are different. (3) ImageBilateral: Only edges are preserved where ImageJoint has edges.

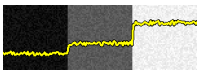
If ImageJoint is constant, bilateral_filter is equivalent to a Gaussian smoothing with SigmaSpatial (see gauss_filter or smooth_image).

(1) (2) (3)

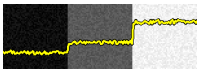
(1) Image. (2) ImageJoint is constant. (3) ImageBilateral is equal to Image after Gaussian smoothing.

Influence of the smoothing parameters

The following examples show the influence of SigmaRange on an artificial image. In this image, the noise level is 10 gray values, the left edge has a contrast of 50 gray values, the right edge has a contrast of 100 gray values. The yellow line shows a gray-value profile of a horizontal cross section.



Original image with overlaid gray profile, used as Image and ImageJoint.



Filter result with SigmaRange = 1: No effect because SigmaRange is below noise level. Therefore noise is treated as edge and preserved.

Filter result with SigmaRange = 25: Noise is smoothed, edges are preserved.

Filter result with SigmaRange = 50: The weaker edge is smoothed, the stronger edge is preserved.

Filter result with SigmaRange = 100: Both edges are smoothed.

Generic Parameters

The following values for GenParamName are supported:

'sampling_method' Per default, bilateral_filter uses an approximation of the bilateral filter that only uses a subset of sampled points for the calculation of the local filter masks.

By setting *'sampling_method'*, the used approximation can be selected. Possible values are:

'grid' **(default)** Uses a regular grid for subsampling the filter masks.

'poisson_disk' Uses a Poisson disk sampling. This method is slower than *'grid'*, but may produce less artifacts.

'exact' Uses all available points. This method is slowest, but the most accurate. If *'exact'* is used, *'sampling_ratio'* is ignored.

'sampling_ratio' Controls how many points are used for the subsampling of the local filter masks.

By setting *'sampling_ratio'* to *1.0*, the exact method is used. Using a lower sampling ratio leads to faster filtering, but also to slightly less accurate results.

Suggested values: 0.25, 0.5, 0.75, 1.0

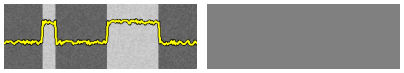
Default: 0.50

Rolling Bilateral Filter

bilateral_filter can be applied iteratively. In this case, the result of one iteration is used as guidance image for the next iteration. This can be useful, e.g., to remove small structures from the original image even if they have a high contrast.

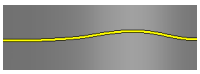
The following example shows the effect of a rolling filter on an artificial image. In this image, the noise level is 10 gray values, the contrast between dark and bright areas is 100 gray values, the left bright bar is 10 pixels wide, the right bar is 40 pixels wide. The yellow line shows a gray-value profile of a horizontal cross section. Used parameters: ImageJoint constant, SigmaSpatial = 25, SigmaRange = 15.

```
* Apply the rolling bilateral filter
* (use a constant guide for the first iteration).
gen_image_proto(Image, ImageJoint, 128)
for I := 1 to 6 by 1
   bilateral_filter(Image, ImageJoint, ImageJoint, 25, 15, [], [])
endfor
```



(1) (2)

(1) Input `Image` and (2) `ImageJoint` for first iteration of the rolling filter.



Result after first iteration: The smaller bar is removed.

Result after third iteration: The edges of the right bar are partly restored.

Result after sixth iteration: The edges of the right bar are restored completely.

Mathematical Background

The calculation of the filtered gray values I'_i is done on the basis of the following formula:

$$I'_i = \frac{1}{K_i} \sum_{k \in \omega_i} c_{ik} \cdot s_{ik} \cdot I_k$$

where c_{ik} is a closeness function

$$c_{ik} = exp\left(\frac{-\|i-k\|^2}{2 \cdot SigmaSpatial^2}\right)$$

s_{ik} is a similarity function

$$s_{ik} = exp\left(\frac{-(J_i - J_k)^2}{2 \cdot SigmaRange^2}\right)$$

K_i is a normalization factor

$$K_i = \sum_{k \in \omega_i} c_{ik} \cdot s_{ik}$$

where I'_i, I_i and J_i are the gray values of `Image` and `ImageJoint` at the pixel position i, and ω_i is the neighborhood around the pixel i.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Image to be filtered.
- ▷ **ImageJoint** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Joint image.
- ▷ **ImageBilateral** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Filtered output image.
- ▷ **SigmaSpatial** (input_control) . . . . . real ⇝ *real*
  Size of the Gaussian of the closeness function.
  Default: 3.0
  Suggested values: SigmaSpatial ∈ {1.0, 2.0, 3.0, 10.0}
  Restriction: SigmaSpatial > 0.6
- ▷ **SigmaRange** (input_control) . . . . . real ⇝ *real*
  Size of the Gaussian of the similarity function.
  Default: 20.0
  Suggested values: SigmaRange ∈ {3.0, 10.0, 20.0, 50.0, 100.0}
  Restriction: SigmaRange > 0.0001
- ▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
  Generic parameter name.
  Default: []
  List of values: GenParamName ∈ {'sampling_ratio', 'sampling_method'}
- ▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string
  Generic parameter value.
  Default: []
  Suggested values: GenParamValue ∈ {'grid', 'poisson_disk', 'exact', 0.5, 0.25, 0.75, 1.0}

Example

```
read_image (Image, 'mreut')
* Edge-preserving smoothing
bilateral_filter (Image, Image, ImageBilateral, 5, 20, [], [])
* Rolling filter (5 iterations)
gen_image_proto (Image, ImageJoint, 0)
for I := 1 to 5 by 1
  bilateral_filter (Image, ImageJoint, ImageJoint, 5, 20, [], [])
endfor
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Predecessors

read_image

Possible Successors

threshold, dyn_threshold, var_threshold, regiongrowing

Alternatives

Module

Foundation

binomial_filter (Image : ImageBinomial : MaskWidth, MaskHeight :)

Smooth an image using the binomial filter.

binomial_filter smooths the image Image using a binomial filter with a mask size of MaskWidth × MaskHeight pixels and returns the smoothed image in ImageBinomial. The binomial filter is a very good approximation of a Gaussian filter that can be implemented extremely efficiently using only integer operations. Hence, binomial_filter is very fast. Let m = MaskHeight and n = MaskWidth. Then, the filter coefficients b_{ij} are given by binomial coefficients

$$\binom{l}{k} = \frac{l!}{k!(l-k)!}$$

as follows:

$$b_{ij} = \frac{1}{2^{n+m-2}} \binom{m-1}{i} \binom{n-1}{j}$$

Here, $i = 0, \ldots, m-1$ and $j = 0, \ldots, n-1$. The binomial filter performs approximately the same smoothing as a Gaussian filter with $\sigma = \sqrt{n-1}/2$, where for simplicity it is assumed that $m = n$. In detail, the relationship between n and σ is:

n	σ
3	0.7523
5	1.0317
7	1.2505
9	1.4365
11	1.6010
13	1.7502
15	1.8876
17	2.0157
19	2.1361
21	2.2501
23	2.3586
25	2.4623
27	2.5618
29	2.6576
31	2.7500
33	2.8395
35	2.9262
37	3.0104

If different values are chosen for MaskHeight and MaskWidth, the above relation between n and σ still holds and refers to the amount of smoothing in the row and column directions.

binomial_filter can be executed on OpenCL devices for all supported image types.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **ImageBinomial** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Smoothed image.

▷ **MaskWidth** (input_control) ..... integer ⇝ *integer*
Filter width.
Default: 5
List of values: MaskWidth ∈ {1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37}

▷ **MaskHeight** (input_control) ..... integer ⇝ *integer*
Filter height.
Default: 5
List of values: MaskHeight ∈ {1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37}

Result

If the parameter values are correct the operator binomial_filter returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

eliminate_min_max (Image : FilteredImage : MaskWidth, MaskHeight, Gap, Mode :)

Smooth an image in the spatial domain to suppress noise.

eliminate_min_max smooths an image by replacing gray values with neighboring mean values, or local minima/maxima. In order to prevent edges and lines from being smoothed, only those gray values that represent local minima or maxima are replaced (if there is a line or edge within an image there will be at least one neighboring pixel with a comparable gray value). Gap controls the strictness of replacement: Only gray values that exceed all other values within their local neighborhood more than Gap and all values that fall below their neighboring more than Gap are replaced.

Thus, with $g(x, y)$ being the gray value at position (x, y) and $E(x, y)$ representing the gray values of a MaskWidth × MaskHeight sized rectangular neighborhood of a pixel at position (x, y), containing all pixels within the neighborhood except the pixel itself, a pixel is replaced

- if $g(x,y) \geq$ Gap $+ max(E(x,y))$, or
- else if $g(x,y) +$ Gap $<= min(E(x,y))$.
- Elsewise $g(x,y)$ is adopted without change.

Mode specifies how to perform the new value in case of a replacement.

- Mode = *1*: replace a local maximum with next minor local maximum and replace a local minimum with next bigger local minimum.
- Mode = *2*: replace with mean value of all pixels within the local neighborhood (including the replaced pixel).
- Mode = *3*: replace with median value of all pixels within the local neighborhood (including the replaced pixel (also used if Mode has got any other value than *1* or *2*).

MaskWidth and MaskHeight specify the width and height of the rectangular neighborhood. Border treatment: Pixels outside the image border are not considered (e.g., with a local 3×3-mask the neighborhood of a pixel at $(0,0)$ reduces to the pixels at $(1,0)$, $(0,1)$, and $(1,1)$).

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

If MaskWidth or MaskHeight is an even number, it is replaced by the next higher odd number (this allows the unique extraction of the center of the filter mask). Width/height of the mask may not exceed the image width/height.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Image to smooth.

▷ **FilteredImage** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Smoothed image.

▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *integer*
Width of filter mask.
Default: 3
Suggested values: MaskWidth ∈ {3, 5, 7, 9}
Value range: 3 ≤ MaskWidth ≤ width(Image)
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskWidth)

▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
Height of filter mask.
Default: 3
Suggested values: MaskHeight ∈ {3, 5, 7, 9}
Value range: 3 ≤ MaskHeight ≤ width(Image)
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskWidth)

▷ **Gap** (input_control) . . . . . number ⇝ *real*
Gap between local maximum/minimum and all other gray values of the neighborhood.
Default: 1.0
Suggested values: Gap ∈ {1.0, 2.0, 5.0, 10.0}

▷ **Mode** (input_control) . . . . . integer ⇝ *integer*
Replacement rule.
Default: 3
List of values: Mode ∈ {1, 2, 3}

Result

eliminate_min_max returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty eliminate_min_max returns with an error message.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

eliminate_sp (Image : ImageFillSP : MaskWidth, MaskHeight, MinThresh, MaxThresh :)

Replace values outside of thresholds with average value.

The operator eliminate_sp replaces all gray values outside the indicated gray value intervals (MinThresh to MaxThresh) with the neighboring mean values. Only those neighboring pixels which also fall within the gray value interval are used for averaging. If no such pixel is present in the vicinity the original gray value is used. The gray values in the input image falling within the gray value interval are also adopted without change.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

If even values instead of odd values are given for MaskHeight or MaskWidth, the routine uses the next larger odd values instead (this way the center of the filter mask is always explicitly determined).

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Input image.

▷ **ImageFillSP** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Smoothed image.

▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *integer*
Width of filter mask.
Default: 3
Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11}
Value range: 3 ≤ MaskWidth (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskWidth) && MaskWidth < width(Image) * 2

▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
Height of filter mask.
Default: 3
Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11}
Value range: 3 ≤ MaskHeight (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskHeight) && MaskHeight < height(Image) * 2

▷ **MinThresh** (input_control) . . . . . integer ⇝ *integer*
Minimum gray value.
Default: 1
Suggested values: MinThresh ∈ {1, 5, 7, 9, 11, 15, 23, 31, 43, 61, 101}

▷ **MaxThresh** (input_control) . . . . . integer ⇝ *integer*
Maximum gray value.
Default: 254
Suggested values: MaxThresh ∈ {5, 7, 9, 11, 15, 23, 31, 43, 61, 101, 200, 230, 250, 254}
Restriction: MinThresh <= MaxThresh

Example

```
read_image(Image,'mreut')
dev_display(Image)
eliminate_sp(Image,ImageFillSP,3,3,101,201)
dev_display(ImageFillSP)
```

Execution Information

fill_interlace (ImageCamera : ImageFilled : Mode :)

Interpolate 2 video half images.

The operator fill_interlace calculates an interpolated full image or removes odd/even lines from a video image composed of two half images. If an image is recorded with a video camera it consists of two half images recorded at different times but stored in one image in the digital form. This can lead to several errors in further processing. In order to reduce these errors the video image is modified. Every second line is re-calculated or removed. The parameter Mode determines whether this must be done for even (*'even'*, *'rmeven'*) or odd (*'odd'*, *'rmodd'*) line numbers. If you choose *'even'* or *'odd'* the gray values in the generated lines are calculated as mean values from the direct neighbors above or below the current pixel, respectively. If you choose *'rmeven'* or *'rmodd'* the even or odd lines numbers are removed (in that case the resulting image is only half as high as the input image). The value *'switch'* for Mode cause the odd and even lines to be exchanged.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **ImageCamera** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Gray image consisting of two half images.

▷ **ImageFilled** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Full image with interpolated/removed lines.

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Instruction whether even or odd lines should be replaced/removed.
Default: 'odd'
List of values: `Mode` ∈ {'odd', 'even', 'rmodd', 'rmeven', 'switch'}

Example

```
read_image(Image,'video_image')
fill_interlace(Image,New,'odd')
sobel_amp(New,Sobel,'sum_abs',3)
```

Complexity

For each pixel: $O(2)$.

Result

If the parameter values are correct the operator `fill_interlace` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system ('no_object_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Module

Foundation

gauss_filter (Image : ImageGauss : Size :)

Smooth using discrete Gauss functions.

The operator `gauss_filter` smoothes images using the discrete Gaussian, a discrete approximation of the Gaussian function,

$$G_\sigma(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(\frac{-x^2}{2\sigma^2}\right)$$

The smoothing effect increases with increasing filter size. The following filter sizes (`Size`) are supported (the sigma value of the Gauss function is indicated in brackets):

- *3* (0.600)
- *5* (1.075)
- *7* (1.550)
- *9* (2.025)
- *11* (2.550)

For border treatment the gray values of the images are reflected at the image borders. Notice that, contrary to the operator `gauss_image`, the relationship between the filter mask size and its respective value for the sigma parameter is linear.

The operator `binomial_filter` can be used as an alternative to `gauss_filter`. `binomial_filter` is significantly faster than `gauss_filter`. It should be noted that the mask size in `binomial_filter` does not lead to the same amount of smoothing as the mask size in `gauss_filter`. Corresponding mask sizes can be determined based on the respective values of the Gaussian smoothing parameter sigma.

`gauss_filter` can be executed on OpenCL devices for all supported image types. However, the OpenCL implementation can produce slightly different results from the scalar implementation.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

In order to be able to process `gauss_filter` on an OpenCL device, `Image` must be at least 64 pixels in both width and height.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Image to be smoothed.

▷ **`ImageGauss`** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Filtered image.

▷ **`Size`** (input_control) . . . . . integer ⇝ *integer*
Required filter size.
Default: 5
List of values: `Size` ∈ {3, 5, 7, 9, 11}

Example

```
gauss_filter(Input,Gauss,7)
regiongrowing(Gauss,Segments,7,7,5,100)
```

Complexity

For each pixel: $O(Size * 2)$.

Result

If the parameter values are correct the operator `gauss_filter` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system ('no_object_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

guided_filter (Image, ImageGuide : ImageGuided : Radius, Amplitude :)

Guided filtering of an image.

guided_filter filters the input Image using the guidance image ImageGuide and returns the result in ImageGuided. Image and ImageGuide must be of the same size and type.

The Radius is the size of the filter mask. Bigger values increase the area of influence of the filter and less detail is preserved. The value of Radius does not influence the runtime of the operator.

Amplitude is used to decide what is an edge and what is a homogeneous area. Bigger values of Amplitude lead to stronger edges being smoothed. As a rule of thumb, Amplitude should be lower than the contrast of the edges that should be preserved. Please note that the contrast in uint2 or real images may differ significantly from the default values of Amplitude and adjust the parameter accordingly.

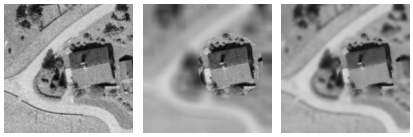
Influence of the Guidance Image

If Image and ImageGuide are identical, guided_filter behaves like an edge-preserving smoothing with a filter mask with Radius. Pixels at edges that have a contrast significantly greater than Amplitude are preserved, while pixels in homogeneous areas are smoothed. Hence, guided_filter is a fast alternative to anisotropic_diffusion or bilateral_filter.

(1) (2) (3)

(1) Image and (2) ImageGuide are identical. That leads to edge-preserving smoothing in (3) ImageGuided.

If Image and ImageGuide are different, Image is smoothed with a filter mask with Radius, except in areas where ImageGuide has edges with a contrast significantly greater than Amplitude.



(1) (2) (3)

(1) Image and (2) ImageGuide are different. (3) ImageGuided: Only edges are preserved where ImageGuide has edges.

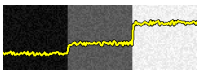
If ImageGuide is constant, guided_filter is equivalent to 2 consecutive calls of mean_image with mask size 2*Radius+1.

(1) (2) (3)

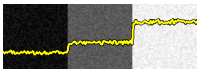
(2) ImageGuide is constant. This is equivalent to a double smoothing of (1) Image with mean_image. (3) ImageGuided

Influence of the smoothing parameters

The following examples show the influence of Amplitude on an artificial image. In this image, the noise level is 10 gray values, the left edge has a contrast of 50 gray values, the right edge has a contrast of 100 gray values. The yellow line shows a gray-value profile of a horizontal cross section.



Original image with overlaid gray profile, used as Image and ImageGuide.



Filter result with Amplitude = 1: No effect because Amplitude is below noise level. Therefore noise is treated as edge and preserved.

Filter result with Amplitude = 25: Noise is smoothed, edges are preserved.

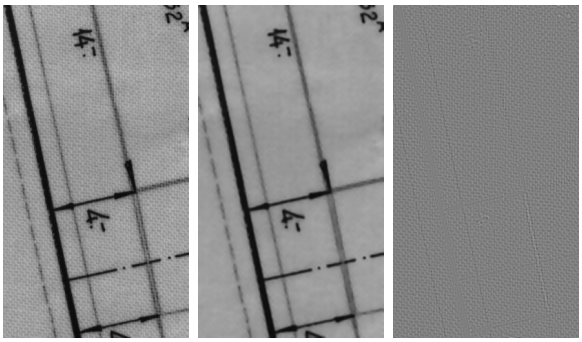
Filter result with Amplitude = 50: The weaker edge is smoothed, the stronger edge is preserved.

Filter result with Amplitude = 100: Both edges are smoothed.

Rolling Guided Filter

guided_filter can be applied iteratively. In this case, the result of one iteration is used as guidance image for the next iteration. This can be useful, e.g., to remove small structures from the original image even if they have a high contrast.

In the following example, the rolling guided filter is used to separate the texture from the original image.



(1) (2) (3)

Texture removal with the rolling guided filter: (1) Original, (2) separated structure, (3) separated texture.

```
* Apply the rolling guided filter
* (use a constant guide for the first iteration).
gen_image_proto(Image, ImageStructure, 0)
for I := 1 to 4 by 1
    guided_filter(Image, ImageStructure, ImageStructure, 1.5, 10)
endfor
* Separate texture by subtracting large structures from the
original.
sub_image(Image, ImageStructure, ImageTexture, 1, 128)
```

Since `guided_filter` with a constant `ImageGuide` is similar to `mean_image`, the first iteration could be replaced by a call of `mean_image` (or a similar smoothing filter), which is faster.

Mathematical Background

The calculation of the filtered gray value I'_i at the position i is done according to the following formula:

$$I'_i = \overline{a_i} G_i + \overline{b_i}$$

where

$$a_i = \frac{\frac{1}{|\omega_i|} \sum_{k \in \omega_i} G_k I_k - \overline{G_i} \overline{I_i}}{\sigma^2_{G_i} + Amplitude^2}$$

and

$$b_i = \overline{I_i} - a_i \overline{G_i}$$

where I_i and G_i are the gray values of `Image` and `ImageGuide` at the pixel position i, ω_i is the neighborhood with radius `Radius` around the pixel i, $\overline{a_i}$, $\overline{b_i}$, $\overline{I_i}$, and $\overline{G_i}$ are the mean of all a, b, I, or G in ω_i, σ_{G_i} is the standard deviation of all gray values of G in ω_i, and $|\omega_i|$ is the number of pixels in ω_i.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **ImageGuide** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Guidance image.
- ▷ **ImageGuided** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **Radius** (input_control) ..... integer ⇝ *integer*
  Radius of the filtering operation.
  Default: 3
  Suggested values: `Radius` ∈ {1, 2, 3, 5, 10}
  Restriction: Radius > 0
- ▷ **Amplitude** (input_control) ..... real ⇝ *real*
  Controls the influence of edges on the smoothing.
  Default: 20.0
  Suggested values: `Amplitude` ∈ {3.0, 10.0, 20.0, 50.0, 100.0}
  Restriction: Amplitude > 0

Example

```
read_image (Image, 'mreut')
* Edge-preserving smoothing
guided_filter (Image, Image, ImageGuided, 5, 20)
```

```
* Rolling filter (5 iterations)
gen_image_proto (Image, ImageGuide, 0)
for I := 1 to 5 by 1
  guided_filter (Image, ImageGuide, ImageGuide, 5, 20)
endfor
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Predecessors

info_smooth (: : Filter, Alpha : Size, Coeffs)

Information on smoothing filter `smooth_image`.

The operator `info_smooth` returns an estimation of the width of the smoothing filters used in routine `smooth_image`. For this purpose the underlying continuous impulse answers of `Filter` are scanned until a filter coefficient is smaller than five percent of the maximum coefficient (at the origin). `Alpha` is the filter parameter (see `smooth_image`). Currently four filters are supported (parameter `Filter`):

'deriche1', 'deriche2', 'shen' and 'gauss'.

The gauss filter was conventionally implemented with filter masks (the other three are recursive filters). In the case of the gauss filter the filter coefficients (of the one-dimensional impulse answer $f(n)$ with $n \geq 0$) are returned in `Coeffs` in addition to the filter size.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Filter** (input_control) . . . . . string ⇝ *string*
Name of required filter.
Default: 'deriche2'
List of values: `Filter` ∈ {'deriche1', 'deriche2', 'shen', 'gauss'}

▷ **Alpha** (input_control) . . . . . real ⇝ *real*
Filter parameter: small values effect strong smoothing (reversed in case of 'gauss').
Default: 0.5
Suggested values: `Alpha` ∈ {0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 4.0, 5.0, 7.0, 10.0}
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Alpha > 0.0

▷ **Size** (output_control) . . . . . integer ⇝ *integer*
Width of filter is approx. size x size pixels.

▷ **Coeffs** (output_control) . . . . . integer-array ⇝ *integer*
In case of gauss filter: coefficients of the "positive" half of the 1D impulse answer.

Example

```
info_smooth('deriche2',0.5,Size,Coeffs)
smooth_image(Input,Smooth,'deriche2',7)
```

Result

If the parameter values are correct the operator `info_smooth` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`smooth_image`

Module

Foundation

isotropic_diffusion (Image : SmoothedImage : Sigma, Iterations :)

Perform an isotropic diffusion of an image.

The operator `isotropic_diffusion` performs an isotropic diffusion of the input image `Image`. This corresponds to a convolution of the image matrix with a Gaussian mask of standard deviation `Sigma`. If the parameter `Iterations` is set to *0*, such a convolution is performed explicitly. For input images with a full ROI, `isotropic_diffusion` returns the same results as the operator `derivate_gauss` when choosing *'none'* for its parameter `Component`. If the gray value matrix is larger than the ROI of `Image` the two operators differ since `derivate_gauss` takes the gray values outside of the ROI into account, while `isotropic_diffusion` mirrors the values at the boundary of the ROI in any case. The computational complexity increases linearly with the value of `Sigma`.

If `Iterations` has a positive value the smoothing process is considered as an application of the heat equation

$$u_t = \Delta u$$

on the gray value function u with the initial value $u = u_0$ defined by the gray values of `Image` at a time t_0. This equation is then solved up to a time $t_0 + \frac{1}{2}\texttt{Sigma}^2$, which is equivalent to the above convolution, using an iterative procedure for parabolic partial differential equations. The computational complexity is proportional to the value of `Iterations` and independent of `Sigma` in this case. For small values of `Iterations`, the computational accuracy is very low, however. For this reason, choosing `Iterations` < 3 is not recommended.

For smaller values of `Sigma`, the convolution implementation is typically the faster method. Since the runtime of the partial differential equation solver only depends on the number of iterations and not on the value of `Sigma`, it is typically faster for large values of `Sigma` if few iterations are chosen (e.g., `Iterations` $= 3$).

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **SmoothedImage** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
Output image.

▷ **Sigma** (input_control) ..... real ⇝ *real*
Standard deviation of the Gauss distribution.
Default: 1.0
Suggested values: Sigma ∈ {0.1, 0.5, 1.0, 3.0, 10.0, 20.0, 50.0}
Restriction: Sigma > 0

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 10
Suggested values: Iterations ∈ {0, 3, 10, 100, 500}
Restriction: Iterations >= 0

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

Module

Foundation

mean_image (Image : ImageMean : MaskWidth, MaskHeight :)

Smooth by averaging.

The operator mean_image carries out a linear smoothing with the gray values of all input images (Image). The filter matrix consists of ones (evaluated equally) and has the size MaskHeight × MaskWidth. The result of the convolution is divided by MaskHeight × MaskWidth. For border treatment the gray values are reflected at the image edges.

For mean_image special optimizations are implemented that use SIMD technology. The actual application of these special optimizations is controlled by the system parameter *'mmx_enable'* (see set_system). If *'mmx_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations are performed using SIMD technology. Note that SIMD technology performs best on large, compact input regions. Depending on the input region and the capabilities of the hardware the execution of mean_image might even take significantly more time with SIMD technology than without.

At any rate, it is advantageous for the performance of mean_image to choose the input region of Image such that any border treatment is avoided.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

If even values instead of odd values are given for MaskHeight or MaskWidth, the routine uses the next larger odd values instead (this way the center of the filter mask is always explicitly determined).

The mean filter value on real images is calculated internally using single precision floating point. This can lead to overflows (and thus incorrect results) if the full dynamic range is used.

mean_image can be executed on OpenCL devices for byte, int2, uint2, int4 and real images if MaskHeight is less than twice the height of Image. For OpenCL, the mean filter value is calculated internally using either 32 bit signed integers (for all integer image types) or single precision floating point (for real images). This can

lead to overflows (and thus incorrect results) if Image is either an int4 or real image and the full dynamic range is used. Additionally, to improve performance a full scan of each row of Image is calculated (again using either 32 bit integer or single precision floating point arithmetic) if MaskWidth is bigger than 9. This can also lead to overflows with very wide images even for byte, int2, or uint2 images. In these cases, the CPU version of mean_image should be used.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / int8 / real / vector_field

Image to be smoothed.

▷ **ImageMean** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / int8 / real / vector_field

Smoothed image.

▷ **MaskWidth** (input_control) ..... extent.x ⇝ *integer*

Width of filter mask.
Default: 9
Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 15, 23, 31, 43, 61, 101}
Value range: 1 ≤ MaskWidth
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskWidth) && MaskWidth < width(Image) * 2

▷ **MaskHeight** (input_control) ..... extent.y ⇝ *integer*

Height of filter mask.
Default: 9
Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 15, 23, 31, 43, 61, 101}
Value range: 1 ≤ MaskHeight
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskHeight) && MaskHeight < height(Image) * 2

Example

```
read_image(Image,'fabrik')
mean_image(Image,Mean,3,3)
dev_display(Mean)
```

Complexity

For each pixel: O(15).

Result

If the parameter values are correct the operator mean_image returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

mean_image_shape (Image, Mask : ImageMean : :)

Smooth image using a mean filter with arbitrary mask.

mean_image_shape performs a mean filter operation on the input image Image with a mask that is specified by the region Mask and returns the filtered image in ImageMean. The shape of the mask can be chosen arbitrarily and can, for example, be created with operators like gen_circle or draw_region. The position of the mask does not influence the result since the center of gravity of the mask region is used as the reference point of the mask. For border treatment the gray values are reflected at the image edges.

For mean_image_shape special optimizations are implemented that use SIMD technology. The actual application of these special optimizations is controlled by the system parameter *'avx2_enable'* (see set_system). If *'avx2_enable'* is set to *'true'* (and the SIMD instruction set is available), the internal calculations are performed using SIMD technology. Furthermore, these optimizations are only used for byte images and if the area of the filter mask provided by Mask is smaller than 129.

Note that mean_image_shape performs best on compact input regions.

At any rate, it is advantageous for the performance of mean_image_shape to choose the input region of Image such that any border treatment is avoided.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Image to be filtered.
- ▷ **Mask** (input_object) ..... region ⇝ *object*
  Filter mask.
- ▷ **ImageMean** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Filtered image.

Example

```
read_image (Image, 'fabrik')
gen_circle (Circle, 10, 10, 2)
mean_image_shape (Image, Circle, ImageMean)
dev_display (ImageMean)
```

Result

If the parameter values are correct the operator mean_image_shape returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

- Automatically parallelized on internal data level.

mean_n (Image : ImageMean : :)

Average gray values over several channels.

The operator mean_n generates the pixel-by-pixel mean value of all channels . For each coordinate point the sum of all gray values at this coordinate is calculated. The result is the mean of the gray values (sum divided by the number of channels). The output image has one channel.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Multichannel gray image.

▷ **ImageMean** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Result of averaging.

Example

```
compose3(Channel1,Channel2,Channel3,&MultiChannel);
mean_n(MultiChannel,&Mean);
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

mean_sp (Image : ImageSPMean : MaskWidth, MaskHeight, MinThresh, MaxThresh :)

Suppress salt and pepper noise.

The operator mean_sp carries out a smoothing by averaging the values. Only the gray values within the interval from MinThresh to MaxThresh are averaged. Gray values which are too light or too dark are ignored during summation. If no gray value lies within the default interval during summation the original gray value is adopted. If the thresholds are set at *0* or *255*, respectively, the operator mean_sp behaves like mean_image except for the running time.

The operator mean_sp is used to suppress extreme gray values (salt and pepper noise = white and black dots).

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

If even values instead of odd values are given for MaskHeight or MaskWidth, the routine uses the next larger odd values instead (this way the center of the filter mask is always explicitly determined).

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
  Input image.
- ▷ **ImageSPMean** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
  Smoothed image.
- ▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *integer*
  Width of filter mask.
  Default: 3
  Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11}
  (lin)
  Minimum increment: 2
  Recommended increment: 2
  Restriction: odd(MaskWidth) && MaskWidth < width(Image) * 2
- ▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
  Height of filter mask.
  Default: 3
  Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11}
  (lin)
  Minimum increment: 2
  Recommended increment: 2
  Restriction: odd(MaskHeight) && MaskHeight < height(Image) * 2
- ▷ **MinThresh** (input_control) . . . . . integer ⇝ *integer*
  Minimum gray value.
  Default: 1
  Suggested values: MinThresh ∈ {1, 5, 7, 9, 11, 15, 23, 31, 43, 61, 101}
  Value range: 0 ≤ MinThresh
- ▷ **MaxThresh** (input_control) . . . . . integer ⇝ *integer*
  Maximum gray value.
  Default: 254
  Suggested values: MaxThresh ∈ {5, 7, 9, 11, 15, 23, 31, 43, 61, 101, 200, 230, 250, 254}
  Restriction: MinThresh <= MaxThresh

Example

```
read_image(Image,'mreut')
dev_display(Image)
mean_sp(Image,ImageMeansp,3,3,101,201)
dev_display(ImageMeansp)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

median_image (Image : ImageMedian : MaskType, Radius, Margin :)

Compute a median filter with various masks.

median_image performs a median filter on the input image Image with a square or circular mask and returns the filtered image in ImageMedian. The shape of the mask can be selected with MaskType. The radius of the mask can be selected with Radius.

Conceptually, the median filter sorts all gray values within the mask in ascending order and then selects the median of the gray values. The median is the "middle" one of the sorted gray values, i.e., the gray value with rank (position) $(N-1)/2+1$ of the sorted gray values, where N denotes the number of pixels covered by the filter mask. Here, the rank 1 corresponds to the smallest gray value and the rank N corresponds to the largest gray value within the mask (see also rank_image).

The filter mask is determined by Radius, defining the size, and MaskType, defining the shape of the mask. For latter one, the following options are available:

'circle' The mask consists of the pixel within a circle with Radius around the pixel of the mask center.

'square' The mask consists of the pixel within a square with an edge length of $2 \cdot$Radius $+1$ pixel.

median_image can be used, for example, to smooth images, to suppress unwanted objects (e.g., point-like or line-like structures) that are smaller than the mask, and can therefore be used to estimate the background illumination for a shading correction or as a preprocessing step for the dynamic threshold operation (see dyn_threshold).

Several border treatments can be chosen for filtering via the parameter Margin:

gray value Pixels outside of the image border are assumed to be constant (with the indicated gray value).

'continued' Continuation of the gray values at the image border.

'cyclic' Cyclic continuation at the image borders.

'mirrored' Reflection of pixels at the image borders.

When using the MaskType *'square'* with Radius 1 or 2 (resulting in a 3x3 or 5x5 pixel filter mask) and the border treatment 'mirrored', median_image can be executed on OpenCL devices.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

median_image uses an algorithm with a runtime per pixel that depends on the mask height $2 \cdot$ Radius $+1$. Therefore, median_image is slower than median_rect for square masks with a large mask height. The precise mask height for which median_rect will become faster than median_image depends on the computer architecture (processor type, availability of SIMD instructions like SSE2 or MMX, cache size and throughput,

memory throughput). Typically, this is the case for mask heights > 15, but can also be the case only for larger mask sizes, e.g., if SIMD instructions are unavailable and memory throughput is low.

Furthermore, it should be noted that median_rect uses a recursive implementation, which internally computes the filter response on the smallest enclosing rectangle of the domain of the input image. Therefore, if the domain of the input image only covers a small fraction of the smallest enclosing rectangle, it can happen that median_image is faster than median_rect even for larger mask heights.

Due to performance reasons, the input Image is not checked whether it contains NaNs. Using an input image with NaNs crashes HALCON.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Image to be filtered.

▷ **ImageMedian** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Filtered image.

▷ **MaskType** (input_control) . . . . . string ⇝ *string*
Filter mask type.
Default: 'circle'
List of values: MaskType ∈ {'circle', 'square'}

▷ **Radius** (input_control) . . . . . integer ⇝ *integer*
Radius of the filter mask.
Default: 1
Suggested values: Radius ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 11, 15, 19, 25, 31, 39, 47, 59}
Value range: $1 \leq$ Radius ≤ 4095
Minimum increment: 1
Recommended increment: 2

▷ **Margin** (input_control) . . . . . string ⇝ *string* / integer / real
Border treatment.
Default: 'mirrored'
Suggested values: Margin ∈ {'mirrored', 'cyclic', 'continued', 0, 30, 60, 90, 120, 150, 180, 210, 240, 255}

Example

```
read_image (Image, 'fabrik')
median_image (Image, Median, 'circle', 3, 'continued')
dev_display(Median)
```

Complexity

For each pixel: $O(2 \cdot \text{Radius} + 1)$.

Result

If the parameter values are correct the operator median_image returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

median_rect (Image : ImageMedian : MaskWidth, MaskHeight :)

Compute a median filter with rectangular masks.

median_rect performs a median filter on the input image Image with a rectangular mask of size MaskWidth × MaskHeight and returns the filtered image in ImageMedian.

Conceptually, the median filter sorts all gray values within the mask in ascending order and then selects the median of the gray values. The median is the "middle" one of the sorted gray values, i.e., the gray value with rank (position) $(\text{MaskWidth} \cdot \text{MaskHeight} - 1)/2 + 1$ of the sorted gray values, where the rank 1 corresponds to the smallest gray value and the rank $\text{MaskWidth} \cdot \text{MaskHeight}$ corresponds to the largest gray value within the mask (see also rank_rect).

median_rect can be used, for example, to smooth images, to suppress unwanted objects (e.g., point-like or line-like structures) that are smaller than the mask, and can therefore be used to estimate the background illumination for a shading correction or as a preprocessing step for the dynamic threshold operation (see dyn_threshold).

When using a 3x3 or 5x5 filter mask, median_rect can be executed on OpenCL devices.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

If even values instead of odd values are passed in MaskHeight or MaskWidth, median_rect uses the next larger odd values instead.

median_rect uses an algorithm with constant runtime per pixel, i.e., the runtime only depends on the size of the input image and not on the mask size. Therefore, for large mask sizes median_rect is the fastest implementation of the median filter in HALCON. Depending on the computer architecture (processor type, availability of SIMD instructions like SSE2 or MMX, cache size and throughput, memory throughput), for small mask sizes the implementation used in median_image and rank_image is faster than median_rect. Typically, this is the case for MaskHeight ≤ 15, but can also happen for larger mask sizes, e.g., if SIMD instructions are unavailable and memory throughput is low.

Furthermore, it should be noted that median_rect uses a recursive implementation, which internally computes the filter response on the smallest enclosing rectangle of the domain of the input image. Therefore, if the domain of the input image only covers a small fraction of the smallest enclosing rectangle, it can happen that median_image and rank_image are faster than median_rect even for larger values of MaskHeight.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
  Image to be filtered.
- ▷ **ImageMedian** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
  Filtered image.

▷ **MaskWidth** (input_control) . . . . . integer ⇝ *integer*
Width of the filter mask.
Default: 15
Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 31, 49, 51, 61, 71, 81, 91, 101}
Value range: 3 ≤ MaskWidth ≤ 4095
Minimum increment: 2
Recommended increment: 2

▷ **MaskHeight** (input_control) . . . . . integer ⇝ *integer*
Height of the filter mask.
Default: 15
Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 31, 49, 51, 61, 71, 81, 91, 101}
Value range: 3 ≤ MaskHeight ≤ 4095
Minimum increment: 2
Recommended increment: 2

Complexity

For each pixel: $O(1)$.

Result

If the parameter values are correct the operator median_rect returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

median_separate (Image : ImageSMedian : MaskWidth, MaskHeight, Margin :)

Separated median filtering with rectangle masks.

The operator median_separate carries out a variation of the median filtering: First two auxiliary images are created. The first one originates from a median filtering with a horizontal mask having a height of one pixel and the

width MaskWidth followed by filtering with a vertical mask having the height MaskHeight and width of one pixel. The second auxiliary image is created by filtering with the same masks, but with a reversed sequence of the operation: first the vertical, then the horizontal mask. The output image results from averaging the two auxiliary images pixel by pixel.

The operator median_separate is clearly faster than the normal operator median_image because both masks are one pixel wide, facilitating a very efficient processing. The runtime is practically *independent* of the size of the mask. For example, the operator median_separate can be well used after texture filters, where large masks are needed.

The filter can also be used several times in a row in order to enhance the smoothing.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Due to performance reasons, the input Image is not checked whether it contains NaNs. Using an input image with NaNs crashes HALCON.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
  Image to be filtered.
- ▷ **ImageSMedian** (output_object) . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
  Median filtered image.
- ▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *integer*
  Width of rank mask.
  Default: 25
  Suggested values: MaskWidth ∈ {1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 27, 43, 51, 67, 91, 121, 151}
  Value range: 1 ≤ MaskWidth ≤ 401
  Minimum increment: 2
  Recommended increment: 2
- ▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
  Height of rank mask.
  Default: 25
  Suggested values: MaskHeight ∈ {1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 27, 43, 51, 67, 91, 121, 151}
  Value range: 1 ≤ MaskHeight ≤ 401
  Minimum increment: 2
  Recommended increment: 2
- ▷ **Margin** (input_control) . . . . . string ⇝ *string* / integer / real
  Border treatment.
  Default: 'mirrored'
  Suggested values: Margin ∈ {'mirrored', 'cyclic', 'continued', 0, 30, 60, 90, 120, 150, 180, 210, 240, 255}

Example

```
read_image(Image,'fabrik')
median_separate(Image,MedianSeparate,5,5,3)
dev_display(MedianSeparate)
```

Complexity

For each pixel: O(40).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

median_weighted (Image : ImageWMedian : MaskType, MaskSize :)

Weighted median filtering with different rank masks.

The operator median_weighted calculates the median of the gray values within a local environment. In contrast to median_image, which uses all gray values within the environment exactly once, the operator median_weighted weights all gray values several times depending on their position. A gray value is received into the field to be sorted several times according to its weighting. The following masks are available:

’gauss’ (MaskSize = 3)

$$\begin{matrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{matrix}$$

’inner’ (MaskSize = 3)

$$\begin{matrix} 1 & 1 & 1 \\ 1 & 3 & 1 \\ 1 & 1 & 1 \end{matrix}$$

The operator median_weighted means that, contrary to median_image, gray value corners remain.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Image to be filtered.
- ▷ **ImageWMedian** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Median filtered image.
- ▷ **MaskType** (input_control) . . . . . string ⇝ *string*
  Type of median mask.
  Default: ’inner’
  List of values: MaskType ∈ {’inner’, ’gauss’}
- ▷ **MaskSize** (input_control) . . . . . integer ⇝ *integer*
  mask size.
  Default: 3
  List of values: MaskSize ∈ {3}

Example

```
read_image(Image,'fabrik')
median_weighted(Image,MedianWeighted,'gauss',3)
dev_display(MedianWeighted)
```

Complexity

For each pixel: $O(F * log(F))$ with F = area of `MaskType`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

midrange_image (Image, Mask : ImageMidrange : Margin :)

Calculate the average of maximum and minimum inside any mask.

The operator `midrange_image` forms the average of maximum and minimum inside the indicated mask in the whole image. Several border treatments (`Margin`) can be chosen for filtering:

gray value Pixels outside of the image border are assumed to be constant (with the indicated gray value).

'continued' Continuation of the gray values at the image border.

'cyclic' Cyclic continuation at the image borders.

'mirrored' Reflection of pixels at the image borders.

The indicated mask (= region of the mask image) is put over the image to be filtered in such a way that the center of the mask touches all pixels once.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Image to be filtered.

▷ **Mask** (input_object) . . . . . region ⇝ *object*
Filter mask.

▷ **ImageMidrange** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Filtered image.

▷ **Margin** (input_control) ..... string ⇝ *string* / integer / real
Border treatment.
Default: 'mirrored'
Suggested values: Margin ∈ {'mirrored', 'cyclic', 'continued', 0, 30, 60, 90, 120, 150, 180, 210, 240, 255}

Example

```
read_image(Image,'fabrik')
draw_region(Region,WindowHandle)
midrange_image(Image,Region,Midrange,'mirrored')
dev_display(Midrange)
```

Complexity

For each pixel: $O(sqrt(F) * 5)$ with F = area of Mask.

Result

If the parameter values are correct the operator midrange_image returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

rank_image (Image, Mask : ImageRank : Rank, Margin :)

Compute a rank filter with arbitrary masks.

rank_image performs a rank filter on the input image Image with a mask that is specified by the region Mask and returns the filtered image in ImageRank. The shape of the mask can be chosen arbitrarily and can, for example, be created with operators like gen_circle or draw_region. The position of the mask does not influence the result since the center of gravity of the mask region is used as the reference point of the mask.

Conceptually, the rank filter sorts all gray values within the mask in ascending order and then selects the gray value with rank Rank. The rank 1 corresponds to the smallest gray value and the rank A corresponds to the largest gray value within the mask. Here, A denotes the area of Mask (see area_center). For Rank $= (A-1)/2+1$,

rank_image returns the median gray value (see median_image). For Rank = 1, rank_image performs a gray value erosion (see gray_erosion_rect, gray_erosion_shape, and gray_erosion), while for Rank = A rank_image performs a gray value dilation (see gray_dilation_rect, gray_dilation_shape, and gray_dilation).

rank_image can be used, for example, to suppress noise or to suppress unwanted objects that are smaller than the mask. Furthermore, rank_image is less sensitive to noise than the corresponding gray value morphology operators. Therefore, to obtain a more robust version of the gray value morphology, instead of using 1 or A, slightly larger or smaller values should be selected for Rank.

Several border treatments can be chosen for filtering via the parameter Margin:

gray value Pixels outside of the image border are assumed to be constant (with the indicated gray value).

'continued' Continuation of the gray values at the image border.

'cyclic' Cyclic continuation at the image borders.

'mirrored' Reflection of pixels at the image borders.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

rank_image uses an algorithm with a runtime per pixel that depends on the number of runs in the mask Mask. Therefore, rank_image is slower than rank_rect for rectangular masks with a large mask height. The precise mask height for which rank_rect will become faster than rank_image depends on the computer architecture (processor type, availability of SIMD instructions like SSE2 or MMX, cache size and throughput, memory throughput). Typically, this is the case for mask heights > 15, but can also be the case only for larger mask sizes, e.g., if SIMD instructions are unavailable and memory throughput is low.

Furthermore, it should be noted that rank_rect uses a recursive implementation, which internally computes the filter response on the smallest enclosing rectangle of the domain of the input image. Therefore, if the domain of the input image only covers a small fraction of the smallest enclosing rectangle, it can happen that rank_image is faster than rank_rect even for larger mask heights.

rank_image should neither be used with Rank = 1 to perform a gray value erosion nor with Rank = A to perform a gray value dilation. In these cases, the operators gray_erosion_rect, gray_erosion_shape, or gray_erosion and gray_dilation_rect, gray_dilation_shape, or gray_dilation, respectively, are typically faster than rank_image.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Image to be filtered.

▷ **Mask** (input_object) . . . . . region ⇝ *object*
Filter mask.

▷ **ImageRank** (output_object) . . . . . multichannel-image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Filtered image.

▷ **Rank** (input_control) . . . . . integer ⇝ *integer*
Rank of the output gray value.
Default: 5
Suggested values: Rank ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 31, 49, 51, 61, 71, 81, 91, 101}
Value range: 1 ≤ Rank ≤ 4095
Minimum increment: 1
Recommended increment: 2

▷ **Margin** (input_control) . . . . . string ⇝ *string* / integer / real
Border treatment.
Default: 'mirrored'
Suggested values: Margin ∈ {'mirrored', 'cyclic', 'continued', 0, 30, 60, 90, 120, 150, 180, 210, 240, 255}

Example

```
read_image (Image, 'fabrik')
```

```
draw_region (Region, WindowHandle)
rank_image (Image, Region, ImageRank, 5, 'mirrored')
dev_display(ImageRank)
```

Complexity

For each pixel: $O(N)$, where N is the number of runs of Mask (see runlength_features).

Result

If the parameter values are correct the operator rank_image returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Predecessors

read_image, draw_region, gen_circle, gen_rectangle1, gen_rectangle2

Possible Successors

threshold, dyn_threshold, regiongrowing

Alternatives

rank_rect, median_image, median_rect

rank_n (Image : RankImage : RankIndex :)

Return gray values with given rank from multiple channels.

The operator rank_n returns pixel-by-pixel the result of the rank-function over all channels.

For every pixel in the input image the following is being done: The gray values of all channels at this position are sorted in ascending order. Then the pixel with index RankIndex is selected and placed in the output image at the same position. The output image has one channel.

In the special cases RankIndex = *1* and RankIndex = *'(Number of channels)'* the minimum and maximum are returned. RankIndex = *'(Number of channels + 1) / 2'* returns the median (here, / denotes integer division). Hence, for a five-channel image, *3* returns the median.

The operator rank_n should not be confused with the operator rank_image which computes the rank within a certain mask.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / int8 / real
Multichannel gray image.

▷ **RankImage** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / int2 / uint2 / int4 / int8 / real
Result of the rank function.

▷ **RankIndex** (input_control) . . . . . integer ⇝ *integer*
Rank of the gray value images to return.
Default: 2
Suggested values: RankIndex ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20}

Example

```
compose5 (Image1, Image2, Image3, Image4, Image5, MultiChannelImage)
rank_n (MultiChannelImage, ImageMin, 1)
rank_n (MultiChannelImage, ImageMax, 5)
rank_n (MultiChannelImage, ImageMedian, 3)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

rank_rect (Image : ImageRank : MaskWidth, MaskHeight, Rank :)

Compute a rank filter with rectangular masks.

rank_rect performs a rank filter on the input image Image with a rectangular mask of size MaskWidth × MaskHeight and returns the filtered image in ImageRank.

Conceptually, the rank filter sorts all gray values within the mask in ascending order and then selects the gray value with rank Rank. The rank 1 corresponds to the smallest gray value and the rank MaskWidth · MaskHeight corresponds to the largest gray value within the mask. For Rank = (MaskWidth · MaskHeight − 1)/2 + 1, rank_rect returns the median gray value (see median_rect). For Rank = 1, rank_rect performs a gray value erosion (see gray_erosion_rect, gray_erosion_shape, and gray_erosion), while for Rank = MaskWidth · MaskHeight rank_rect performs a gray value dilation (see gray_dilation_rect, gray_dilation_shape, and gray_dilation).

rank_rect can be used, for example, to suppress noise or to suppress unwanted objects that are smaller than the mask. Furthermore, rank_rect is less sensitive to noise than the corresponding gray value morphology operators. Therefore, to obtain a more robust version of the gray value morphology, instead of using 1 or MaskWidth · MaskHeight, slightly larger or smaller values should be selected for Rank.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

If even values instead of odd values are passed in MaskHeight or MaskWidth, rank_rect uses the next larger odd values instead.

rank_rect uses an algorithm with constant runtime per pixel, i.e., the runtime only depends on the size of the input image and not on the mask size. Therefore, for large mask sizes rank_rect is the fastest implementation of the rank filter in HALCON. Depending on the computer architecture (processor type, availability of SIMD instructions like SSE2 or MMX, cache size and throughput, memory throughput), for small mask sizes the implementation used in rank_image is faster than rank_rect. Typically, this is the case for MaskHeight ≤ 15, but can also happen for larger mask sizes, e.g., if SIMD instructions are unavailable and memory throughput is low.

Furthermore, it should be noted that rank_rect uses a recursive implementation, which internally computes the filter response on the smallest enclosing rectangle of the domain of the input image. Therefore, if the domain of the input image only covers a small fraction of the smallest enclosing rectangle, it can happen that rank_image is faster than rank_rect even for larger values of MaskHeight.

rank_rect should neither be used with Rank $= 1$ to perform a gray value erosion nor with Rank $=$ MaskWidth $\cdot$ MaskHeight to perform a gray value dilation. In these cases, the operators gray_erosion_rect or gray_erosion_shape and gray_dilation_rect or gray_dilation_shape, respectively, are faster than rank_rect for almost all mask sizes.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Image to be filtered.

▷ **ImageRank** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Filtered image.

▷ **MaskWidth** (input_control) ..... integer ⇝ *integer*
Width of the filter mask.
Default: 15
Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 31, 49, 51, 61, 71, 81, 91, 101}
Value range: 3 ≤ MaskWidth ≤ 4095
Minimum increment: 2
Recommended increment: 2

▷ **MaskHeight** (input_control) ..... integer ⇝ *integer*
Height of the filter mask.
Default: 15
Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 31, 49, 51, 61, 71, 81, 91, 101}
Value range: 3 ≤ MaskHeight ≤ 4095
Minimum increment: 2
Recommended increment: 2

▷ **Rank** (input_control) ..... integer ⇝ *integer*
Rank of the output gray value.
Default: 5
Suggested values: Rank ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 31, 49, 51, 61, 71, 81, 91, 101}
Minimum increment: 1
Recommended increment: 2
Restriction: 1 <= Rank && Rank <= MaskWidth * MaskHeight

Complexity

For each pixel: $O(1)$.

Result

If the parameter values are correct the operator rank_rect returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

sigma_image (Image : ImageSigma : MaskHeight, MaskWidth, Sigma :)

Non-linear smoothing with the sigma filter.

The operator sigma_image carries out a non-linear smoothing of the gray values of all input images (Image). All pixels in a rectangular window (MaskHeight × MaskWidth) are used to determine the new gray value of the central pixel of this window. First, the gray value standard deviation of all pixels in the window is calculated. Then, all pixels of the window with a gray value that differs from the gray value of the central pixel by less than Sigma times this standard deviation are used to calculate the new gray value of the central pixel. The gray value of the central pixel is the average of the gray values of the selected pixels. If no pixel could be selected for the averaging of the gray values, the gray value of the central pixel remains unchanged.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

If even values instead of odd values are given for MaskHeight or MaskWidth, the routine uses the next larger odd values instead (this way the center of the filter mask is always explicitly determined).

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / cyclic / int1 / int2 / uint2 / int4 / real

Image to be smoothed.

▷ **ImageSigma** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / cyclic / int1 / int2 / uint2 / int4 / real

Smoothed image.

▷ **MaskHeight** (input_control) ..... extent.y ⇝ *integer*

Height of the mask (number of lines).
Default: 5
Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15}
Value range: 3 ≤ MaskHeight
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskHeight)

▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *integer*
Width of the mask (number of columns).
Default: 5
Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15}
Value range: 3 ≤ MaskWidth
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskWidth)

▷ **Sigma** (input_control) . . . . . integer ⇝ *integer*
Max. deviation to the average.
Default: 3
Suggested values: Sigma ∈ {3, 5, 7, 9, 11, 20, 30, 50}
Value range: 0 ≤ Sigma
Minimum increment: 1
Recommended increment: 2

Example

```
read_image(Image,'fabrik')
sigma_image(Image,ImageSigma,5,5,3)
dev_display(ImageSigma)
```

Complexity

For each pixel: O(MaskHeight × MaskWidth).

Result

If the parameter values are correct the operator sigma_image returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

smooth_image (Image : ImageSmooth : Filter, Alpha :)

Smooth an image using various filters.

smooth_image smooths gray images using recursive filters originally developed by Deriche and Shen and using the non-recursive Gaussian filter. The following filters can be chosen via the parameter Filter:

'deriche1', 'deriche2', 'shen' and 'gauss'.

The "filter width" (i.e., the range of the filter and thereby result of the filter) can be of any size. In the case that the Deriche or Shen is chosen it decreases by increasing the filter parameter `Alpha` and increases in the case of the Gauss filter (and `Alpha` corresponds to the standard deviation of the Gaussian function). An approximation of the appropriate size of the filter width `Alpha` is performed by the operator `info_smooth`.

Non-recursive filters like the Gaussian filter are often implemented using filter-masks. In this case the runtime of the operator increases with increasing size of the filter mask. The runtime of the recursive filters remains constant; except the border treatment becomes a little bit more time consuming. The Gaussian filter becomes slow in comparison to the recursive ones but is in contrast to them isotropic (the filter 'deriche2' is only weakly direction sensitive). A comparable result of the smoothing is achieved by choosing the following values for the parameter:

$$\begin{aligned} \texttt{Alpha}('deriche2') &= \frac{\texttt{Alpha}('deriche1')}{2} \\ \texttt{Alpha}('shen') &= \frac{\texttt{Alpha}('deriche1')}{2} \\ \texttt{Alpha}('gauss') &= \frac{1.77}{\texttt{Alpha}('deriche1')} \end{aligned}$$

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Image to be smoothed.

▷ **`ImageSmooth`** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Smoothed image.

▷ **`Filter`** (input_control) ..... string ⇝ *string*
Filter.
Default: 'deriche2'
List of values: `Filter` ∈ {'deriche1', 'deriche2', 'shen', 'gauss'}

▷ **`Alpha`** (input_control) ..... real ⇝ *real*
Filter parameter: small values cause strong smoothing (vice versa by using *'gauss'*).
Default: 0.5
Suggested values: `Alpha` ∈ {0.1, 0.2, 0.3, 0.5, 1.0, 1.5, 2.0, 2.5, 3.0, 4.0, 5.0, 7.0, 10.0}
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Alpha > 0

Example

```
info_smooth('deriche2',0.5,Size,Coeffs)
smooth_image(Input,Smooth,'deriche2',7)
```

Result

If the parameter values are correct the operator `smooth_image` returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no input images available) is set via the operator `set_system ('no_object_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

trimmed_mean (Image, Mask : ImageTMean : Number, Margin :)

Smooth an image with an arbitrary rank mask.

The operator trimmed_mean carries out a non-linear smoothing of the gray values of all input images (Image). The filter mask (Mask) is passed in the form of a region. The average of Number gray values located near the median is calculated. Several border treatments can be chosen for filtering (Margin):

gray value Pixels outside of the image border are assumed to be constant (with the indicated gray value).

'continued' Continuation of the gray values at the image border.

'cyclic' Cyclic continuation at the image borders.

'mirrored' Reflection of pixels at the image borders.

The indicated mask (= region of the mask image) is put over the image to be filtered in such a way that the center of the mask touches all pixels once. For each of these pixels all neighboring pixels covered by the mask are sorted in an ascending sequence according to their gray values. Thus, each of these sorted gray value sequences contains exactly as many gray values as the mask has pixels. If F is the area of the mask the average of these sequences is calculated as follows: The first (F - Number)/2 gray values are ignored. Then the following Number gray values are summed up and divided by Number. Again the remaining (F - Number)/2 gray values are ignored.

For an explanation of the concept of smoothing filters see the introduction of chapter Filters / Smoothing.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Image to be filtered.

▷ **Mask** (input_object) . . . . . region ⇝ *object*
Image whose region serves as filter mask.

▷ **ImageTMean** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
Filtered output image.

▷ **Number** (input_control) . . . . . integer ⇝ *integer*
Number of averaged pixels. Typical value: Surface(Mask) / 2.
Default: 5
Suggested values: Number ∈ {1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31}
Value range: 1 ≤ Number ≤ 401
Minimum increment: 1
Recommended increment: 2

▷ **Margin** (input_control) . . . . . string ⇝ *string* / integer / real
Border treatment.
Default: 'mirrored'
Suggested values: Margin ∈ {'mirrored', 'cyclic', 'continued', 0, 30, 60, 90, 120, 150, 180, 210, 240, 255}

Example

```
read_image(Image,'fabrik')
draw_region(Region,WindowHandle)
trimmed_mean(Image,Region,TrimmedMean,5,'mirrored')
dev_display(TrimmedMean)
```

Result

If the parameter values are correct the operator trimmed_mean returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no input images available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

12.17 Texture Inspection

deviation_image (Image : ImageDeviation : Width, Height :)

Calculate the standard deviation of gray values within rectangular windows.

deviation_image calculates the standard deviation of gray values in the image Image within a rectangular mask of size (Height, Width). The resulting image is returned in ImageDeviation. To better use the range of gray values available in the output image, the result is multiplied by 2. If the parameters Height and Width are even, they are changed to the next larger odd value. At the image borders the gray values are mirrored.

Attention

deviation_image can be executed on OpenCL devices. As the same OpenCL code is used, the same limitations as for mean_image apply. Since deviation_image uses single precision floating point arithmetic internally, the results may differ slightly from the CPU version.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int4 / real / int2 / uint2
Image for which the standard deviation is to be calculated.

▷ **ImageDeviation** (output_object) . . . . . image(-array) ⇝ *object :* byte / int4 / real / int2 / uint2
Image containing the standard deviation.

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the mask in which the standard deviation is calculated.
Default: 11
Suggested values: `Width` ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25}
Restriction: 3 <= Width && odd(Width) && Width < width(Image) * 2

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the mask in which the standard deviation is calculated.
Default: 11
Suggested values: `Height` ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25}
Restriction: 3 <= Height && odd(Height) && Height < height(Image) * 2

Example

```
read_image(Image,'fabrik')
dev_display(Image)
deviation_image(Image,Deviation,9,9)
dev_display(Image)
```

Result

`deviation_image` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

`disp_image`

Alternatives

`entropy_image`, `entropy_gray`

Module

Foundation

entropy_image (Image : ImageEntropy : Width, Height :)

Calculate the entropy of gray values within a rectangular window.

`entropy_image` calculates the entropy of gray values in the image `Image` within a rectangular mask of size (`Height`, `Width`). The resulting image is returned in `ImageEntropy`, in which the entropy is multiplied by 32. If the parameters `Height` and `Width` are even, they are changed to the next larger odd value. At the image borders the gray values are mirrored.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Image for which the entropy is to be calculated.

▷ **ImageEntropy** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Entropy image.

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the mask in which the entropy is calculated.
Default: 9
Suggested values: Width ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25}
Restriction: 3 <= Width && odd(Width)

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the mask in which the entropy is calculated.
Default: 9
Suggested values: Height ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25}
Restriction: 3 <= Height && odd(Height)

Example

```
read_image(Image,'fabrik')
dev_display(Image)
entropy_image(Image,Entropy,9,9)
dev_display(Entropy)
```

Result

entropy_image returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

texture_laws (Image : ImageTexture : FilterTypes, Shift, FilterSize :)

Filter an image using a Laws texture filter.

texture_laws applies a texture transformation (according to Laws) to an image. This is done by convolving the input image with a special filter mask. The filters are:

9 different 3×3 matrices obtainable from the following three vectors:

$$\begin{array}{lll} \mathrm{l} & = & [\ 1 \quad 2 \quad 1] \\ \mathrm{e} & = & [-1 \quad 0 \quad 1] \\ \mathrm{s} & = & [-1 \quad 2 \quad -1] \end{array}$$

25 different 5×5 matrices obtainable from the following five vectors:

$$\begin{array}{lll} \mathrm{l} & = & [\ 1 \quad 4 \quad 6 \quad 4 \quad 1] \\ \mathrm{e} & = & [-1 \quad -2 \quad 0 \quad 2 \quad 1] \\ \mathrm{s} & = & [-1 \quad 0 \quad 2 \quad 0 \quad -1] \\ \mathrm{w} & = & [-1 \quad 2 \quad 0 \quad -2 \quad 1] \\ \mathrm{r} & = & [\ 1 \quad -4 \quad 6 \quad -4 \quad 1] \end{array}$$

49 different 7×7 matrices obtainable from the following seven vectors:

$$\begin{array}{lll} \mathrm{l} & = & [\ 1 \quad 6 \quad 15 \quad 20 \quad 15 \quad 6 \quad 1] \\ \mathrm{e} & = & [-1 \quad -4 \quad -5 \quad 0 \quad 5 \quad 4 \quad 1] \\ \mathrm{s} & = & [-1 \quad -2 \quad 1 \quad 4 \quad 1 \quad -2 \quad -1] \\ \mathrm{w} & = & [-1 \quad 0 \quad 3 \quad 0 \quad -3 \quad 0 \quad 1] \\ \mathrm{r} & = & [\ 1 \quad -2 \quad -1 \quad 4 \quad -1 \quad -2 \quad -1] \\ \mathrm{u} & = & [\ 1 \quad -4 \quad 5 \quad 0 \quad -5 \quad 4 \quad -1] \\ \mathrm{o} & = & [-1 \quad 6 \quad -15 \quad 20 \quad -15 \quad 6 \quad -1] \end{array}$$

The names of the filters are mnemonics for “level,” “edge,” “spot,” “wave,” “ripple,” “undulation,” and “oscillation.”

For most of the filters the resulting gray values must be modified by a `Shift`. This makes the different textures in the output image more comparable to each other, provided suitable filters are used.

The name of the filter is composed of the letters of the two vectors used, where the first letter denotes convolution in the column direction while the second letter denotes convolution in the row direction.

Attention

`texture_laws` can be executed on OpenCL devices.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **`Image`** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Images to which the texture transformation is to be applied.
- ▷ **`ImageTexture`** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / int2 / uint2
  Texture images.
- ▷ **`FilterTypes`** (input_control) . . . . . string ⇝ *string*
  Desired filter.
  Default: ’el’
  Suggested values: `FilterTypes` ∈ {’ll’, ’le’, ’ls’, ’lw’, ’lr’, ’lu’, ’lo’, ’el’, ’ee’, ’es’, ’ew’, ’er’, ’eu’, ’eo’, ’sl’, ’se’, ’ss’, ’sw’, ’sr’, ’su’, ’so’, ’wl’, ’we’, ’ws’, ’ww’, ’wr’, ’wu’, ’wo’, ’rl’, ’re’, ’rs’, ’rw’, ’rr’, ’ru’, ’ro’, ’ul’, ’ue’, ’us’, ’uw’, ’ur’, ’uu’, ’uo’, ’ol’, ’oe’, ’os’, ’ow’, ’or’, ’ou’, ’oo’}
- ▷ **`Shift`** (input_control) . . . . . integer ⇝ *integer*
  Shift to reduce the gray value dynamics.
  Default: 2
  Suggested values: `Shift` ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9}
- ▷ **`FilterSize`** (input_control) . . . . . integer ⇝ *integer*
  Size of the filter kernel.
  Default: 5
  List of values: `FilterSize` ∈ {3, 5, 7}

Example

```
* Simple two-dimensional pixel classification
dev_get_window (WindowHandle)
read_image(Image,'combine')
texture_laws(Image,Texture1,'es',3,7)
texture_laws(Image,Texture2,'le',7,7)
MaskSize := 51
mean_image(Texture1,H1,MaskSize,MaskSize)
mean_image(Texture2,H2,MaskSize,MaskSize)
dev_clear_window ()
dev_display (Image)
dev_set_color ('green')
write_string (WindowHandle, 'Mark region within one texture area')
draw_region(Region,WindowHandle)
reduce_domain(H1,Region,Foreground1)
reduce_domain(H2,Region,Foreground2)
histo_2dim(Region,Foreground1,Foreground2,Histo)
get_image_size (Image, Width, Height)
threshold(Histo,Characteristic_area,1,Width*Height)
ShowIntermediateResult := 0
if (ShowIntermediateResult)
  histo_2dim(H1,H1,H2,HistoFull)
  dev_clear_window ()
  dev_set_lut ('sqrt')
  dev_display (HistoFull)
  dev_set_draw ('margin')
  dev_display (Characteristic_area)
  stop ()
  dev_set_lut ('default')
  dev_set_draw ('fill')
endif
class_2dim_sup(H1,H2,Characteristic_area,Seg)
dev_display (Image)
dev_set_color ('red')
dev_display (Seg)
```

Result

`texture_laws` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Possible Successors

`mean_image`, `binomial_filter`, `gauss_filter`, `median_image`, `histo_2dim`, `learn_ndim_norm`, `threshold`

Alternatives

`convol_image`

12.18 Wiener Filter

gen_psf_defocus (: Psf : PSFwidth, PSFheight, Blurring :)

Generate an impulse response of an uniform out-of-focus blurring.

gen_psf_defocus generates an impulse response (spatial domain) of an uniform out-of-focus blurring and writes it into an image of HALCON image type real. Blurring specifies the extent of blurring by defining the "blur radius" (out-of-focus blurring maps each image pixel on a small circle with a radius of Blurring - specified in "number of pixels"). If specified less than zero, the absolute value of Blurring is used. The result image of gen_psf_defocus encloses an spatial domain impulse response of the specified blurring. Its representation presumes the origin in the upper left corner. This results in the following disposition of an NxM sized image:

- first rectangle ("upper left"): (image coordinates $xb = 0..(N/2) - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the fourth quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 0..N/2$ and $y = 0.. - M/2$
- second rectangle ("upper right"): (image coordinates $xb = N/2..N - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the third quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2.. - 1$ and $y = -1.. - M/2$
- third rectangle ("lower left"): (image coordinates $xb = 0..(N/2) - 1$, $yb = M/2..M - 1$)
  - conforms to the first quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 1..N/2$ and $y = M/2..0$
- fourth rectangle ("lower right"): (image coordinates $xb = N/2..N - 1$, $yb = M/2..M - 1$)
  - conforms to the second quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2.. - 1$ and $y = M/2..1$

This representation conforms to that of the impulse response parameter of the HALCON-operator wiener_filter. So one can use gen_psf_defocus to generate an impulse response for Wiener filtering.

Parameters

▷ **Psf** (output_object) ..... image ⇝ *object :* real
Impulse response of uniform out-of-focus blurring.

▷ **PSFwidth** (input_control) ..... integer ⇝ *integer*
Width of result image.
Default: 256
Suggested values: PSFwidth ∈ {128, 256, 512, 1024}
Value range: 1 ≤ PSFwidth

▷ **PSFheight** (input_control) ..... integer ⇝ *integer*
Height of result image.
Default: 256
Suggested values: PSFheight ∈ {128, 256, 512, 1024}
Value range: 1 ≤ PSFheight

▷ **Blurring** (input_control) ..... real ⇝ *real*
Degree of Blurring.
Default: 5.0
Suggested values: Blurring ∈ {1.0, 5.0, 10.0, 15.0, 18.0}

Result

gen_psf_defocus returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

gen_psf_motion (: Psf : PSFwidth, PSFheight, Blurring, Angle, Type :)

Generate an impulse response of a (linearly) motion blurring.

gen_psf_motion generates an impulse response (spatial domain) of a blurring caused by a relative motion between the object and the camera during exposure. The generated impulse response is output into an image of HALCON image type real. PSFwidth and PSFheight define the width and height of the output image. The blurring motion moves along an even. Angle fixes its direction by specifying the angle between the motion direction and the x-axis (anticlockwise, measured in degrees). To specify different velocity behavior five PSF prototypes can be generated. Type switches between the following prototypes:

1. reverse ramp (crude model for acceleration)
2. reverse trapezoid (crude model for high acceleration)
3. square pulse (exact model for constant velocity), this is default
4. forward trapezoid (crude model for deceleration)
5. forward ramp (crude model for high deceleration)

(default value is 3.)

The blurring affects all part of the image uniformly. Blurring controls the extent of blurring. It specifies the number of pixels (lying one after another) that are affetcetd by the blurring. This number is determined by velocity of the motion and exposure time. If Blurring is a negative number, an adequate blurring in reverse direction is simulated. If Angle is a negative number, it is interpreted clockwise. If Angle exceeds 360 or falls below -360, it is transformed modulo(360) in an adequate number between $[0..360]$ resp. $[-360..0]$. The result image of gen_psf_motion encloses an spatial domain impulse response of the specified blurring. Its representation presumes the origin in the upper left corner. This results in the following disposition of an NxM sized image:

- first rectangle ("upper left"): (image coordinates $xb = 0..(N/2) - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the fourth quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 0..N/2$ and $y = 0.. - M/2$
- second rectangle ("upper right"): (image coordinates $xb = N/2..N - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the third quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2.. - 1$ and $y = -1.. - M/2$
- third rectangle ("lower left"): (image coordinates $xb = 0..(N/2) - 1$, $yb = M/2..M - 1$)
  - conforms to the first quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 1..N/2$ and $y = M/2..0$

- fourth rectangle (“lower right”): (image coordinates $xb = N/2..N-1$, $yb = M/2..M-1$)
  - conforms to the second quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2..-1$ and $y = M/2..1$

This representation conforms to that of the impulse response parameter of the HALCON-operator `wiener_filter`. So one can use `gen_psf_motion` to generate an impulse response for Wiener filtering a motion blurred image.

Parameters

▷ **`Psf`** (output_object) ..... image ⇝ *object :* real
Impulse response of motion-blur.

▷ **`PSFwidth`** (input_control) ..... integer ⇝ *integer*
Width of impulse response image.
Default: 256
Suggested values: `PSFwidth` ∈ {128, 256, 512, 1024}
Value range: 1 ≤ PSFwidth

▷ **`PSFheight`** (input_control) ..... integer ⇝ *integer*
Height of impulse response image.
Default: 256
Suggested values: `PSFheight` ∈ {128, 256, 512, 1024}
Value range: 1 ≤ PSFheight

▷ **`Blurring`** (input_control) ..... real ⇝ *real*
Degree of motion-blur.
Default: 20.0
Suggested values: `Blurring` ∈ {5.0, 10.0, 20.0, 30.0, 40.0}

▷ **`Angle`** (input_control) ..... integer ⇝ *integer*
Angle between direction of motion and x-axis (anticlockwise).
Default: 0
Suggested values: `Angle` ∈ {0, 45, 90, 180, 270}

▷ **`Type`** (input_control) ..... integer ⇝ *integer*
PSF prototype resp. type of motion.
Default: 3
List of values: `Type` ∈ {1, 2, 3, 4, 5}

Result

`gen_psf_motion` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

simulate_defocus (Image : DefocusedImage : Blurring :)

Simulate an uniform out-of-focus blurring of an image.

simulate_defocus simulates out-of-focus blurring of an image. All parts of the image are blurred uniformly. Blurring specifies the extent of blurring by defining the "blur radius" (out-of-focus blurring maps each image pixel on a small circle with a radius of Blurring - specified in "number of pixels"). If specified less than null, the absolute value of Blurring is used. Simulation of blurring is done by a convolution of the image with a blurring specific impulse response. The convolution is realized by multiplication in the Fourier domain.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Image to blur.

▷ **DefocusedImage** (output_object) ..... image(-array) ⇝ *object :* real
Blurred image.

▷ **Blurring** (input_control) ..... real ⇝ *real*
Degree of blurring.
Default: 5.0
Suggested values: Blurring ∈ {1.0, 5.0, 10.0, 15.0, 18.0}

Result

simulate_defocus returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty simulate_defocus returns with an error message.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

simulate_motion (Image : MovedImage : Blurring, Angle, Type :)

Simulation of (linearly) motion blur.

simulate_motion simulates blurring caused by a relative motion between the object and the camera during exposure. The simulated motion moves along an even. Angle fixes its direction by specifying the angle between the motion direction and the x-axis (anticlockwise, measured in degrees). Simulation is done by a convolution of the image with a blurring specific impulse response. The convolution is realized by multiplication in the Fourier domain. simulate_motion offers five prototypes of impulse responses conforming to different acceleration behaviors. Type allows to choose one of the following PSF prototypes:

1. reverse ramp (crude model for acceleration)
2. reverse trapezoid (crude model for high acceleration)
3. square pulse (exact model for constant velocity), this is default
4. forward trapezoid (crude model for deceleration)
5. forward ramp (crude model for high deceleration)

(default value is 3.)

The simulated blurring affects all part of the image uniformly. `Blurring` controls the extent of blurring. It specifies the number of pixels (lying one after another) that are affected by the blurring. This number is determined by velocity of the motion and exposure time. If `Blurring` is a negative number, an adequate blurring in reverse direction is simulated. If `Angle` is a negative number, it is interpreted clockwise. If `Angle` exceeds 360 or falls below -360, it is transformed modulo(360) in an adequate number between $[0..360]$ resp. $[-360..0]$.

Parameters

▷ **`Image`** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
image to be blurred.

▷ **`MovedImage`** (output_object) ..... image ⇝ *object :* real
motion blurred image.

▷ **`Blurring`** (input_control) ..... real ⇝ *real*
extent of blurring.
Default: 20.0
Suggested values: `Blurring` ∈ {5.0, 10.0, 20.0, 30.0, 40.0}

▷ **`Angle`** (input_control) ..... integer ⇝ *integer*
Angle between direction of motion and x-axis (anticlockwise).
Default: 0
Suggested values: `Angle` ∈ {0, 45, 90, 180, 270}

▷ **`Type`** (input_control) ..... integer ⇝ *integer*
impulse response of motion blur.
Default: 3
List of values: `Type` ∈ {1, 2, 3, 4, 5}

Result

`simulate_motion` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty `simulate_motion` returns with an error message.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.

wiener_filter (Image, Psf, FilteredImage : RestoredImage : :)

Image restoration by Wiener filtering.

wiener_filter produces an estimate of the original image (= image without noise and blurring) by minimizing the mean square error between estimated and original image. wiener_filter can be used to restore images corrupted by noise and/or blurring (e.g., motion blur, atmospheric turbulence or out-of-focus blur). Method and realization of this restoration technique bases on the following model: The corrupted image is interpreted as the output of a (disturbed) linear system. Functionality of a linear system is determined by its specific impulse response. So the convolution of original image and impulse response results in the corrupted image. The specific impulse response describes image acquisition and the occurred degradations. In the presence of additive noise an additional noise term must be considered. So the corrupted image can be modeled as the result of

$[convolution(impulse\_response, original\_image)] + noise\_term$

The noise term encloses two different terms describing image-dependent and image-independent noise. According to this model, two terms must be known for restoration by Wiener filtering:

1. degradation-specific impulse response
2. noise term

So wiener_filter needs a smoothed version of the input image to estimate the power spectral density of noise and original image. One can use one of the smoothing HALCON-filters (e.g., eliminate_min_max) to get this version. wiener_filter needs further the impulse response that describes the specific degradation. This impulse response (represented in spatial domain) must fit into an image of HALCON image type real. There exist two HALCON-operators for generation of an impulse response for motion blur and out-of-focus (see gen_psf_motion, gen_psf_defocus). The representation of the impulse response presumes the origin in the upper left corner. This results in the following disposition of an NxM sized image:

- first rectangle (“upper left”): (image coordinates $xb = 0..(N/2) - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the fourth quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 0..N/2$ and $y = 0.. - M/2$
- second rectangle (“upper right”): (image coordinates $xb = N/2..N - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the third quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2.. - 1$ and $y = -1.. - M/2$
- third rectangle (“lower left”): (image coordinates $xb = 0..(N/2) - 1$, $yb = M/2..M - 1$)
  - conforms to the first quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 1..N/2$ and $y = M/2..0$
- fourth rectangle (“lower right”): (image coordinates $xb = N/2..N - 1$, $yb = M/2..M - 1$)
  - conforms to the second quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2.. - 1$ and $y = M/2..1$

wiener_filter works as follows:

- estimation of the power spectrum density of the original image by using the smoothed version of the corrupted image,
- estimation of the power spectrum density of each pixel by subtracting smoothed version from not smoothed version,
- building the Wiener filter kernel with the quotient of power spectrum densities of noise and original image and with the impulse response,
- processing the convolution of image and Wiener filter frequency response.

The result image has got image type real.

Attention

Psf must be of image type real and conform to Image and FilteredImage in image width and height.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Corrupted image.

▷ **Psf** (input_object) ..... (multichannel-)image ⇝ *object :* real
impulse response (PSF) of degradation (in spatial domain).

▷ **FilteredImage** (input_object) ..... (multichannel-)image ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Smoothed version of corrupted image.

▷ **RestoredImage** (output_object) ..... image ⇝ *object :* real
Restored image.

Example

```
/* Restoration of a noisy image (size=256x256), that was blurred by motion*/
Hobject object;
Hobject restored;
Hobject psf;
Hobject noisefiltered;
/* 1. Generate a Point-Spread-Function for a motion-blur with       */
/*    parameter a=10 and direction along the x-axis                 */
gen_psf_motion(&psf,256,256,10,0,3);
/* 2. Noisefiltering of the image                                   */
median_image(object,&noisefiltered,"circle",2,0);
/* 3. Wiener-filtering                                              */
wiener_filter(object,psf,noisefiltered,&restored);
```

Result

`wiener_filter` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty `wiener_filter` returns with an error message.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on channel level.

wiener_filter_ni (Image, Psf, NoiseRegion : RestoredImage : MaskWidth, MaskHeight :)

Image restoration by Wiener filtering.

wiener_filter_ni (ni = noise-estimation integrated) produces an estimate of the original image (= image without noise and blurring) by minimizing the mean square error between estimated and original image. wiener_filter can be used to restore images corrupted by noise and/or blurring (e.g., motion blur, atmospheric turbulence or out-of-focus blur). Method and realization of this restoration technique bases on the following model: The corrupted image is interpreted as the output of a (disturbed) linear system. Functionality of a linear system is determined by its specific impulse response. So the convolution of original image and impulse response results in the corrupted image. The specific impulse response describes image acquisition and the occurred degradations. In the presence of additive noise an additional noise term must be considered. So the corrupted image can be modeled as the result of

$$[convolution(impulse\_response, original\_image)] + noise\_term$$

The noise term encloses two different terms describing image-dependent and image-independent noise. According to this model, two terms must be known for restoration by Wiener filtering:

1. degradation-specific impulse response
2. noise term

wiener_filter_ni estimates the noise term as follows: The user defines a region that is suitable for noise estimation within the image (homogeneous as possible, as edges or textures aggravate noise estimation). After smoothing within this region by an (unweighted) median filter and subtracting smoothed version from unsmoothed, the average noise amplitude of the region is processed within wiener_filter_ni. This amplitude together with the average gray value within the region allows estimating the quotient of the power spectral densities of noise and original image (in contrast to wiener_filter wiener_filter_ni assumes a rather constant quotient within the whole image). The user can define width and height of the rectangular (median-)filter mask to influence the noise estimation (MaskWidth, MaskHeight). wiener_filter_ni needs further the impulse response that describes the specific degradation. This impulse response (represented in spatial domain) must fit into an image of HALCON image type real. There exist two HALCON-operators for generation of an impulse response for motion blur and out-of-focus (see gen_psf_motion, gen_psf_defocus). The representation of the impulse response presumes the origin in the upper left corner. This results in the following disposition of an NxM sized image:

- first rectangle (“upper left”): (image coordinates $xb = 0..(N/2) - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the fourth quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 0..N/2$ and $y = 0.. - M/2$
- second rectangle (“upper right”): (image coordinates $xb = N/2..N - 1$, $yb = 0..(M/2) - 1$)
  - conforms to the third quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2.. - 1$ and $y = -1.. - M/2$
- third rectangle (“lower left”): (image coordinates $xb = 0..(N/2) - 1$, $yb = M/2..M - 1$)
  - conforms to the first quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = 1..N/2$ and $y = M/2..0$
- fourth rectangle (“lower right”): (image coordinates $xb = N/2..N - 1$, $yb = M/2..M - 1$)
  - conforms to the second quadrant of the Cartesian coordinate system, encloses values of the impulse response at position $x = -N/2.. - 1$ and $y = M/2..1$

wiener_filter works as follows:

- estimating the quotient of the power spectrum densities of noise and original image,
- building the Wiener filter kernel with the quotient of power spectrum densities of noise and original image and with the impulse response,
- processing the convolution of image and Wiener filter frequency response.

The result image has got image type real.

Attention

Psf must be of image type real and conform to Image in width and height. The Region used for noise estimation must lie completely within the image. If MaskWidth or MaskHeight is an even number, it is replaced by the next higher odd number (this allows the unique extraction of the center of the filter mask). Width/height of the mask may not exceed the image width/height or be less than null.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real
Corrupted image.

▷ **Psf** (input_object) ..... (multichannel-)image ⇝ *object :* real
impulse response (PSF) of degradation (in spatial domain).

▷ **NoiseRegion** (input_object) ..... region(-array) ⇝ *object*
Region for noise estimation.

▷ **RestoredImage** (output_object) ..... image ⇝ *object :* real
Restored image.

▷ **MaskWidth** (input_control) ..... integer ⇝ *integer*
Width of filter mask.
Default: 3
Suggested values: `MaskWidth` ∈ {3, 5, 7, 9}
Value range: 0 ≤ `MaskWidth` ≤ width(Image)

▷ **MaskHeight** (input_control) ..... integer ⇝ *integer*
Height of filter mask.
Default: 3
Suggested values: `MaskHeight` ∈ {3, 5, 7, 9}
Value range: 0 ≤ `MaskHeight` ≤ height(Image)

Example

```
/* Restoration of a noisy image (size=256x256), that was blurred by motion*/
Hobject object;
Hobject restored;
Hobject psf;
Hobject noise_region;
/* 1. Generate a Point-Spread-Function for a motion-blur with       */
/*    parameter a=10 and direction of the x-axis                    */
gen_psf_motion(&psf,256,256,10,0,3);
/* 2. Segmentation of a region for the noise-estimation             */
open_window(0,0,256,256,0,"visible",&WindowHandle);
disp_image(object,WindowHandle);
draw_region(&noise_region,draw_region);
/* 3. Wiener-filtering                                              */
wiener_filter_ni(object,psf,noise_region,&restored,3,3);
```

Result

`wiener_filter_ni` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty `wiener_filter_ni` returns with an error message.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on channel level.

Possible Predecessors

Chapter 13

Graphics

13.1 3D Scene

add_scene_3d_camera (: : Scene3D, CameraParam : CameraIndex)

Add a camera to a 3D scene.

add_scene_3d_camera adds a new camera to the 3D scene Scene3D and returns the index of this camera in CameraIndex. The camera parameters of the camera must be given in CameraParam. By default the new camera is located at the origin of the world coordinate system. The pose of the camera CameraIndex can be set with set_scene_3d_camera_pose.

Attention

Cameras with hypercentric lenses are not supported. For displaying large faces (or primitives) with a non-zero distortion in CameraParam, note that the distortion is only applied to the points of the model. In the projection, these points are subsequently connected by straight lines. For a good approximation of the distorted lines, please use a triangulation with sufficiently small triangles.

Parameters

- ▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
  Handle of the 3D scene.
- ▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
  Parameters of the new camera.
- ▷ **CameraIndex** (output_control) . . . . . integer ⇝ *integer*
  Index of the new camera in the 3D scene.

Result

add_scene_3d_camera returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_scene_3d

Possible Successors

set_scene_3d_camera_pose, display_scene_3d

Module

3D Metrology

add_scene_3d_instance (: : Scene3D, ObjectModel3D, Pose : InstanceIndex)

Add an instance of a 3D object model to a 3D scene.

add_scene_3d_instance adds an instance of the 3D model ObjectModel3D to the 3D scene Scene3D and returns its index in InstanceIndex. If multiple 3D object models are supplied, it is possible to set one pose for all instances or one pose for every instance.

The pose of the object instance in the scene coordinate system must be given in Pose. The operator set_scene_3d_instance_pose can be used to change this pose. As long as no global scene pose is set with set_scene_3d_to_world_pose, this pose is evaluated relative to the world coordinate system.

Parameters of the instance, such as its color, are set with the operator set_scene_3d_instance_param.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **Pose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
Pose of the 3D object model.
Number of elements: 7

▷ **InstanceIndex** (output_control) . . . . . integer ⇝ *integer*
Index of the new instance in the 3D scene.

Result

add_scene_3d_instance returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_scene_3d

remove_scene_3d_instance

Module

3D Metrology

add_scene_3d_label (: : Scene3D, Text, ReferencePoint, Position, RelatesTo : LabelIndex)

Add a text label to a 3D scene.

add_scene_3d_label adds a label with the text in Text to the 3D scene Scene3D and returns its index in LabelIndex.

The reference point of the label must be given as *[X,Y,Z]* point in the coordinate system of the 3D scene in ReferencePoint. It is valid to create labels without a reference point by passing an empty tuple to ReferencePoint, however RelatesTo must be set to *'window'* in this case (see the description of RelatesTo below).

If multiple label texts are supplied in Text, multiple labels are created. It is possible to set one reference point for all labels or a specific reference point for each label. The same applies to Position and RelatesTo.

Labels can be positioned fixed in window coordinates or relative to the projection of the reference point. The two parameters `Position` and `RelatesTo` are used for positioning.

Fixed positioning

If `RelatesTo` is set to *'window'*, the Label is shown at a fixed position in the window (or rendered image), even if the pose of the 3D scene is changed. There are two ways to specify the position. You can either supply the *[Row,Column]* coordinates of the top left corner of the label in `Position` or use one of the predefined positions:

'top_left'	*'top'*	*'top_right'*
'left'	*'center'*	*'right'*
'bottom_left'	*'bottom'*	*'bottom_right'*

Relative positioning

If `RelatesTo` is set to *'point'*, the Label is shown at a position relative to the projection of the reference point. This way, the label moves with the reference point if the pose of the 3D scene is changed. There are two ways to specify the position. You can either supply the *[Row,Column]* offset of the top left corner of the label in `Position` or use one of the predefined positions:

'top_left'	*'top'*	*'top_right'*
'left'	*'center'*	*'right'*
'bottom_left'	*'bottom'*	*'bottom_right'*

The operator `set_scene_3d_label_param` can be used to change these values and to set other parameters such as the label's color and font.

Parameters

- ▷ **`Scene3D`** (input_control) . . . . . scene_3d ⇝ *handle*
  Handle of the 3D scene.
- ▷ **`Text`** (input_control) . . . . . string(-array) ⇝ *string*
  Text of the label.
  Default: 'label'
- ▷ **`ReferencePoint`** (input_control) . . . . . point-array ⇝ *real* / integer
  Point of reference of the label.
  Number of elements: 3
- ▷ **`Position`** (input_control) . . . . . point-array ⇝ *string* / real / integer
  Position of the label.
  Default: 'top'
  List of values: `Position` ∈ {'top_left', 'top', 'top_right', 'left', 'center', 'right', 'bottom_left', 'bottom', 'bottom_right'}
- ▷ **`RelatesTo`** (input_control) . . . . . string-array ⇝ *string*
  Indicates fixed or relative positioning.
  Number of elements: 1
  Default: 'point'
  List of values: `RelatesTo` ∈ {'point', 'window'}
- ▷ **`LabelIndex`** (output_control) . . . . . integer ⇝ *integer*
  Index of the new label in the 3D scene.

Result

`add_scene_3d_label` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

add_scene_3d_light (: : Scene3D, LightPosition, LightKind : LightIndex)

Add a light source to a 3D scene.

add_scene_3d_light adds a new light source to the scene Scene3D and returns its index in LightIndex. The kind of the light source must be specified in LightKind. For LightKind = *'point_light'*, LightPosition is interpreted as the position of the light source. For LightKind = *'directional_light'*, LightPosition is interpreted as the vector of the directional light source.

Currently only one light source is supported, such that add_scene_3d_light overwrites the existing light source. This may be changed in future versions.

If no light source is set, a point light source at [-100.0, -100.0, 0.0] is used.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **LightPosition** (input_control) . . . . . real-array ⇝ *real* / integer
Position of the new light source.
Default: [-100.0,-100.0,0.0]

▷ **LightKind** (input_control) . . . . . string ⇝ *string*
Type of the new light source.
Default: 'point_light'
List of values: LightKind ∈ {'point_light', 'directional_light'}

▷ **LightIndex** (output_control) . . . . . integer ⇝ *integer*
Index of the new light source in the 3D scene.

Result

add_scene_3d_light returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_scene_3d

Possible Successors

set_scene_3d_light_param

remove_scene_3d_light

Module

3D Metrology

clear_scene_3d (: : Scene3D :)

Delete a 3D scene and free all allocated memory.

clear_scene_3d deletes the 3D scene Scene3D.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d(-array) ⇝ *handle*
Handle of the 3D scene.

Result

clear_scene_3d returns 2 (H_MSG_TRUE) if the scene was valid and could be deleted. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- Scene3D

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

display_scene_3d

Module

3D Metrology

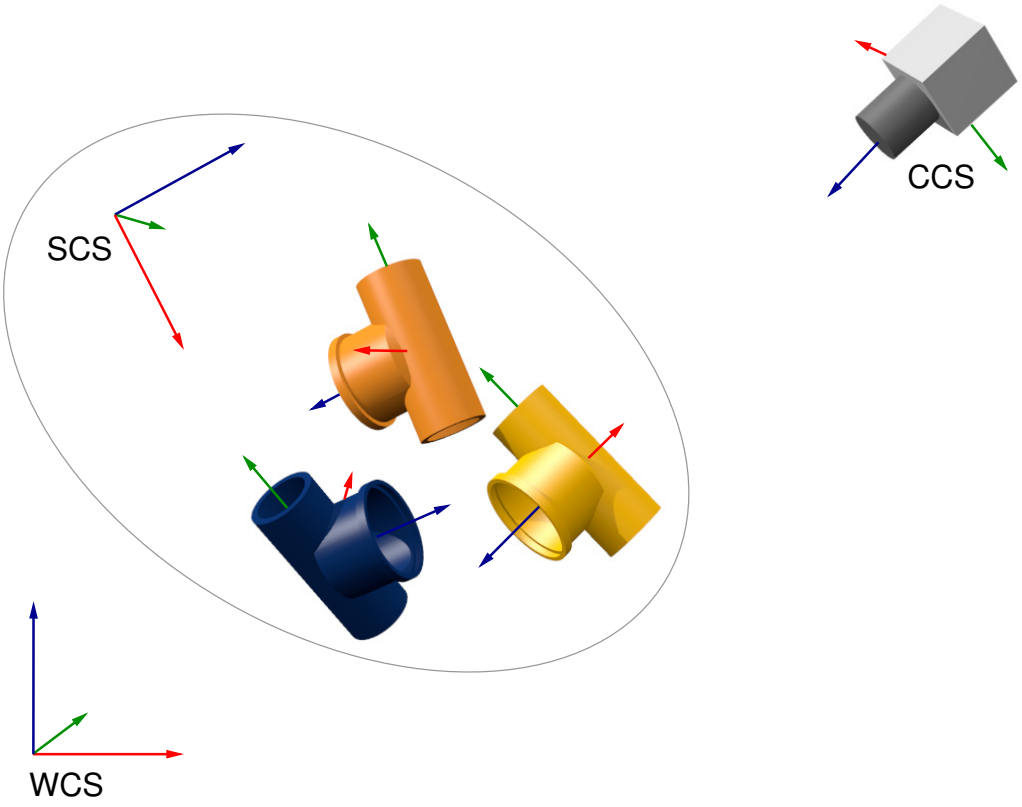
create_scene_3d (: : : Scene3D)

Create the data structure that is needed to visualize collections of 3D objects.

create_scene_3d creates a new 3D scene and returns it in Scene3D.

A 3D scene is a collection of instances of 3D object models, cameras, and light sources. Use the operators add_scene_3d_instance, add_scene_3d_camera, and add_scene_3d_light to add these objects to Scene3D. Use display_scene_3d to display a 3D scene in a window.

A pose is associated (with add_scene_3d_instance or set_scene_3d_instance_pose) to each instance in the Scene, which represents the instance's position within the scene coordinate system SCS. The pose of the scene in the world coordinate system WCS can be set with set_scene_3d_to_world_pose. The pose of the camera in the world coordinate system can be set with set_scene_3d_camera_pose and defines the camera coordinate system CCS.



The coordinate systems in a 3D scene

Parameters influencing the whole scene such as the quality of the rendering can be set with set_scene_3d_param.

Parameters

▷ **Scene3D** (output_control) ..... scene_3d ⇝ *handle*
Handle of the 3D scene.

Example

```
* Create a new scene
create_scene_3d (Scene)
* A scene needs at least one camera. The default pose
* of a camera is located at the origin. The pose can be
* changed with set_scene_3d_camera_pose.
add_scene_3d_camera (Scene, CameraParam, CameraIndex)
* Further a scene needs at least one light.
add_scene_3d_light (Scene, [42.0, 42.0, 42.0], 'point_light', LightIndex)
*
* To add an object, add_scene_3d_instance is called with a
* 3d object model and a pose. add_scene_3d returns an InstanceIndex
* which must be used to reference this instance in subsequent calls.
add_scene_3d_instance (Scene, ObjectModel3D, Pose, InstanceIndex)
* Set its color.
set_scene_3d_instance_param (Scene, InstanceIndex, 'color', 'green')
* Display the scene.
display_scene_3d (WindowHandle, Scene, CameraIndex)
clear_scene_3d (Scene)
```

Result

create_scene_3d returns 2 (H_MSG_TRUE) if the scene could be created successfully. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

add_scene_3d_instance, add_scene_3d_light, add_scene_3d_camera, set_scene_3d_param

See also

clear_scene_3d

Module

3D Metrology

display_scene_3d (: : WindowHandle, Scene3D, CameraIndex :)

Display a 3D scene.

display_scene_3d displays the 3D scene Scene3D in the window WindowHandle. The view of the camera CameraIndex is used to render the scene. Note that sometimes the aspect ratio of WindowHandle should be similar to width and height of the camera in order to obtain the wanted results. See create_scene_3d for a short example.

display_scene_3d requires OpenGL 2.1, GLSL 1.2, and the OpenGL extensions GL_EXT_framebuffer_object and GL_EXT_framebuffer_blit. Otherwise the compatibility mode with less requirements but lower quality is automatically enabled. On graphics cards with low memory the following error messages could occur if rendering in a window with high resolution:

Low level error: 'Incomplete attachment'

Unhanded Exception: 'Required framebuffer object is unsupported'

Solutions:

Set the parameter *'quality'* to *'low'* using set_scene_3d_param or use the compatibility mode to reduce the requirements of the graphics card.

The system variable (see set_system) *'opengl_compatibility_mode_enable'* can be set to *'true'* to permanently enable the visualization in compatibility mode with lower OpenGL requirements. This mode requires OpenGL 1.1. In compatibility mode the parameters *'object_index_persistence'*, *'depth_persistence'* and *'quality'* are not used.

On Linux Remote Desktop *'disp_background'* is not supported.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Scene3D** (input_control) ..... scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **CameraIndex** (input_control) ..... integer ⇝ *string* / integer
Index of the camera used to display the scene.

Result

display_scene_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`create_scene_3d`, `render_scene_3d`

Module

3D Metrology

get_display_scene_3d_info (: : WindowHandle, Scene3D, Row, Column, Information : Value)

Get the depth or the index of instances in a displayed 3D scene.

`get_display_scene_3d_info` returns information on the 3D object models in the 3D scene `Scene3D` that have been displayed with `display_scene_3d` in the window `WindowHandle`. The requested information at the positions (`Row`, `Column`) is returned in `Value`.

The following values can be queried via `Information`:

'object_index' The indices of the 3D object models that have been displayed at the positions (`Row`, `Column`). If no 3D object model was displayed at this position, -1 is returned. In order to retrieve this information, the parameter *'object_index_persistence'* must have been set to *'true'* with `set_scene_3d_param`.

'depth' The depth (i.e. the Z coordinate in the camera coordinate system) at the positions (`Row`, `Column`). If no 3D object model was displayed at one of these positions, -1.0 is returned for this position. In order to retrieve this information, the parameter *'depth_persistence'* must have been set to *'true'* with `set_scene_3d_param`.

The window coordinates `Row`, `Column` must be provided with respect to the current image part. As a consequence, these coordinates are subpixel coordinates. Given the current image part (row1,column1,row2, column2), the upper left corner corresponds to the coordinates (row1 - 0.5, col1 - 0.5). Accordingly, the bottom right corner corresponds to the coordinates (row2 - 0.5, col2 - 0.5). Use `get_mposition_sub_pix` or `get_mbutton_sub_pix` to obtain these coordinates directly.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Scene3D** (input_control) ..... scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **Row** (input_control) ..... integer(-array) ⇝ *real* / integer
Row coordinates.

▷ **Column** (input_control) ..... integer(-array) ⇝ *real* / integer
Column coordinates.

▷ **Information** (input_control) ..... string(-array) ⇝ *string*
Information.
Default: 'depth'
List of values: `Information` ∈ {'depth', 'object_index'}

▷ **Value** (output_control) ..... integer(-array) ⇝ *integer* / real
Indices or the depth of the objects at (Row,Column).

Result

`get_display_scene_3d_info` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

3D Metrology

remove_scene_3d_camera (: : Scene3D, CameraIndex :)

Remove a camera from a 3D scene.

remove_scene_3d_camera removes the camera CameraIndex from the 3D scene Scene3D.

Parameters

- ▷ **Scene3D** (input_control) ..... scene_3d ⇝ *handle*
  Handle of the 3D scene.
- ▷ **CameraIndex** (input_control) ..... integer ⇝ *integer*
  Index of the camera to remove.

Result

remove_scene_3d_camera returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

add_scene_3d_camera

Module

3D Metrology

remove_scene_3d_instance (: : Scene3D, InstanceIndex :)

Remove an object instance from a 3D scene.

remove_scene_3d_instance removes the instance InstanceIndex from the 3D scene Scene3D.

Parameters

- ▷ **Scene3D** (input_control) ..... scene_3d ⇝ *handle*
  Handle of the 3D scene.
- ▷ **InstanceIndex** (input_control) ..... integer(-array) ⇝ *integer*
  Index of the instance to remove.

Result

remove_scene_3d_instance returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

add_scene_3d_instance

Module

3D Metrology

remove_scene_3d_label (: : Scene3D, LabelIndex :)

Remove a text label from a 3D scene.

remove_scene_3d_label removes the text label LabelIndex from the 3D scene Scene3D.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **LabelIndex** (input_control) . . . . . integer(-array) ⇝ *integer*
Index of the text label to remove.

Result

remove_scene_3d_label returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

add_scene_3d_label

Module

3D Metrology

remove_scene_3d_light (: : Scene3D, LightIndex :)

Remove a light from a 3D scene.

remove_scene_3d_light removes the light LightIndex from the 3D scene Scene3D in future versions. Currently only one light source is supported.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **LightIndex** (input_control) . . . . . integer ⇝ *integer*
Light to remove.

Result

remove_scene_3d_light returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

add_scene_3d_light

Module

3D Metrology

render_scene_3d (: Image : Scene3D, CameraIndex :)

Render an image of a 3D scene.

render_scene_3d renders an image of the 3D scene Scene3D and returns the result in Image. The view of the camera CameraIndex is used to render the image.

The set_scene_3d_param parameters *'object_index_persistence'* and *'disp_background'* are ignored. The background of Image is black.

render_scene_3d requires OpenGL 2.1, GLSL 1.2, and the OpenGL extensions GL_EXT_framebuffer_object and GL_EXT_framebuffer_blit. Otherwise the compatibility mode is automatically enabled. The compatibility mode requires OpenGL 1.1.

Parameters

- ▷ **Image** (output_object) ..... (multichannel-)image ⇝ *object :* byte
  Rendered 3D scene.
- ▷ **Scene3D** (input_control) ..... scene_3d ⇝ *handle*
  Handle of the 3D scene.
- ▷ **CameraIndex** (input_control) ..... integer ⇝ *integer*
  Index of the camera used to display the scene.

Result

render_scene_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

create_scene_3d

Module

3D Metrology

set_scene_3d_camera_pose (: : Scene3D, CameraIndex, Pose :)

Set the pose of a camera in a 3D scene.

set_scene_3d_camera_pose sets the Pose of the camera CameraIndex in the 3D scene Scene3D.

See create_scene_3d for more details on the coordinate systems used in 3D scenes.

Parameters

- ▷ **Scene3D** (input_control) ..... scene_3d ⇝ *handle*
  Handle of the 3D scene.
- ▷ **CameraIndex** (input_control) ..... integer ⇝ *integer*
  Index of the camera.
- ▷ **Pose** (input_control) ..... pose ⇝ *real* / integer
  New pose of the camera.

Result

`set_scene_3d_camera_pose` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

3D Metrology

set_scene_3d_instance_param (: : Scene3D, InstanceIndex, GenParamName, GenParamValue :)

Set parameters of an instance in a 3D scene.

`set_scene_3d_instance_param` sets parameters of the instance `InstanceIndex` in the 3D scene `Scene3D`. The name and value of a parameter must be given in `GenParamName` and `GenParamValue`. All parameters are applied to all instances.

The following values can be set:

'visible' Visibility of the 3D object models. If set to *'false'* this instance is not displayed.
List of values: *'true'*, *'false'*.
Default: *'true'*.

'attribute' Explicitly select in which way a 3D object model is visualized.
List of values: *'auto'*, *'faces'*, *'primitive'*, *'points'*, *'lines'*.
Default: *'auto'*.

'color': Color of the 3D object model. The available colors can be queried with the operator `query_color`. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where *'rr'*, *'gg'*, and *'bb'* are hexadecimal numbers between *'00'* and *'ff'*, respectively.
Suggested values: *'red'*, *'green'*.
Default: *'white'*

'alpha': Transparency of the 3D object models. Displaying 3D object models with transparency set to less than 1.0 may significantly increase the runtime of `display_scene_3d` and `render_scene_3d`.
Value range: floating point value between 0.0 (fully transparent) and 1.0 (fully opaque).
Default: 1.0

'disp_pose': Flag, if the pose of the 3D object models should be visualized.
List of values: *'true'*, *'false'*.
Default: *'false'*.

'disp_lines': Flag, if the contours of the 3D object models' polygons should be displayed.
List of values: *'true'*, *'false'*.
Default: *'false'*.

'disp_normals': Flag, if the surface normals of the 3D object models should be visualized.
List of values: *'true'*, *'false'*.
Default: *'false'*.

'line_color': Color of the lines if *'disp_lines'* is set to *'true'*. The available colors can be queried with the operator query_color. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where *'rr'*, *'gg'*, and *'bb'* are hexadecimal numbers.

Suggested values: *'red'*, *'green'*.

Default: The value of *'color'*.

'line_width': Sets the width of lines in pixel.

Default: *1.0*

'normal_color': Color of the visualized normals if *'disp_normals'* is set to *'true'*. The available colors can be queried with the operator query_color. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where *'rr'*, *'gg'*, and *'bb'* are hexadecimal numbers.

Suggested values: *'red'*, *'green'*.

Default: The value of *'color'*

'point_size': Sets the diameter of the points in pixel.

Default: *3.5*.

'lut': Sets the LUT that transforms the values of the attribute set with *'color_attrib'* into a color.

See set_lut for available LUTs. If *'lut'* is set to anything but *'default'*, *'color'* is ignored.

Default: *'default'*.

'color_attrib': Name of a point attribute that is used for false color visualization.

If an attribute is set, the color of the displayed 3D points is determined by the point's attribute value and the currently set LUT (see *'lut'*). This way, it is possible to visualize attributes in false colors.

Example: If *'color_attrib'* is set to *'coord_z'*, and *'lut'* is set to *'color1'*, the z-coordinates will be color coded from red to blue.

If *'lut'* is set to *'default'*, the attribute values are used to scale the color that was set by the parameter *'color'*.

If *'lut'* is set to a different value, the attribute values of all points are internally scaled to the interval [0,255] and used as input value for the LUT function.

The mapping is also controlled by the parameters *'color_attrib_start'* and *'color_attrib_end'* (see below).

If faces are displayed, their color is interpolated between the color of the corner points.

Suggested values: *'none'*, *'&distance'*, *'coord_x'*, *'coord_y'*, *'coord_z'*, user defined point attributes, or any other point attribute available.

Default: *'none'*.

'color_attrib_start',*'color_attrib_end'*: The range of interest of the values of the attribute set with *'color_attrib'*.

The attribute values between *'color_attrib_start'* and *'color_attrib_end'* are scaled to the start and end of the selected LUT. Attribute values outside the selected range are clipped. This allows to use a fixed color mapping which will not be distorted by outliers.

If set to *'auto'*, the minimum attribute value is mapped to the start of the LUT, the maximum is mapped to the end of the LUT, *except* if *'color_attrib'* is *'normal_x'*, *'normal_y'*, or *'normal_z'*. In this case, start and end are automatically set to -1 and 1.

It is possible to enter start value that is higher than the end value. This will in effect flip the used LUT.

Suggested values: *0*, *0.1*, *1*, *100*, *255*, *'auto'*.

Default: *'auto'*.

'red_channel_attrib', *'green_channel_attrib'*, *'blue_channel_attrib'*: Name of a point attribute that is used for the red, green, or blue color channel.

This is most useful when used with a group of three connected attributes, like RGB colors or normal vectors. This way it is possible to display points in colored texture, e.g., display the object model with overlayed RGB-sensor data, or display point normals in false colors.

To display only a single attribute in false colors, please use *'color_attrib'* (see above).

By default, the attribute values are assumed to lie between 0 and 255. If the attributes have a different range, you additionally have to set the parameters *'rgb_channel_attrib_start'* and *'rgb_channel_attrib_end'* (see below).

If only 1 or 2 channels are set, the remaining channels use the RGB value of the color set with *'color'*.

If faces are displayed, their color is interpolated between the color of the corner points.

Suggested values: *'none'*, *'&red'*, *'&green'*, *'&blue'*, *'normal_x'*, *'normal_y'*, *'normal_z'*, user defined point attributes, or any other point attribute available.

Default: *'none'*.

'rgb_channel_attrib_start', *'rgb_channel_attrib_end'*: The range of interest of the values of attributes set with *'red_channel_attrib'*, *'green_channel_attrib'*, and *'blue_channel_attrib'*.

These parameters define the value range that is scaled to the full RGB channels. This is useful, if the input attribute values are not in the interval [0,255].

If set to *'auto'*, the minimum attribute value is mapped to 0, the maximum is mapped to 255, *except* if the attribute is *'normal_x'*, *'normal_y'*, or *'normal_z'*. In this case, start and end are automatically set to -1 and 1.

It is possible to enter start value that is higher than the end value. This will in effect invert the displayed RGB colors.

The range can be set for the channels individually by replacing *'rgb'* in the parameter name with the channel name, e.g., *'green_channel_attrib_start'*.

Suggested values: *'auto'*, *0*, *0.1*, *1*, *100*, *255*.

Default: *0*, *255*.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **InstanceIndex** (input_control) . . . . . integer(-array) ⇝ *integer*
Index of the instance.

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of the generic parameters.
Default: 'color'
List of values: `GenParamName` ∈ {'alpha', 'attribute', 'color', 'disp_lines', 'disp_pose', 'disp_normals', 'line_color', 'line_width', 'normal_color', 'color_attrib', 'red_channel_attrib', 'green_channel_attrib', 'blue_channel_attrib', 'rgb_channel_attrib_start', 'rgb_channel_attrib_end', 'color_attrib_start', 'color_attrib_end', 'lut', 'visible', 'point_size'}

▷ **GenParamValue** (input_control) . . . . . string-array ⇝ *string* / integer / real
Values of the generic parameters.
Default: 'green'
Suggested values: `GenParamValue` ∈ {'true', 'false', 'coord_x', 'coord_y', 'coord_z', 'normal_x', 'normal_y', 'normal_z', 'red', 'green', 'blue', 'auto', 'faces', 'primitive', 'points', 'lines'}

Result

`set_scene_3d_instance_param` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

set_scene_3d_instance_pose (: : Scene3D, InstanceIndex, Pose :)

Set the pose of an instance in a 3D scene.

`set_scene_3d_instance_pose` sets the pose of the instance `InstanceIndex` in the 3D scene `Scene3D` to `Pose`. It's possible to set one pose for multiple instances or one pose for each instance.

See the documentation of create_scene_3d for more details on the coordinate systems used in 3D scenes.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **InstanceIndex** (input_control) . . . . . integer(-array) ⇝ *integer*
Index of the instance.

▷ **Pose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
New pose of the instance.

Result

set_scene_3d_instance_pose returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

set_scene_3d_label_param (: : Scene3D, LabelIndex, GenParamName, GenParamValue :)

Set parameters of a text label in a 3D scene.

set_scene_3d_label_param sets parameters of the label LabelIndex in the 3D scene Scene3D. The name and value of a parameter must be given in GenParamName and GenParamValue. It is only possible to provide one GenParamName,GenParamValue pair but multiple labels. The parameter is applied to all labels in LabelIndex.

The following values can be set:

'reference_point': Coordinates of the reference point, as a tuple of *[X, Y, Z]* coordinates. To remove the current reference point, it is possible to pass an empty tuple for *'reference_point'*. This is only possible if *'relates_to'* is *'window'*.

'position': Position (relative or absolute depending on the parameter *'relates_to'*) of the label, as a tuple of *[Row, Column]* coordinates or one of the following predefined positions.

List of values: *'top_left'*, *'top'*, *'top_right'*, *'left'*, *'center'*, *'right'*, *'bottom_left'*, *'bottom'*, or *'bottom_right'*.

'relates_to': Relation of the position. May be *'window'* (fixed positioning in window coordinates) or *'point'* (positioning relative to the reference point). *'relates_to'* cannot be set to *'point'* if the reference point has been set to an empty tuple.

List of values: *'window'* , *'point'*.

Default: *'window'*.

'text': Text of the label. Multiple Lines must be separated with *'\n'*.

'font': Font of the text label.

Suggested values: Available fonts can be queried using query_font.

Default: Font of the first window the scene is displayed in, default system font otherwise.

'text_color': Color of the text on the label. The available colors can be queried with the operator query_color. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where *'rr'*, *'gg'*, and *'bb'* are hexadecimal numbers between *'00'* and *'ff'*, respectively.

Suggested values: *'red'*, *'green'*.

Default: *'white'*.

'alpha': Transparency of the text label's background.

Value range: floating point value between 0.0 (fully transparent) and 1.0 (fully opaque).

Default: *1.0*.

'color': Color of the label itself. The available colors can be queried with the operator query_color. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where *'rr'*, *'gg'*, and *'bb'* are hexadecimal numbers between *'00'* and *'ff'*, respectively.

Suggested values: *'red'*, *'green'*.

Default: *'gray'*.

'disp_background': Flag that determines if the background of the label should be visualized.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'disp_connecting_line': Flag that determines if the connecting line between the label and reference 3D point should be visualized.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'visible': Sets the visibility of the label. If set to *'if_point_is_visible'*, the label is only visible if its reference point is visible. If the compatibility mode is enabled or no reference point is set, *'if_point_is_visible'* is equal to *'true'*.

List of values: *'true'*, *'false'*, *'if_point_is_visible'*.

Default: *'true'*.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **LabelIndex** (input_control) . . . . . integer(-array) ⇝ *integer*
Index of the text label.

▷ **GenParamName** (input_control) . . . . . string ⇝ *string*
Names of the generic parameters.
Default: 'color'
List of values: GenParamName ∈ {'reference_point', 'position', 'relates_to', 'color', 'text_color', 'font', 'text', 'disp_connecting_line', 'disp_background', 'visible'}

▷ **GenParamValue** (input_control) . . . . . string-array ⇝ *string* / integer / real
Values of the generic parameters.
Default: 'red'
List of values: GenParamValue ∈ {'red', 'green', 'blue', 'window', 'point', 'top_left', 'top', 'top_right', 'left', 'center', 'right', 'bottom_left', 'bottom', 'bottom_right'}

Result

set_scene_3d_label_param returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

add_scene_3d_label

Module

3D Metrology

set_scene_3d_light_param (: : Scene3D, LightIndex, GenParamName, GenParamValue :)

Set parameters of a light in a 3D scene.

set_scene_3d_light_param sets parameters of a light source in the 3D scene Scene3D. The name and value of a parameter must be given in GenParamName and GenParamValue. The following parameters can be set:

'ambient': Ambient part of the light source. Must be given as a tuple of three numbers.
Default: *[0.2, 0.2, 0.2]*.

'diffuse': Diffuse part of the light source. Must be given as a tuple of three numbers.
Default: *[0.8, 0.8, 0.8]*.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **LightIndex** (input_control) . . . . . integer ⇝ *integer*
Index of the light source.

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Names of the generic parameters.
Default: 'ambient'
List of values: GenParamName ∈ {'ambient', 'diffuse'}

▷ **GenParamValue** (input_control) . . . . . string(-array) ⇝ *string* / integer / real
Values of the generic parameters.
Default: [0.2,0.2,0.2]
Suggested values: GenParamValue ∈ {[0.2,0.2,0.2]}

Result

set_scene_3d_light_param returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

add_scene_3d_instance

Module

3D Metrology

set_scene_3d_param (: : Scene3D, GenParamName, GenParamValue :)

Set parameters of a 3D scene.

set_scene_3d_param sets parameters of the 3D scene Scene3D. The name and value of a parameter must be given in GenParamName and GenParamValue.

All parameters that can be set with set_scene_3d_instance_param can be set with set_scene_3d_param for all instances of a scene.

Additionally, the following parameters can be set:

'disp_background': Flag, if the current window content should be used as background.
List of values: *'true'*, *'false'*.
Default: *'false'*.

'colored': Set the colors of all currently added instances to different colors. The value of this parameter defines the number of colors that are used.
List of values: *3*, *6*, *12*.
Default: All objects are displayed white.

'object_index_persistence': Must be set to *'true'* to enable the object index query with `get_display_scene_3d_info`.
List of values: *'true'*, *'false'*.
Default: *'false'*.

'depth_persistence': Must be set to *'true'* to enable the depth query with `get_display_scene_3d_info`.
List of values: *'true'*, *'false'*.
Default: *'false'*.

'quality': Must be set to *'low'* to enable faster rendering without anti aliasing.
List of values: *'low'*, *'high'*.
Default: *'high'*.

'compatibility_mode_enable': Enforce the usage of the fallback mode to OpenGL 1.1.
List of values: *'true'*, *'false'*.
Default: *'false'*.

Parameters

▷ **Scene3D** (input_control) . . . . . scene_3d ⇝ *handle*
Handle of the 3D scene.

▷ **GenParamName** (input_control) . . . . . string ⇝ *string*
Names of the generic parameters.
Default: 'quality'
List of values: `GenParamName` ∈ {'alpha', 'attribute', 'color', 'colored', 'depth_persistence', 'disp_background', 'disp_lines', 'disp_pose', 'disp_normals', 'line_color', 'line_width', 'normal_color', 'object_index_persistence', 'point_size', 'quality', 'compatibility_mode_enable', 'color_attrib', 'color_attrib_start', 'color_attrib_end', 'red_channel_attrib', 'green_channel_attrib', 'blue_channel_attrib', 'rgb_channel_attrib_start', 'rgb_channel_attrib_end', 'lut', 'visible'}

▷ **GenParamValue** (input_control) . . . . . string ⇝ *string* / integer / real
Values of the generic parameters.
Default: 'high'
Suggested values: `GenParamValue` ∈ {'true', 'false', 'high', 'low', 'coord_x', 'coord_y', 'coord_z', 'normal_x', 'normal_y', 'normal_z', 'red', 'green', 'blue', 'auto', 'faces', 'primitive', 'points', 'lines'}

Result

`set_scene_3d_param` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

13.2 Drawing

This chapter describes operators that allow the user to manually draw geometric shapes. They require mouse interaction and in general block the application until the mouse interaction is finished. For non-blocking interactive creation of geometric shapes, HALCON also provides drawing objects with the operators listed in Graphics / Object.

General Objectives

The draw operators draw_region, draw_xld, draw_xld_mod, draw_nurbs, draw_nurbs_mod, draw_nurbs_interp, draw_nurbs_interp_mod, as well as drag_region1, drag_region2 and drag_region3 return iconic objects. All other draw operators return the geometric parameters that are needed to create regions or contours in the respective shape (see table). Most draw operators have a modifying variant that allows the user to specify the initial parameters of the shown shape.

Drawing in Buffer Windows

Because the draw operators rely on mouse interaction, they generally do not work when used with buffer windows (see open_window), so you should use drawing objects instead. Nevertheless some operators (see table) can be used in buffer windows. These operators are controlled through a mouse state. In order to use these operators (and to not cause a deadlock) the application has to provide the mouse state with the operators send_mouse_double_click_event, send_mouse_down_event, send_mouse_drag_event and send_mouse_up_event as well as the state of the modifier keys (also by using send_mouse_drag_event), whereas the draw operators themselves must be run in another thread. While using the draw operator, the image section must not be changed.

Drawing Operators	Output	Generate Object	Works in Buffer Windows
draw_point	Row, Column	gen_cross_contour_xld	yes
draw_line	Row1, Column1, Row2, Column2	gen_contour_polygon_xld	yes
draw_rectangle1	Row1, Column1, Row2, Column2	gen_rectangle1	yes
draw_rectangle2	Row, Column, Phi, Length1, Length2	gen_rectangle2, gen_rectangle2_contour_xld	yes
draw_circle	Row, Column, Radius	gen_circle, gen_circle_contour_xld	yes
draw_ellipse	Row, Column, Phi, Radius1, Radius2	gen_ellipse, gen_ellipse_contour_xld	yes
draw_xld	Contour	-	yes
draw_region	Region	-	yes
draw_polygon	Region	-	yes
draw_nurbs	Contour, Rows, Columns, Weights	-	no
draw_nurbs_interp	Contour, Rows, Columns, Knots, Tangents	-	no
drag_region1	Region	-	no
drag_region2	Region	-	no
drag_region3	Region	-	no

drag_region1 (SourceRegion : DestinationRegion : WindowHandle :)

Interactive moving of a region.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

drag_region1 is used to move a region on the display by mouse. Calling drag_region1 turns the region visible as soon as the left mouse button is pressed. Therefore the region's edges are displayed only. As representation mode the mode 'not' (see set_draw) is used during procedure's permanence. During the movement the cursor resides in the region's barycenter. If you move the mouse with pressed left mouse button, the depicted region follows - delayed - this movement. If you press the right mouse button you terminate drag_region1. The depicted region disappears from the display. Output is a region which corresponds to the last position on the display. You may pass even several regions at once. The operator affine_trans_image moves the gray values.

Attention

Gray values of regions are not moved. With moving the input region it is not sure whether the gray values of the output regions are filled reasonable. This may occur if the gray values of the input regions do not comprise the whole image.

Parameters

- ▷ **SourceRegion** (input_object) ..... region-array ⇝ *object*
  Regions to move.
- ▷ **DestinationRegion** (output_object) ..... region-array ⇝ *object*
  Moved Regions.
- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.

Example

```
draw_region(Obj,WindowHandle)
dev_set_color ('green')
drag_region1(Obj,New,WindowHandle)
dev_display(New)
get_region_runs (Obj, Rows1, ColumnBegins1, ColumnEnds1)
get_region_runs (New, Rows2, ColumnBegins2, ColumnEnds2)
Row1 := Rows1[0]
Column1 := ColumnBegins1[0]
Row2 := Rows2[0]
Column2 := ColumnBegins2[0]
dev_set_color ('white')
gen_arrow_contour_xld (Arrow, Row1,Column1,Row2,Column2, 5, 5)
dev_display (Arrow)
```

Result

drag_region1 returns 2 (H_MSG_TRUE), if a region is entered, the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised. You may determine the behavior after an empty input with set_system(::'no_object_result',<Result>:).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

drag_region2 (SourceRegion : DestinationRegion : WindowHandle, Row, Column :)

Interactive movement of a region with fixpoint specification.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

You use drag_region2 to move a region on the display by mouse. It corresponds to the operator drag_region1 with the difference, that the position of the mouse cursor can be determined.

Attention

Gray values of the regions are not moved. With moving the input region it is not sure whether the gray values of the output regions are filled reasonable. This may occur if the gray values of the input regions do not comprise the whole image.

Parameters

▷ **SourceRegion** (input_object) ..... region-array ⇝ *object*
Regions to move.

▷ **DestinationRegion** (output_object) ..... region-array ⇝ *object*
Moved regions.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (input_control) ..... point.y ⇝ *integer*
Row index of the reference point.
Default: 100
Suggested values: Row ∈ {0, 64, 128, 256, 512}
Value range: 0 ≤ Row ≤ 1024

▷ **Column** (input_control) ..... point.x ⇝ *integer*
Column index of the reference point.
Default: 100
Suggested values: Column ∈ {0, 64, 128, 256, 512}
Value range: 0 ≤ Column ≤ 1024

Result

drag_region2 returns 2 (H_MSG_TRUE), if a region is entered, the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised. You may determine the behavior after an empty input with set_system(::'no_object_result',<Result>:).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

drag_region3 (SourceRegion, MaskRegion : DestinationRegion : WindowHandle, Row, Column :)

Interactive movement of a region with restriction of positions.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

You use drag_region3 to move a region on the display by mouse. It corresponds to the operator drag_region2 with the enhancement, that all points are specified which can be entered by mouse. If you move the mouse outside of this area (MaskRegion), the region on the point with the smallest distance inside MaskRegion will be displayed.

Attention

The region's gray values are not moved. With moving the input region it is not sure whether the gray values of the output regions are filled reasonable. This may occur if the gray values of the input regions do not comprise the whole image.

Parameters

▷ **SourceRegion** (input_object) . . . . . region-array ⇝ *object*
Regions to move.

▷ **MaskRegion** (input_object) . . . . . region-array ⇝ *object*
Points on which it is allowed for a region to move.

▷ **DestinationRegion** (output_object) . . . . . region-array ⇝ *object*
Moved regions.

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (input_control) . . . . . point.y ⇝ *integer*
Row index of the reference point.
Default: 100
Suggested values: Row ∈ {0, 64, 128, 256, 512}
Value range: 0 ≤ Row ≤ 1024

▷ **Column** (input_control) . . . . . point.x ⇝ *integer*
Column index of the reference point.
Default: 100
Suggested values: Column ∈ {0, 64, 128, 256, 512}
Value range: 0 ≤ Column ≤ 1024

Result

drag_region3 returns 2 (H_MSG_TRUE), if a region is entered, if the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised. You may determine the behavior after an empty input with set_system(::'no_object_result',<Result>:).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, get_mposition

Possible Successors

reduce_domain, disp_region, set_colored, set_line_width, set_draw, set_insert, affine_trans_image

Alternatives

get_mposition, move_region, drag_region1, drag_region2

See also

set_insert, set_draw, affine_trans_image

Module

Foundation

draw_circle (: : WindowHandle : Row, Column, Radius)

Interactive drawing of a circle.

draw_circle produces the parameter for a circle created interactive by the user in the window.

To create a circle you have to press the mouse button at the location which is used as the center of that circle. While keeping the mouse button pressed, the Radius's length can be modified through moving the mouse. After another mouse click in the created circle center you can move it. A clicking close to the circular arc you can modify the Radius of the circle. Pressing the right mouse button terminates the procedure. After terminating the procedure the circle is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (output_control) ..... circle.center.y ⇝ *real*
Barycenter's row index.

▷ **Column** (output_control) ..... circle.center.x ⇝ *real*
Barycenter's column index.

▷ **Radius** (output_control) ..... circle.radius ⇝ *real*
Circle's radius.

Example

```
read_image(Image,'monkey')
draw_circle(WindowHandle,Row,Column,Radius)
gen_circle(Circle,Row,Column,Radius)
reduce_domain(Image,Circle,ImageReduced)
invert_image (ImageReduced, ImageInvert)
dev_display (ImageInvert)
```

Result

`draw_circle` returns `2` (`H_MSG_TRUE`) if the window is valid and the needed drawing mode (see `set_insert`) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_circle_mod (: : WindowHandle, RowIn, ColumnIn, RadiusIn : Row, Column, Radius)

Interactive drawing of a circle.

`draw_circle_mod` produces the parameter for a circle created interactive by the user in the window.

To create a circle are expected the coordinates `RowIn` and `ColumnIn` of the center of a circle with radius `RadiusIn`. After another mouse click in the created circle center you can move it. A clicking close to the circular arc you can modify the `Radius` of the circle. Pressing the right mouse button terminates the procedure. After terminating the procedure the circle is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **RowIn** (input_control) ..... circle.center.y ⇝ *real*
Row index of the center.

▷ **ColumnIn** (input_control) ..... circle.center.x ⇝ *real*
Column index of the center.

▷ **RadiusIn** (input_control) ..... circle.radius ⇝ *real*
Radius of the circle.

▷ **Row** (output_control) ..... circle.center.y ⇝ *real*
Row index of the center.

▷ **Column** (output_control) ..... circle.center.x ⇝ *real*
Column index of the center.

▷ **Radius** (output_control) ..... circle.radius ⇝ *real*
Circle's radius.

Example

```
read_image(Image,'monkey')
draw_circle_mod(WindowHandle,20,20,15,Row,Column,Radius)
gen_circle(Circle,Row,Column,Radius)
reduce_domain(Image,Circle,ImageReduced)
invert_image (ImageReduced, ImageInvert)
dev_display (ImageInvert)
```

Result

`draw_circle_mod` returns `2` (`H_MSG_TRUE`) if the window is valid and the needed drawing mode (see `set_insert`) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

Foundation

draw_ellipse (: : WindowHandle : Row, Column, Phi, Radius1, Radius2)

Interactive drawing of an ellipse.

`draw_ellipse` returns the parameter for any orientated ellipse, which has been created interactively by the user in the window.

The created ellipse is described by its center, `Row` and `Column`, its orientation, `Phi`, and its two half axes, `Radius1` and `Radius2`.

To create an ellipse you have to determine the center of the ellipse with the left mouse button. Keeping the button pressed determines the length (Radius1) and the orientation (Phi) of the first half axis. In doing so a temporary default length for the second half axis is assumed, which may be modified afterwards on demand. After another mouse click in the center of the created ellipse you can move it. A mouse click close to a vertex "grips" it to modify the length of the appropriate half axis. You may modify the orientation only, if a vertex of the first half axis is gripped.

Pressing the right mouse button terminates the procedure. After terminating the procedure the ellipse is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Row** (output_control) ..... ellipse.center.y ⇝ *real*
  Row index of the center.
- ▷ **Column** (output_control) ..... ellipse.center.x ⇝ *real*
  Column index of the center.
- ▷ **Phi** (output_control) ..... ellipse.angle.rad ⇝ *real*
  Orientation of the first half axis in radians.
- ▷ **Radius1** (output_control) ..... ellipse.radius1 ⇝ *real*
  First half axis.
- ▷ **Radius2** (output_control) ..... ellipse.radius2 ⇝ *real*
  Second half axis.

Example

```
read_image(Image,'monkey')
draw_ellipse(WindowHandle,Row,Column,Phi,Radius1,Radius2)
gen_ellipse(Ellipse,Row,Column,Phi,Radius1,Radius2)
reduce_domain(Image,Ellipse,GrayEllipse)
sobel_amp(GrayEllipse,Sobel,'sum_abs',3)
dev_display(Sobel)
```

Result

draw_ellipse returns 2 (H_MSG_TRUE), if the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

draw_ellipse_mod (: : WindowHandle, RowIn, ColumnIn, PhiIn, Radius1In, Radius2In : Row, Column, Phi, Radius1, Radius2)

Interactive drawing of an ellipse.

draw_ellipse_mod returns the parameter for any orientated ellipse, which has been created interactively by the user in the window.

The created ellipse is described by its center, its two half axes and the angle between the first half axis and the horizontal coordinate axis.

To create an ellipse are expected the parameters RowIn, ColumnIn,PhiIn,Radius1In,Radius2In. Keeping the button pressed determines the length (Radius1) and the orientation (Phi) of the first half axis. In doing so a temporary default length for the second half axis is assumed, which may be modified afterwards on demand. After another mouse click in the center of the created ellipse you can move it. A mouse click close to a vertex "grips" it to modify the length of the appropriate half axis. You may modify the orientation only, if a vertex of the first half axis is gripped.

Pressing the right mouse button terminates the procedure. After terminating the procedure the ellipse is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **RowIn** (input_control) ..... ellipse.center.y ⇝ *real*
  Row index of the center.
- ▷ **ColumnIn** (input_control) ..... ellipse.center.x ⇝ *real*
  Column index of the center.
- ▷ **PhiIn** (input_control) ..... ellipse.angle.rad ⇝ *real*
  Orientation of the bigger half axis in radians.
- ▷ **Radius1In** (input_control) ..... ellipse.radius1 ⇝ *real*
  Bigger half axis.
- ▷ **Radius2In** (input_control) ..... ellipse.radius2 ⇝ *real*
  Smaller half axis.
- ▷ **Row** (output_control) ..... ellipse.center.y ⇝ *real*
  Row index of the center.
- ▷ **Column** (output_control) ..... ellipse.center.x ⇝ *real*
  Column index of the center.
- ▷ **Phi** (output_control) ..... ellipse.angle.rad ⇝ *real*
  Orientation of the first half axis in radians.
- ▷ **Radius1** (output_control) ..... ellipse.radius1 ⇝ *real*
  First half axis.
- ▷ **Radius2** (output_control) ..... ellipse.radius2 ⇝ *real*
  Second half axis.

Example

```
read_image(Image,'monkey')
draw_ellipse_mod(WindowHandle,RowIn,ColumnIn,PhiIn,Radius1In,Radius2In,\
                 Row,Column,Phi,Radius1,Radius2)
gen_ellipse(Ellipse,Row,Column,Phi,Radius1,Radius2)
reduce_domain(Image,Ellipse,GrayEllipse)
sobel_amp(GrayEllipse,Sobel,'sum_abs',3)
dev_display(Sobel)
```

Result

draw_ellipse_mod returns 2 (H_MSG_TRUE), if the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_line (: : WindowHandle : Row1, Column1, Row2, Column2)

Draw a line.

draw_line returns the parameter for a line, which has been created interactively by the user in the window.

To create a line you have to press the left mouse button determining a start point of the line. While keeping the button pressed you may "drag" the line in any direction. After another mouse click in the middle of the created line you can move it. If you click on one end point of the created line, you may move this point. Pressing the right mouse button terminates the procedure.

After terminating the procedure the line is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row1** (output_control) ..... line.begin.y ⇝ *real*
Row index of the first point of the line.

▷ **Column1** (output_control) ..... line.begin.x ⇝ *real*
Column index of the first point of the line.

▷ **Row2** (output_control) ..... line.end.y ⇝ *real*
Row index of the second point of the line.

▷ **Column2** (output_control) ..... line.end.x ⇝ *real*
Column index of the second point of the line.

Example

```
draw_line(WindowHandle,Row1,Column1,Row2,Column2)
gen_contour_polygon_xld (Line, [Row1,Row2], [Column1,Column2])
dev_display (Line)
```

Result

draw_line returns 2 (H_MSG_TRUE), if the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_line_mod (: : WindowHandle, Row1In, Column1In, Row2In, Column2In : Row1, Column1, Row2, Column2)

Draw a line.

draw_line_mod returns the parameter for a line, which has been created interactively by the user in the window.

To create a line are expected the coordinates of the start point Row1In, Column1In and of the end point Row2In,Column2In. If you click on one end point of the created line, you may move this point. After another mouse click in the middle of the created line you can move it.

Pressing the right mouse button terminates the procedure.

After terminating the procedure the line is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row1In** (input_control) ..... line.begin.y ⇝ *real*
Row index of the first point of the line.

▷ **Column1In** (input_control) ..... line.begin.x ⇝ *real*
Column index of the first point of the line.

▷ **Row2In** (input_control) ..... line.end.y ⇝ *real*
Row index of the second point of the line.

▷ **Column2In** (input_control) ..... line.end.x ⇝ *real*
Column index of the second point of the line.

▷ **Row1** (output_control) ..... line.begin.y ⇝ *real*
Row index of the first point of the line.

▷ **Column1** (output_control) ..... line.begin.x ⇝ *real*
Column index of the first point of the line.

▷ **Row2** (output_control) ..... line.end.y ⇝ *real*
Row index of the second point of the line.

▷ **Column2** (output_control) ..... line.end.x ⇝ *real*
Column index of the second point of the line.

Example

```
draw_line_mod(WindowHandle,10,20,55,124,Row1,Column1,Row2,Column2)
gen_contour_polygon_xld (Line, [Row1,Row2], [Column1,Column2])
dev_display (Line)
```

Result

draw_line_mod returns 2 (H_MSG_TRUE), if the window is valid and the needed drawing mode is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_nurbs (: ContOut : WindowHandle, Rotate, Move, Scale, KeepRatio, Degree : Rows, Cols, Weights)

Interactive drawing of a NURBS curve.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

draw_nurbs returns the contour ContOut and control information (Rows, Cols, and Weights) of a NURBS curve of degree Degree, which has been created interactively by the user in the window WindowHandle. For additional information concerning NURBS curves, see the documentation of gen_contour_nurbs_xld. To use the control information Rows, Cols, and Weights in a subsequent call to the operator gen_contour_nurbs_xld, the knot vector Knots should be set to *'auto'*.

The NURBS curve is created and manipulated by the means of its control polygon. By contrast, using the operator draw_nurbs_interp, it is possible to create a NURBS curve that interpolates points specified by the user. Directly after calling draw_nurbs, you can add control points by clicking with the left mouse button in the window at the desired positions.

When there are three control points or more, the first and the last point will be marked with an additional square. By clicking on them you can close the curve or open it again. You delete the point appended last by pressing the Ctrl key.

As soon as the number of control points exceeds Degree, the NURBS curve given by the specified control polygon and weight vector is displayed in addition to the control polygon.

The control point which was handled last is surrounded by a circle representing its weight. By simply dragging the circle you can increase or decrease the weight of this control point.

Existing control points can be moved by dragging them with the mouse. Further new points on the control polygon (to refine the control polygon) can be inserted by a left click on the desired position on the control polygon.

By pressing the Shift key, you can switch into the transformation mode. In this mode you can rotate, move, and scale the contour as a whole, but only if you set the parameters Rotate, Move, and Scale, respectively, to *'true'*. Instead of the pick points and the control polygon, 3 symbols are displayed with the contour: a cross in the middle and an arrow to the right if Rotate is set to *'true'*, and a double-headed arrow to the upper right if Scale is set to *'true'*.

You can

- move the curve by clicking the left mouse button on the cross in the center and then dragging it to the new position,

- rotate it by clicking with the left mouse button on the arrow and then dragging it, till the curve has the right direction, and
- scale it by dragging the double arrow. To keep the ratio the parameter `KeepRatio` has to be set to *'true'*.

By pressing the Shift key again you can switch back to the edit mode. Pressing the right mouse button terminates the procedure.

The appearance of the curve while drawing is determined by the line width, size, and color set via the operators `set_color`, `set_colored`, `set_line_width`, and `set_line_style`. The control polygon and all handles are displayed in the second color set by `set_color` or `set_colored`. Their line width is fixed to 1 and their line style is fixed to a drawn-through line.

Parameters

▷ **`ContOut`** (output_object) . . . . . xld_cont ⇝ *object*
Contour approximating the NURBS curve.

▷ **`WindowHandle`** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **`Rotate`** (input_control) . . . . . string ⇝ *string*
Enable rotation?
Default: 'true'
List of values: `Rotate` ∈ {'true', 'false'}

▷ **`Move`** (input_control) . . . . . string ⇝ *string*
Enable moving?
Default: 'true'
List of values: `Move` ∈ {'true', 'false'}

▷ **`Scale`** (input_control) . . . . . string ⇝ *string*
Enable scaling?
Default: 'true'
List of values: `Scale` ∈ {'true', 'false'}

▷ **`KeepRatio`** (input_control) . . . . . string ⇝ *string*
Keep ratio while scaling?
Default: 'true'
List of values: `KeepRatio` ∈ {'true', 'false'}

▷ **`Degree`** (input_control) . . . . . integer ⇝ *integer*
The degree p of the NURBS curve. Reasonable values are 3 to 25.
Default: 3
Suggested values: `Degree` ∈ {2, 3, 4, 5}
Restriction: Degree >= 2

▷ **`Rows`** (output_control) . . . . . coordinates.y-array ⇝ *real*
Row coordinates of the control polygon.

▷ **`Cols`** (output_control) . . . . . coordinates.x-array ⇝ *real*
Columns coordinates of the control polygon.

▷ **`Weights`** (output_control) . . . . . real-array ⇝ *real*
Weight vector.

Result

`draw_nurbs` returns `2` (`H_MSG_TRUE`), if the window is valid. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

Possible Successors

`set_colored`, `set_line_width`, `set_draw`, `set_insert`

Module

Foundation

draw_nurbs_interp (: ContOut : WindowHandle, Rotate, Move, Scale, KeepRatio, Degree : ControlRows, ControlCols, Knots, Rows, Cols, Tangents)

Interactive drawing of a NURBS curve using interpolation.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

draw_nurbs_interp returns the contour ContOut of a NURBS curve of degree Degree, which has been created interactively by the user in the window WindowHandle using interpolation. That means, that the user specifies a set of points and the operator computes the parameters of a NURBS curve that includes this points. By contrast, using the Operator draw_nurbs it is possible to create a NURBS curve by drawing its control polygon.

In addition to ContOut, the control information of the curve (ControlRows, ControlCols, and Knots), the interpolation points (Rows, Cols) specified by the user and the tangents at the first and the last point (Tangents) are returned. Tangents consists of four values. The first two values correspond to the y (row) and the x (column) value of the tangent at the start of the curve and the second two values to the tangent at the end of the curve, respectively.

The weight vector is not returned because it consists of equal entries. As a consequence, one can use *'auto'* as weight vector if the control information is used in a subsequent call to the operator gen_contour_nurbs_xld. For more information on NURBS see the documentation of gen_contour_nurbs_xld.

Directly after calling draw_nurbs_interp, you can add interpolation points by clicking with the left mouse button in the window at the desired positions. If enough points are specified (at least Degree $-$ 1), a NURBS curve that goes through all specified points (in the order of their generation) is computed and displayed.

When there are three points or more, the first and the last point will be marked with an additional square. By clicking on them you can close the curve or open it again. You delete the point appended last by pressing the Ctrl key.

The tangents (i.e. the first derivative of the curve) of the first and the last point are displayed as lines. They can be modified by dragging their ends using the mouse.

Existing points can be moved by dragging them with the mouse. Further new points on the curve can be inserted by a left click on the desired position on the curve.

By pressing the Shift key, you can switch into the transformation mode. In this mode you can rotate, move, and scale the curve as a whole, but only if you set the parameters Rotate, Move, and Scale, respectively, to *'true'*. Instead of the pick points and the two tangents, 3 symbols are displayed with the curve: a cross in the middle and an arrow to the right if Rotate is set to *'true'*, and a double-headed arrow to the upper right if Scale is set to *'true'*.

You can

- move the curve by clicking the left mouse button on the cross in the center and then dragging it to the new position,
- rotate it by clicking with the left mouse button on the arrow and then dragging it, till the curve has the right direction, and
- scale it by dragging the double arrow. To keep the ratio, the parameter KeepRatio has to be set to *'true'*.

By pressing the Shift key again you can switch back to the edit mode. Pressing the right mouse button terminates the procedure.

The appearance of the curve while drawing is determined by the line width, size, and color set via the operators set_color, set_colored, set_line_width, and set_line_style. The tangents and all handles are

displayed in the second color set by set_color or set_colored. Their line width is fixed to 1 and their line style is fixed to a drawn-through line.

Attention

In contrast to draw_nurbs, each point specified by the user influences the whole curve. Thus, if one point is moved, the whole curve can and will change. To minimize this effects, it is recommended to use a small degree (3-5) and to place the points such that they are approximately equally spaced. In general, uneven degrees will perform slightly better than even degrees.

Parameters

- ▷ **ContOut** (output_object) . . . . . xld_cont ⇝ *object*
  Contour of the curve.
- ▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
  Window handle.
- ▷ **Rotate** (input_control) . . . . . string ⇝ *string*
  Enable rotation?
  Default: 'true'
  List of values: Rotate ∈ {'true', 'false'}
- ▷ **Move** (input_control) . . . . . string ⇝ *string*
  Enable moving?
  Default: 'true'
  List of values: Move ∈ {'true', 'false'}
- ▷ **Scale** (input_control) . . . . . string ⇝ *string*
  Enable scaling?
  Default: 'true'
  List of values: Scale ∈ {'true', 'false'}
- ▷ **KeepRatio** (input_control) . . . . . string ⇝ *string*
  Keep ratio while scaling?
  Default: 'true'
  List of values: KeepRatio ∈ {'true', 'false'}
- ▷ **Degree** (input_control) . . . . . integer ⇝ *integer*
  The degree p of the NURBS curve. Reasonable values are 3 to 5.
  Default: 3
  Suggested values: Degree ∈ {2, 3, 4, 5}
  Restriction: Degree >= 2 && Degree <= 9
- ▷ **ControlRows** (output_control) . . . . . coordinates.y-array ⇝ *real*
  Row coordinates of the control polygon.
- ▷ **ControlCols** (output_control) . . . . . coordinates.x-array ⇝ *real*
  Column coordinates of the control polygon.
- ▷ **Knots** (output_control) . . . . . real-array ⇝ *real*
  Knot vector.
- ▷ **Rows** (output_control) . . . . . coordinates.y-array ⇝ *real*
  Row coordinates of the points specified by the user.
- ▷ **Cols** (output_control) . . . . . coordinates.x-array ⇝ *real*
  Column coordinates of the points specified by the user.
- ▷ **Tangents** (output_control) . . . . . real-array ⇝ *real*
  Tangents specified by the user.

Result

draw_nurbs_interp returns 2 (H_MSG_TRUE), if the window is valid. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

```
draw_nurbs_interp_mod ( : ContOut : WindowHandle, Rotate, Move,
    Scale, KeepRatio, Edit, Degree, RowsIn, ColsIn,
    TangentsIn : ControlRows, ControlCols, Knots, Rows, Cols,
    Tangents )
```

Interactive modification of a NURBS curve using interpolation.

This operator does not work in an HDevelop graphics window opened with `dev_open_window`.

draw_nurbs_interp_mod returns the contour ContOut of a NURBS curve of degree Degree, which has been modified interactively by the user in the window WindowHandle.

In addition to ContOut the control information of the curve (ControlRows, ControlCols, and Knots), the interpolation points (Rows, Cols) specified by the user and the tangents at the first and the last point (Tangents) are returned. Tangents consists of four values. The first two values correspond to the y (row) and the x (column) value of the tangent at the start of the curve and the second two values to the tangent at the end of the curve, respectively.

The weight vector is not returned because it consists of equal entries. As a consequence one can use *'auto'* as weight vector, if the control information is used in a subsequent call to the operator gen_contour_nurbs_xld. For more information on NURBS see the documentation of gen_contour_nurbs_xld.

The input curve is specified by the interpolation points (RowsIn, ColsIn), its degree Degree and the tangents TangentsIn, such that draw_nurbs_interp_mod can be applied to the output data of draw_nurbs_interp.

You can modify the curve in two ways: by editing the interpolation points, e.g., by inserting or moving points, or by transforming the curve as a whole, e.g., by rotating moving or scaling it. Note that you can only edit the curve if Edit is set to *'true'*. Similarly, you can only rotate, move or scale it if Rotate, Move, and Scale, respectively, are set to *'true'*.

draw_nurbs_interp_mod starts in the transformation mode. In this mode, the curve is displayed together with 3 symbols: a cross in the middle and an arrow to the right if Rotate is set to *'true'*, and a double-headed arrow to the upper right if Scale is set to *'true'*. To switch into the edit mode, press the Shift key; by pressing it again, you can switch back into the transformation mode.

Transformation Mode

In this mode a NURBS curve can be rotated, moved and scaled, as long as the respective parameter Rotate, Move and Scale are set to *'true'*. The NURBS curve is displayed along with a cross in its center, an arrow pointing to the right (if Rotate is set to *'true'*), and a double arrow (if Scale is set to *'true'*).

- To move the curve, click with the left mouse button on the cross in the center and then drag it to the new position, i.e., keep the mouse button pressed while moving the mouse.
- To rotate it, click with the left mouse button on the arrow and then drag it, till the curve has the right direction.
- Scaling is achieved by dragging the double arrow. To keep the ratio, the parameter KeepRatio has to be set to *'true'*.

Edit Mode

In this mode, the curve is displayed together with its interpolation points and the start and end tangent. Start and end point are marked by an additional square. You can perform the following modifications:

- To append new points, click with the left mouse button in the window and a new point is added at this position.

- You can delete the point appended last by pressing the Ctrl key.
- To move a point, drag it with the mouse.
- To insert a point on the curve, click on the desired position on the curve.
- To close respectively open the curve, click on the first or on the last point.

Pressing the right mouse button terminates the procedure.

The appearance of the curve while drawing is determined by the line width, size and color set via the operators `set_color`, `set_colored`, `set_line_width`, and `set_line_style`. The tangents and all handles are displayed in the second color set by `set_color` or `set_colored`. Their line width is fixed to 1 and their line style is fixed to a drawn-through line.

Attention

In contrast to `draw_nurbs`, each point specified by the user influences the whole curve. Thus, if one point is moved, the whole curve can and will change. To minimize this effects, it is recommended to use a small degree (3-5) and to place the points such that they are approximately equally spaced. In general, uneven degrees will perform slightly better than even degrees.

Parameters

▷ **ContOut** (output_object) ..... xld_cont ⇝ *object*
Contour of the modified curve.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Rotate** (input_control) ..... string ⇝ *string*
Enable rotation?
Default: 'true'
List of values: `Rotate` ∈ {'true', 'false'}

▷ **Move** (input_control) ..... string ⇝ *string*
Enable moving?
Default: 'true'
List of values: `Move` ∈ {'true', 'false'}

▷ **Scale** (input_control) ..... string ⇝ *string*
Enable scaling?
Default: 'true'
List of values: `Scale` ∈ {'true', 'false'}

▷ **KeepRatio** (input_control) ..... string ⇝ *string*
Keep ratio while scaling?
Default: 'true'
List of values: `KeepRatio` ∈ {'true', 'false'}

▷ **Edit** (input_control) ..... string ⇝ *string*
Enable editing?
Default: 'true'
List of values: `Edit` ∈ {'true', 'false'}

▷ **Degree** (input_control) ..... integer ⇝ *integer*
The degree p of the NURBS curve. Reasonable values are 3 to 5.
Default: 3
Suggested values: `Degree` ∈ {2, 3, 4, 5}
Restriction: Degree >= 2 && Degree <= 9

▷ **RowsIn** (input_control) ..... coordinates.y-array ⇝ *real*
Row coordinates of the input interpolation points.

▷ **ColsIn** (input_control) ..... coordinates.x-array ⇝ *real*
Column coordinates of the input interpolation points.

▷ **TangentsIn** (input_control) ..... real-array ⇝ *real*
Input tangents.

▷ **ControlRows** (output_control) ..... coordinates.y-array ⇝ *real*
Row coordinates of the control polygon.

▷ **ControlCols** (output_control) ..... coordinates.x-array ⇝ *real*
Column coordinates of the control polygon.

▷ **Knots** (output_control) . . . . . real-array ⇝ *real*
Knot vector.
▷ **Rows** (output_control) . . . . . coordinates.y-array ⇝ *real*
Row coordinates of the points specified by the user.
▷ **Cols** (output_control) . . . . . coordinates.x-array ⇝ *real*
Column coordinates of the points specified by the user.
▷ **Tangents** (output_control) . . . . . real-array ⇝ *real*
Tangents specified by the user.

Result

`draw_nurbs_interp_mod` returns `2` (`H_MSG_TRUE`), if the window is valid. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_nurbs_mod (: ContOut : WindowHandle, Rotate, Move, Scale, KeepRatio, Edit, Degree, RowsIn, ColsIn, WeightsIn : Rows, Cols, Weights)

Interactive modification of a NURBS curve.

This operator does not work in an HDevelop graphics window opened with `dev_open_window`.

`draw_nurbs_mod` returns the contour `ContOut` and control information (`Rows`, `Cols`, and `Weights`) of a NURBS curve of degree `Degree`, which has been interactively modified by the user in the window `WindowHandle`. For additional information concerning NURBS curves, see the documentation of `gen_contour_nurbs_xld`. To use the control information `Rows`, `Cols`, and `Weights` in a subsequent call to the operator `gen_contour_nurbs_xld`, the knot vector `Knots` should be set to *'auto'*.

The input NURBS curve is specified by its control polygon (`RowsIn`, `ColsIn`), its weight vector `WeightsIn` and its degree `Degree`. The knot vector is assumed to be uniform (i.e. *'auto'* in `gen_contour_nurbs_xld`).

You can modify the curve in two ways: by editing the control polygon, e.g., by inserting or moving control points, or by transforming the contour as a whole, e.g., by rotating moving or scaling it. Note that you can only edit the control polygon if `Edit` is set to *'true'*. Similarly, you can only rotate, move or scale it if `Rotate`, `Move`, and `Scale`, respectively, are set to *'true'*.

`draw_nurbs_mod` starts in the transformation mode. In this mode, the curve is displayed together with 3 symbols: a cross in the middle and an arrow to the right if `Rotate` is set to *'true'*, and a double-headed arrow to the upper right if `Scale` is set to *'true'*. To switch into the edit mode, press the Shift key; by pressing it again, you can switch back into the transformation mode.

Transformation Mode

In this mode a curve can be rotated, moved and scaled, as long as the respective parameter `Rotate`, `Move` and `Scale` are set to *'true'*. The curve is displayed along with a cross in its center, an arrow pointing to the right (if `Rotate` is set to *'true'*), and a double arrow (if `Scale` is set to *'true'*).

- To move the curve, click with the left mouse button on the cross in the center and then drag it to the new position, i.e., keep the mouse button pressed while moving the mouse.
- To rotate it, click with the left mouse button on the arrow and then drag it, till the curve has the right direction.
- Scaling is achieved by dragging the double arrow. To keep the ratio, the parameter `KeepRatio` has to be set to *'true'*.

Edit Mode

In this mode, the curve is displayed together with its control polygon. Start and end point are marked by an additional square and the point which was handled last is surrounded by a circle representing its weight. You can perform the following modifications:

- To append control points, click with the left mouse button in the window and a new point is added at this position.
- You can delete the point appended last by pressing the Ctrl key.
- To move a point, drag it with the mouse.
- To insert a point on the control polygon, click on the desired position on the polygon.
- To close respectively open the curve, click on the first or on the last control point.
- You can modify the weight of a control point by first clicking on the point itself (if it is not already the point which was modified or created last) and then dragging the circle around the point.

Pressing the right mouse button terminates the procedure.

The appearance of the curve while drawing is determined by the line width, size and color set via the operators `set_color`, `set_colored`, `set_line_width`, and `set_line_style`. The control polygon and all handles are displayed in the second color set by `set_color` or `set_colored`. Their line width is fixed to 1 and their line style is fixed to a drawn-through line.

Parameters

▷ **`ContOut`** (output_object) ..... xld_cont ⇝ *object*
Contour of the modified curve.

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **`Rotate`** (input_control) ..... string ⇝ *string*
Enable rotation?
Default: 'true'
List of values: `Rotate` ∈ {'true', 'false'}

▷ **`Move`** (input_control) ..... string ⇝ *string*
Enable moving?
Default: 'true'
List of values: `Move` ∈ {'true', 'false'}

▷ **`Scale`** (input_control) ..... string ⇝ *string*
Enable scaling?
Default: 'true'
List of values: `Scale` ∈ {'true', 'false'}

▷ **`KeepRatio`** (input_control) ..... string ⇝ *string*
Keep ratio while scaling?
Default: 'true'
List of values: `KeepRatio` ∈ {'true', 'false'}

▷ **`Edit`** (input_control) ..... string ⇝ *string*
Enable editing?
Default: 'true'
List of values: `Edit` ∈ {'true', 'false'}

▷ **`Degree`** (input_control) ..... integer ⇝ *integer*
The degree p of the NURBS curve. Reasonable values are 3 to 25.
Default: 3
Suggested values: `Degree` ∈ {2, 3, 4, 5}
Restriction: Degree >= 2

▷ **RowsIn** (input_control) ..... coordinates.y-array ⇝ *real*
Row coordinates of the input control polygon.

▷ **ColsIn** (input_control) ..... coordinates.x-array ⇝ *real*
Column coordinates of the input control polygon.

▷ **WeightsIn** (input_control) ..... real-array ⇝ *real*
Input weight vector.

▷ **Rows** (output_control) ..... coordinates.y-array ⇝ *real*
Row coordinates of the control polygon.

▷ **Cols** (output_control) ..... coordinates.x-array ⇝ *real*
Columns coordinates of the control polygon.

▷ **Weights** (output_control) ..... real-array ⇝ *real*
Weight vector.

Result

`draw_nurbs_mod` returns `2` (`H_MSG_TRUE`), if the window is valid. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`draw_nurbs`, `draw_nurbs_interp`, `gen_contour_nurbs_xld`

Module

Foundation

draw_point (: : WindowHandle : Row, Column)

Draw a point.

`draw_point` returns the parameter for a point, which has been created interactively by the user in the window.

To create a point you have to press the left mouse button. While keeping the button pressed you may “drag” the point in any direction. Pressing the right mouse button terminates the procedure.

After terminating the procedure the point is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (output_control) ..... point.y ⇝ *real*
Row index of the point.

▷ **Column** (output_control) ..... point.x ⇝ *real*
Column index of the point.

Example

```
draw_point(WindowHandle,Row,Column)
gen_cross_contour_xld (Cross, Row, Column, 6, 0)
```

Result

`draw_point` returns `2` (`H_MSG_TRUE`), if the window is valid and the needed drawing mode is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_point_mod (: : WindowHandle, RowIn, ColumnIn : Row, Column)

Draw a point.

`draw_point_mod` returns the parameter for a point, which has been created interactively by the user in the window.

To create a point are expected the coordinates `RowIn` and `ColumnIn`. While keeping the button pressed you may "drag" the point in any direction. Pressing the right mouse button terminates the procedure.

After terminating the procedure the point is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **RowIn** (input_control) ..... point.y ⇝ *real*
  Row index of the point.
- ▷ **ColumnIn** (input_control) ..... point.x ⇝ *real*
  Column index of the point.
- ▷ **Row** (output_control) ..... point.y ⇝ *real*
  Row index of the point.
- ▷ **Column** (output_control) ..... point.x ⇝ *real*
  Column index of the point.

Example

```
draw_point_mod (WindowHandle, 100, 100, Row,Column)
gen_cross_contour_xld (Cross, Row, Column, 6, 0)
```

Result

draw_point_mod returns 2 (H_MSG_TRUE), if the window is valid and the needed drawing mode is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

See also

draw_point, draw_circle, draw_ellipse, set_insert

Module

Foundation

draw_polygon (: PolygonRegion : WindowHandle :)

Interactive drawing of a polygon row.

draw_polygon produces an image. The region of that image spans exactly the image points entered interactively by mouse clicks (gray values remain undefined).

Painting in the output window happens while pressing the left mouse button. Releasing the left mouse button and repressing it at another position effects drawing a line between these two points. Pressing the right mouse button terminates the input. Painting uses that color which has been set by set_color, set_rgb, etc. .

To put gray values on the created PolygonRegion for further processing, you may use the operator reduce_domain.

Attention

The painted contour is not closed automatically, in particular it is not "filled up" either.

Output object's gray values are not defined.

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **PolygonRegion** (output_object) ..... region ⇝ *object*
Region, which encompasses all painted points.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

Example

```
draw_polygon(Polygon,WindowHandle)
shape_trans(Polygon,Filled,'convex')
dev_display (Filled)
```

Result

If the window is valid, draw_polygon returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Predecessors

open_window

Possible Successors

reduce_domain, disp_region, set_colored, set_line_width, set_draw

Alternatives

See also

reduce_domain, fill_up, set_color

Module

Foundation

draw_rectangle1 (: : WindowHandle : Row1, Column1, Row2, Column2)

Draw a rectangle parallel to the coordinate axis.

draw_rectangle1 returns the parameter for a rectangle parallel to the coordinate axes, which has been created interactively by the user in the window.

To create a rectangle you have to press the left mouse button determining a corner of the rectangle. While keeping the button pressed you may "drag" the rectangle in any direction. After another mouse click in the middle of the created rectangle you can move it. A click close to one side "grips" it to modify the rectangle's dimension in perpendicular direction to this side. If you click on one corner of the created rectangle, you may move this corner. Pressing the right mouse button terminates the procedure.

After terminating the procedure the rectangle is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Row1** (output_control) ..... rectangle.origin.y ⇝ *real*
  Row index of the left upper corner.
- ▷ **Column1** (output_control) ..... rectangle.origin.x ⇝ *real*
  Column index of the left upper corner.
- ▷ **Row2** (output_control) ..... rectangle.corner.y ⇝ *real*
  Row index of the right lower corner.
- ▷ **Column2** (output_control) ..... rectangle.corner.x ⇝ *real*
  Column index of the right lower corner.

Example

```
read_image(Image,'monkey')
get_image_size (Image, Width, Height)
dev_display (Image)
draw_rectangle1(WindowHandle,Row1,Column1,Row2,Column2)
dev_set_part (Row1, Column1, Row2, Column2)
dev_display (Image)
```

Result

draw_rectangle1 returns 2 (H_MSG_TRUE), if the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

draw_rectangle1_mod (: : WindowHandle, Row1In, Column1In, Row2In, Column2In : Row1, Column1, Row2, Column2)

Draw a rectangle parallel to the coordinate axis.

draw_rectangle1_mod returns the parameter for a rectangle parallel to the coordinate axes, which has been created interactively by the user in the window.

To create a rectangle are expected the parameters Row1In, Column1In,Row2In and Column2In. After a mouse click in the middle of the created rectangle you can move it. A click close to one side "grips" it to modify the rectangle's dimension in perpendicular direction to this side. If you click on one corner of the created rectangle, you may move this corner. Pressing the right mouse button terminates the procedure.

After terminating the procedure the rectangle is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row1In** (input_control) ..... rectangle.origin.y ⇝ *real*
Row index of the left upper corner.

▷ **Column1In** (input_control) ..... rectangle.origin.x ⇝ *real*
Column index of the left upper corner.

▷ **Row2In** (input_control) ..... rectangle.corner.y ⇝ *real*
Row index of the right lower corner.

▷ **Column2In** (input_control) ..... rectangle.corner.x ⇝ *real*
Column index of the right lower corner.

▷ **Row1** (output_control) ..... rectangle.origin.y ⇝ *real*
Row index of the left upper corner.

▷ **Column1** (output_control) ..... rectangle.origin.x ⇝ *real*
Column index of the left upper corner.

▷ **Row2** (output_control) ..... rectangle.corner.y ⇝ *real*
Row index of the right lower corner.

▷ **Column2** (output_control) ..... rectangle.corner.x ⇝ *real*
Column index of the right lower corner.

Example

```
read_image(Image,'monkey')
get_image_size (Image, Width, Height)
```

```
dev_display (Image)
draw_rectangle1_mod(WindowHandle,100,100,200,300,\
                    Row1,Column1,Row2,Column2)
dev_set_part (Row1, Column1, Row2, Column2)
dev_display (Image)
```

Result

`draw_rectangle1_mod` returns `2` (`H_MSG_TRUE`), if the window is valid and the needed drawing mode (see `set_insert`) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

draw_rectangle2 (: : WindowHandle : Row, Column, Phi, Length1, Length2)

Interactive drawing of any orientated rectangle.

`draw_rectangle2` returns the parameter for any orientated rectangle, which has been created interactively by the user in the window.

The created rectangle is described by its center, its two half axes and the angle between the first half axis and the horizontal coordinate axis.

To create a rectangle you have to press the left mouse button for the center of the rectangle. While keeping the button pressed you may dimension the length (`Length1`) and the orientation (`Phi`) of the first half axis. In doing so a temporary default length for the second half axis is assumed, which may be modified afterwards on demand. After another mouse click in the middle of the created rectangle, you can move it. A click close to one side "grips" it to modify the rectangle's dimension in perpendicular direction to this side. You only can modify the orientation, if you grip a side perpendicular to the first half axis. Pressing the right mouse button terminates the procedure.

After terminating the procedure the rectangle is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (output_control) ..... rectangle2.center.y ⇝ *real*
Row index of the center.

▷ **Column** (output_control) ..... rectangle2.center.x ⇝ *real*
Column index of the center.

▷ **Phi** (output_control) . . . . . rectangle2.angle.rad ⇝ *real*
Orientation of the bigger half axis in radians.
▷ **Length1** (output_control) . . . . . rectangle2.hwidth ⇝ *real*
Bigger half axis.
▷ **Length2** (output_control) . . . . . rectangle2.hheight ⇝ *real*
Smaller half axis.

Result

`draw_rectangle2` returns `2` (`H_MSG_TRUE`), if the window is valid and the needed drawing mode (see `set_insert`) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_rectangle2_mod (: : WindowHandle, RowIn, ColumnIn, PhiIn, Length1In, Length2In : Row, Column, Phi, Length1, Length2)

Interactive drawing of any orientated rectangle.

`draw_rectangle2_mod` returns the parameter for any orientated rectangle, which has been created interactively by the user in the window.

The created rectangle is described by its center, its two half axes and the angle between the first half axis and the horizontal coordinate axis.

To create a rectangle are expected the parameters `RowIn`, `ColumnIn`,`PhiIn`,`Length1In`,`Length2In`. A click close to one side "grips" it to modify the rectangle's dimension in perpendicular direction (`Length2`) to this side. You only can modify the orientation (`Phi`), if you grip a side perpendicular to the first half axis. After another mouse click in the middle of the created rectangle, you can move it. Pressing the right mouse button terminates the procedure.

After terminating the procedure the rectangle is not visible in the window any longer.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.
▷ **RowIn** (input_control) . . . . . rectangle2.center.y ⇝ *real*
Row index of the center.
▷ **ColumnIn** (input_control) . . . . . rectangle2.center.x ⇝ *real*
Column index of the center.
▷ **PhiIn** (input_control) . . . . . rectangle2.angle.rad ⇝ *real*
Orientation of the bigger half axis in radians.

▷ **Length1In** (input_control) . . . . . rectangle2.hwidth ⇝ *real*
Bigger half axis.

▷ **Length2In** (input_control) . . . . . rectangle2.hheight ⇝ *real*
Smaller half axis.

▷ **Row** (output_control) . . . . . rectangle2.center.y ⇝ *real*
Row index of the center.

▷ **Column** (output_control) . . . . . rectangle2.center.x ⇝ *real*
Column index of the center.

▷ **Phi** (output_control) . . . . . rectangle2.angle.rad ⇝ *real*
Orientation of the bigger half axis in radians.

▷ **Length1** (output_control) . . . . . rectangle2.hwidth ⇝ *real*
Bigger half axis.

▷ **Length2** (output_control) . . . . . rectangle2.hheight ⇝ *real*
Smaller half axis.

Result

`draw_rectangle2_mod` returns `2` (`H_MSG_TRUE`), if the window is valid and the needed drawing mode (see `set_insert`) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

draw_region (: Region : WindowHandle :)

Interactive drawing of a closed region.

`draw_region` produces an image. The region of that image spans exactly the image region entered interactively by mouse clicks (gray values remain undefined). Painting happens in the output window while keeping the left mouse button pressed. The left mouse button even operates by clicking in the output window; through this a line between the previous clicked points is drawn. Clicking the right mouse button terminates input and closes the outline. Subsequently the image is “filled up”. Also it contains the whole image area enclosed by the mouse.

Painting uses that color which has been set by `set_color`, `set_rgb`, etc. .

Pressing the right mouse button terminates the procedure.

Attention

The output object’s gray values are not defined.

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **Region** (output_object) ..... region ⇝ *object*
Interactive created region.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

Example

```
read_image(Image,'fabrik')
dev_display (Image)
draw_region(Region,WindowHandle)
reduce_domain(Image,Region,ImageReduced)
invert_image (ImageReduced, ImageInvert)
dev_display (ImageInvert)
```

Result

If the window is valid, `draw_region` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

Possible Successors

Module

Foundation

draw_xld (: ContOut : WindowHandle, Rotate, Move, Scale, KeepRatio :)

Interactive drawing of a contour.

`draw_xld` returns a contour, which has been created interactively by the user in the window.

Directly after calling `draw_xld` you can add contour points by clicking with the left mouse button in the window at the desired positions. You delete the point appended last by pressing the Ctrl key. As soon as you add three contour points, 5 so-called pick points are displayed, one in the middle and 4 at the corners of the surrounding rectangle. By clicking on a pick point you can close the contour or open it again. If the contour is closed, the pick points are displayed in form of squares, otherwise they are shaped like a 'u'.

If the contour is closed you can

- move contour points by clicking with the left mouse button on a point marked by a rectangle and keep the mouse button pressed while moving the mouse,
- insert contour points by clicking with the left mouse button in the vicinity of a line and then move the mouse to the position where you want the new point to be placed, and
- delete contour points by selecting the point which should be deleted with the left mouse button and then press the Ctrl key.

By pressing the Shift key, you can switch into the transformation mode. In this mode you can rotate, move, and scale the contour as a whole, but only if you set the parameters `Rotate`, `Move`, and `Scale`, respectively, to *'true'*. Instead of the pick points, 3 symbols are displayed with the contour: a cross in the middle and an arrow to the right if `Rotate` is set to *'true'*, and a double-headed arrow to the upper right if `Scale` is set to *'true'*.

You can

- move the contour by clicking the left mouse button on the cross in the center and then dragging it to the new position,
- rotate it by clicking with the left mouse button on the arrow and then dragging it, till the contour has the right direction, and
- scale it by dragging the double arrow. To keep the ratio the parameter `KeepRatio` has to be set to *'true'*.

Pressing the right mouse button terminates the procedure.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **`ContOut`** (output_object) ..... xld_cont ⇝ *object*
Modified contour.

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **`Rotate`** (input_control) ..... string ⇝ *string*
Enable rotation?
Default: 'true'
List of values: `Rotate` ∈ {'true', 'false'}

▷ **`Move`** (input_control) ..... string ⇝ *string*
Enable moving?
Default: 'true'
List of values: `Move` ∈ {'true', 'false'}

▷ **`Scale`** (input_control) ..... string ⇝ *string*
Enable scaling?
Default: 'true'
List of values: `Scale` ∈ {'true', 'false'}

▷ **`KeepRatio`** (input_control) ..... string ⇝ *string*
Keep ratio while scaling?
Default: 'true'
List of values: `KeepRatio` ∈ {'true', 'false'}

Result

`draw_xld` returns `2` (`H_MSG_TRUE`), if the window is valid and the needed drawing mode (see `set_insert`) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

draw_xld_mod (ContIn : ContOut : WindowHandle, Rotate, Move, Scale, KeepRatio, Edit :)

Interactive modification of a contour.

draw_xld_mod returns a contour, which has been interactively modified by the user in the window.

You can modify the contour in two ways: by editing the contour itself, e.g., by inserting or moving contour points, or by transforming the contour as a whole, e.g., by rotating moving or scaling it. Note that you can only edit a contour if Edit is set to *'true'*. Similarly, you can only rotate, move or scale it if Rotate, Move, and Scale, respectively, are set to *'true'*.

draw_xld_mod starts in the transformation mode. In this mode, the contour is displayed together with 3 symbols: a cross in the middle and an arrow to the right if Rotate is set to *'true'*, and a double-headed arrow to the upper right if Scale is set to *'true'*. To switch into the edit mode, press the Shift key; by pressing it again, you can switch back into the transformation mode.

Transformation Mode

In this mode a contour can be rotated, moved and scaled, as long as the respective parameter Rotate, Move and Scale are set to *'true'*. The contour is displayed along with a cross in its center, an arrow pointing to the right (if Rotate is set to *'true'*), and a double arrow (if Scale is set to *'true'*).

- To move the contour, click with the left mouse button on the cross in the center and then drag it to the new position, i.e., keep the mouse button pressed while moving the mouse.
- To rotate it, click with the left mouse button on the arrow and then drag it, till the contour has the right direction.
- Scaling is achieved by dragging the double arrow. To keep the ratio the parameter KeepRatio has to be set to *'true'*.

Edit Mode

In this mode, the contour is display together with 5 pick points, which are located in the middle and at the corners of the surrounding rectangle. If the contour is closed, the pick points are displayed as squares, otherwise shaped like a 'u'. By clicking on a pick point, you can close an open contour and vice versa. Depending on the state of the contour, you can perform different modifications. Open contours (pick points shaped like a 'u')

- To append points, click with the left mouse button in the window and a new point is added at this position.
- You can delete the point appended last by pressing the Ctrl key.
- To move or insert points, you must first close the contour by clicking on one of the pick points.

Closed contours (square pick points)

- To move a point, click with the left mouse button on a point marked by a rectangle and then drag it to the new position.
- To insert a point, click with the left mouse button in the vicinity of a line and then move the mouse to the position where you want the new point to be placed.
- To delete a point, select the point which should be deleted with the left mouse button and then press the Ctrl key.

Pressing the right mouse button terminates the procedure.

Attention

If used in a buffer window, mouse events have to be supplied by the application, while the draw operator must be run in another thread.

Parameters

▷ **ContIn** (input_object) ..... xld_cont ⇝ *object*
Input contour.

▷ **ContOut** (output_object) ..... xld_cont ⇝ *object*
Modified contour.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Rotate** (input_control) . . . . . string ⇝ *string*
Enable rotation?
Default: 'true'
List of values: Rotate ∈ {'true', 'false'}

▷ **Move** (input_control) . . . . . string ⇝ *string*
Enable moving?
Default: 'true'
List of values: Move ∈ {'true', 'false'}

▷ **Scale** (input_control) . . . . . string ⇝ *string*
Enable scaling?
Default: 'true'
List of values: Scale ∈ {'true', 'false'}

▷ **KeepRatio** (input_control) . . . . . string ⇝ *string*
Keep ratio while scaling?
Default: 'true'
List of values: KeepRatio ∈ {'true', 'false'}

▷ **Edit** (input_control) . . . . . string ⇝ *string*
Enable editing?
Default: 'true'
List of values: Edit ∈ {'true', 'false'}

Result

draw_xld_mod returns 2 (H_MSG_TRUE), if the window is valid and the needed drawing mode (see set_insert) is available. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

13.3 LUT

get_lut (: : WindowHandle : LookUpTable)

Get current look-up-table (lut).

get_lut returns the name or the values of the look-up-table (lut) of the window, currently used by disp_image (or indirectly by disp_region, etc.) for output. To set a look-up-table use set_lut. If the current table is a system table without any modification (by set_fix), the name of the table is returned. If it is a modified table, a table read from a file or a table for output with pseudo real colors, the RGB-values of the table are returned.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **LookUpTable** (output_control) . . . . . string-array ⇝ *string* / integer
Name of look-up-table or tuple of RGB-values.

Result

`get_lut` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`set_lut`

See also

`set_lut`

Module

Foundation

query_lut (: : WindowHandle : LookUpTable)

Query all available look-up-tables (lut).

`query_lut` returns the names of all look-up-tables available on the current used device. These tables can be set with `set_lut`. An table named 'default' is always available.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **LookUpTable** (output_control) . . . . . string-array ⇝ *string*
Names of look-up-tables.

Result

`query_lut` returns `2` (`H_MSG_TRUE`) if a window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`set_lut`, `disp_lut`

See also

`set_lut`

Module

Foundation

set_lut (: : WindowHandle, LookUpTable :)

Set "look-up-table" (lut).

set_lut sets look-up-table of the device (monitor) displaying the output window. A look-up-table defines the transformation of a “gray value” within an image into a gray value or color on the screen. It describes the screen gray value/color as a combination of red, green and blue for any image gray value (0..255) (so it is a ’table’ to ’look up’ the screen gray value/color for each image gray value: look-up-table). Transformation into screen-colors is performed in real-time at every time the screen is displayed new (typically this happens about 60 - 70 times per second). So it is possible to change the look-up-table to get a new look of images or regions. Please remind that not all machines support changing the look-up-table (e.g., monochrome resp. real color).

Look-up-tables within HALCON (and on a machine that supports 256 colors) are divided into three areas:

S: system area resp. user area,

G: graphic colors,

B: image data.

Colors in S descend from applications that were active before starting HALCON and should not get lost. Graphic colors in G are used for operators such as disp_region, disp_circle etc. and are set unique within all look-up-tables. An output in a graphic color has always got the same (color-)look, even if different look-up-tables are used. set_color and set_rgb set graphic colors. Gray values resp. colors in B are used by disp_image to display an image. They can change according to the current look-up-table. There exist two exceptions to this concept:

- set_gray allows setting of colors of the area B for operators such as disp_region,

For common monitors only one look-up-table can be loaded per screen. Whereas set_lut can be activated separately for each window. There is the following solution for this problem: It will always be activated the look-up-table that is assigned to the “active window” (a window is set into the state “active” by the window manager).

look-up-table can also be used with true-color displays. In this case the look-up-table will be simulated in software. This means, that the look-up-table will be used each time an image is displayed.

query_lut lists the names of all look-up-tables. They differ from each other in the area used for gray values. Within this area the following behavior is defined:

Gray value tables (1-7 image levels)

Value	Description
’default’	Only the two basic colors (generally black and white) are used.

Color tables (real color, static gray value steps)

Value	Description
’default’	Table proposed by the hardware.

Gray value tables (256 colors)

Value	Description
’default’	As *’linear’*.
’linear’	Linear increasing of gray values from 0 (black) to 255 (white).
’inverse’	Inverse function of *’linear’*.
’sqr’	Gray values increase according to square function.
’inv_sqr’	Inverse function of *’sqr’*.
’cube’	Gray values increase according to cubic function.
’inv_cube’	Inverse function of *’cube’*.
’sqrt’	Gray values increase according to square-root function.
’inv_sqrt’	Inverse Function of *’sqrt’*.
’cubic_root’	Gray values increase according to cubic-root function.
’inv_cubic_root’	Inverse Function of *’cubic_root’*.

Color tables (256 colors)

Value	Description
'color1'	Linear transition from red via green to blue.
'color2'	Smooth transition from yellow via red, blue to green.
'color3'	Smooth transition from yellow via red, blue, green, red to blue.
'color4'	Smooth transition from yellow via red to blue.
'three'	Displaying the three colors red, green and blue.
'six'	Displaying the six basic colors yellow, red, magenta, blue, cyan and green.
'twelve'	Displaying 12 colors.
'twenty_four'	Displaying 24 colors.
'rainbow'	Displaying the spectral colors from red via green to blue.
'temperature'	Temperature table from black via red, yellow to white.
'change1'	Color changes after every pixel within the table alternating the six basic colors.
'change2'	Fivefold color changes from green via red to blue.
'change3'	Threefold color changes from green via red to blue.
'jet'	Smooth transition from blue via green, yellow to red.
'inverse_jet'	Smooth transition from red via yellow, green to blue.
'batlow'	Perceptually uniform and color-vision-deficiency friendly.
'inverse_batlow'	Perceptually uniform and color-vision-deficiency friendly.

The look-up-table `LookUpTable` to be used in `WindowHandle` can be set in the following ways:

Name of the look-up-table Select the look-up-table by setting its name (see `query_lut`).

File name of look-up-table Read a look-up-table from a file. Every line of such a file must contain three numbers in the range of 0 to 255, with the first number describing the amount of red, the second the amount of green and the third the amount of blue of the represented display color. The number of lines can vary. The first line contains information for the first gray value and the last line for the last value. If there are less lines than gray values, the available information values are distributed over the whole interval. If there are more lines than gray values, a number of (uniformly distributed) lines is ignored. The file-name must conform to "`LookUpTable.lut`". Within the parameter the name is specified without file extension. HALCON will search for the file in the current directory and after that in a specified directory (see *'lut_dir'* in `set_system`).

Tuple Set RGB values directly as a tuple. The number of parameter values must conform to the number of pixels currently used within the look-up-table.

Any of the above combined with custom value range Set a custom value range to be mapped by the look-up-table. By default, HALCON uses the minimum and maximum gray values g_min and g_max of an image (except `byte` images) and maps these values to 0 and 255 when applying the look-up-table. It is possible to override this behavior by passing a tuple to `set_lut` in the form *[LUT, g_min, g_max]* (where *'LUT'* is any of the options above). This feature can be particularly useful when dealing with outliers in a `real` image.
The default behavior is reset by using one of the options above without minimum and maximum gray values.

Attention

`set_lut` can only be used with monitors supporting 256 gray levels/colors.

Parameters

▷ **`WindowHandle`** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **`LookUpTable`** (input_control) . . . . . filename.read(-array) ⇝ *string* / integer / real
Name of look-up-table, values of look-up-table (RGB) or file name.
Default: 'default'
Suggested values: `LookUpTable` ∈ {'default', 'linear', 'inverse', 'sqr', 'inv_sqr', 'cube', 'inv_cube', 'sqrt', 'inv_sqrt', 'cubic_root', 'inv_cubic_root', 'color1', 'color2', 'color3', 'color4', 'three', 'six', 'twelve',

'twenty_four', 'rainbow', 'temperature', 'cyclic_gray', 'cyclic_temperature', 'hsi', 'change1', 'change2', 'change3', 'jet', 'inverse_jet', 'batlow', 'inverse_batlow'}

File extension: .lut

Example

```
read_image(Image,'monkey')
query_lut(WindowHandle,LUTs)
for i := 0 to |LUTs|-1 by 1
  set_lut(WindowHandle,LUTs[i])
  fwrite_string(FileHandle, ['current table ',LUTs[i]])
  fnew_line(FileHandle)
  get_mbutton(WindowHandle,_,_,_)
endfor
```

Result

set_lut returns 2 (H_MSG_TRUE) if the hardware supports a look-up-table and the parameter is correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

13.4 Mouse

get_mbutton (: : WindowHandle : Row, Column, Button)

Wait until a mouse button is pressed.

get_mbutton returns the pixel accurate image coordinates of the mouse pointer in the output window and the mouse button pressed. In addition the state of the modifier keys is returned. The following values are assigned to the individual buttons and keys:

1: Left button,

2: Middle button,

4: Right button,

8: Shift key,

16: Ctrl key,

32: Alt key.

The sum of the values for all pressed keys added to the value of the pressed mouse button is returned in Button.

The operator waits until a mouse button is pressed in the output window. For graphics windows the coordinates Row and Column are expressed with consideration of the current image part (see set_part).

If subpixel accurate image coordinates are required, you can use the operator get_mbutton_sub_pix.

Attention

get_mbutton only returns if a mouse button is pressed in the window.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (output_control) . . . . . point.y ⇝ *integer*
Row coordinate of the mouse cursor in the image coordinate system.

▷ **Column** (output_control) . . . . . point.x ⇝ *integer*
Column coordinate of the mouse cursor in the image coordinate system.

▷ **Button** (output_control) . . . . . integer ⇝ *integer*
Mouse button(s) pressed.

Result

`get_mbutton` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_mbutton_sub_pix (: : WindowHandle : Row, Column, Button)

Wait until a mouse button is pressed and get the subpixel mouse position.

`get_mbutton_sub_pix` returns the subpixel accurate image coordinates of the mouse pointer in the output window and the mouse button pressed. In addition the state of the modifier keys is returned. The following values are assigned to the individual buttons and keys:

1: Left button,

2: Middle button,

4: Right button,

8: Shift key,

16: Ctrl key,

32: Alt key.

The sum of the values for all pressed keys added to the value of the pressed mouse button is returned in `Button`.

The operator waits until a button is pressed in the output window. For graphics windows the coordinates `Row` and `Column` are expressed with consideration of the current image part (see `set_part`).

If only pixel accurate image coordinates are required, you can use the operator `get_mbutton`.

Attention

`get_mbutton_sub_pix` only returns if a mouse button is pressed in the window.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (output_control) . . . . . point.y ⇝ *real*
Row coordinate of the mouse cursor in the image coordinate system.

▷ **Column** (output_control) . . . . . point.x ⇝ *real*
Column coordinate of the mouse cursor in the image coordinate system.

▷ **Button** (output_control) . . . . . integer ⇝ *integer*
Mouse button(s) pressed.

Result

`get_mbutton_sub_pix` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_mposition (: : WindowHandle : Row, Column, Button)

Query the mouse position.

`get_mposition` returns the pixel accurate image coordinates of the mouse pointer in the output window and the mouse button pressed. These values are returned regardless of the state of the mouse buttons (pressed or not pressed). If at least one mouse button is pressed, the state of the modifier keys is returned as well. If no mouse button is pressed, `get_mposition` returns 0 in `Button`, even if a modifier key is pressed. The following values are assigned to the individual buttons and keys:

0: No button,

1: Left button,

2: Middle button,

4: Right button,

8: Shift key,

16: Ctrl key,

32: Alt key.

The sum of the values for all pressed buttons/keys is returned in `Button`.

The origin of the coordinate system is located in the left upper corner of the window. For graphics windows the coordinates `Row` and `Column` are expressed with consideration of the current image part (see `set_part`).

If subpixel accurate image coordinates are required, you can use the operator `get_mposition_sub_pix`.

Attention

`get_mposition` fails (returns `5` (`H_MSG_FAIL`)) if the mouse pointer is not located within the window. In this case, no values are returned.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (output_control) . . . . . point.y ⇝ *integer*
Row coordinate of the mouse cursor in the image coordinate system.

▷ **Column** (output_control) . . . . . point.x ⇝ *integer*
Column coordinate of the mouse cursor in the image coordinate system.

▷ **Button** (output_control) . . . . . integer ⇝ *integer*
Mouse button(s) pressed or 0.

Result

`get_mposition` returns the value `2` (`H_MSG_TRUE`). If the mouse pointer is not located within the window, `5` (`H_MSG_FAIL`) is returned.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

get_mposition_sub_pix (: : WindowHandle : Row, Column, Button)

Query the subpixel mouse position.

`get_mposition_sub_pix` returns the subpixel accurate image coordinates of the mouse pointer in the output window and the mouse button pressed. These values are returned regardless of the state of the mouse buttons (pressed or not pressed). If at least one mouse button is pressed, the state of the modifier keys is returned as well. If no mouse button is pressed, `get_mposition` returns 0 in `Button`, even if a modifier key is pressed. The following values are assigned to the individual buttons and keys:

0: No button,
1: Left button,
2: Middle button,
4: Right button,
8: Shift key,
16: Ctrl key,
32: Alt key.

The sum of the values for all pressed buttons/keys is returned in `Button`.

For graphics windows the coordinates `Row` and `Column` are expressed with consideration of the current image part (see `set_part`).

If only pixel accurate image coordinates are required, you can use the operator `get_mposition`.

Attention

`get_mposition_sub_pix` fails (returns `5` (`H_MSG_FAIL`)) if the mouse pointer is not located within the window. In this case, no values are returned.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (output_control) . . . . . point.y ⇝ *real*
Row coordinate of the mouse cursor in the image coordinate system.

▷ **Column** (output_control) . . . . . point.x ⇝ *real*
Column coordinate of the mouse cursor in the image coordinate system.

▷ **Button** (output_control) . . . . . integer ⇝ *integer*
Mouse button(s) pressed or 0.

Result

If the mouse pointer is not located within the window, `5` (`H_MSG_FAIL`) is returned.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

get_mshape (: : WindowHandle : Cursor)

Query the current mouse pointer shape.

This operator does not work in an HDevelop graphics window opened with `dev_open_window`.

`get_mshape` returns the name of the pointer shape set for the window. The mouse pointer shape can be used in the operator `set_mshape`.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Cursor** (output_control) . . . . . string ⇝ *string*
Mouse pointer name.

Result

`get_mshape` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `query_mshape`

Possible Successors

`set_mshape`

Module

Foundation

query_mshape (: : WindowHandle : ShapeNames)

Query all available mouse pointer shapes.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

query_mshape returns the names of all available mouse pointer shapes for the window. These can be used in the operator set_mshape. If no mouse pointers are available, the empty tuple is returned.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **ShapeNames** (output_control) ..... string-array ⇝ *string*
Available mouse pointer names.

Result

query_mshape returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

send_mouse_double_click_event (: : WindowHandle, Row, Column, Button : Processed)

Send an event to a buffer window signaling a mouse double click event.

send_mouse_double_click_event sends an event at the position (Row, Column) to the buffer window WindowHandle, signaling that the mouse button encoded by Button has been double clicked. Please refer to get_mbutton to see how to encode Button.

The purpose of this operator is to select a drawing object in a situation where multiple drawing objects are stacked on top of each other in a buffer window. If the double click happens on either one of the markers of the object border of the active object the object below is selected. To simplify the interaction with the drawing object, the coordinates Row and Column are given in the image coordinate system. To convert window coordinates into image coordinates, the operator convert_coordinates_window_to_image can be used.

If the event could be processed, send_mouse_double_click_event returns *'true'* in Processed. If no action for the event could be determined (e.g., because there is no drawing object below the mouse position), *'false'* is returned in Processed. In this case the caller may determine an action for the event.

The operators send_mouse_down_event, send_mouse_up_event, send_mouse_drag_event and send_mouse_double_click_event are the only means to manipulate drawing objects in buffer windows.

Attention

send_mouse_double_click_event depends on the library libcanvas, which might not be available on embedded systems.

Parameters

- ▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
  Window handle of the buffer window.
- ▷ **Row** (input_control) . . . . . point.y ⇝ *integer* / real
  Row coordinate of the mouse cursor in the image coordinate system.
- ▷ **Column** (input_control) . . . . . point.x ⇝ *integer* / real
  Column coordinate of the mouse cursor in the image coordinate system.
- ▷ **Button** (input_control) . . . . . integer ⇝ *integer*
  Mouse button(s) pressed.
- ▷ **Processed** (output_control) . . . . . string ⇝ *string*
  'true', if HALCON processed the event.

Result

send_mouse_double_click_event returns the value 2 (H_MSG_TRUE) if the window handle WindowHandle corresponds to a window of valid type, and the event is properly encoded. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window

send_mouse_up_event, send_mouse_down_event, open_window

Module

Foundation

send_mouse_down_event (: : WindowHandle, Row, Column, Button : Processed)

Send an event to a window buffer signaling a mouse down event.

send_mouse_down_event sends an event at the position (Row, Column) to the buffer window WindowHandle, signaling that the mouse button encoded by Button has been pressed. Please refer to get_mbutton to see how to encode Button.

The purpose of this operator is to manipulate drawing objects in a buffer window. If the coordinates Row and Column are pointing on a drawing object, it is activated and can be moved or changed by sending more events with the send_mouse_down_event operator. To simplify the interaction with the drawing object, the coordinates Row and Column are given in the image coordinate system. To convert window coordinates into image coordinates, the operator convert_coordinates_window_to_image can be used.

If the event could be processed, send_mouse_down_event returns *'true'* in Processed. If no action for the event could be determined (e.g., because there is no drawing object below the mouse position), *'false'* is returned in Processed. In this case the caller may determine an action for the event.

The operators send_mouse_down_event, send_mouse_up_event, send_mouse_drag_event and send_mouse_double_click_event are the only means to manipulate drawing objects in buffer windows.

Attention

send_mouse_down_event depends on the library libcanvas, which might not be available on embedded systems.

Parameters

- ▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
  Window handle of the buffer window.
- ▷ **Row** (input_control) . . . . . point.y ⇝ *integer* / real
  Row coordinate of the mouse cursor in the image coordinate system.
- ▷ **Column** (input_control) . . . . . point.x ⇝ *integer* / real
  Column coordinate of the mouse cursor in the image coordinate system.
- ▷ **Button** (input_control) . . . . . integer ⇝ *integer*
  Mouse button(s) pressed.
- ▷ **Processed** (output_control) . . . . . string ⇝ *string*
  'true', if HALCON processed the event.

Result

`send_mouse_down_event` returns the value `2` (`H_MSG_TRUE`) if the window handle `WindowHandle` corresponds to a window of valid type, and the event is properly encoded. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`send_mouse_up_event`, `send_mouse_double_click_event`, `open_window`

Module

Foundation

send_mouse_drag_event (: : WindowHandle, Row, Column, Button : Processed)

Send an event to a buffer window signaling a mouse drag event.

`send_mouse_drag_event` sends an event at the position (`Row`, `Column`) to the buffer window `WindowHandle`, signaling that the mouse button encoded by `Button` is been dragged. Please refer to `get_mbutton` to see how to encode `Button`.

If the event could be processed, `send_mouse_drag_event` returns *'true'* in `Processed`. If no action for the event could be determined (e.g., because there is no drawing object below the mouse position), *'false'* is returned in `Processed`. In this case the caller may determine an action for the event.

The operators `send_mouse_down_event`, `send_mouse_up_event`, `send_mouse_drag_event` and `send_mouse_double_click_event` are the only means to manipulate drawing objects in buffer windows.

Attention

`send_mouse_drag_event` depends on the library libcanvas, which might not be available on embedded systems.

Parameters

- ▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
  Window handle of the buffer window.
- ▷ **Row** (input_control) . . . . . point.y ⇝ *integer* / real
  Row coordinate of the mouse cursor in the image coordinate system.
- ▷ **Column** (input_control) . . . . . point.x ⇝ *integer* / real
  Column coordinate of the mouse cursor in the image coordinate system.
- ▷ **Button** (input_control) . . . . . integer ⇝ *integer*
  Mouse button(s) pressed.

▷ **Processed** (output_control) . . . . . string ⇝ *string*
'true', if HALCON processed the event.

Result

send_mouse_drag_event returns the value 2 (H_MSG_TRUE) if the window handle WindowHandle corresponds to a window of valid type, and the event is properly encoded. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

send_mouse_up_event (: : WindowHandle, Row, Column, Button : Processed)

Send an event to a buffer window signaling a mouse up event.

send_mouse_up_event sends an event at the position (Row, Column) to the buffer window WindowHandle, signaling that the mouse button encoded by Button has been released. Please refer to get_mbutton to see how to encode Button.

The purpose of this operator is to release manipulated drawing objects in a buffer window. For example, a drawing object that has been moved by a (sequence of) send_mouse_down_event will be released. To simplify the interaction with the drawing object, the coordinates Row and Column are given in the image coordinate system. To convert window coordinates into image coordinates, the operator convert_coordinates_window_to_image can be used.

If the event could be processed, send_mouse_up_event returns *'true'* in Processed. If no action for the event could be determined (e.g., because there is no drawing object below the mouse position), *'false'* is returned in Processed. In this case the caller may determine an action for the event.

The operators send_mouse_down_event, send_mouse_up_event, send_mouse_drag_event and send_mouse_double_click_event are the only means to manipulate drawing objects in buffer windows.

Attention

send_mouse_up_event depends on the library libcanvas, which might not be available on embedded systems.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle of the buffer window.

▷ **Row** (input_control) . . . . . point.y ⇝ *integer* / real
Row coordinate of the mouse cursor in the image coordinate system.

▷ **Column** (input_control) . . . . . point.x ⇝ *integer* / real
Column coordinate of the mouse cursor in the image coordinate system.

▷ **Button** (input_control) . . . . . integer ⇝ *integer*
Mouse button(s) pressed.

▷ **Processed** (output_control) . . . . . string ⇝ *string*
'true', if HALCON processed the event.

Result

send_mouse_up_event returns the value 2 (H_MSG_TRUE) if the window handle WindowHandle corresponds to a window of valid type, and the event is properly encoded. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_mshape (: : WindowHandle, Cursor :)

Set the current mouse pointer shape.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

set_mshape sets the shape of the mouse pointer for the window. A list of the names of all available mouse pointer shapes can be obtained by calling query_mshape. The mouse pointer shape given by Cursor is used if the mouse pointer enters the window, irrespective of which window is the output window at present.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Cursor** (input_control) ..... string ⇝ *string*
Mouse pointer name.
Default: 'arrow'

Result

set_mshape returns the value 2 (H_MSG_TRUE) if the mouse pointer shape Cursor is defined for this window. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

13.5 Object

attach_background_to_window (Image : : WindowHandle :)

Attach a background image to a HALCON window.

This operator attaches the background image passed in Image to a HALCON window defined in WindowHandle. The input image is copied. Thus it can be freed safely.

The background image is instantly displayed in the HALCON window when calling attach_background_to_window. All HALCON objects that were previously displayed in the window will still be displayed when calling this operator. Thus the previous window content will not be overwritten.

The window contents are displayed in the following order: first the background image, then HALCON objects, and finally the drawing objects. Thus, the drawing object is displayed always on top. Note that the window will be redrawn for each user interaction within the window and each call of set_part. HALCON objects can be deleted from the window with clear_window.

The background image can be removed from the window with the operator detach_background_from_window.

Attention

Note that using any synchronous operator which actively probe the event queue, e.g., get_mbutton or read_char, will conflict with the interaction with the drawing objects. In case the state of the cursor has to be read, please refer to the documentation of your framework of choice for an appropriate, non-invasive alternative.

Furthermore, the event based functionality should not be used together with the former blocking operators draw_rectangle1, draw_rectangle2, draw_region, draw_xld or draw_circle. They conflict with the event based functionality, since they actively fetch all events sent to the HALCON window.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Background image.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*

Window handle.

Result

If the window exists and the specified parameters are correct attach_background_to_window returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window

Possible Successors

detach_background_from_window

Module

Foundation

attach_drawing_object_to_window (: : WindowHandle, DrawHandle :)

Attach an existing drawing object to a HALCON window.

attach_drawing_object_to_window attaches the drawing object DrawHandle to the HALCON window specified in WindowHandle. When attached to a window the drawing object is displayed in the specified window. The drawing object can be modified interactively in the HALCON window. The window is automatically updated when the objects properties are modified using the operator set_drawing_object_params.

When two or more drawing objects overlap, a double-click on the currently selected drawing object will shift the focus to the next drawing object.

Furthermore it is possible to react to modifications of the drawing object caused by user interaction when using any of the language interface. Please see the documentation of set_drawing_object_callback for more details.

The drawing object can be removed from the current window with the operator detach_drawing_object_from_window.

As soon as a drawing object is attached to the window, each HALCON object which is displayed by any of the graphical operators, namely disp_obj, disp_region, disp_image and disp_xld, is stored internally in a graphical stack associated with the WindowHandle, so that they can be displayed together with the attached drawing object. These remain in the stack until the user calls clear_window or the window is closed.

The size of this graphical stack can be queried and modified with get_system and set_system, respectively. See the corresponding documentation reference for further details.

Attention

Note that using any synchronous operator which actively probe the event queue, e.g., get_mbutton or read_char, will conflict with the interaction with the drawing objects. In case you need to read the state of the cursor, please refer to the documentation of your framework of choice for an appropriate, non-invasive alternative.

Furthermore, the event based functionality should not be used together with the former blocking operators draw_rectangle1, draw_rectangle2, draw_region, draw_xld or draw_circle. They conflict with the event based functionality, since they actively fetch all events sent to the HALCON window.

When working under UNIX/Linux it is necessary to turn on the support for multithreading in the Xlib. This is achieved by calling the function XInitThreads() before any other function of the Xlib library. This means that you need to call it before any other function or method of your graphical development environment of choice. See the documentation of the function XInitThreads() in the corresponding manual page for further details.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **DrawHandle** (input_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

attach_drawing_object_to_window returns 2 (H_MSG_TRUE), if the DrawHandle and WindowHandle are valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

set_drawing_object_callback, get_drawing_object_iconic, get_drawing_object_params

Module

Foundation

clear_drawing_object (: : DrawID :)

Delete drawing object.

This operator deletes the drawing object DrawID. The object is automatically detached from the windows to which it had been previously attached. After calling clear_drawing_object the draw object can no longer be used.

Parameters

▷ **DrawID** (input_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

clear_drawing_object returns 2 (H_MSG_TRUE), if the DrawID is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DrawID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Foundation

create_drawing_object_circle (: : Row, Column, Radius : DrawID)

Create a circle which can be modified interactively.

create_drawing_object_circle creates a circular region which can be interactively modified in a HALCON window by the user. The circle is defined by the coordinates Row and Column of its center, and by its Radius. The created circle is returned in the handle DrawID.

These parameters can be queried any time with get_drawing_object_params, as well as its corresponding HALCON object with get_drawing_object_iconic.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See set_drawing_object_params for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See attach_drawing_object_to_window for further details. Once attached, the circle is editable by the user through interaction within the window. There are two possible transformations for a circle object: resizing and displacement. By clicking close to the circular arc you can modify the Radius of the circle. By clicking on the center, the circle can be dragged across the HALCON window.

In contrast to the operator draw_circle, this interaction does not block the calling thread.

Parameters

▷ **Row** (input_control) ..... circle.center.y ⇝ *real*
Row coordinate of the center.
Default: 100

▷ **Column** (input_control) ..... circle.center.x ⇝ *real*
Column coordinate of the center.
Default: 100

▷ **Radius** (input_control) ..... circle.radius ⇝ *real*
Radius of the circle.
Default: 80

▷ **DrawID** (output_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct the operator create_drawing_object_circle returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

create_drawing_object_circle_sector (: : Row, Column, Radius, StartAngle, EndAngle : DrawID)

Create a circle sector which can be modified interactively.

create_drawing_object_circle_sector creates a circle sector region which can be modified interactively in a HALCON window by the user. The circle sector is defined by the coordinates Row and Column of the center point, the Radius, and the start and end angle StartAngle and EndAngle.

These parameters can be queried any time with get_drawing_object_params, as well as its corresponding HALCON object with get_drawing_object_iconic.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See set_drawing_object_params for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See attach_drawing_object_to_window for further details. Once attached, the circle is editable by the user through interaction with the window. There are three possible transformations for a circle sector object: resizing, displacement and changing the arc angle. The Radius of the circle can be modified by dragging the circular arc. By clicking on the center, the circle sector can be moved across the HALCON window. The angle arc can be modified by dragging the handles of the circle sector.

In contrast to the operator draw_circle, this interaction does not block the calling thread.

Parameters

▷ **Row** (input_control) ..... coordinates.y ⇝ *real*
Row coordinate of the center.
Default: 100

▷ **Column** (input_control) ..... coordinates.x ⇝ *real*
Column coordinate of the center.
Default: 100

▷ **Radius** (input_control) ..... number ⇝ *real*
Radius of the circle.
Default: 80

▷ **StartAngle** (input_control) ..... angle.rad ⇝ *real*
Start angle of the arc.
Default: 0

▷ **EndAngle** (input_control) ..... angle.rad ⇝ *real*
End angle of the arc.
Default: 3.14159

▷ **DrawID** (output_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct the operator create_drawing_object_circle_sector returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

create_drawing_object_ellipse (: : Row, Column, Phi, Radius1, Radius2 : DrawID)

Create an ellipse which can be modified interactively.

create_drawing_object_ellipse creates an ellipse which can be modified interactively in a HALCON window by the user. The ellipse is defined by the coordinates of its center point, Row and Column, the lengths of its respective half axis, Radius1 and Radius2, and its orientation Phi.

The parameters can be queried with get_drawing_object_params, as well as its corresponding HALCON object with get_drawing_object_iconic.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See set_drawing_object_params for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See attach_drawing_object_to_window for further details. Once attached, the ellipse is editable by the user through interaction with the window. There are three possible transformations for an ellipse object: resizing, displacement and rotation. The ellipse can be resized by clicking close to the vertex handles. The orientation and thus the rotation of the ellipse can be modified by dragging on a vertex of the first half axis. The ellipse can be moved in the HALCON window by dragging the center.

In contrast to the operator draw_ellipse, this interaction does not block the calling thread.

Parameters

- ▷ **Row** (input_control) ..... ellipse.center.y ⇝ *real*
  Row index of the center.
  Default: 200
- ▷ **Column** (input_control) ..... ellipse.center.x ⇝ *real*
  Column index of the center.
  Default: 200
- ▷ **Phi** (input_control) ..... ellipse.angle.rad ⇝ *real*
  Orientation of the first half axis in radians.
  Default: 0
- ▷ **Radius1** (input_control) ..... ellipse.radius1 ⇝ *real*
  First half axis.
  Default: 100
- ▷ **Radius2** (input_control) ..... ellipse.radius2 ⇝ *real*
  Second half axis.
  Default: 60
- ▷ **DrawID** (output_control) ..... drawing_object ⇝ *handle*
  Handle of the drawing object.

Result

If the parameter values are correct the operator create_drawing_object_ellipse returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

create_drawing_object_ellipse_sector (: : Row, Column, Phi, Radius1, Radius2, StartAngle, EndAngle : DrawID)

Create an elliptic sector which can be modified interactively.

create_drawing_object_ellipse_sector creates an ellipse sector which can be modified interactively in a HALCON window by the user. The ellipse sector is defined by the coordinates Row and Column of its center, the lengths of its respective half axis, Radius1 and Radius2, the start and end angles of the arc, StartAngle and EndAngle, and its orientation Phi.

These parameters can be queried any time with get_drawing_object_params, as well as its corresponding HALCON object with get_drawing_object_iconic.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See set_drawing_object_params for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See attach_drawing_object_to_window for further details. Once attached, the ellipse sector is editable by the user through interaction with the window. There are four possible transformations for an ellipse sector object: resizing, displacement, rotation, and changing the arc angle. The ellipse sector can be moved in the HALCON window by dragging the center. The orientation and thus the rotation of the ellipse sector can also be modified by dragging on a vertex handle of the first half axis. The size and angles of the ellipse sector can be modified by dragging close to the vertex handles.

In contrast to the operator draw_ellipse, this interaction does not block the calling thread.

Parameters

▷ **Row** (input_control) . . . . . coordinates.y ⇝ *real*
Row index of the center.
Default: 200

▷ **Column** (input_control) . . . . . coordinates.x ⇝ *real*
Column index of the center.
Default: 200

▷ **Phi** (input_control) . . . . . angle.rad ⇝ *real*
Orientation of the first half axis in radians.
Default: 0

▷ **Radius1** (input_control) . . . . . number ⇝ *real*
First half axis.
Default: 100

▷ **Radius2** (input_control) . . . . . number ⇝ *real*
Second half axis.
Default: 60

▷ **StartAngle** (input_control) . . . . . angle.rad ⇝ *real*
Start angle of the arc.
Default: 0

▷ **EndAngle** (input_control) . . . . . angle.rad ⇝ *real*
End angle of the arc.
Default: 3.14159

▷ **DrawID** (output_control) . . . . . drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct the operator `create_drawing_object_ellipse_sector` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`open_window`

Possible Successors

`attach_drawing_object_to_window`, `get_drawing_object_params`, `get_drawing_object_iconic`

Alternatives

`draw_ellipse_mod`, `draw_ellipse`, `draw_region`, `create_drawing_object_ellipse`

See also

Module

Foundation

create_drawing_object_line (: : Row1, Column1, Row2, Column2 : DrawID)

Create a line which can be modified interactively.

`create_drawing_object_line` creates a line which can be modified interactively in a HALCON window by the user. The line is defined by the coordinates of the first line point, `Row1` and `Column1`, and the second line point, `Row2` and `Column2`.

These parameters can be queried any time with `get_drawing_object_params`, as well as its corresponding HALCON object with `get_drawing_object_iconic`.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See `set_drawing_object_params` for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See `attach_drawing_object_to_window` for further details. Once attached, the line is editable by the user through interaction with the window. There are two possible transformations for a line object: resizing and displacement. A line point can be moved by dragging on the point handle. The whole line can be moved by dragging the center of the line.

In contrast to the operator `draw_line`, this interaction does not block the calling thread.

Parameters

▷ **Row1** (input_control) ..... line.begin.y ⇝ *real*
Row coordinate of the first line point.
Default: 100

▷ **Column1** (input_control) ..... line.begin.x ⇝ *real*
Column coordinate of the first line point.
Default: 100

▷ **Row2** (input_control) ..... line.end.y ⇝ *real*
Row coordinate of the second line point.
Default: 200

▷ **Column2** (input_control) ..... line.end.x ⇝ *real*
Column coordinate of the second line point.
Default: 200

▷ **DrawID** (output_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct the operator `create_drawing_object_circle_sector` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

Alternatives

`draw_line`, `draw_line_mod`, `create_drawing_object_xld`

See also

`create_drawing_object_rectangle1`, `create_drawing_object_rectangle2`, `create_drawing_object_ellipse`, `create_drawing_object_circle_sector`, `create_drawing_object_ellipse_sector`, `create_drawing_object_xld`

Module

Foundation

create_drawing_object_rectangle1 (: : Row1, Column1, Row2, Column2 : DrawID)

Create a rectangle parallel to the coordinate axis which can be modified interactively.

`create_drawing_object_rectangle1` creates a rectangle aligned along the coordinate axis which can be modified interactively in a HALCON window by the user. The rectangle is defined by the coordinates `Row1`, `Column1`, `Row2`, and `Column2` of its upper left and lower right corner. The created rectangle is returned in the handle `DrawID`.

These parameters can be queried any time with `get_drawing_object_params`, as well as its corresponding HALCON object with `get_drawing_object_iconic`.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See `set_drawing_object_params` for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See `attach_drawing_object_to_window` for further details. Once attached, the rectangle is editable by the user through interaction with the window. There are two possible transformations for a rectangle1 object: resizing and displacement. The rectangle can be moved by dragging in the middle of the rectangle and resized by dragging the handles of the corners.

In contrast to the operator `draw_rectangle1`, this interaction does not block the calling thread.

Parameters

▷ **Row1** (input_control) . . . . . rectangle.origin.y ⇝ *real*
Row coordinate of the upper left corner.
Default: 100

▷ **Column1** (input_control) . . . . . rectangle.origin.x ⇝ *real*
Column coordinate of the upper left corner.
Default: 100

▷ **Row2** (input_control) . . . . . rectangle.corner.y ⇝ *real*
Row coordinate of the lower right corner.
Default: 200

▷ **Column2** (input_control) . . . . . rectangle.corner.x ⇝ *real*
Column coordinate of the lower right corner.
Default: 200

▷ **DrawID** (output_control) . . . . . drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct, the operator `create_drawing_object_rectangle1` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`open_window`

Possible Successors

See also

`gen_rectangle1`, `draw_circle`, `draw_ellipse`, `set_insert`

Module

Foundation

create_drawing_object_rectangle2 (: : Row, Column, Phi, Length1, Length2 : DrawID)

Create a rectangle of any orientation which can be modified interactively.

`create_drawing_object_rectangle2` creates an oriented rectangle which can be modified interactively in a HALCON window by the user. The rectangle is defined by the coordinates `Row` and `Column` of its center, its orientation `Phi`, and the lengths of its half axis, `Length1` and `Length2` respectively. The created rectangle is returned in the handle `DrawID`.

These parameters can be queried any time with `get_drawing_object_params`, as well as its corresponding HALCON object with `get_drawing_object_iconic`.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See `set_drawing_object_params` for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See attach_drawing_object_to_window for further details. Once attached, the rectangle is editable by the user through interaction with the window. There are three possible transformations for a rectangle2 object: resizing, displacement and rotation. The rectangle can be moved by dragging its center. By dragging the side handles, the size of the rectangle can be modified. The rectangle's orientation can only be changed by gripping a side perpendicular to the first half axis.

In contrast to the operator draw_rectangle2, this interaction does not block the calling thread.

Parameters

▷ **Row** (input_control) ..... rectangle2.center.y ⇝ *real*
Row coordinate of the center.
Default: 150

▷ **Column** (input_control) ..... rectangle2.center.x ⇝ *real*
Column coordinate of the center.
Default: 150

▷ **Phi** (input_control) ..... rectangle2.angle.rad ⇝ *real*
Orientation of the first half axis in radians.
Default: 0

▷ **Length1** (input_control) ..... rectangle2.hwidth ⇝ *real*
First half axis.
Default: 100

▷ **Length2** (input_control) ..... rectangle2.hheight ⇝ *real*
Second half axis.
Default: 100

▷ **DrawID** (output_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct the operator create_drawing_object_rectangle2 returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

create_drawing_object_text (: : Row, Column, String : DrawID)

Create a text object which can be moved interactively.

create_drawing_object_text creates a text object which can be moved interactively across a HALCON window. The coordinates Row and Column define the position of the text.

These parameters can be queried any time with get_drawing_object_params, as well as its corresponding HALCON object with get_drawing_object_iconic.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See set_drawing_object_params for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the text object must be attached to an existing window. See attach_drawing_object_to_window for further details. The text will be displayed with the current font settings of the HALCON window by default. However, the font setting can be adjusted with set_drawing_object_params. Once attached, the text can be moved by the user through interaction with the window.

Parameters

▷ **Row** (input_control) ..... point.y ⇝ *integer*
Row coordinate of the text position.
Default: 12

▷ **Column** (input_control) ..... point.x ⇝ *integer*
Column coordinate of the text position.
Default: 12

▷ **String** (input_control) ..... string ⇝ *string*
Character string to be displayed.
Default: 'Text'

▷ **DrawID** (output_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct, the operator create_drawing_object_text returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

create_drawing_object_xld (: : Row, Column : DrawID)

Create a XLD contour which can be modified interactively.

create_drawing_object_xld creates an XLD contour which can be modified interactively in a HALCON window by the user. The contour is defined by the coordinates Row and Column of its points.

These parameters can be queried any time with get_drawing_object_params, as well as its corresponding HALCON object with get_drawing_object_iconic.

In addition to those parameters, every drawing object has a number of parameters which determine the appearance of the object in the HALCON window. See set_drawing_object_params for details on the number and meaning of those parameters.

In order to enable the interactive modification with the drawing object, the object must be attached to an existing window. See attach_drawing_object_to_window for further details. Once attached, the contour is editable by the user through interaction with the window. Further points can be added by left clicking on the window. When clicking the contour segment between two consecutive points, a new point is added between those points. Each contour point can be moved by dragging its point handle. A single contour point can be deleted by dragging it over one of the neighboring contour points directly connected to it. The contour can be closed by moving the last point onto the first contour point. The contour can be moved as a whole by dragging it by the handle in the center. In addition, it is possible to assign a new contour to a drawing object with set_drawing_object_xld.

In contrast to the operator draw_xld, this interaction does not block the calling thread.

Parameters

▷ **Row** (input_control) . . . . . coordinates.y-array ⇝ *real* / integer
Row coordinates of the polygon.
Default: [100,200,200,100]
Suggested values: Row ∈ {0, 10, 20, 50, 100, 200, 500}

▷ **Column** (input_control) . . . . . coordinates.x-array ⇝ *real* / integer
Column coordinates of the polygon.
Default: [100,100,200,200]
Suggested values: Column ∈ {0, 10, 20, 50, 100, 200, 500}

▷ **DrawID** (output_control) . . . . . drawing_object ⇝ *handle*
Handle of the drawing object.

Result

If the parameter values are correct the operator create_drawing_object_xld returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

detach_background_from_window (: : WindowHandle :)

Detach the background image from a HALCON window.

This operator detaches the background image that was previously attached with attach_background_to_window from the HALCON window defined in WindowHandle. Thus the background of the window will be cleared.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

Result

If the window exists and the specified parameters are correct detach_background_from_window returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

attach_background_to_window

Module

Foundation

detach_drawing_object_from_window (: : WindowHandle, DrawHandle :)

Detach an existing drawing object from a HALCON window.

This operator can be used to detach the drawing object DrawHandle from the HALCON window WindowHandle to which it is currently attached. The drawing object will not longer be displayed in the window. If a callback function was defined for the drawing object on the event 'on_detach' or 'on_select' with set_drawing_object_callback this will also be called.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window Handle.

▷ **DrawHandle** (input_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

detach_drawing_object_from_window returns 2 (H_MSG_TRUE), if the DrawHandle and WindowHandle are valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_drawing_object_iconic (: Object : DrawID :)

Return the iconic object of a drawing object.

get_drawing_object_iconic returns the iconic object Object that corresponds to the drawing object DrawID. In addition, the parameters that define the drawing object can be queried with the operator get_drawing_object_params.

Parameters

▷ **Object** (output_object) ..... object(-array) ⇝ *object*
Copy of the iconic object represented by the drawing object.

▷ **DrawID** (input_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

clear_drawing_object returns 2 (H_MSG_TRUE), if the DrawID is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_drawing_object_params, attach_drawing_object_to_window

Module

Foundation

get_drawing_object_params (: : DrawID, GenParamName : GenParamValue)

Get the parameters of a drawing object.

get_drawing_object_params can be used to query the parameters that describe the drawing object DrawID. One may specify one or several parameters which will be retrieved in the output tuple GenParamValue, in the same order as specified in the input tuple GenParamName.

In addition to the parameters described in set_drawing_object_params following parameters are possible for GenParamName:

'type': Returns the type of the drawing object. Possible return values are: *'circle'*, *'circle_sector'*, *'ellipse'*, *'ellipse_sector'*, *'rectangle1'*, *'rectangle2'*, *'line'*, *'xld'*, *'text'*

Parameters

▷ **DrawID** (input_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Parameter names of the drawing object.
List of values: GenParamName ∈ {'row1', 'row2', 'column1', 'column2', 'radius', 'row', 'column', 'length1', 'length2', 'string', 'phi', 'start_angle', 'end_angle', 'radius1', 'radius2', 'color', 'font', 'line_width', 'line_style', 'marker_size', 'type'}

▷ **GenParamValue** (output_control) . . . . . attribute.name(-array) ⇝ *real* / integer / string
Parameter values.

Result

get_drawing_object_params returns 2 (H_MSG_TRUE), if the DrawID is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_drawing_object_rectangle1, create_drawing_object_rectangle2, create_drawing_object_ellipse, create_drawing_object_circle, create_drawing_object_line, create_drawing_object_ellipse_sector, create_drawing_object_circle_sector, create_drawing_object_xld, create_drawing_object_text, attach_drawing_object_to_window

Alternatives

get_drawing_object_iconic

See also

attach_drawing_object_to_window, get_drawing_object_iconic, set_drawing_object_params

Module

Foundation

get_window_background_image (: BackgroundImage : WindowHandle :)

Gets a copy of the background image of the HALCON window.

get_window_background_image returns a copy of the background image BackgroundImage set in the window WindowHandle. This operator is specially useful in cases where the user would like to perform some operations in one of the callback functions of a drawing object attached to the window. See set_drawing_object_callback for more details.

Parameters

▷ **BackgroundImage** (output_object) . . . . . (multichannel-)image ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Copy of the background image.

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

Result

If the window exists and the specified parameters are correct get_window_background_image returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

attach_background_to_window

See also

attach_background_to_window, detach_drawing_object_from_window

Module

Foundation

set_content_update_callback (: : WindowHandle, CallbackFunction, CallbackContext :)

Sets the callback for content updates in buffer window.

set_content_update_callback sets a callback CallbackFunction, which is called whenever the contents of the buffer window WindowHandle change. The parameter CallbackContext is always passed to the callback.

The type of CallbackFunction is: Herror callback(void *context)

On Windows systems, the __stdcall calling convention is used: Herror __stdcall callback(void *context)

The callback function must not call a HALCON operator. Doing so is undefined behavior. It is advised to perform only computationally inexpensive tasks in the callback, e.g., setting a flag or triggering an asynchronous operation.

In combination with the operators send_mouse_down_event, send_mouse_up_event, and send_mouse_double_click_event, set_content_update_callback can be used to create a buffer based control for a GUI Toolkit (such as Qt), where the control passes mouse events to the buffer, while the buffer notifies the control on changes by calling the function CallbackFunction. The control then can obtain the contents of the buffer with dump_window_image and display them.

Attention

set_content_update_callback depends on the library libcanvas, which might not be available on embedded systems.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **CallbackFunction** (input_control) ..... pointer ⇝ *integer*
  Callback for content updates.
- ▷ **CallbackContext** (input_control) ..... pointer ⇝ *integer* / handle
  Parameter to CallbackFunction.

Result

If the window exists and is a buffer window, set_content_update_callback returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

flush_buffer

Module

Foundation

set_drawing_object_callback (: : DrawHandle, DrawObjectEvent, CallbackFunction :)

Add a callback function to a drawing object.

set_drawing_object_callback adds the callback function CallbackFunction to be called on the event(s) defined in DrawObjectEvent to the drawing object DrawHandle. An event is an action, i.e., a user interaction with the mouse or a call to a HALCON operator, e.g., attach_drawing_object_to_window), that changes the current state of a given drawing object. The operator set_drawing_object_callback allows to define how to react to those events.

The following predefined events are available:

'on_attach' The corresponding callback will be called right after the object has been attached to the HALCON window and is ready for interaction.

'on_detach' The corresponding callback will be called right after the object has been detached from the window and is no longer available for interaction.

'on_drag' The corresponding callback will be called right after the object has been dragged with mouse interaction.

'on_resize' The corresponding callback will be called right after the object has been resized with mouse interaction.

'on_select' The corresponding callback will be called right after the object has been selected with mouse interaction.

It is possible to specify a particular callback for each desired event. Then the input parameters DrawObjectEvent and CallbackFunction must have the same length. It is also possible to use the same callback for different events. Then DrawObjectEvent has an arbitrary length and CallbackFunction contains one single value.

The callback is an integer of long type containing a pointer to a C function with the following signature:

Herror HDrawObjectCallback(Hphandle DrawHandle, Hphandle WindowHandle, char* type)

On Windows systems, the __stdcall naming convention is used:

Herror __stdcall HDrawObjectCallback(Hphandle DrawHandle, Hphandle WindowHandle, char* type)

The first parameter of the callback function contains the handle to the draw object that generated the event, the second one contains the handle of the window where the interaction took place. Finally, the third parameter indicates which event occurred.

Attention

No graphical operator should be called within the callback, like for example disp_obj, for otherwise a deadlock may occur.

Parameters

▷ **DrawHandle** (input_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

▷ **DrawObjectEvent** (input_control) ..... string(-array) ⇝ *string*
Events to be captured.
Suggested values: DrawObjectEvent ∈ {'on_resize', 'on_drag', 'on_attach', 'on_detach', 'on_select'}

▷ **CallbackFunction** (input_control) ..... pointer(-array) ⇝ *integer*
Callback functions.

Result

set_drawing_object_callback returns 2 (H_MSG_TRUE), if DrawHandle is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_drawing_object_params (: : DrawID, GenParamName, GenParamValue :)

Set the parameters of a drawing object.

set_drawing_object_params is used to set the parameters GenParamName of the drawing object DrawID to the values specified in GenParamValue.

Depending on the type of the drawing object the following parameters can be set for the different types of drawing object:

circle: *'row'*: Row coordinate of the center of the circle.
'column': Column coordinate of the center of the circle.
'radius': Radius of the circle.

circle_sector: *'row'*: Row coordinate of the center.
'column': Column coordinate of the center.
'radius': Radius of the circle.
'start_angle': Start angle of the circle arc.
'end_angle': End angle of the circle arc.

ellipse: *'row'*: Row coordinate of the center of the ellipse.
'column': Column coordinate of the center of the ellipse.
'phi': Orientation of the first half axis in radians.
'radius1': Length of the first half axis.
'radius2': Length of the second half axis.

ellipse_sector: *'row'*: Row coordinate of the center of the ellipse sector.
'column': Column coordinate of the center of the ellipse sector.
'phi': Orientation of the first half axis in radians.
'radius1': Length of the first half axis.
'radius2': Length of the second half axis.
'start_angle': Starting angle of the ellipse arc.
'end_angle': End angle of the ellipse arc.

rectangle1: *'row1'*: Row coordinate of the upper left corner.
'column1': Column coordinate of the upper left corner.
'row2': Row coordinate of the lower right corner.
'column2': Column coordinate of the lower right corner.

rectangle2: *'row'*: Row coordinate of the center of the rectangle.
'column': Column coordinate of the center of the rectangle.
'phi': Orientation of the first half axis in radians.
'length1': Length of the first half axis.
'length2': Length of the second half axis.

line: *'row1'*: Row coordinate of the first line point.
'column1': Column coordinate of the first line point.
'row2': Row coordinate of the second line point.
'column2': Column coordinate of the second line point.

xld: *'row'*: Row coordinates of the contour points.
'column': Column coordinates of the contour points.
It is possible to either set only the row or column coordinates of the contour points, or both at the same time. In the first case, the number of elements in the input tuple must be the same as the number of points in the contour. In the second case, all existing contour points are discarded and replaced by new ones. The new coordinates are specified in `GenParamValue` in the following order: *[Row_0, Row_1, ..., Row_n, Column_0, Column_1, ... Column_n]*.

text: *'row'*: Row coordinate of the text position.
'column': Column coordinate of the text position.
'string': Text string to be displayed.

In addition, there is an additional number of attributes that model the appearance of the drawing object in the window it is attached to. Depending on the type of the drawing object the following attributes can be set.

- Draw objects of type 'text':
  'color': Set the color of a text object. The color can be specified either by name, e.g., 'green', or by RGB values, e.g., '#ffb529'. See `set_color` for more information.
  'font': Set the font of a text object. A list of all available fonts can be queried with `query_font`. See `set_font` for a detailed description of the available values.
- Draw objects of type 'circle', 'circle_sector', 'ellipse', 'ellipse_sector', 'rectangle1', 'rectangle1', 'xld', 'line':
  'color': Set the color of a drawing object. The color can be specified either by name, e.g., 'green', or by RGB values, e.g., '#ffb529'. See `set_color` for more information.
  'line_style': Set the line style of the drawing object. This attribute requires at least one pair of attribute values in form of a tuple. The first defines the length of the visible part, the second defines the length of the invisible part. See `set_line_style` for more details. Please notice that since the length of the input tuple may vary, *'line_style'* must not be combined with other parameters or attributes in the same call. Otherwise an exception will the thrown.
  'line_width': Set the line width of the drawing object in pixel. See `set_line_width` for more information.
  'marker_size': Set the width and height of the markers used as anchor points for manipulating this drawing object.
  Value range: [*7 ... 32768*]

If more than one parameter shall be set, they have to be passed as a tuple in `GenParamName` containing the name of the parameters. The corresponding values have to be passed as a tuple in `GenParamValue`.

If the drawing object is currently attached to a window, this window is redrawn for each call of `set_drawing_object_params`.

Parameters

▷ **DrawID** (input_control) . . . . . drawing_object ⇝ *handle*
Handle of the drawing object.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Parameter names of the drawing object.
List of values: `GenParamName` ∈ {'row1', 'row2', 'column1', 'column2', 'radius', 'row', 'column', 'length1', 'length2', 'string', 'phi', 'start_angle', 'end_angle', 'radius1', 'radius2', 'color', 'font', 'line_width', 'line_style', 'marker_size'}

▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *real* / integer / string
Parameter values.

Result

set_drawing_object_params returns 2 (H_MSG_TRUE), if the DrawID is valid, and the pairs of names and values of the tuples GenParamName and GenParamValue are coherent with the corresponding drawing object type. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_drawing_object_rectangle1, create_drawing_object_rectangle2, create_drawing_object_ellipse, create_drawing_object_circle, create_drawing_object_line, create_drawing_object_ellipse_sector, create_drawing_object_circle_sector, create_drawing_object_xld, attach_drawing_object_to_window

Module

Foundation

set_drawing_object_xld (Contour : : DrawID :)

Set the contour of an interactive draw XLD.

set_drawing_object_xld substitutes the XLD currently contained in the draw object by the new Contour. The contour must contain at least two points, so that the interaction as described in create_drawing_object_xld is possible.

In addition, if the drawing object DrawID is currently attached to a HALCON window, the window will be redrawn with each call of set_drawing_object_xld.

Parameters

▷ **Contour** (input_object) ..... xld_cont ⇝ *object*
XLD contour.

▷ **DrawID** (input_control) ..... drawing_object ⇝ *handle*
Handle of the drawing object.

Result

set_drawing_object_xld returns 2 (H_MSG_TRUE), if the DrawID is valid and Contour is a contour consisting of at least two points. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

13.6 Output

disp_arc (: : WindowHandle, CenterRow, CenterCol, Angle, BeginRow, BeginCol :)

Displays circular arcs in a window.

`disp_arc` displays one or several circular arcs in the output window. An arc is described by its center point (`CenterRow`,`CenterCol`), the angle between start and end of the arc (`Angle` in radians) and the first point of the arc (`BeginRow`,`BeginCol`). The arc is displayed in clockwise direction. The parameters for output can be determined - as with the output of regions - with the operators `set_color`, `set_gray`, `set_draw`, etc. It is possible to draw several arcs with one call by using tuple parameters. For the use of colors with several arcs, see `set_color`.

Attention

The center point has to be within the window. The radius of the arc has be at least 2 pixel.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **CenterRow** (input_control) . . . . . arc.center.y ⇝ *real* / integer
Row coordinate of center point.
Default: 64
Suggested values: CenterRow ∈ {0, 64, 128, 256}
Value range: 0 ≤ CenterRow ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **CenterCol** (input_control) . . . . . arc.center.x ⇝ *real* / integer
Column coordinate of center point.
Default: 64
Suggested values: CenterCol ∈ {0, 64, 128, 256}
Value range: 0 ≤ CenterCol ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Angle** (input_control) . . . . . arc.angle.rad ⇝ *real* / integer
Angle between start and end of the arc (in radians).
Default: 3.1415926
Suggested values: Angle ∈ {0.0, 0.785398, 1.570796, 3.1415926, 6.283185}
Value range: 0.0 ≤ Angle ≤ 6.283185 (lin)
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Angle > 0.0

▷ **BeginRow** (input_control) . . . . . arc.begin.y(-array) ⇝ *integer* / real
Row coordinate of the start of the arc.
Default: 32
Suggested values: BeginRow ∈ {0, 64, 128, 256}
Value range: 0 ≤ BeginRow ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **BeginCol** (input_control) . . . . . arc.begin.x(-array) ⇝ *integer* / real
Column coordinate of the start of the arc.
Default: 32
Suggested values: BeginCol ∈ {0, 64, 128, 256}
Value range: 0 ≤ BeginCol ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Example

```
open_window(0,0,-1,-1,'root','visible','',WindowHandle)
set_draw(WindowHandle,'fill')
set_color(WindowHandle,'white')
Row := 100
Column := 100
disp_arc(WindowHandle,Row,Column,3.14,Row+10,Column+10)
close_window(WindowHandle)
```

Result

disp_arc returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

disp_arrow (: : WindowHandle, Row1, Column1, Row2, Column2, Size :)

Displays arrows in a window.

disp_arrow displays one or several arrows in the output window. An arrow is described by the coordinates of the start (Row1,Column1) and the end (Row2,Column2). An arrowhead is displayed at the end of the arrow. The size of the arrowhead is specified by the parameter Size. If the arrow consists of just one point (start = end) nothing is displayed. The operators used to control the display of regions (e.g., set_draw, set_color, set_line_width) can also be used with arrows. Several arrows can be displayed with one call by using tuple parameters. For the use of colors with several arcs, see set_color.

Attention

The start and the end of the arrows must fall within the window.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row1** (input_control) . . . . . line.begin.y(-array) ⇝ *real* / integer
Row index of the start.
Default: 10.0
Suggested values: Row1 ∈ {0.0, 64.0, 128.0, 256.0}
Value range: 0.0 ≤ Row1 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 1.0

▷ **Column1** (input_control) . . . . . line.begin.x(-array) ⇝ *real* / integer
Column index of the start.
Default: 10.0
Suggested values: Column1 ∈ {0.0, 64.0, 128.0, 256.0}
Value range: 0.0 ≤ Column1 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 1.0

▷ **Row2** (input_control) . . . . . line.end.y(-array) ⇝ *real* / integer
Row index of the end.
Default: 118.0
Suggested values: Row2 ∈ {0.0, 64.0, 128.0, 256.0}
Value range: 0.0 ≤ Row2 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 1.0

▷ **Column2** (input_control) . . . . . line.end.x(-array) ⇝ *real* / integer
Column index of the end.
Default: 118.0
Suggested values: Column2 ∈ {0.0, 64.0, 128.0, 256.0}
Value range: 0.0 ≤ Column2 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 1.0

▷ **Size** (input_control) . . . . . number ⇝ *real* / integer
Size of the arrowhead.
Default: 1.0
Suggested values: Size ∈ {1.0, 2.0, 3.0, 5.0}
Value range: 0.0 ≤ Size ≤ 20.0 (lin)
Minimum increment: 1.0
Recommended increment: 1.0
Restriction: Size > 0.0

Example

```
set_color(WindowHandle,['red','green'])
disp_arrow(WindowHandle,[10,10],[10,10],[118,110],[118,118],1.0)
```

Result

disp_arrow returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

disp_channel (MultichannelImage : : WindowHandle, Channel :)

Displays images with several channels.

disp_channel displays an image in the output window. It is possible to display several images with one call. In this case the images are displayed one after another. If the definition domains of the images overlap only the last image is visible. The parameter Channel defines the number of the channel that is displayed. For RGB-images the three color channels have to be used within a tuple parameter. For more information see disp_image.

Parameters

▷ **MultichannelImage** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Multichannel images to be displayed.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*

Window handle.

▷ **Channel** (input_control) ..... integer(-array) ⇝ *integer*

Number of channel or the numbers of the RGB-channels

Default: 1

Suggested values: Channel ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

Example

```
read_image(Image,'patras')
count_channels (Image, Channels)
for I := 1 to Channels by 1
    disp_channel (Image, WindowHandle, I)
endfor
```

Result

If the used images contain valid values and a correct output mode is set, disp_channel returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_rgb, set_lut, set_hsi

Alternatives

disp_image, disp_color

disp_circle (: : WindowHandle, Row, Column, Radius :)

Displays circles in a window.

disp_circle displays one or several circles in the output window. A circle is described by the center (Row, Column) and the radius Radius. If the used coordinates are not within the window the circle is clipped accordingly.

The operators used to control the display of regions (e.g., set_draw, set_gray, set_draw) can also be used with circles. Several circles can be displayed with one call by using tuple parameters. For the use of colors with several circles, see set_color.

Attention

The center of the circle must be within the window.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (input_control) ..... circle.center.y(-array) ⇝ *real* / integer
Row index of the center.
Default: 64
Suggested values: Row ∈ {0, 64, 128, 256}
Value range: 0 ≤ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) ..... circle.center.x(-array) ⇝ *real* / integer
Column index of the center.
Default: 64
Suggested values: Column ∈ {0, 64, 128, 256}
Value range: 0 ≤ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Radius** (input_control) ..... circle.radius(-array) ⇝ *real* / integer
Radius of the circle.
Default: 64
Suggested values: Radius ∈ {0, 64, 128, 256}
Value range: 0 ≤ Radius ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: Radius > 0.0

Example

```
open_window(0,0,-1,-1,'root','visible','',WindowHandle)
set_draw(WindowHandle,'fill')
set_color(WindowHandle,'white')
repeat
  get_mbutton(WindowHandle,Row,Column,Button)
  disp_circle(WindowHandle,Row,Column,(Row + Column) % 50)
until(Button == 1)
close_window(WindowHandle)
```

Result

disp_circle returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_draw, set_color, set_colored, set_line_width, set_rgb, set_hsi

Alternatives

disp_ellipse, disp_region, gen_circle, gen_ellipse

See also

open_window, set_color, set_draw, set_rgb, set_hsi

Module

Foundation

disp_color (ColorImage : : WindowHandle :)

Displays a color (RGB) image

disp_color displays the three channels of a color image in the output window. The channels are ordered in the sequence (red,green,blue). disp_color can be simulated by disp_channel.

Attention

Due to the restricted number of available colors the color appearance is usually different from the original.

Parameters

▷ **ColorImage** (input_object) ..... multichannel-image ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Color image to display.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*

Window handle.

Example

```
/* disp_color(ColorImage) is identical to: */
Herror my_disp_color(Hobject ColorImage, Htuple *WindowHandle) {
  Htuple  Tupel;
  create_tuple(&Tupel,3);
  set_i(Tupel,1,0);
  set_i(Tupel,2,1);
  set_i(Tupel,3,2);
  T_disp_channel(ColorImage,*WindowHandle,Tupel);
  destroy_tuple(Tupel);
}
```

Result

If the used image contains valid values and a correct output mode is set, disp_color returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_rgb, set_lut, set_hsi

Alternatives

disp_image, open_window, reset_obj_db, set_lut, dump_window

Module

Foundation

disp_cross (: : WindowHandle, Row, Column, Size, Angle :)

Displays crosses in a window.

disp_cross displays one or several crosses in the output window. A cross is described by the coordinates of the center point (Row,Column), the length of its bars Size and the orientation Angle. The operators used to control the display of regions (e.g., set_color, set_gray, set_draw, set_line_width) can also be used with crosses. Several crosses can be displayed with one call by using tuple parameters. For the use of colors with several crosses, see set_color.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (input_control) . . . . . coordinates.y(-array) ⇝ *real*
Row coordinate of the center.
Default: 32.0
Suggested values: Row ∈ {0.0, 64.0, 128.0, 256.0, 511.0}

▷ **Column** (input_control) . . . . . coordinates.x(-array) ⇝ *real*
Column coordinate of the center.
Default: 32.0
Suggested values: Column ∈ {0.0, 64.0, 128.0, 256.0, 511.0}

▷ **Size** (input_control) . . . . . number ⇝ *real*
Length of the bars.
Default: 6.0
Suggested values: Size ∈ {4.0, 6.0, 8.0, 10.0}
Value range: 0.0 ≤ Size

▷ **Angle** (input_control) . . . . . angle.rad ⇝ *real*
Orientation.
Default: 0.0
Suggested values: Angle ∈ {0.0, 0.78539816339744830961566084581988}

Result

disp_cross returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_color, set_rgb, set_hsi, set_insert, set_line_width

Module

Foundation

disp_ellipse (: : WindowHandle, CenterRow, CenterCol, Phi, Radius1, Radius2 :)

Displays ellipses.

disp_ellipse displays one or several ellipses in the output window. An ellipse is described by the center (CenterRow, CenterCol), the orientation Phi (in radians) and the radii of the major and the minor axis (Radius1 and Radius2).

The operators used to control the display of regions (e.g., set_draw, set_gray, set_draw) can also be used with ellipses. Several ellipses can be displayed with one call by using tuple parameters. For the use of colors with several ellipses, see set_color.

Attention

The center of the ellipse must be within the window.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **CenterRow** (input_control) . . . . . ellipse.center.y(-array) ⇝ *integer*
Row index of center.
Default: 64
Suggested values: CenterRow ∈ {0, 64, 128, 256}
Value range: 0 ≤ CenterRow ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **CenterCol** (input_control) . . . . . ellipse.center.x(-array) ⇝ *integer*
Column index of center.
Default: 64
Suggested values: CenterCol ∈ {0, 64, 128, 256}
Value range: 0 ≤ CenterCol ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Phi** (input_control) . . . . . ellipse.angle.rad(-array) ⇝ *real* / integer
Orientation of the ellipse in radians
Default: 0.0
Suggested values: Phi ∈ {0.0, 0.785398, 1.570796, 3.1415926, 6.283185}
Value range: 0.0 ≤ Phi ≤ 6.283185 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Radius1** (input_control) . . . . . ellipse.radius1(-array) ⇝ *real* / integer
Radius of major axis.
Default: 24.0
Suggested values: Radius1 ∈ {0.0, 64.0, 128.0, 256.0}
Value range: 0.0 ≤ Radius1 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Radius2** (input_control) . . . . . ellipse.radius2(-array) ⇝ *real* / integer
Radius of minor axis.
Default: 14.0
Suggested values: Radius2 ∈ {0.0, 64.0, 128.0, 256.0}
Value range: 0.0 ≤ Radius2 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

Example

```
set_color(WindowHandle,'red')
draw_region(MyRegion,WindowHandle)
elliptic_axis(MyRegion,Ra,Rb,Phi)
area_center(MyRegion,_,Row,Column)
disp_ellipse(WindowHandle,Row,Column,Phi,Ra,Rb)
```

Result

disp_ellipse returns 2 (H_MSG_TRUE), if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

disp_image (Image : : WindowHandle :)

Displays gray value images.

disp_image displays the gray values of an image in the output window. The gray value pixels of the definition domain (set_comprise(::WindowHandle,'object':)) or of the whole image (set_comprise(::WindowHandle,'image':)) are used. Restriction to the definition domain is the default.

For the display of gray value images the number of gray values is usually reduced. This is due to the fact that colors have to be reserved for the display of graphics (e.g., set_color) and the window manager. Also depending on the number of bit planes on the used output device often less than 256 colors (eight bit planes) are available. The number of "colors" actually reserved for the display of gray values can be queried by get_system. Before opening the first window this value can be modified by set_system. For instance for 8 bit planes 200 real gray values are the default.

The reduction of the number of gray values does not pose problems as long as only gray value information is displayed, humans cannot distinguish 256 different shades of gray. If certain gray values are used for the representation of region information (which is not the style commonly used in HALCON), confusions might be the result, since different numerical values are displayed on the screen with the same gray value. The operator label_to_region should be used on these images in order to transform the label data into HALCON objects.

If images of type int2, int4, int8, real or complex are displayed, the smallest and largest gray value is computed. For images of the type complex this computation is based on the corresponding power spectrum. Afterwards the pixel data is rescaled according to the number of available gray values (depending on the output device, e.g., 200). It is possible that some pixels have a very different value than the other pixels. This might lead to the display of an (almost) completely white or black image. In order to decide if the current image is a binary image min_max_gray can be used. If necessary the image can be transformed or converted by scale_image and convert_image_type before it is displayed.

Attention

If a wrong output mode was set by set_paint, the error will be reported when disp_image is used.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field

Gray value image to display.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*

Window handle.

Example

```
* Output of a gray image:
read_image(Image,'monkey')
disp_image(Image,WindowHandle)
```

Result

If the used image contains valid values and a correct output mode is set, disp_image returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

See also

open_window, reset_obj_db, set_paint, set_lut, paint_gray, scale_image, convert_image_type, dump_window

Module

Foundation

disp_line (: : WindowHandle, Row1, Column1, Row2, Column2 :)

Draws lines in a window.

disp_line displays one or several lines in the output window. A line is described by the coordinates of the start (Row1,Column1) and the coordinates of the end (Row2,Column2). The operators used to control the display of regions (e.g., set_color, set_gray, set_draw, set_line_width) can also be used with lines. Several lines can be displayed with one call by using tuple parameters. For the use of colors with several lines, see set_color.

Attention

The starting points and the ending points of the lines must be in the window.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row1** (input_control) ..... line.begin.y(-array) ⇝ *real*
Row index of the start.
Default: 32.0
Suggested values: Row1 ∈ {0.0, 64.0, 128.0, 256.0, 511.0}
Value range: 0 ≤ Row1 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Column1** (input_control) ..... line.begin.x(-array) ⇝ *real*
Column index of the start.
Default: 32.0
Suggested values: Column1 ∈ {0.0, 64.0, 128.0, 256.0, 511.0}
Value range: 0 ≤ Column1 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Row2** (input_control) ..... line.end.y(-array) ⇝ *real*
Row index of end.
Default: 64.0
Suggested values: Row2 ∈ {0.0, 64.0, 128.0, 256.0, 511.0}
Value range: 0 ≤ Row2 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Column2** (input_control) ..... line.end.x(-array) ⇝ *real*
Column index of end.
Default: 64.0
Suggested values: Column2 ∈ {0.0, 64.0, 128.0, 256.0, 511.0}
Value range: 0 ≤ Column2 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

Example

```
* Display contour of a rectangle
disp_line(WindowHandle,Row1,Column1,Row1,Column2)
disp_line(WindowHandle,Row1,Column2,Row2,Column2)
disp_line(WindowHandle,Row2,Column2,Row2,Column1)
disp_line(WindowHandle,Row2,Column1,Row1,Column1)
```

Result

disp_line returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_rgb, set_lut, set_hsi, set_draw, set_color, set_colored, set_line_width

Alternatives

disp_arrow, disp_rectangle1, disp_rectangle2, disp_region, gen_region_polygon, gen_region_points

See also

open_window, set_color, set_rgb, set_hsi, set_insert, set_line_width

Module

Foundation

disp_obj (Object : : WindowHandle :)

Displays image objects (image, region, XLD).

disp_obj displays objects depending of their kind. disp_obj is equivalent to disp_image for one channel images, equivalent to disp_color for three channel images, equivalent to disp_region for regions and equivalent to disp_xld for XLDs.

Parameters

▷ **Object** (input_object) ..... object(-array) ⇝ *object*
Image object to be displayed.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

Example

```
* Output of a gray image:
read_image(Image1,'monkey')
disp_obj(Image1,WindowHandle)
threshold(Image,Region,0,128)
disp_obj(Region,WindowHandle)
```

Result

If the used object is valid and a correct output mode is set, disp_obj returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_rgb, set_lut, set_hsi, scale_image, convert_image_type, min_max_gray

Alternatives

disp_color, disp_image, disp_xld, disp_region

See also

open_window, reset_obj_db, set_paint, set_lut, paint_gray, scale_image, convert_image_type, dump_window

Module

Foundation

disp_object_model_3d (: : WindowHandle, ObjectModel3D, CamParam, Pose, GenParamName, GenParamValue :)

Display 3D object models.

disp_object_model_3d displays the 3D object models of ObjectModel3D in the window WindowHandle. Set CamParam and the individual poses (in Pose) of the 3D object models to setup the displayed scene. If an empty tuple is given for CamParam, disp_object_model_3d uses default camera parameters that correspond to the window size. If CamParam is not empty, note that sometimes the aspect ratio of WindowHandle should be similar to width and height stored in CamParam in order to obtain the wanted results. Pose can contain either multiple poses (one pose for each 3D object model) or one pose for all 3D object models. Thereby the poses are in the form ${}^{ccs}\mathbf{P}_{mcs}$, where *ccs* denotes the camera coordinate system and *mcs* the model coordinate system (which is a 3D world coordinate system), see Transformations / Poses and "Solution Guide III-C - 3D Vision".

If an empty tuple is given for Pose, disp_object_model_3d estimates a pose, such that all 3D object models are visible.

3D object models containing triangles or polygons are displayed as solids, whereas 3D object models containing only coordinates are displayed as point clouds. 3D primitives (e.g., obtained by fit_primitives_object_model_3d) are displayed as solids as well. The generic parameter *'attribute'* can be used to explicitly select in which way a 3D object model is visualized.

To render the 3D object models into an image, the operator render_object_model_3d can be used.

GenParamName and GenParamValue are used to further configure the scene. The following values influence the whole scene:

'disp_background': Flag, if the current window content should be used as background.
List of values: *'true'*, *'false'*.
Default: *'false'*.

'light_position': Position of the light source. Must be given as a string containing four space separated floating point numbers. If the fourth number is 0.0, a directional light source is used (the first three components represent the direction), otherwise a point light source is used (with the first three components representing the position).
Default: *'-100.0 -100.0 0.0 1.0'*.

'light_ambient': Ambient part of the light source. Must be given as a string containing three space separated floating point numbers.
Default: *'0.2 0.2 0.2'*.

'light_diffuse': Diffuse part of the light source. Must be given as a string containing three space separated floating point numbers.

Default: *'0.8 0.8 0.8'*.

'colored': Display 3D object models in different colors. The value of this parameter defines the number of colors that are used.

List of values: *3*, *6*, *12*.

Default: all objects are displayed white.

'object_index_persistence': Must be set to *'true'* to enable the object index query with `get_disp_object_model_3d_info`.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'depth_persistence': Must be set to *'true'* to enable the depth query with `get_disp_object_model_3d_info`.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'quality': Must be set to *'low'* to enable faster rendering without anti aliasing.

List of values: *'low'*, *'high'*.

Default: *'high'*.

The following parameters can be set for all 3D object models in the scene or for a specific 3D object model by appending the index of the 3D object model to the parameter name (e.g., *'color_0'* to set the color of the first 3D object model).

'attribute' Explicitly select in which way a 3D object model is visualized.

List of values: *'auto'*, *'faces'*, *'primitive'*, *'points'*, *'lines'*.

Default: *'auto'*.

'color': Color of the 3D object models. The available colors can be queried with the operator `query_color`. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where 'rr', 'gg', and 'bb' are hexadecimal numbers between '00' and 'ff', respectively.

Suggested values: *'red'*, *'green'*.

Default: *'white'*.

'alpha': Translucency of the 3D object models. Displaying 3D object models with translucency set to less than 1.0 may significantly increase the runtime of `disp_object_model_3d`.

Value range: [*0.0* (fully transparent) ... *1.0* (fully opaque)].

Default: *1.0*.

'disp_pose': Flag, if the pose of the 3D object models should be visualized.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'disp_lines': Flag, if the contours of the 3D object models' polygons should be displayed.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'disp_normals': Flag, if the surface normals of the 3D object models should be visualized.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'line_color': Color of the lines if *'disp_lines'* is set to *'true'*. The available colors can be queried with the operator `query_color`. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where 'rr', 'gg', and 'bb' are hexadecimal numbers.

Suggested values: *'red'*, *'green'*.

Default: The value of *'color'*.

'line_width': Sets the width of lines in pixel.

Default: *1.0*.

'normal_color': Color of the visualized normals if *'disp_normals'* is set to *'true'*. The available colors can be queried with the operator `query_color`. In addition, the color may be specified as an RGB triplet in the form *'#rrggbb'*, where 'rr', 'gg', and 'bb' are hexadecimal numbers.

Suggested values: *'red'*, *'green'*.

Default: The value of *'color'*.

'point_size': Sets the diameter of the points in pixel.

Default: *3.5*.

'lut': Sets the LUT that transforms the values of the attribute set with *'color_attrib'* into a color.

See `set_lut` for available LUTs. If *'lut'* is set to anything but *'default'*, *'color'* is ignored.

Default: *'default'*.

'color_attrib': Name of a point attribute that is used for false color visualization.

If an attribute is set, the color of the displayed 3D points is determined by the point's attribute value and the currently set LUT (see *'lut'*). This way, it is possible to visualize attributes in false colors.

Example: If *'color_attrib'* is set to *'coord_z'*, and *'lut'* is set to *'color1'*, the z-coordinates will be color coded from red to blue.

If *'lut'* is set to *'default'*, the attribute values are used to scale the color that was set by the parameter *'color'*.

If *'lut'* is set to a different value, the attribute values of all points are internally scaled to the interval [0,255] and used as input value for the LUT function.

The mapping is also controlled by the parameters *'color_attrib_start'* and *'color_attrib_end'* (see below).

If faces are displayed, their color is interpolated between the color of the corner points.

Suggested values: *'none'*, *'&distance'*, *'coord_x'*, *'coord_y'*, *'coord_z'*, user defined point attributes, or any other point attribute available.

Default: *'none'*.

'color_attrib_start',*'color_attrib_end'*: The range of interest of the values of the attribute set with *'color_attrib'*.

The attribute values between *'color_attrib_start'* and *'color_attrib_end'* are scaled to the start and end of the selected LUT. Attribute values outside the selected range are clipped. This allows to use a fixed color mapping which will not be distorted by outliers.

If set to *'auto'*, the minimum attribute value is mapped to the start of the LUT, the maximum is mapped to the end of the LUT, *except* if *'color_attrib'* is *'normal_x'*, *'normal_y'*, or *'normal_z'*. In this case, start and end are automatically set to *-1* and *1*.

It is possible to enter start value that is higher than the end value. This will in effect flip the used LUT.

Suggested values: *'auto'*, *0*, *0.1*, *1*, *100*, *255*.

Default: *'auto'*.

'red_channel_attrib', *'green_channel_attrib'*, *'blue_channel_attrib'*: Name of a point attribute that is used for the red, green, or blue color channel.

This is most useful when used with a group of three connected attributes, like RGB colors or normal vectors. This way it is possible to display points in colored texture, e.g., display the object model with overlayed RGB-sensor data, or display point normals in false colors.

To display only a single attribute in false colors, please use *'color_attrib'* (see above).

By default, the attribute values are assumed to lie between *0* and *255*. If the attributes have a different range, you additionally have to set the parameters *'rgb_channel_attrib_start'* and *'rgb_channel_attrib_end'* (see below).

If only 1 or 2 channels are set, the remaining channels use the RGB value of the color set with *'color'*.

If faces are displayed, their color is interpolated between the color of the corner points.

Suggested values: *'none'*, *'&red'*, *'&green'*, *'&blue'*, *'normal_x'*, *'normal_y'*, *'normal_z'*, user defined point attributes, or any other point attribute available.

Default: *'none'*.

'rgb_channel_attrib_start', *'rgb_channel_attrib_end'*: The range of interest of the values of attributes set with *'red_channel_attrib'*, *'green_channel_attrib'*, and *'blue_channel_attrib'*.

These parameters define the value range that is scaled to the full RGB channels. This is useful, if the input attribute values are not in the interval [0,255].

If set to *'auto'*, the minimum attribute value is mapped to *0*, the maximum is mapped to *255*, *except* if the attribute is *'normal_x'*, *'normal_y'*, or *'normal_z'*. In this case, start and end are automatically set to *-1* and *1*.

It is possible to enter start value that is higher than the end value. This will in effect invert the displayed RGB colors.

The range can be set for the channels individually by replacing *'rgb'* in the parameter name with the channel name, e.g., *'green_channel_attrib_start'*.

Suggested values: *'auto'*, *0*, *0.1*, *1*, *100*, *255*.

Default: *0*, *255*.

All generic parameters are evaluated from left to right. For example, to set the color of the first 3D object model to red and the color of all other 3D object models to green, set `GenParamName` to *['color','color_0']* and `GenParamValue` to *['green','red']*.

`disp_object_model_3d` requires OpenGL 2.1, GLSL 1.2, and the OpenGL extensions GL_EXT_framebuffer_object and GL_EXT_framebuffer_blit. Otherwise the compatibility mode is automatically enabled. On graphics cards with low memory the following error messages could occur if rendering in a window with high resolution:

Low level error: 'Incomplete attachment'

Unhanded Exception: 'Required framebuffer object is unsupported'

Solutions:

Set the parameter *'quality'* to *'low'* or use the compatibility mode to reduce the requirements of the graphics card.

The system variable (see `set_system`) *'opengl_compatibility_mode_enable'* can be set to *'true'* to permanently enable the visualization in compatibility mode with lower OpenGL requirements. This mode requires OpenGL 1.1. In compatibility mode the parameters *'object_index_persistence'*, *'depth_persistence'* and *'quality'* are not used.

On Linux Remote Desktop *'disp_background'* is not supported.

Attention

Cameras with hypercentric lenses are not supported. For displaying large faces (or primitives) with a non-zero distortion in `CamParam`, note that the distortion is only applied to the points of the model. In the projection, these points are subsequently connected by straight lines. For a good approximation of the distorted lines, please use a triangulation with sufficiently small triangles.

Parameters

- ▷ **`WindowHandle`** (input_control) . . . . . window ⇝ *handle*
  Window handle.
- ▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
  Handles of the 3D object models.
- ▷ **`CamParam`** (input_control) . . . . . campar ⇝ *real* / integer / string
  Camera parameters of the scene.
  Default: []
- ▷ **`Pose`** (input_control) . . . . . pose(-array) ⇝ *real* / integer
  3D poses of the objects.
  Default: []
- ▷ **`GenParamName`** (input_control) . . . . . string-array ⇝ *string*
  Names of the generic parameters.
  Default: []
  List of values: `GenParamName` ∈ {'alpha', 'attribute', 'color', 'colored', 'depth_persistence', 'disp_background', 'disp_lines', 'disp_pose', 'disp_normals', 'light_position', 'light_ambient', 'light_diffuse', 'line_color', 'line_width', 'normal_color', 'object_index_persistence', 'point_size', 'quality', 'compatibility_mode_enable', 'color_attrib', 'color_attrib_start', 'color_attrib_end', 'red_channel_attrib', 'green_channel_attrib', 'blue_channel_attrib', 'rgb_channel_attrib_start', 'rgb_channel_attrib_end', 'lut'}
- ▷ **`GenParamValue`** (input_control) . . . . . string-array ⇝ *string* / integer / real
  Values of the generic parameters.
  Default: []
  List of values: `GenParamValue` ∈ {'true', 'false', 'coord_x', 'coord_y', 'coord_z', 'normal_x', 'normal_y', 'normal_z', 'red', 'green', 'blue', 'auto', 'faces', 'primitive', 'points', 'lines'}

Result

`disp_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised. If the image rendering exceeds the available memory of the graphics card, the error 5188 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

disp_polygon (: : WindowHandle, Row, Column :)

Displays a polyline.

`disp_polygon` displays a polyline with the row coordinates `Row` and the column coordinates `Column` in the output window. The parameters `Row` and `Column` have to be provided as tuples. Straight lines are drawn between the given points. The start and the end of the polyline are not connected.

The operators used to control the display of regions (e.g., `set_color`, `set_gray`, `set_draw`, `set_line_width`) can also be used with polylines.

Attention

The given coordinates must lie within the window.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (input_control) ..... polygon.y-array ⇝ *integer* / real
Row index
Default: [16,80,80]
Suggested values: Row ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Column** (input_control) ..... polygon.x-array ⇝ *integer* / real
Column index
Default: [48,16,80]
Suggested values: Column ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

Example

```
/* display a rectangle */

disp_rectangle1_margin1(Htuple WindowHandle,
                        Hlong Row1, long Column1,
                        Hlong Row2, long Column2)
{
```

```
  Htuple Row, Col;
  create_tuple(&Row,4);
  create_tuple(&Col,4);

  set_i(Row,Row1,0);
  set_i(Col,Column1,0);

  set_i(Row,Row1,1);
  set_i(Col,Column2,1);

  set_i(Row,Row2,2);
  set_i(Col,Column2,2);

  set_i(Row,Row2,3);
  set_i(Col,Column1,3);

  set_i(Row,Row1,4);
  set_i(Col,Column1,4);

  T_disp_polygon(WindowHandle,Row,Col);

}
```

Result

`disp_polygon` returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`open_window`, `set_color`, `set_rgb`, `set_hsi`, `set_insert`, `set_line_width`

Module

Foundation

disp_rectangle1 (: : WindowHandle, Row1, Column1, Row2, Column2 :)

Display of rectangles aligned to the coordinate axes.

`disp_rectangle1` displays one or several rectangles in the output window. A rectangle is described by the upper left corner (`Row1`,`Column1`) and the lower right corner (`Row2`,`Column2`). If the given coordinates are not within the boundary of the window the rectangle is clipped accordingly. The operators used to control the display of regions (e.g., `set_color`, `set_gray`, `set_draw`, `set_line_width`) can also be used with rectangles. Several rectangles can be displayed with one call by using tuple parameters.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row1** (input_control) . . . . . rectangle.origin.y(-array) ⇝ *real* / integer
Row index of the upper left corner.
Default: 16
Suggested values: Row1 ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Row1 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Column1** (input_control) . . . . . rectangle.origin.x(-array) ⇝ *real* / integer
Column index of the upper left corner.
Default: 16
Suggested values: Column1 ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Column1 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Row2** (input_control) . . . . . rectangle.corner.y(-array) ⇝ *real* / integer
Row index of the lower right corner.
Default: 48
Suggested values: Row2 ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Row2 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Row2 >= Row1

▷ **Column2** (input_control) . . . . . rectangle.corner.x(-array) ⇝ *real* / integer
Column index of the lower right corner.
Default: 80
Suggested values: Column2 ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Column2 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Column2 >= Column1

Example

```
set_color(WindowHandle,'green')
draw_region(MyRegion,WindowHandle)
smallest_rectangle1(MyRegion,R1,C1,R2,C2)
disp_rectangle1(WindowHandle,R1,C1,R2,C2)
```

Result

disp_rectangle1 returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Alternatives

disp_rectangle2, gen_rectangle1, disp_region, disp_line, set_shape

See also

open_window, set_color, set_draw, set_line_width

Module

Foundation

disp_rectangle2 (: : WindowHandle, CenterRow, CenterCol, Phi, Length1, Length2 :)

Displays arbitrarily oriented rectangles.

disp_rectangle2 draws one or several arbitrarily oriented rectangles in the output window. A rectangle is described by the center (CenterRow,CenterCol), the orientation Phi (in radians) and half the lengths of the edges Length1 and Length2. The operators used to control the display of regions (e.g., set_draw, set_gray, set_draw) can also be used with rectangles. Several rectangles can be displayed with one call by using tuple parameters. For the use of colors with several rectangles, see set_color.

Attention

The center must lie within the window boundaries.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **CenterRow** (input_control) . . . . . rectangle2.center.y(-array) ⇝ *real* / integer
Row index of the center.
Default: 48
Suggested values: CenterRow ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ CenterRow ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **CenterCol** (input_control) . . . . . rectangle2.center.x(-array) ⇝ *real* / integer
Column index of the center.
Default: 64
Suggested values: CenterCol ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ CenterCol ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Phi** (input_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real* / integer
Orientation of rectangle in radians.
Default: 0.0
Suggested values: Phi ∈ {0.0, 0.785398, 1.570796, 3.1415926, 6.283185}
Value range: 0.0 ≤ Phi ≤ 6.283185 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Length1** (input_control) . . . . . rectangle2.hwidth(-array) ⇝ *real* / integer
Half of the length of the longer side.
Default: 48
Suggested values: Length1 ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Length1 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Length2** (input_control) . . . . . rectangle2.hheight(-array) ⇝ *real* / integer
Half of the length of the shorter side.
Default: 32
Suggested values: Length2 ∈ {0, 64, 128, 256, 511}
Value range: 0 ≤ Length2 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Length2 < Length1

Example

```
set_color(WindowHandle,'green')
draw_region(MyRegion,WindowHandle)
elliptic_axis(MyRegion,Ra,Rb,Phi)
area_center(MyRegion,_,Row,Column)
disp_rectangle2(WindowHandle,Row,Column,Phi,Ra,Rb)
```

Result

disp_rectangle2 returns 2 (H_MSG_TRUE), if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_rgb, set_lut, set_hsi, set_draw, set_color, set_colored, set_line_width

Alternatives

disp_region, gen_rectangle2, disp_rectangle1, set_shape

See also

open_window, disp_region, set_color, set_draw, set_line_width

Module

Foundation

disp_region (DispRegions : : WindowHandle :)

Displays regions in a window.

disp_region displays the regions in DispRegions in the output window. The parameters for output can be set with the operators set_color, set_gray, set_draw, set_line_width, etc.

The color(s) for the display of the regions are determined with set_color, set_rgb, set_gray or set_colored. If more than one region is displayed and more than one color is set, the colors are assigned in a cyclic way to the regions.

The form of the region for output can be modified by set_paint (e.g., encompassing circle, convex hull). The command set_draw determines if the region is filled or only the boundary is drawn. If only the boundary is drawn, the thickness of the boundary will be determined by set_line_width and the style by set_line_style.

Parameters

▷ **DispRegions** (input_object) ..... region(-array) ⇝ *object*
Regions to display.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

Example

```
* Output with 12 colors:
set_colored(WindowHandle,12)
disp_region(SomeSegments,WindowHandle)

* Symbolic representation:
set_draw(WindowHandle,'margin')
set_color(WindowHandle,'red')
set_shape(WindowHandle,'ellipse')
disp_region(SomeSegments,WindowHandle)

* Representation of a margin with pattern:
set_draw(WindowHandle,'margin')
set_color(WindowHandle,'blue')
set_line_style(WindowHandle,[12,3])
disp_region(Segments,WindowHandle)
```

Result

`disp_region` returns 2 (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_rgb`, `set_lut`, `set_hsi`, `set_shape`, `set_line_style`, `set_insert`, `set_draw`, `set_color`, `set_colored`, `set_line_width`

Alternatives

`disp_obj`, `disp_arrow`, `disp_line`, `disp_circle`, `disp_rectangle1`, `disp_rectangle2`, `disp_ellipse`

See also

Module

Foundation

`disp_xld` (XLDObject : : WindowHandle :)

Display an XLD object.

`disp_xld` serves to display an XLD object of arbitrary type.

Parameters

▷ **`XLDObject`** (input_object) ..... xld-array ⇝ *object*
XLD object to display.

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

13.7 Parameters

`convert_coordinates_image_to_window` (: : WindowHandle, RowImage, ColumnImage : RowWindow, ColumnWindow)

Convert image coordinates to window coordinates

`convert_coordinates_image_to_window` converts image coordinates `RowImage` and `ColumnImage` into window coordinates `RowWindow` and `ColumnWindow` based on the displayed image part and the window size of the window defined in `WindowHandle`.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle

▷ **RowImage** (input_control) ..... coordinates.y(-array) ⇝ *real*
Row in image coordinates.

▷ **ColumnImage** (input_control) ..... coordinates.x(-array) ⇝ *real*
Column in image coordinates.

▷ **RowWindow** (output_control) ..... coordinates.y(-array) ⇝ *real*
Row (Y) in window coordinates.

▷ **ColumnWindow** (output_control) ..... coordinates.x(-array) ⇝ *real*
Column (X) in window coordinates.

Example

```
read_image (Image, 'printer_chip/printer_chip_01')
dev_get_window (WindowHandle)
get_window_extents (WindowHandle, Row, Column, Width, Height)
dev_set_part (450, 300, 750, 600)
dev_display (Image)
*
* Generate rectangle in image coordinates
Row := [474, 746]
Column := [314, 589]
gen_rectangle1 (Rectangle1, Row[0], Column[0], Row[1], Column[1])
* Convert rectangle corner points to window coordinates
convert_coordinates_image_to_window (WindowHandle, Row[[0,1,0,1]], \
    Column[[0,0,1,1]], RowWindow, ColumnWindow)
*
* Window center in window coordinates
WindowCenterRow := Height/2-1
WindowCenterColumn := Width/2-1
* Convert window center to image coordinates
convert_coordinates_window_to_image (WindowHandle, WindowCenterRow, \
    WindowCenterColumn, RowImage, ColumnImage)
*
* Display all points in image coordinates
dev_display (Image)
disp_cross (WindowHandle, Row[[0,1,0,1]], Column[[0,0,1,1]], 6, rad(45))
disp_cross (WindowHandle, RowImage, ColumnImage, 6, 0)
```

Result

`convert_coordinates_image_to_window` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`set_window_extents`, `set_part`

`convert_coordinates_window_to_image`

Module

Foundation

convert_coordinates_window_to_image (: : WindowHandle, RowWindow, ColumnWindow : RowImage, ColumnImage)

Convert window coordinates to image coordinates

convert_coordinates_window_to_image converts window coordinates RowWindow and ColumnWindow into image coordinates RowImage and ColumnImage based on the displayed image part and the window size of the window defined in WindowHandle.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **RowWindow** (input_control) ..... coordinates.y(-array) ⇝ *real*
  Row (Y) in window coordinates.
- ▷ **ColumnWindow** (input_control) ..... coordinates.x(-array) ⇝ *real*
  Column (X) in window coordinates.
- ▷ **RowImage** (output_control) ..... coordinates.y(-array) ⇝ *real*
  Row in image coordinates.
- ▷ **ColumnImage** (output_control) ..... coordinates.x(-array) ⇝ *real*
  Column in image coordinates.

Example

```
read_image (Image, 'printer_chip/printer_chip_01')
dev_get_window (WindowHandle)
get_window_extents (WindowHandle, Row, Column, Width, Height)
dev_set_part (450, 300, 750, 600)
dev_display (Image)
*
* Generate rectangle in image coordinates
Row := [474, 746]
Column := [314, 589]
gen_rectangle1 (Rectangle1, Row[0], Column[0], Row[1], Column[1])
* Convert rectangle corner points to window coordinates
convert_coordinates_image_to_window (WindowHandle, Row[[0,1,0,1]], \
    Column[[0,0,1,1]], RowWindow, ColumnWindow)
*
* Window center in window coordinates
WindowCenterRow := Height/2-1
WindowCenterColumn := Width/2-1
* Convert window center to image coordinates
convert_coordinates_window_to_image (WindowHandle, WindowCenterRow, \
    WindowCenterColumn, RowImage, ColumnImage)
*
* Display all points in image coordinates
dev_display (Image)
disp_cross (WindowHandle, Row[[0,1,0,1]], Column[[0,0,1,1]], 6, rad(45))
disp_cross (WindowHandle, RowImage, ColumnImage, 6, 0)
```

Result

convert_coordinates_window_to_image returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

set_window_extents, set_part

convert_coordinates_image_to_window

Module

Foundation

get_contour_style (: : WindowHandle : Style)

Get the current contour display fill style.

get_contour_style returns the contour fill style of the output window as set with set_contour_style.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Style** (output_control) . . . . . string ⇝ *string*
Current contour fill style.

Result

get_contour_style returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_contour_style, disp_xld

See also

set_contour_style, disp_xld

Module

Foundation

get_draw (: : WindowHandle : Mode)

Get the current region fill mode.

get_draw returns the region fill mode of the output window. It is used by operators as disp_region, disp_circle, disp_arrow, disp_rectangle1, disp_rectangle2 etc. The region fill mode is set with set_draw.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Mode** (output_control) . . . . . string ⇝ *string*
Current region fill mode.

Result

get_draw returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Successors

set_draw, disp_region

See also

set_draw, disp_region, set_paint

Module

Foundation

get_hsi (: : WindowHandle : Hue, Saturation, Intensity)

Get the HSI coding of the current color.

get_hsi returns the output color or gray values, respectively, for the window, described in Hue, Saturation and Intensity. The values returned by get_hsi can be set with set_hsi.

Attention

The values returned by get_hsi may be inaccurate due to rounding errors. They do not necessarily match the values set with set_hsi exactly (colors are stored in RGB internally).

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Hue** (output_control) ..... integer-array ⇝ *integer*
  Hue (color value) of the current color.
- ▷ **Saturation** (output_control) ..... integer-array ⇝ *integer*
  Saturation of the current color.
- ▷ **Intensity** (output_control) ..... integer-array ⇝ *integer*
  Intensity of the current color.

Result

get_hsi returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_hsi, set_rgb, disp_image

See also

set_hsi, set_color, set_rgb, trans_to_rgb, trans_from_rgb

Module

Foundation

get_icon (: Icon : WindowHandle :)

Query the icon for region output

get_icon queries the icon that was set with set_icon.

Parameters

- ▷ **Icon** (output_object) ..... region ⇝ *object*
  Icon for the regions center of gravity.
- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.

Example

```
/* draw a region and an icon.  */
/* set it and get it again.    */
T_draw_region(&Region,WindowHandle);
T_draw_region(&Icon,WindowHandle);
set_icon(Icon);
create_tuple_s(&icon,"icon");
T_set_shape(WindowHandle,icon);
destroy_tuple(icon);
T_disp_region(Region,WindowHandle);
get_icon(&OldIcon);
T_disp_region(OldIcon,WindowHandle);
```

Result

`get_icon` always returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`set_icon`

Possible Successors

`disp_region`

Module

Foundation

`get_line_style ( : : WindowHandle : Style )`

Get the current graphic mode for contours.

`get_line_style` returns the display mode for contours when displaying regions. It is used by operators like `disp_region`, `disp_line`, `disp_polygon`, etc. `Style` is set with the operator `set_line_style`. `Style` is only important for displaying the contour of objects, especially if a line style was set with `set_line_style`.

Parameters

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **`Style`** (output_control) ..... integer-array ⇝ *integer*
Template for contour display.

Result

`get_line_style` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`set_line_style`, `disp_region`

Module

Foundation

get_line_width (: : WindowHandle : Width)

Get the current line width for contour display.

get_line_width returns the line width for region display in the window. It is used by operators like disp_region, disp_line, disp_polygon, etc. Width is set with the operator set_line_width. Width is only important for displaying the contour of objects.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Width** (output_control) ..... real ⇝ *real*
Current line width for contour display.

Result

get_line_width returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_line_width, set_line_style, disp_region

See also

set_line_width, disp_region

Module

Foundation

get_paint (: : WindowHandle : Mode)

Get the current display mode for gray values.

get_paint returns the display mode for gray values in the window. Mode is used by the operator disp_image. get_paint is used for temporary changes of the gray value display mode. The current value is queried, then changed (with the operator set_paint) and finally the old value is written back. The available modes can be viewed with the operator query_paint. Mode is the name of the display mode. If a mode can be customized with parameters, the parameter values are passed in a tuple after the mode name. The order of values is the same as in set_paint.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Mode** (output_control) ..... string-array ⇝ *string* / integer / real
Name and parameter values of the current display mode.

Result

get_paint returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

query_paint

Possible Successors

set_paint, disp_region, disp_image

See also

set_paint, query_paint, disp_image

Module

Foundation

get_part (: : WindowHandle : Row1, Column1, Row2, Column2)

Get the image part.

get_part returns the upper left and lower right corner of the image part shown in the window. The image part can be changed with the operator set_part (Default is the whole image).

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Row1** (output_control) ..... rectangle.origin.y ⇝ *integer* / real
  Row index of the image part's upper left corner.
- ▷ **Column1** (output_control) ..... rectangle.origin.x ⇝ *integer* / real
  Column index of the image part's upper left corner.
- ▷ **Row2** (output_control) ..... rectangle.corner.y ⇝ *integer* / real
  Row index of the image part's lower right corner.
- ▷ **Column2** (output_control) ..... rectangle.corner.x ⇝ *integer* / real
  Column index of the image part's lower right corner.

Result

get_part returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_part, disp_region, disp_image

See also

set_part, disp_image, disp_region, disp_color

Module

Foundation

get_part_style (: : WindowHandle : Style)

Get the current interpolation mode for gray value display.

get_part_style returns the interpolation mode used for displaying an image part in the window. An interpolation takes place if the output window is larger than the image format or the image output format (see set_part). HALCON supports three interpolation modes:

0 no interpolation (low quality, very fast).

1 unweighted interpolation (average quality and computation time)

2 weighted interpolation (high quality, slow)

The current mode can be changed with set_part_style.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Style** (output_control) . . . . . integer ⇝ *integer*
Interpolation mode for image display: 0 (fast, low quality) to 2 (slow, high quality).
List of values: Style ∈ {0, 1, 2}

Result

get_part_style returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_part_style, disp_region, disp_image

See also

set_part_style, set_part, disp_image, disp_color

Module

Foundation

get_rgb (: : WindowHandle : Red, Green, Blue)

Get the current color in RGB-coding.

get_rgb returns the output colors or gray values, respectively, for the output window. They are defined by the three color components red, green and blue.

The values returned by get_rgb can be set with set_rgb.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Red** (output_control) . . . . . integer-array ⇝ *integer*
The current color's red value.

▷ **Green** (output_control) . . . . . integer-array ⇝ *integer*
The current color's green value.

▷ **Blue** (output_control) . . . . . integer-array ⇝ *integer*
The current color's blue value.

Result

get_rgb returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_rgb, disp_region, disp_image

See also

set_rgb

Module

Foundation

get_rgba (: : WindowHandle : Red, Green, Blue, Alpha)

Get the current color in RGBA-coding.

get_rgba returns the output colors or gray values, respectively, for the output window. They are defined by the four color components red, green, blue and alpha.

The values returned by get_rgba can be set with set_rgba.

Attention

get_rgba depends on the library libcanvas, which might not be available on embedded systems.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Red** (output_control) ..... integer-array ⇝ *integer*
The current color's red value.

▷ **Green** (output_control) ..... integer-array ⇝ *integer*
The current color's green value.

▷ **Blue** (output_control) ..... integer-array ⇝ *integer*
The current color's blue value.

▷ **Alpha** (output_control) ..... integer-array ⇝ *integer*
The current color's alpha value.

Result

get_rgba returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_rgba, disp_obj

See also

set_rgba

Module

Foundation

get_shape (: : WindowHandle : DisplayShape)

Get the current region output shape.

get_shape returns the shape in which regions are displayed. The available shapes can be queried with query_shape and then changed with set_shape.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **DisplayShape** (output_control) ..... string ⇝ *string*
Current region output shape.

Result

get_shape returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

query_shape

Possible Successors

set_shape, disp_region

See also

set_shape, query_shape, disp_region

Module

Foundation

get_window_param (: : WindowHandle, Param : Value)

Get window parameters.

The operator get_window_param allows querying different parameters of an open window. For detailed descriptions of the individual parameters see set_window_param.

General window parameters:

'flush' *'true'* if automatic flushing is enabled, *'false'* otherwise.

'region_quality' Quality of the rendering of regions.

'background_color' The background color of the window WindowHandle.

'window_title' The text in the title bar of the window WindowHandle.

'anti_aliasing' *'true'* if anti aliasing is enabled, *'false'* otherwise.

'graphics_stack' *'true'* if the graphics stack is enabled, *'false'* otherwise.

'graphics_stack_max_element_num' Maximum number of elements in the graphics stack.

'graphics_stack_max_memory_size' Maximum memory consumption of the graphics stack.

'pixel_grid_enable' *'true'* if the pixel grid is enabled for the window WindowHandle.

'pixel_grid_min_resolution' Minimal required resolution of one pixel in the window WindowHandle such that the pixel grid becomes visible.

'pixel_grid_color' Color of the pixel grid lines.

'pixel_grid_line_width' Line width of the pixel grid lines.

Parameters concerning the *'3d_plot'*:

'angle_of_view' The angle of view of the virtual camera used to display the 3D plot.

'axis_captions' The captions for row, column, and height axis.

'plot_quality' The quality of the 3D plot.

'scale_plot' *'true'* if the height values of an image are transformed into the interval [0,255] before display, *'false'* otherwise.

'display_grid' *'true'* if the grid is displayed.

'display_axes' *'true'* if the coordinate axes are displayed.

Attention

The parameters *'anti_aliasing'*, *'flush'*, *'graphics_stack'*, *'graphics_stack_max_element_num'*, *'graphics_stack_max_memory_size'*, and *'region_quality'* depend on the library libcanvas, which might not be available on embedded systems.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Param** (input_control) . . . . . string ⇝ *string*
Name of the parameter.
Default: 'flush'
List of values: Param ∈ {'plot_quality', 'axis_captions', 'scale_plot', 'angle_of_view', 'display_grid', 'display_axes', 'window_title', 'background_color', 'graphics_stack', 'graphics_stack_max_element_num', 'graphics_stack_max_memory_size', 'pixel_grid_enable', 'pixel_grid_min_resolution', 'pixel_grid_color', 'pixel_grid_line_width', 'flush', 'region_quality'}

▷ **Value** (output_control) . . . . . string(-array) ⇝ *string* / real / integer
Value of the parameter.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window

Possible Successors

set_window_param

See also

get_window_attr, get_part_style

Module

Foundation

query_all_colors (: : WindowHandle : Colors)

Query all color names.

query_all_colors returns the names of all colors that are known to HALCON. That doesn't mean that these colors are available for specific screens. On some screens there may only be a subset of colors available (see query_color). The HALCON colors are used to display regions (disp_region, disp_polygon, disp_circle, etc.). They can be defined with set_color.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Colors** (output_control) . . . . . string-array ⇝ *string*
Color names.

Result

query_all_colors always returns 2 (H_MSG_TRUE)

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_system, set_color, disp_region

See also

query_color, set_system, set_color, disp_region, open_window

Module

Foundation

query_color (: : WindowHandle : Colors)

Query all color names displayable in the window.

query_color returns the names of all colors that are usable for region output (disp_region, disp_polygon, disp_circle, etc.). On a b/w screen query_color returns *'black'* and *'white'*. These two "colors" are displayable on any screen. In addition to *'black'* and *'white'* several gray values (e.g., *'dim gray'*) are returned on screens capable of gray values. A list of all displayable colors is returned for screens with color lookup table. The returned tuple of colors begins with b/w, followed by the three primaries (*'red'*,*'green'*,*'blue'*) and several gray values. query_all_colors(::WindowHandle:Colors) returns a list of all available colors. For screens with true-color output the same list is returned by query_color. The list of available colors (to HALCON) must not be confused with the list of displayable colors. For screens with true-color output the available colors are only a small subset of the displayable colors. Colors that are not directly available to HALCON can be chosen manually with set_rgb or set_hsi. If colors are chosen that are known to HALCON but cannot be displayed, HALCON can choose a similar color. To use this feature, set_check(::'~color':) must be set.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Colors** (output_control) ..... string-array ⇝ *string*
Color names.

Example

```
open_window(0,0,-1,-1,'root','invisible','',WindowHandle)
query_color(WindowHandle,Colors)
close_window(WindowHandle)
fwrite_string (FileHandle, ['Displayable colors: ',Colors])
```

Result

query_color returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_color, disp_region

See also

query_all_colors, set_color, disp_region, open_window

Module

Foundation

query_colored (: : : PossibleNumberOfColors)

Query the number of colors for color output.

query_colored returns all possible parameter values for set_colored. set_colored defines how many colors are used for region or graphics output.

Parameters

▷ **PossibleNumberOfColors** (output_control) ..... integer-array ⇝ *integer*
Tuple of the possible numbers of colors.

Example

```
regiongrowing(Image,Regions,5,5,6,100)
query_colored(Colors)
dev_set_colored(Colors[1])
dev_display (Regions)
```

Result

`query_colored` always returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`set_colored`, `set_color`, `disp_region`

Alternatives

`query_color`

See also

`set_colored`, `set_color`

Module

Foundation

query_gray (: : WindowHandle : Grayval)

Query the displayable gray values.

`query_gray` returns all gray values that are used for gray value output (`disp_image`) and that can be reproduced exactly in the window. They can be set with the `set_gray` call.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Grayval** (output_control) ..... integer-array ⇝ *integer*
Tuple of all displayable gray values.

Result

`query_gray` returns `2` (`H_MSG_TRUE`), if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`set_gray`, `disp_region`

See also

`set_gray`, `disp_image`

Module

Foundation

query_line_width (: : : Min, Max)

Query the possible line widths.

query_line_width returns the minimal (Min) and maximal (Max) values of widths of region border which can be displayed. Setting of the border width is done with set_line_width. Border width is used by operators like disp_region, disp_line, disp_circle, disp_rectangle1, disp_rectangle2 etc. if the drawing mode is "margin" (set_draw(::WindowHandle,'margin':)).

Parameters

▷ **Min** (output_control) ..... integer ⇝ *integer*
Displayable minimum width.

▷ **Max** (output_control) ..... integer ⇝ *integer*
Displayable maximum width.

Result

query_line_width returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_line_width, set_line_width, set_line_style, disp_line

See also

disp_circle, disp_line, disp_rectangle1, disp_rectangle2, disp_region, set_line_width, get_line_width, set_line_style

Module

Foundation

query_paint (: : WindowHandle : Mode)

Query the gray value display modes.

query_paint returns the names of all gray value display modes (e.g., 'gray', '3d_plot', etc.) for the output window. These modes are used by set_paint. query_paint only returns the names of the display values, not the additional parameters that may be necessary for some modes.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Mode** (output_control) ..... string-array ⇝ *string*
Gray value display mode names.

Result

query_paint returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_paint, set_paint, disp_image

See also

set_paint, get_paint, disp_image

Module

Foundation

query_shape (: : : DisplayShape)

Query the region display modes.

query_shape returns the names of all region display modes (e.g., 'original', 'circle', 'rectangle1', 'rectangle2', 'ellipse', etc.) for the window. They are used by set_shape.

Parameters

▷ **DisplayShape** (output_control) ..... string-array ⇝ *string*
region display mode names.

Result

query_shape returns 2 (H_MSG_TRUE), if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_shape, set_shape, disp_region

See also

set_shape, get_shape, disp_region

Module

Foundation

set_color (: : WindowHandle, Color :)

Set output color.

set_color defines the colors for region output in the window. The available colors can be queried with the operator query_color. In addition, the Color may be specified as hexadecimal RGB triplet or RGBA quadruplet in the form *'#rrggbb'* and *'#rrggbbaa'*. 'rr', 'gg', 'bb', and 'aa' are hexadecimal numbers between '00' and 'ff', respectively. 'aa' denotes the alpha value of a color and can be used to display transparent regions.

The parameter Color can contain a single color or a tuple with up to 256 colors. If only a single color is passed, all output is in this color. If a tuple of colors is passed, the output color of regions is modulo to the number of colors. In the example below, the first circle is displayed red, the second in transparent green and the third in red again. HALCON always begins output with the first color passed. Note, that the number of output colors depends on the number of objects that are displayed in one operator call. If only single objects are displayed, they always appear in the first color, even if they consist of more than one connected component.

The defined colors are used until set_color, set_rgb, set_rgba, set_hsi or set_gray is called again.

Colors are defined separately for each window. They can only be changed for the valid window.

Color is used in operators with region output like disp_region, disp_line, disp_rectangle1, or disp_arrow.

Color name	75% alpha	50% alpha	25% alpha
'black'	'#000000c0'	'#00000080'	'#00000040'
'white'	'#ffffffc0'	'#ffffff80'	'#ffffff40'
'red'	'#ff0000c0'	'#ff000080'	'#ff000040'
'green'	'#00ff00c0'	'#00ff0080'	'#00ff0040'
'blue'	'#0000ffc0'	'#0000ff80'	'#0000ff40'

'light blue'	'#add8e6c0'	'#add8e680'	'#add8e640'
'indian red'	'#cd5c5cc0'	'#cd5c5c80'	'#cd5c5c40'
'violet red'	'#d02090c0'	'#d0209080'	'#d0209040'
'light steel blue'	'#b0c4dec0'	'#b0c4de80'	'#b0c4de40'
'medium blue'	'#0000cdc0'	'#0000cd80'	'#0000cd40'
'khaki'	'#f0e68cc0'	'#f0e68c80'	'#f0e68c40'
'violet'	'#ee82eec0'	'#ee82ee80'	'#ee82ee40'
'firebrick'	'#b22222c0'	'#b2222280'	'#b2222240'
'midnight blue'	'#191970c0'	'#19197080'	'#19197040'

Examples of possible color strings

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Color** (input_control) . . . . . string(-array) ⇝ *string*
Output color names.
Default: 'white'
Suggested values: Color ∈ {'black', 'white', 'red', 'green', 'blue', 'cyan', 'magenta', 'yellow', 'dim gray', 'gray', 'light gray', 'medium slate blue', 'coral', 'slate blue', 'spring green', 'orange red', 'orange', 'dark olive green', 'pink', 'cadet blue', '#003075', '#e53019', '#ffb529', '#f28d26bb'}

Example

```
set_color(WindowHandle, ['red', '#00ff00a0'])
disp_circle(WindowHandle, [100,200,300], [200,300,100], [100,100,100])
```

Result

set_color returns 2 (H_MSG_TRUE) if the window is valid and the passed colors are displayable on the screen. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_colored (: : WindowHandle, NumberOfColors :)

Set multiple output colors.

set_colored is a shortcut for certain set_color calls. It allows the user to display a region set in different colors. NumberOfColors defines the number of colors that are used. Valid values for NumberOfColors can be queried with query_colored.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **NumberOfColors** (input_control) . . . . . integer ⇝ *integer*
Number of output colors.
Default: 12
List of values: NumberOfColors ∈ {3, 6, 12}

Result

set_colored returns 2 (H_MSG_TRUE) if NumberOfColors is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_contour_style (: : WindowHandle, Style :)

Define the contour display fill style.

set_contour_style defines the fill style of contour displays. The following values are supported for Style:

- *'stroke'*: Only the line of the contour gets displayed.
- *'fill'*: The area enclosed by the contour is filled.
- *'stroke_and_fill'*: The line of the contour gets displayed and the enclosed area filled. especially makes a difference for larger line widths, see set_line_width.

For all styles the current drawing color is used.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Style** (input_control) ..... string ⇝ *string*
Fill style of contour displays.
Default: 'stroke'
List of values: Style ∈ {'stroke', 'fill', 'stroke_and_fill'}

Result

set_contour_style returns 2 (H_MSG_TRUE) if Style is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_draw (: : WindowHandle, Mode :)

Define the region fill mode.

set_draw defines the region fill mode. If Mode is set to 'fill', output regions are filled, if set to 'margin', only contours are displayed. Setting Mode only affects the valid window. It is used by operators with region output like disp_region, disp_circle, disp_rectangle1, disp_rectangle2, disp_arrow etc. It is also used by operators with gray value output for some gray value output modes. If the mode is 'margin', the contour can be affected with set_line_width and set_line_style.

Attention

If the output mode is 'margin' and the line width is more than one, objects may not be displayed.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Mode** (input_control) ..... string ⇝ *string*
Fill mode for region output.
Default: 'fill'
List of values: Mode ∈ {'fill', 'margin'}

Result

set_draw returns 2 (H_MSG_TRUE) if Mode is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_gray (: : WindowHandle, GrayValues :)

Define gray values for region output.

set_gray defines the gray values for region output. Gray values are defined as the range of the color lookup table that is used for gray value output with disp_image in conjunction with set_paint(::WindowHandle,'gray':). These entries can be modified by set_lut. So a 'gray value' is the color in which a pixel with the same value is displayed (not necessarily really gray). In general, when changing the color lookup table with set_lut, the colors of the displayed image will change too.

If a gray value is needed as a color for image output (i.e. no color changes with set_lut are possible), it can be set with set_color(::WindowHandle,'gray':).

If only a single gray value is passed, all output will take place in that gray value. If a tuple of gray values is passed, all output will take place in gray values modulo the number of tuple elements. In the example below, the first circle is displayed with gray value 100, the second with 200 and the third with 100 again. Every output operator starts with the first gray value. Note, that the number of output gray values depends on the number of objects that are displayed in one operator call. If only single objects are displayed, they always appear in the first gray value, even if the consist of more than one connected components.

When the operators set_gray, set_color, set_rgb, set_hsi are called, the overwrite the existing values. If not all gray values are displayable on the output device, the number range of GrayValues (0..255) is dithered to the range of displayable gray values. In any case 0 is displayed as black and 255 as white. The displayable gray values can be queried with the operator query_gray. With set_check('~color') error messages can be suppressed if a gray value can't be displayed on the screen. In that case, a similar gray value is displayed.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **GrayValues** (input_control) ..... integer(-array) ⇝ *integer*
Gray values for region output.
Default: 255
Suggested values: GrayValues ∈ {0, 1, 2, 10, 16, 32, 64, 100, 120, 128, 250, 251, 252, 253, 254, 255}
Value range: 0 ≤ GrayValues ≤ 255

Example

```
set_gray(WindowHandle,[100,200])
disp_circle(WindowHandle,[100,200,300],[200,300,100],[100,100,100])
```

Result

set_hsi returns 2 (H_MSG_TRUE) if the window is valid and the given gray value is displayable. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

disp_region

See also

set_color

Module

Foundation

set_hsi (: : WindowHandle, Hue, Saturation, Intensity :)

Define output colors (HSI-coded).

set_hsi sets the region output color(s)/gray value(s) for the valid window. Colors are passed as Hue, Saturation, and Intensity. Transformation from HSI to RGB is done with:

$$
\begin{aligned}
H &= (\texttt{Hue}/255.0) * 2\pi \\
S &= (\texttt{Saturation}/255.0) * 2.0/\sqrt{6} \\
I &= \texttt{Intensity} \\
\\
M1 &= S\cos(H)/\sqrt{6} * 255.0 \\
M2 &= S\sin(H)/\sqrt{2} * 255.0 \\
\\
Red &= 2M1 + I \\
Green &= -M1 + M2 + I \\
Blue &= -M1 - M2 + I
\end{aligned}
$$

The value range is clipped to 0 to 255.

If only one combination is passed, all output will take place in that color. If a tuple of colors is passed, the output color of regions and geometric objects is modulo to the number of colors. HALCON always begins output with the first color passed. Note, that the number of output colors depends on the number of objects that are displayed in one operator call. If only single objects are displayed, they always appear in the first color, even if the consist of more than one connected components.

Selected colors are used until the next call of set_color,set_rgb or set_gray. Colors are relevant to windows, i.e., only the colors of the valid window can be set. Region output colors are used by operators like disp_region, disp_line, disp_rectangle1, disp_rectangle2, disp_arrow, etc. It is also used by operators with gray value output in certain output modes (e.g., *'3d_plot'*, see set_paint).

Attention

The colors are internally stored as RGB triples. Some HSI triples can not be represented by a valid RGB triple (i.e. in the range 0..255). In this case the nearest color which can be represented is used instead.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Hue** (input_control) ..... integer(-array) ⇝ *integer*
  Hue for region output.
  Default: 30
  Value range: $0 \leq$ Hue ≤ 255
- ▷ **Saturation** (input_control) ..... integer(-array) ⇝ *integer*
  Saturation for region output.
  Default: 255
  Value range: $0 \leq$ Saturation ≤ 255
- ▷ **Intensity** (input_control) ..... integer(-array) ⇝ *integer*
  Intensity for region output.
  Default: 84
  Value range: $0 \leq$ Intensity ≤ 255

Result

set_hsi returns 2 (H_MSG_TRUE) if the window is valid and the output colors are displayable. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_icon (Icon : : WindowHandle :)

Icon definition for region output.

set_icon defines an icon for region output (disp_region). It is displayed in the regions center of gravity. The use of this icon is activated with set_shape.

Parameters

▷ **Icon** (input_object) . . . . . region ⇝ *object*
Icon for center of gravity.

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

Example

```
/* draw a region and an icon */
T_draw_region(&Region,WindowHandle);
T_draw_region(&Icon,WindowHandle);
set_icon(Icon);
create_tuple_s(&icon,"icon");
T_set_shape(WindowHandle,icon);
destroy_tuple(icon);
T_disp_region(Region,WindowHandle);
```

Result

`set_icon` returns `2` (`H_MSG_TRUE`), if exactly one region is supplied. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_line_style (: : WindowHandle, Style :)

Define a contour output pattern.

`set_line_style` defines the output pattern of the margin of regions and of XLD contours. The information is used by operators like `disp_region`, `disp_line`, `disp_polygon` etc. The current value can be queried with `get_line_style`. `Style` contains up to five pairs of values. The first value is the length of the visible contour part, the second is the length of the invisible part. The value pairs are used cyclical for contour output.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Style** (input_control) . . . . . integer-array ⇝ *integer*
Contour pattern.
Default: []
Value range: $1 \leq$ `Style` ≤ 120

Example

```
* stroke line: X-Windows
set_line_style(WindowHandle,[20,7])
* point-stroke line: X-Windows
set_line_style(WindowHandle,[20,7,3,7])
* passing line (standard)
set_line_style(WindowHandle,[])
```

Result

`set_line_style` returns `2` (`H_MSG_TRUE`) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`get_line_style`, `set_line_approx`, `disp_region`

Module

Foundation

`set_line_width ( : : WindowHandle, Width : )`

Define the line width for region contour output.

`set_line_width` defines the line width (in pixel) in which a region contour is displayed (e.g., with `disp_region`, `disp_line`, `disp_polygon`, etc.) The operator `get_line_width` returns the current value for the window. Some output devices may not allow to change the contour width. If it is possible for the current device, it can be queried with `query_line_width`.

Attention

The line width is important if the output mode was set to 'margin' (see `set_draw`). If the line width is greater than one, regions may not always be displayed correctly.

Parameters

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **`Width`** (input_control) ..... real ⇝ *real*
Line width for region output in contour mode.
Default: 1.0
Restriction: Width >= 1.0 && Width <= 2000.0

Result

`set_line_width` returns `2` (`H_MSG_TRUE`) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_paint (: : WindowHandle, Mode :)

Define the gray value output mode.

set_paint defines the output mode for gray value display (single- or multichannel) in the window. The mode is used by disp_obj, disp_image, and disp_color.

Different image types and their possible implication on the Mode:

- Gray images can also be interpreted as 3D data, depending on the gray value. To view these 3D plots, select the modes *'3d_plot'*.
- Three-channel images are interpreted as RGB images.
- Vector field images can be viewed as *'vector_field'*.

In most cases the setting Mode *'default'* is the most suitable.

Depending on the selected mode, the Mode may accept a tuple as value. In these cases the entries can be passed the following ways:

- Only the name of the mode is passed: The defaults or the most recently used values are used, respectively.
  Example: `set_paint(WindowHandle,'3d_plot')`
- All values are passed: All output characteristics can be set.
  Example: `set_paint(WindowHandle, ['3d_plot', 'shaded', 8, 0.939, -0.052, 0.296, -0.165, 0.401, 0.072, -0.047, -0.073])`
- Only the first n values are passed: Only the passed values are changed.
  Example: `set_paint(WindowHandle,['3d_plot','texture'])`
- Some of the values are replaced by an asterisk ('*'): The value of the replaced parameters is not changed.
  Example: `set_paint(WindowHandle,['3d_plot', '*' ,8])`

If the current mode is *'default'*, HALCON chooses a suitable algorithm for the output of 2- and 3-channel images. No set_paint call is necessary in this case.

Apart from set_paint there are other operators that affect the output of gray values. The most important of them are set_part, set_part_style and set_lut. Some output modes display gray values using region output (e.g., *'3d_plot'*). In these modes, parameters set with set_color, set_rgb, set_hsi, set_shape, set_line_width and set_insert influence gray value output. In case of unexpected results, check the values of the display parameters.

All available painting modes can be queried with query_paint. Possible values for Mode:

'default' Optimal display on given hardware (default value). Its behavior depends on the number of channels of the input image:

- One-channel image: Output the single channel.
- Two-channel images: Output the first channel.
- Three-channel images: Output as RGB image.

['3d_plot', Mode, Step, qa, qb, qc, qd, ZoomFac, CenterRow, CenterCol, CenterHeight] Gray values are interpreted as a 3D height field and displayed using OpenGL. Thereby the different parameters are:

- *'Mode'*: Specifies the way in which the height field is displayed. The following modes are supported:
  - *'texture'*: The height field is displayed as a closed surface and colored using texture mapping. The texture is passed as the second channel (for a gray-valued texture) or as the second to fourth channel (for a colored texture) of the image to display.
  - *'shaded'*: The height field is displayed as a closed surface and colored using the current LUT.
  - *'hidden_lines'*: The height field is displayed as a hidden line plot and colored using the current LUT.
  - *'contour_lines'*: Height lines are extracted and displayed at their actual height. Again the lines are colored using the current LUT.
- *'Step'*: Step width, i.e., at what intervals samples in row and column direction are taken from the image. The smaller this parameter is chosen, the finer the resulting height field. However, computation time increases while this parameter decreases. In the case of *'contour_lines'* this parameter corresponds to the number of intervals the height range is divided into.

- *'qa'*,*'qb'*,*'qc'*,*'qd'*: The four values of a unit quaternion, describing the orientation of the height field (see `axis_angle_to_quat` for more information on quaternions).
- *'ZoomFac'*: Zooming factor, whereby smaller values implicate higher zooming.
- *'CenterRow'*, *'CenterCol'*, *'CenterHeight'*: Position of the actual center of view defined by row, column, and height. These values must be scaled to the interval [*-0.5*, *0.5*].

Automatic parameter determination: You can set *'qa'* (fourth value in the tuple) or *'ZoomFac'* (eighth value in the tuple) to *'auto'*. Then, the zooming factor and the center of view are determined automatically such that the plot of the height field fills the window as good as possible. By setting *'qa'* to *'auto'*, the previous orientation (or the default one) is kept. By setting *'ZoomFac'* to *'auto'*, the provided orientation is used. It is important that the part of the window is set correctly (using `set_part`) before `set_paint` is called. It is not possible to set any parameters after *'auto'* in the tuple. Furthermore *'auto'* will only work correctly if *'scale_plot'* is set to *'true'* using `set_window_param`.

Example: `set_paint(WindowHandle, ['3d_plot','shaded',4,'auto'])`

This mode allows interactive display of the 3D data. For an interactive rate, your graphics card needs to be powerful enough and support OpenGL. See the operator `update_window_pose` for an intuitive way of modifying the parameters of the 3D plot (e.g., with the mouse).

The colors of the axis are influenced by the colors set using `set_rgb`, `set_color`, and `set_colored`. The first three colors set this way are used as colors for row, column, and height axis (in this order).

Additional parameters concerning the 3D plot can be set using the operator `set_window_param`.

If you intend to use *'3d_plot'* on a Unix-like system, make sure you have sufficient permissions on your graphics device.

Default: *['3d_plot', 'shaded', 8, 0.939, -0.052, 0.296, -0.165, 0.401, 0.072, -0.047, -0.073]*

Restriction: Only for one-channel images.

['vector_field', Mode, Step, MinLength, ScaleLength, CircleSize] Output a vector field. Thus, for `Mode` *'vector_field'* a circle is drawn for each vector at the position of the pixel. Furthermore, a line segment is drawn with the current vector. Thereby the different parameters are:

- *'Mode'*: Tells whether the visualized vector fields contain absolute or relative coordinates. Possible values:
  - *'auto'* (*default*): The visualization depends on the semantic type of the vector field.
  - *'absolute'*: Display vector fields containing absolute coordinates.
  - *'relative'*: Display vector fields containing relative coordinates.
- *'Step'*: Step size for drawing the vectors, i.e., the distance between the drawn vectors.
- *'MinLength'*: Minimum length a vector needs in order to be displayed.
- *'ScaleLength'*: Scales the vector length.
- *'CircleSize'*: Diameter of the drawn circles.

It should be noted that by setting *'vector_field'* only the internal parameters *'Mode'*, *'Step'*, *'MinLength'*, *'ScaleLength'*, and *'CircleSize'* are changed. The current display mode is not changed.

Vector field images are always displayed as vector fields, no matter which `Mode` is selected with `set_paint`.

Example: `set_paint(WindowHandle,['vector_field','auto',16,2,3,5])`

This results in an output of every 16th vector, that is longer than 2 pixels. Each vector is multiplied by 3 for output.

Restriction: Only for vector field images.

Parameters

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **`Mode`** (input_control) ..... string-array ⇝ *string* / integer / real
Output mode. Additional parameters possible.
Default: 'default'
List of values: `Mode` ∈ {'default', '3d_plot', 'vector_field'}

Result

`set_paint` returns `2` (`H_MSG_TRUE`) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_part (: : WindowHandle, Row1, Column1, Row2, Column2 :)

Modify the displayed image part.

set_part modifies the image part that is displayed in the window. (Row1,Column1) denotes the upper left corner and (Row2,Column2) the lower right corner of the image part to display. The changed values are used by gray value output operators (disp_image, disp_color) as well as region output operators (disp_region).

If only part of an image is displayed, it will be zoomed to full window size. The zooming interpolation method can be set with set_part_style. get_part returns the values of the image part to display. Adapting the size of the window to the size of the image part to be displayed will prevent slowing down the display due to necessary interpolations. Thus, the window preferably has the same size as the image part to be displayed, or otherwise half its size, quarter its size, etc.

Beside setting the image part directly, the following special modes are supported:

Row1 = Column1 = Row2 = Column2 = *-1*: The window size is chosen as the image part, i.e. no zooming of the image will be performed.

Row1, Column1 > *-1* and Row2 = Column2 = *-1*: The size of the last displayed image (in this window) is chosen as the image part, i.e. the image can completely be displayed in the image. For this the image will be zoomed if necessary.

Row1 = Column1 = *0* and Row2 = Column2 = *-2*: The size of the last displayed image (in this window) is used to adapt the image part such that the image fits completely into the window, preserving the aspect ratio of the image. For this the image will be zoomed if necessary.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row1** (input_control) ..... rectangle.origin.y ⇝ *integer* / real
Row of the upper left corner of the chosen image part.
Default: 0

▷ **Column1** (input_control) ..... rectangle.origin.x ⇝ *integer* / real
Column of the upper left corner of the chosen image part.
Default: 0

▷ **Row2** (input_control) ..... rectangle.corner.y ⇝ *integer* / real
Row of the lower right corner of the chosen image part.
Default: -1
Restriction: Row2 >= Row1 || Row2 == -1 || Row1 == 0 && Row2 == -2

▷ **Column2** (input_control) ..... rectangle.corner.x ⇝ *integer* / real
Column of the lower right corner of the chosen image part.
Default: -1
Restriction: Column2 >= Column1 || Column2 == -1 || Column1 == 0 && Column2 == -2

Example

```
get_system('width',Width)
get_system('height',Height)
set_part(WindowHandle,0,0,Height-1,Width-1)
disp_image(Image,WindowHandle)
draw_rectangle1(WindowHandle,Row1,Column1,Row2,Column2)
set_part(WindowHandle,Row1,Column1,Row2,Column2)
disp_image(Image,WindowHandle)
```

Result

`set_part` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`get_part`

Possible Successors

`set_part_style`, `disp_image`, `disp_region`

Alternatives

`affine_trans_image`

See also

`get_part`, `set_part_style`, `disp_region`, `disp_image`, `disp_color`

Module

Foundation

set_part_style (: : WindowHandle, Style :)

Define an interpolation method for gray value output.

`set_part_style` defines the interpolation method to zoom an image part which is displayed in the window. Interpolation takes place, if the output window has different size than the image to display (e.g., after a call to `set_part` or a window resize). Three modes are supported:

0 no interpolation (low quality, very fast).

1 unweighted interpolation (medium quality and run time)

2 weighted interpolation (high quality, slow)

The current value can be queried with `get_part_style`.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Style** (input_control) . . . . . integer ⇝ *integer*
Interpolation method for image output: 0 (fast, low quality) to 2 (slow, high quality).
Default: 0
List of values: `Style` ∈ {0, 1, 2}

Result

`set_part_style` returns `2` (`H_MSG_TRUE`) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_part_style, set_part, disp_image, disp_color

Module

Foundation

set_rgb (: : WindowHandle, Red, Green, Blue :)

Set the color definition via RGB values.

set_rgb sets the output color(s) or the gray values, respectively, for region output for the window. The colors are defined with the red, green and blue components. If only one combination is passed, all output takes place in that color. If a tuple is passed, region output and output of geometric objects takes place modulo the passed colors.

For every call of an output operator, output is started with the first color. If only one object is displayed per call, it will always be displayed in the first color. This is even true for objects with multiple connection components. If multiple objects are displayed per operator call, multiple colors are used. The defined colors are used until set_color, set_rgb or set_gray is called again. The values are used by operators like disp_region, disp_line, disp_rectangle1, disp_rectangle2, disp_arrow, etc.

Attention

If a passed color is not available, an exception is raised. If set_check('~color') was called before, HALCON uses a similar color and suppresses the error.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Red** (input_control) ..... integer(-array) ⇝ *integer*
Red component of the color.
Default: 255
Value range: $0 \leq$ Red ≤ 255

▷ **Green** (input_control) ..... integer(-array) ⇝ *integer*
Green component of the color.
Default: 0
Value range: $0 \leq$ Green ≤ 255

▷ **Blue** (input_control) ..... integer(-array) ⇝ *integer*
Blue component of the color.
Default: 0
Value range: $0 \leq$ Blue ≤ 255

Result

set_rgb returns 2 (H_MSG_TRUE) if the window is valid and all passed colors are available and displayable. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Successors

disp_image, disp_region

Alternatives

set_hsi, set_color, set_gray

disp_region

Module

Foundation

set_rgba (: : WindowHandle, Red, Green, Blue, Alpha :)

Set the color definition via RGBA values.

set_rgba sets the output color(s) or the gray values, respectively, for region output for the window. The colors are defined with the red, green, blue, and alpha components. If only one combination is passed, all output takes place in that color. If a tuple is passed, region output and output of geometric objects takes place modulo the passed colors.

For every call of an output operator, output is started with the first color. If only one object is displayed per call, it will always be displayed in the first color. This is even true for objects with multiple connection components. If multiple objects are displayed per operator call, multiple colors are used. The defined colors are used until set_color, set_rgba, or set_rgb is called again. The values are used by operators like disp_region, disp_line, disp_rectangle1, disp_rectangle2, disp_arrow, etc.

Attention

set_rgba depends on the library libcanvas, which might not be available on embedded systems.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Red** (input_control) ..... integer(-array) ⇝ *integer*
Red component of the color.
Default: 255
Value range: 0 ≤ Red ≤ 255
Restriction: 0 <= Red && Red <= 255

▷ **Green** (input_control) ..... integer(-array) ⇝ *integer*
Green component of the color.
Default: 0
Value range: 0 ≤ Green ≤ 255
Restriction: 0 <= Green && Green <= 255

▷ **Blue** (input_control) ..... integer(-array) ⇝ *integer*
Blue component of the color.
Default: 0
Value range: 0 ≤ Blue ≤ 255
Restriction: 0 <= Blue && Blue <= 255

▷ **Alpha** (input_control) ..... integer(-array) ⇝ *integer*
Alpha component of the color.
Default: 255
Value range: 0 ≤ Alpha ≤ 255
Restriction: 0 <= Alpha && Alpha <= 255

Result

set_rgba returns 2 (H_MSG_TRUE) if the window is valid and all passed colors are available and displayable. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

disp_obj

Alternatives

set_rgb, set_color

Module

Foundation

set_shape (: : WindowHandle, Shape :)

Define the region output shape.

set_shape defines the shape for region output. It is only valid for the window with the logical window number WindowHandle. The output shape is used by disp_region. The available shapes can be queried with query_shape.

Available modes:

'original': The shape is displayed unchanged. Nevertheless modifications via parameters like set_line_width can take place. This is also true for all other modes.

'outer_circle': Each region is displayed by the smallest surrounding circle. (See smallest_circle.)

'inner_circle': Each region is displayed by the largest included circle. (See inner_circle.)

'ellipse': Each region is displayed by an ellipse with the same moments and orientation (See elliptic_axis.)

'rectangle1': Each region is displayed by the smallest surrounding rectangle parallel to the coordinate axes. (See smallest_rectangle1.)

'rectangle2': Each region is displayed by the smallest surrounding rectangle. (See smallest_rectangle2.)

'convex': Each region is displayed by its convex hull (See convexity.)

'icon': Each region is displayed by the icon set with set_icon in the center of gravity.

Attention

Caution is advised for gray value output operators with output parameter settings that use region output.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Shape** (input_control) ..... string ⇝ *string*
Region output mode.
Default: 'original'
List of values: Shape ∈ {'original', 'convex', 'outer_circle', 'inner_circle', 'rectangle1', 'rectangle2', 'ellipse', 'icon'}

Example

```
read_image(Image,'fabrik')
regiongrowing(Image,Seg,5,5,6,100)
set_colored(WindowHandle,12)
set_shape(WindowHandle,'rectangle2')
disp_region(Seg,WindowHandle)
```

Result

set_shape returns 2 (H_MSG_TRUE) if the parameter is correct and the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_shape, query_shape, disp_region

Module

Foundation

set_window_param (: : WindowHandle, Param, Value :)

Set window parameters.

The operator set_window_param allows setting different parameters of an open window.

General window parameters:

'flush' Enables or disables flushing the contents of the window after the display of every object. If *'flush'* is set to *'false'*, flush_buffer must be called to update the contents of the window. If you want to interact with the content of the graphics window (e.g., zoom or move the content), you have to set *'flush'* to *'true'*.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'region_quality' Influences the quality of the rendering of region objects. Especially if the region to display has to be scaled down for visualization, *'good'* produces a more accurate and pleasing impression. *'low'* is a bit inaccurate in these cases but significantly faster. If only the border of the region is displayed (see set_draw), the fractional part of the line width (see set_line_width) is ignored.

List of values: *'low'*, *'good'*.

Default: *'low'*.

'background_color' Sets the background color of the window WindowHandle. The operator clear_window uses this color to clear the window.

Suggested values: a string containing the color name (e.g., *'black'*, *'red'*).

'window_title' Allows changing the text in the title bar of an already opened HALCON window.

Note that you cannot set *'window_title'* for buffer windows. This restriction also applies to HDevelop windows, that is windows opened via dev_open_window, which are in fact buffer windows.

Value range: a string containing up to 1023 characters.

'anti_aliasing' Enables or disables the anti aliasing of contours and regions.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'graphics_stack' Enables or disables the graphics stack of a window. With activated graphics stack changing the window part with set_part triggers the display of previously displayed objects with respect to the new part. With this it is possible to move or scale the contents of the window. This parameter has no effect on the graphics stack of a HDevelop graphics window.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'graphics_stack_max_element_num' Maximum number of elements in the graphics stack. This number corresponds to the number of display operations recorded. This parameter has no effect on the graphics stack of a HDevelop graphics window and is effective not before the next call to a display operator.

Suggested values: positive number or *'unlimited'*.

Default: *50*.

'graphics_stack_max_memory_size' Limits the memory consumption of the graphics stack. If this limit is exceeded, older display operations are removed from the graphics stack. This parameter has no effect on the graphics stack of a HDevelop graphics window and is effective not before the next call to a display operator.

Suggested values: memory limit in bytes or *'unlimited'*.

Default: *'unlimited'*.

'pixel_grid_enable' Enables or disables the pixel grid. If the pixel grid is activated, a grid is drawn around the displayed pixels as soon as the image part is enlarged sufficiently (see *'pixel_grid_min_resolution'*). This parameter is effective as soon as the window content is updated.

List of values: *'true'*, *'false'*.

Default: *'false'*.

Restriction: Has no effect, when the HDevelop option `Pixel Grid` is enabled.

'pixel_grid_min_resolution' Specifies the minimum required resolution of an image pixel in the graphics window which is necessary for the pixel grid to be drawn. This parameter has an effect only if *'pixel_grid_enable'* has been set to *'true'*. Assuming this value is set to *20*, the pixel grid will be visible as soon as a pixel in the displayed image part takes up at least *20* x *20* pixels in the graphics window. Furthermore, this parameter is effective as soon as the window content is updated.

Suggested values: Positive integer.

Default: *20*.

'pixel_grid_color' Specifies the color of the lines of the pixel grid. This parameter has an effect only if *'pixel_grid_enable'* has been set to *'true'*. Furthermore, this parameter is effective as soon as the window content is updated.

Suggested values: Color value, see `set_color` for an overview.

Default: *'#696969c0'*.

Restriction: Has no effect, when the HDevelop option `Pixel Grid` is enabled.

'pixel_grid_line_width' Specifies the line width in pixels that is used to display the lines of the pixel grid. This parameter has an effect only if *'pixel_grid_enable'* has been set to *'true'*. Furthermore, this parameter is effective as soon as the window content is updated.

Value range: [*1.0*, *2000.0*].

Default: *1.0*.

Parameters concerning the *'3d_plot'* (see `set_paint`):

'angle_of_view' Set the angle of view of the virtual camera used to display the 3D plot. The angle must be provided in radians and lie within the interval $[0, PI)$. An angle of 0 radians implies orthogonal projection. Another way to choose orthogonal projection is to set *'angle_of_view'* to *'orthogonal'*.

Suggested values: *'orthogonal'* or an angle in radians.

Default: *1.22173* (70 degrees).

'axis_captions' The axis captions for row, column, and height can be set by passing a tuple containing the strings for the captions in the specified order row, column, and height axis, (e.g., ['row','col','height']). Pass empty strings to display no captions at all.

Value range: A tuple containing three strings. Each string can contain up to 31 characters.

Default: *[' ',' ',' ']*.

'caption_color' The color of the axis captions for row, column, and height. You can either pass one color for all three axes or a tuple of three colors to set individual colors for each axis.

Suggested values: a string or tuple with three strings containing the color name (e.g., *'black'*, *'red'*).

Default: *'black'*.

'plot_quality' Influences the quality of the 3D plot. Depending on the capabilities of your graphics card better settings for the quality may reduce the frame rate of the 3D plot significantly.

List of values: *'low'*, *'medium'*, *'good'*, *'best'*.

Default: *'medium'*.

'scale_plot' If set to *'true'* the height values of an image are transformed into the interval [0,255] before display. If set to 'false' the aspect ratio between row/column and height is considered. Images of the type byte, cyclic, or direction are not scaled, i.e. in their cases this parameter is ignored.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'display_grid' If set to *'true'* a grid is displayed at height 0.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'display_axes' If set to *'true'* coordinate axes are displayed. **List of values:** *'true'*, *'false'*.

Default: *'true'*.

Attention

The parameters *'anti_aliasing'*, *'flush'*, *'graphics_stack'*, *'graphics_stack_max_element_num'*, *'graphics_stack_max_memory_size'*, and *'region_quality'* depend on the library libcanvas, which might not be available on embedded systems.

The parameter *'window_title'* cannot be set for buffer windows.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Param** (input_control) ..... string ⇝ *string*
Name of the parameter.
Default: 'flush'
List of values: `Param` ∈ {'plot_quality', 'axis_captions', 'caption_color', 'scale_plot', 'angle_of_view', 'display_grid', 'display_axes', 'window_title', 'background_color', 'anti_aliasing', 'flush', 'graphics_stack', 'graphics_stack_max_element_num', 'graphics_stack_max_memory_size', 'pixel_grid_enable', 'pixel_grid_min_resolution', 'pixel_grid_color', 'pixel_grid_line_width', 'region_quality'}

▷ **Value** (input_control) ..... string(-array) ⇝ *string* / real / integer
Value to be set.
Default: 'false'
List of values: `Value` ∈ {'true', 'false', 'low', 'good', 'medium', 'best', 'orthogonal', 'black', 'white', 'red', 'green', 'blue', 'unlimited'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

13.8 Text

```
disp_text ( : : WindowHandle, String, CoordSystem, Row, Column,
    Color, GenParamName, GenParamValue : )
```

Display text in a window.

`disp_text` displays text in the graphics window `WindowHandle` at the position (`Row`,`Column`).

If only a single position is defined, one text line is displayed for each element of `String`. Also, *'\n'* will be interpreted as a newline character, i.e., a line break is performed.

If multiple positions are defined, only a single string or one string for each position is allowed in `String`. In this case, line breaks have to be forced with *'\n'*.

Newlines (*'\n'*) at the end of `String` are ignored.

The position of the text may be specified in window coordinates (`CoordSystem` = *'window'*) or in image coordinates (`CoordSystem` = *'image'*), which is useful when using zoomed images.

In addition to supplying (`Row`,`Column`) coordinates, it is also possible to pass predefined values to `Row` and `Column` to display the text at a fixed Position in the window (only if `CoordSystem` = *'window'*).:

'top', *'left'*	*'top'*, *'center'*	*'top'*, *'right'*
'center', *'left'*	*'center'*, *'center'*	*'center'*, *'right'*
'bottom', *'left'*	*'bottom'*, *'center'*	*'bottom'*, *'right'*

The parameter `Color` also accepts tuples of values. In that case, the specified colors are used cyclically for every new text position or for every new text line if a single position is used.

Generic Parameters

`disp_text` may display the `String` within a box (default). This behavior and the look of the box are defined with the generic parameters in `GenParamName` and `GenParamValue`.

'box' If *'box'* is set to *'true'*, the text is written within a box. The look of the box and its optional shadow can be configured with the generic parameters below.
List of values: *'true'* and *'false'*
Default: *'true'*

'box_color' Sets the color of the box.
List of values: a string containing the color name (e.g., *'white'*, *'red'*, or *'#aa00bba0'*)
Default: *'#fce9d4'* (which is a light orange)

'shadow' If *'shadow'* is set to *'true'*, an additional shadow is displayed beneath the box (if *'box'* is *'true'*).
List of values: *'true'* and *'false'*
Default: *'true'* if *'box_color'* is set to a color without alpha value, *'false'* otherwise

'shadow_color' Sets the color of the shadow if *'shadow'* is *'true'*.
List of values: a string containing the color name (e.g., *'black'*, *'red'*, or *'#aa00bba0'*)
Default: *'#f28d26'* (which is a darker orange) if *'box_color'* is not set, *'white'* otherwise

'border_radius' Controls the roundness of the box's corners. For sharp corners set it to *0*, for smoother corners to higher values.
List of values: positive real numbers or *0*
Default: 2

'box_padding' Controls to which amount in pixels the box is extended around the text.
List of values: positive real number
Default: 0

'shadow_sigma' Controls to which amount the shadow beneath the box is blurred. Set it to *0* for a sharp shadow.
List of values: positive real number or *0*
Default: 1.5

'shadow_dx' and 'shadow_dy' Controls the offset of the shadow in column (*'shadow_dx'*) and row (*'shadow_dy'*) direction in pixels.
List of values: any real number
Default: 2

'backdrop_blur_sigma' Controls to which amount the background of the box is blurred. s only an effect if *'box'* is *'true'* and *'box_color'* is not opaque (i.e. alpha is not 255). It is recommended to use *'backdrop_blur_sigma'* with *'shadow'* set to *'false'*.
List of values: positive real number or *0*
Default: 0

'rotate_phi' Angle in degrees to rotate the displayed text.
List of values: any real number
Default: 0

'rotate_col' Column coordinate of the rotation center if *'rotate_phi'* is different to zero. Choose either a column coordinate by setting a real number or determine the rotation center on the left edge (*'text_left'*), the right edge (*'text_right'*), or in the center (*'text_center'*) of the text box.

List of values: any real number or *'text_left'*, *'text_center'*, *'text_right'*

Default: *'text_center'*

'rotate_row' Row coordinate of the rotation center if *'rotate_phi'* is different to zero. Choose either a row coordinate by setting a real number or determine the rotation center on the top edge (*'text_top'*), the bottom edge (*'text_bottom'*), or in the center (*'text_center'*) of the text box.

List of values: any real number or *'text_top'*, *'text_center'*, *'text_bottom'*

Default: *'text_center'*

'border_color' Sets the color of the border of the text box.

List of values: a string containing the color name (e.g., *'black'*, *'red'*, or *'#aa00bba0'*)

Default: *'#ffffff'*

'border_width' Controls the width of the text box border.

List of values: positive real numbers or *0*

Default: 0

Attention

`disp_text` depends on the library libhcanvas, which might not be available on embedded systems.

Parameters

▷ **`WindowHandle`** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **`String`** (input_control) . . . . . string(-array) ⇝ *string*
A tuple of strings containing the text message to be displayed. Each value of the tuple will be displayed in a single line.
Default: 'hello'

▷ **`CoordSystem`** (input_control) . . . . . string ⇝ *string*
If set to 'window', the text position is given with respect to the window coordinate system. If set to 'image', image coordinates are used (this may be useful in zoomed images).
Default: 'window'
List of values: `CoordSystem` ∈ {'window', 'image'}

▷ **`Row`** (input_control) . . . . . point.y(-array) ⇝ *integer* / real / string
The vertical text alignment or the row coordinate of the desired text position.
Default: 12
List of values: `Row` ∈ {12, 'bottom', 'center', 'top'}

▷ **`Column`** (input_control) . . . . . point.x(-array) ⇝ *integer* / real / string
The horizontal text alignment or the column coordinate of the desired text position.
Default: 12
List of values: `Column` ∈ {12, 'center', 'left', 'right'}

▷ **`Color`** (input_control) . . . . . string(-array) ⇝ *string*
A tuple of strings defining the colors of the texts.
Default: 'black'
List of values: `Color` ∈ {'black', 'blue', 'yellow', 'red', 'green', 'cyan', 'magenta', 'forest green', 'lime green', 'coral', 'slate blue'}

▷ **`GenParamName`** (input_control) . . . . . attribute.name-array ⇝ *string*
Generic parameter names.
Default: []
List of values: `GenParamName` ∈ {'backdrop_blur_sigma', 'box', 'shadow', 'box_color', 'shadow_color', 'border_radius', 'box_padding', 'shadow_sigma', 'shadow_dx', 'shadow_dy', 'rotate_phi', 'rotate_col', 'rotate_row', 'border_color', 'border_width'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value-array ⇝ *string* / integer / real
Generic parameter values.
Default: []
List of values: `GenParamValue` ∈ {'true', 'false', 'white', 'red', 'forest green', 'black', 'blue', 5.0}

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
disp_text (WindowHandle, 'Display some text in a box', 'window', 12, 12, \
           'black', [], [])
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_font, get_string_extents

Alternatives

write_string

See also

get_string_extents, set_font

Module

Foundation

get_font (: : WindowHandle : Font)

Get the current font.

get_font queries the name of the font used in the output window WindowHandle. The font is used by the operators write_string, read_string etc. The font is set by the operator set_font. Text windows as well as windows for image display use fonts. Both types of windows have a default font that can be modified with set_system('default_font',Font) prior to opening the window. A list of all available fonts can be obtained using query_font.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Font** (output_control) ..... string ⇝ *string*
Name of the current font.

Example

```
get_font(WindowHandle,CurrentFont)
set_font(WindowHandle,MyFont)
write_string(WindowHandle,['The name of my Font is:',Myfont])
new_line(WindowHandle)
set_font(WindowHandle,CurrentFont)
```

Result

get_font returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, query_font

Possible Successors

set_font

See also

set_font, query_font, open_window, set_system

Module

Foundation

get_font_extents (: : WindowHandle : MaxAscent, MaxDescent, MaxWidth, MaxHeight)

Get the maximum size of all characters of a font.

get_font_extents queries the maximum width (MaxWidth), height (MaxHeight), and extension above and below the baseline (MaxAscent and MaxDescent, respectively) of the font that is currently set for the window WindowHandle. The sizes are measured in pixels.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **MaxAscent** (output_control) ..... extent.y ⇝ *integer* / real
  Maximum height above baseline.
- ▷ **MaxDescent** (output_control) ..... extent.y ⇝ *integer* / real
  Maximum extension below baseline.
- ▷ **MaxWidth** (output_control) ..... extent.x ⇝ *integer* / real
  Maximum character width.
- ▷ **MaxHeight** (output_control) ..... extent.y ⇝ *integer* / real
  Maximum character height.

Result

get_font_extents returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_font

Possible Successors

See also

get_string_extents, set_tposition, set_font

Module

Foundation

get_string_extents (: : WindowHandle, Values : Ascent, Descent, Width, Height)

Get the spatial size of a string.

get_string_extents queries width and height of the output size of a string using the font of the window. Thereby strings with multiple lines are treated as if concatenated into a single line. In addition, the extension above and below the baseline is returned (Ascent and Descent, respectively).

The sizes are measured in the coordinate system of the window (for text windows in pixels). Using get_string_extents, it is possible to determine text output and input independently from the used font. The conversion from integer numbers and floating point numbers to text strings is the same as in write_string.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Values** (input_control) ..... string(-array) ⇝ *string* / real / integer
  Values to consider.
  Default: 'test_string'
- ▷ **Ascent** (output_control) ..... extent.y ⇝ *integer* / real
  Maximum height above baseline.
- ▷ **Descent** (output_control) ..... extent.y ⇝ *integer* / real
  Maximum extension below baseline.
- ▷ **Width** (output_control) ..... extent.x ⇝ *integer* / real
  Text width.
- ▷ **Height** (output_control) ..... extent.y ⇝ *integer* / real
  Text height.

Result

get_string_extents returns 2 (H_MSG_TRUE) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_font

Possible Successors

set_tposition, write_string, read_string, read_char

See also

get_font_extents, set_tposition, set_font

Module

Foundation

get_tposition (: : WindowHandle : Row, Column)

Get cursor position.

get_tposition queries the current position of the text cursor in the output window. The position is measured in the image coordinate system. The next output of text in this window starts at the cursor position. The left end of the baseline for writing the next string (not considering descenders) is placed on this position. The position is changed by the output or input of text (write_string, read_string) or by an explicit change of position by (set_tposition, new_line).

Attention

If the output text does not fit completely into the window, an exception is raised. This can be avoided by set_check('~text').

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Row** (output_control) ..... point.y ⇝ *integer*
  Row index of text cursor position.

▷ **Column** (output_control) . . . . . point.x ⇝ *integer*
Column index of text cursor position.

Result

`get_tposition` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_font`

Possible Successors

`set_tposition`, `write_string`, `read_string`, `read_char`

See also

`new_line`, `read_string`, `set_tposition`, `write_string`, `set_check`

Module

Foundation

new_line (: : WindowHandle :)

Set the position of the text cursor to the beginning of the next line.

`new_line` sets the position of the text cursor to the beginning of the next line. The new position depends on the current font. The left end of the baseline for writing the following text string (not considering descenders) is placed on this position.

If the next line does not fit into the window the content of the window is scrolled by the height of one line in the upper direction. In order to reach the correct new cursor position the font used in the next line must be set before `new_line` is called. The position is changed by the output or input of text (`write_string`, `read_string`) or by an explicit change of position by (`set_tposition`).

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

Result

`new_line` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_font`, `write_string`

Alternatives

`get_tposition`, `get_string_extents`, `set_tposition`

See also

`write_string`, `set_font`

Module

Foundation

query_font (: : WindowHandle : Font)

Query the available fonts.

query_font queries the fonts available for text output in the output window. They can be set with the operator set_font using the appropriate syntax. Fonts are used by the operators write_string, read_char, read_string and new_line.

Attention

For different machines the available fonts may differ a lot. Therefore query_font will return different fonts on different machines.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Font** (output_control) ..... string-array ⇝ *string*
  Tuple with available font names.

Example

```
open_window(0,0,-1,-1,'root','visible','',WindowHandle)
set_check('~text')
query_font(WindowHandle,Fontlist)
set_color(WindowHandle,'white')
for i:=0 to |Fontlist|-1 by 1
  set_display_font (WindowHandle,16,Fontlist[i],'true','false')
  write_string(WindowHandle,Fontlist[i])
  new_line(WindowHandle)
endfor
```

Result

query_font returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window

Possible Successors

set_font, write_string, read_string, read_char

See also

set_font, write_string, read_string, read_char, new_line

Module

Foundation

read_char (: : WindowHandle : Char, Code)

Read a character from a window.

read_char reads a character from the keyboard in the input window (= output window). If the character is printable it is returned in Char. If a control key has been pressed, this will be indicated by the value of Code. Some important keys are recognizable by this value. Possible values are:

'character': printable character

'left': cursor left

'right': cursor right

'up': cursor up

'down': cursor down

'insert': insert

'none': none of these keys

'canceled': `read_char` has been canceled (not always possible, e.g., in native X11 windows)

Parameters

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **`Char`** (output_control) ..... string ⇝ *string*
Input character (if it is not a control character).

▷ **`Code`** (output_control) ..... string ⇝ *string*
Code for input character.

Result

`read_char` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_font`

Alternatives

`read_string`, `fread_char`, `fread_string`

See also

`write_string`, `set_font`

Module

Foundation

`read_string` `( : : WindowHandle, InString, Length : OutString )`

Read a string in a text window.

This operator does not work in an HDevelop graphics window opened with `dev_open_window`.

`read_string` reads a string with a predetermined maximum length (`Length`) from the keyboard in the input window (= output window). The string is read from the current position of the text cursor using the current font. The maximum length has to be small enough to keep the string within the right window boundary. A default string which can be edited or simply accepted by the user may be provided. After text input the text cursor is positioned at the end of the edited string. Commands for editing:

RETURN finish input

BACKSPACE delete the character on the left side of the cursor and move the cursor to this position.

The length is stated as number of characters. If *'filename_encoding'* is set to *'locale'* with `set_system`, the length is stated in number of bytes.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **InString** (input_control) . . . . . string ⇝ *string*
Default string (visible before input).
Default: ”

▷ **Length** (input_control) . . . . . integer ⇝ *integer*
Maximum number of characters.
Default: 32
Restriction: Length > 0 && Length <= 1024

▷ **OutString** (output_control) . . . . . string ⇝ *string*
Read string.

Result

`read_string` returns `2` (`H_MSG_TRUE`) if the text window is valid and a string of maximal length fits within the right window boundary. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_font`

Alternatives

`read_char`, `fread_string`, `fread_char`

See also

`set_tposition`, `new_line`, `open_window`, `set_font`, `set_color`

Module

Foundation

set_font (: : WindowHandle, Font :)

Set the font used for text output.

`set_font` sets the font `Font` for the output window `WindowHandle`. All subsequent text outputs (e.g., with the operators `disp_text`, `write_string` or `read_string`) will now use the new font instead of the default font (see `set_system('default_font',Font)`). All available fonts can be queried with `query_font`.

The syntax for the specification of `Font` is the following:

```
FONTNAME[-STYLE]-FONT\_SIZE.
```

The optional STYLE may be one of the following (other values are possible as well):

- Normal,
- Bold,
- BoldItalic, or
- Italic.

The FONT_SIZE is measured in pixels.

An example of a valid string for `Font` would be

’Courier-Bold-14’.

Attention

For different machines the available fonts may differ a lot. Therefore it is suggested to use the operator query_font or the procedure set_display_font.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Font** (input_control) ..... string ⇝ *string*
Name of new font.

Example

```
dev_get_window (WindowHandle)
query_font (WindowHandle, Font)
* Specify font name and size
FontWithSize := Font[0]+'-20'
set_font (WindowHandle, FontWithSize)
dev_disp_text ('Font set to: '+FontWithSize, 'window', 20, 12, 'black', \
               [], [])
* Specify font name, style, and size
FontWithStyleAndSize := Font[0]+'-Bold-20'
set_font (WindowHandle, FontWithStyleAndSize)
dev_disp_text ('Font set to: '+FontWithStyleAndSize, 'window', 50, 12, \
               'black', [], [])
```

Result

set_font returns 2 (H_MSG_TRUE) if the font name can be resolved. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window

Possible Successors

query_font

See also

get_font, query_font, open_window

Module

Foundation

set_tposition (: : WindowHandle, Row, Column :)

Set the position of the text cursor.

set_tposition sets the position of the text cursor in the output window. The reference position is the upper left corner of an upper case character.

The position is measured in the image coordinate system. The position of the text cursor can be marked, e.g., by an underscore. The next text output in this window starts at the cursor position. The left end of the baseline for writing the following text string (not considering descenders) is placed on this position.

The position is changed by the output or input of text (write_string, read_string) or by an explicit change of position by (set_tposition, new_line). In order to stop the display of the cursor, the operator set_tshape with the parameter ”invisible” can be used.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (input_control) . . . . . point.y ⇝ *integer*
Row index of text cursor position.
Default: 24

▷ **Column** (input_control) . . . . . point.x ⇝ *integer*
Column index of text cursor position.
Default: 12

Result

`set_tposition` returns `2` (`H_MSG_TRUE`) if the window is valid. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

Possible Successors

`write_string`, `read_string`

Alternatives

`new_line`

See also

`read_string`, `write_string`

Module

Foundation

write_string (: : WindowHandle, String :)

Print text in a window.

`write_string` prints `String` in the output window starting at the current cursor position. The output text has to fit within the right window boundary (the width of the string can be queried by `get_string_extents`).

The font currently assigned to the window will used. The text cursor is positioned at the end of the text.

`write_string` can output all three types of data used in HALCON . The conversion to a string is guided by the following rules:

- strings are not converted.
- integer numbers are converted without any spaces before or after the number.
- floating numbers are printed (if possible) with a floating point and without an exponent.
- the resulting strings are concatenated without spaces.

For buffering of texts see `set_system` with the flag 'flush_graphic'.

Attention

If clipping at the window boundary is desired, exceptions can be switched off by `set_check('~text')`.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **String** (input_control) . . . . . string(-array) ⇝ *string* / integer / real
Tuple of output values (all types).
Default: 'hello'

Result

`write_string` returns `2` (`H_MSG_TRUE`) if the window is valid and the output text fits within the current line (see `set_check`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_font`, `get_string_extents`

Alternatives

`fwrite_string`

See also

`set_tposition`, `get_string_extents`, `set_font`, `set_system`, `set_check`

Module

Foundation

13.9 Window

clear_window (: : WindowHandle :)

Delete the contents of an output window.

`clear_window` deletes all entries in the output window. The window (background and edge) is reset to its original state. Parameters assigned to this window (e.g., with `set_color`, `set_paint`, etc.) remain unmodified.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

Result

If the output window is valid `clear_window` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

Alternatives

`clear_rectangle`, `disp_rectangle1`

See also

`open_window`

Module

Foundation

close_window (: : WindowHandle :)

Close an output window.

close_window closes a window which have been opened by open_window. Afterwards the output device or the window area, respectively, is ready to accept new calls of open_window.

Parameters

▷ **WindowHandle** (input_control) ..... window(-array) ⇝ *handle*
Window handle.

Result

If the output window is valid close_window returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- WindowHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

open_window

See also

open_window

Module

Foundation

copy_rectangle (: : WindowHandleSource, WindowHandleDestination, Row1, Column1, Row2, Column2, DestRow, DestColumn :)

Copy all pixels within rectangles between output windows.

copy_rectangle copies all pixels from the window WindowHandleSource in the window WindowHandleDestination. It copies pixels which reside inside a rectangle which is specified by parameters Row1, Column1, Row2 and Column2. The target position is specified through the upper left corner of the rectangle (DestRow, DestColumn).

If you want to move more than one rectangle, you may pass them at once (in form of the tuple mode).

You may use copy_rectangle to copy edited graphics from an “invisible” window in a visible window. Therefore a window with the option ’buffer’ is opened. The graphics is then displayed in this window and is copied in a visible window afterwards. The advantage of this strategy is, that copy_rectangle is much more rapid than output operators as, e.g., disp_channel. This means a particular advantage while using demo programs. You could even realize short “clips”: you have to create for every image of a sequence a window of a ’buffer’ type and pass the data into it. Output is the image sequence whereat all buffers are copied one after another in a visible window.

Attention

Both windows have to reside on the same display.

Parameters

▷ **WindowHandleSource** (input_control) . . . . . window ⇝ *handle*
Source window handle.

▷ **WindowHandleDestination** (input_control) . . . . . window ⇝ *handle*
Destination window handle.

▷ **Row1** (input_control) . . . . . rectangle.origin.y(-array) ⇝ *integer*
Row index of upper left corner in the source window.
Default: 0
Value range: 0 ≤ `Row1` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Column1** (input_control) . . . . . rectangle.origin.x(-array) ⇝ *integer*
Column index of upper left corner in the source window.
Default: 0
Value range: 0 ≤ `Column1` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Row2** (input_control) . . . . . rectangle.corner.y(-array) ⇝ *integer*
Row index of lower right corner in the source window.
Default: 128
Value range: 0 ≤ `Row2` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: Row2 >= Row1

▷ **Column2** (input_control) . . . . . rectangle.corner.x(-array) ⇝ *integer*
Column index of lower right corner in the source window.
Default: 128
Value range: 0 ≤ `Column2` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: Column2 >= Column1

▷ **DestRow** (input_control) . . . . . point.y(-array) ⇝ *integer*
Row index of upper left corner in the target window.
Default: 0
Value range: 0 ≤ `DestRow` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **DestColumn** (input_control) . . . . . point.x(-array) ⇝ *integer*
Column index of upper left corner in the target window.
Default: 0
Value range: 0 ≤ `DestColumn` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Example

```
read_image(Image,'monkey')
open_window(0,0,-1,-1,'root','buffer','',WindowHandleBuffer)
disp_obj(Image,WindowHandleBuffer)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
draw_rectangle1 (WindowHandle, Row1, Column1, Row2, Column2)
copy_rectangle(WindowHandleBuffer,WindowHandle,\
               Row1, Column1, Row2, Column2,Row1,Column1)
close_window(WindowHandleBuffer)
```

Result

If the output window is valid and if the specified parameters are correct `close_window` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

Possible Successors

`close_window`

Alternatives

`move_rectangle`, `slide_image`

See also

`open_window`

Module

Foundation

dump_window (: : WindowHandle, Device, FileName :)

Write the window content to a file.

`dump_window` writes the content of the window to a file. You may continue to process this file by convenient printers or other programs. The content of a display is prepared for each special device (`Device`), i.e., it is formatted in a manner, that you may print this file directly or it can be processed furthermore by a graphical program.

To transform gray values the current color table of the window is used.

Possible values for `Device`

'postscript': PostScript - file. File extension: '.ps'

'postscript',Width,Height: PostScript - file with specification of the output size. $Width$ and $Height$ refer to the size. In this case a tuple with three values as `Device` is passed.
File extension: '.ps'

'tiff': TIFF format; Compression is possible with Adobe deflate compression (*'deflate [num]'*, lossless), JPEG (*'jpeg [num]'*, lossy), LZW (*'lzw'*, lossless), and PackBits (*'packbits'*, lossless). Here, *'[num]'* denotes an optional specification of a compression parameter. For *'deflate'*, a number between *0* (no compression) and *9* (maximum compression) can be specified. For *'jpeg'*, a number between *0* and *100* can be specified. The semantics are identical to the semantics of 'jpeg' described below. The different options can be accumulated by appending them separated by a space character. Examples: *'tiff deflate 9'*: Maximum Adobe deflate compression; *'tiff jpeg 90'*: JPEG compression with high quality; *'tiff lzw'*: LZW compression; *'tiff'* or *'tiff none'*: no compression.
File extension: '.tif'

'bmp': Windows-BMP format, RGB image, 3 bytes per pixel. The color resolution depends on the VGA card.
File extension: '.bmp'

'jpeg': JPEG format, with lost of information; together with the format string the quality value determining the compression rate can be provided: e.g., 'jpeg 30'.
File extension: '.jpg'

'jpegxr': JPEG-XR format (lossless and lossy compression); together with the format string the quality value determining the compression rate can be provided: e.g., 'jpegxr 30'.
File extension: '.jxr'

'jp2': JPEG2000 format (lossless and lossy compression); together with the format string the quality value determining the compression rate can be provided (e.g., 'jp2 40'). This value corresponds to the ratio of the size

of the compressed image and the size of the uncompressed image (in percent). As lossless JPEG2000 compression reduces the file size significantly already, only smaller values (typically smaller than 50) influence the file size. Is no value provided (and only then), the image is compressed without loss.

File extension: '.jp2'

'png': PNG format (lossless compression); together with the format string, a compression level between 0 and 9 can be specified, where 0 corresponds to no compression and 9 to the best possible compression. Alternatively, the compression can be selected with the following strings: 'best', 'fastest', and 'none'. Hence, examples for correct parameters are 'png', 'png 7', and 'png none'.

File extension: '.png'

Attention

Under Unix-like systems, the graphics window must be completely visible on the root window, because otherwise the contents of the window cannot be read due to limitations in X Windows. If larger graphical displays are to be written to a file, the window type *'pixmap'* can be used.

Parameters

▷ **`WindowHandle`** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **`Device`** (input_control) ..... string(-array) ⇝ *string* / integer
Name of the target device or of the graphic format.
Default: 'postscript'
Suggested values: `Device` ∈ {'postscript', 'tiff', 'tiff deflate 9', 'tiff jpeg 90', 'tiff lzw', 'tiff packbits', 'bmp', 'jpeg', 'jpeg 100', 'jpeg 80', 'jpeg 60', 'jpeg 40', 'jpeg 20', 'jpegxr', 'jpegxr 50', 'jpegxr 40', 'jpegxr 30', 'jpegxr 20', 'jp2', 'jp2 50', 'jp2 40', 'jp2 30', 'jp2 20', 'png', 'png best', 'png fastest', 'png none'}

▷ **`FileName`** (input_control) ..... filename.write ⇝ *string*
File name (without extension).
Default: 'halcon_dump'

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
read_image (Image, 'fabrik')
gen_circle (Circle, 200, 200, 100.5)
dev_display (Image)
dev_display (Circle)
dump_window(WindowHandle,'postscript','halcon_dump')
```

Result

If the appropriate window is valid and the specified parameters are correct `dump_window` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_draw`, `set_color`, `set_colored`, `set_line_width`, `disp_region`

Possible Successors

See also

`open_window`, `set_system`, `dump_window_image`

Module

Foundation

dump_window_image (: Image : WindowHandle :)

Write the window content in an image object.

dump_window_image writes the content of the graphics window (WindowHandle) in an image (Image). To transform gray values the current color table of the window is used.

Attention

Under Unix-like systems, the graphics window must be completely visible on the root window, because otherwise the contents of the window cannot be read due to limitations in X Windows.

Parameters

▷ **Image** (output_object) ..... image ⇝ *object :* byte
Saved image.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

Result

If the window is valid dump_window_image returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_draw, set_color, set_colored, set_line_width, disp_region

See also

open_window, set_system, dump_window

Module

Foundation

flush_buffer (: : WindowHandle :)

Flush the contents of a window.

flush_buffer flushes the contents of the window WindowHandle.

flush_buffer is only necessary if the window parameter *'flush'* has been set to *'false'* with set_window_param. If *'flush'* is *'false'* all display operations (such as disp_obj or disp_text) are redirected to a buffer and have no effect on WindowHandle (this applies for all window modes). flush_buffer copies the contents of this buffer to the window WindowHandle.

This is very useful to avoid flickering by batching several display operations (e.g., a clear_window followed by a disp_obj) and displaying the final result with flush_buffer.

This does not apply to drawing objects, which are always updated.

Attention

flush_buffer depends on the library libcanvas, which might not be available on embedded systems.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

Example

```
read_image (Image, 'printer_chip/printer_chip_01')
threshold (Image, Region, 128, 255)
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
```

```
set_window_param (WindowHandle, 'flush', 'false')
dev_display (Image)
dev_display (Region)
disp_text (WindowHandle, 'Result of threshold', 'window', \
           12, 12, 'black', [], [])
* nothing is displayed until flush_buffer is called
flush_buffer (WindowHandle)
```

Result

If the window exists `flush_buffer` returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`set_window_param`

Module

Foundation

get_disp_object_model_3d_info (: : WindowHandle, Row, Column, Information : Value)

Get the depth or the index of a displayed 3D object model.

`get_disp_object_model_3d_info` returns information on the 3D object models that have been displayed with `disp_object_model_3d` in the window `WindowHandle`. The requested information at the positions (`Row`, `Column`) is returned in `Value`.

The following values can be queried via `Information`:

'object_index' The indices of the 3D object models that have been displayed at the positions (`Row`, `Column`). If no 3D object model was displayed at this position, -1 is returned. In order to retrieve this information, `disp_object_model_3d` must have been called with the generic parameter *'object_index_persistence'* set to *'true'*.

'depth' The depth (i.e. the Z coordinate in the camera coordinate system) at the positions (`Row`, `Column`). If no 3D object model was displayed at one of these positions, -1.0 is returned for this position. In order to retrieve this information, `disp_object_model_3d` must have been called with the generic parameter *'depth_persistence'* set to *'true'*.

The window coordinates `Row`, `Column` must be provided in respect to the current image part. Thereby they are understood in edge centered subpixel accurate coordinates, see Transformations / 2D Transformations. Given the current image part (`row1`,`column1`,`row2`,`column2`, in the HALCON standard coordinate system), the upper left corner corresponds to the coordinates (`row1` - 0.5, `column1` - 0.5). Accordingly, the bottom right corner corresponds to the coordinates (`row2` - 0.5, `column2` - 0.5). Use `get_mposition_sub_pix` or `get_mbutton_sub_pix` to obtain these coordinates directly. In case the window coordinates correspond to values outside the current image part, the operator behavior is undefined.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (input_control) ..... integer(-array) ⇝ *real* / integer
Row coordinates.

▷ **Column** (input_control) ..... integer(-array) ⇝ *real* / integer
Column coordinates.

▷ **Information** (input_control) ..... string(-array) ⇝ *string*
Information.
Default: 'depth'
List of values: `Information` ∈ {'depth', 'object_index'}

▷ **Value** (output_control) ..... integer(-array) ⇝ *integer* / real
Indices or the depth of the objects at (Row,Column).

Result

`get_disp_object_model_3d_info` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`disp_object_model_3d`, `get_mbutton`, `get_mbutton_sub_pix`, `get_mposition`, `get_mposition_sub_pix`

Module

3D Metrology

get_os_window_handle (: : WindowHandle : OSWindowHandle, OSDisplayHandle)

Get the operating system window handle.

This operator does not work in an HDevelop graphics window opened with `dev_open_window`.

`get_os_window_handle` returns the operating system window handle of the HALCON window `WindowHandle` in `OSWindowHandle`. Under Unix-like systems, additionally the operating system display handle is returned in `OSDisplayHandle`. The operating system window handle can be used to access the window using functions from the operating system, e.g., to draw in a user-defined manner into the window. Under Windows, `OSWindowHandle` can be cast to a variable of type HWND. Under Unix-like systems, `OSWindowHandle` can be cast into a variable of type Window, while `OSDisplayHandle` can be cast into a variable of type Display.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **OSWindowHandle** (output_control) ..... pointer ⇝ *integer*
Operating system window handle.

▷ **OSDisplayHandle** (output_control) ..... pointer ⇝ *integer*
Operating system display handle (under Unix-like systems only).

Example

```
/* Draw a line into a HALCON window under Unix-like systems using X11 calls. */
```

```
#include "HalconC.h"
#include <X11/X.h>
#include <X11/Xlib.h>

int main(int argc, char **argv)
{
  Hlong hwin, win, disp;
  Display *display;
  Window window;
  GC gc;
  XGCValues values;
  static char dashes[] = { 20, 20 };

  open_window(0, 0, 500, 500, 0, "visible", "", &hwin);
  get_os_window_handle(hwin, &win, &disp);
  display = (Display *)disp;
  window = (Window)win;
  gc = XCreateGC(display, window, 0, &values);
  XSetFunction(display, gc, GXset);
  XSetLineAttributes(display, gc, 10, LineOnOffDash, CapRound, JoinRound);
  XSetDashes(display, gc, 0, dashes, 2);
  XSetForeground(display, gc, WhitePixel(display, DefaultScreen(display)));
  XSetBackground(display, gc, BlackPixel(display, DefaultScreen(display)));
  XDrawLine(display, win, gc, 20, 20, 480, 480);
  XFlush(display);
  XFreeGC(display, gc);
  wait_seconds(5);
  return 0;
}

/* Draw a line into a HALCON window under Windows using GDI calls. */
#include "HalconC.h"
#include "windows.h"

int main(int argc, char **argv)
{
  Hlong hwin, win, disp;
  HDC hdc;
  HPEN hpen;
  HPEN *hpen_old;
  LOGBRUSH logbrush;
  POINT point;
  static DWORD dashes[] = { 20, 20 };

  open_window(0, 0, 500, 500, 0, "visible", "", &hwin);
  get_os_window_handle(hwin, &win, &disp);
  logbrush.lbColor = RGB(255,255,255);
  logbrush.lbStyle = BS_SOLID;
  hpen =  ExtCreatePen(PS_USERSTYLE|PS_GEOMETRIC, 10, &logbrush, 2, dashes);
  hdc = GetDC((HWND)win);
  hpen_old = (HPEN *)SelectObject(hdc, hpen);
  MoveToEx(hdc, 20, 20, &point);
  LineTo(hdc, 480, 480);
  DeleteObject(SelectObject(hdc, hpen_old));
  ReleaseDC((HWND)win, hdc);
  wait_seconds(5);
  return 0;
}
```

Result

If the window is valid `get_os_window_handle` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

Module

Foundation

`get_window_attr` `( : : AttributeName : AttributeValue )`

Get window characteristics.

The operator `get_window_attr` can be used to read characteristics of graphics windows that were set using `set_window_attr`. The following parameters of a window may be queried:

'border_width' Width of the window border in pixels.

'border_color' Color of the window border.

'background_color' Background color of the window.

'window_title' Name of the window in the title bar.

Parameters

▷ **`AttributeName`** (input_control) ..... string ⇝ *string*
Name of the attribute that should be returned.
List of values: `AttributeName` ∈ {'border_width', 'border_color', 'background_color', 'window_title'}

▷ **`AttributeValue`** (output_control) ..... string ⇝ *string* / integer
Attribute value.

Result

If the parameters are correct `get_window_attr` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`, `set_window_attr`

Module

Foundation

`get_window_extents` `( : : WindowHandle : Row, Column, Width, Height )`

Information about a window's size and position.

get_window_extents returns the position of the upper left corner, as well as width and height of the output window.

Attention

Size and position of a window may be modified by the window manager, without explicit instruction in the program. Therefore the values which are returned by get_window_extents may change cause of side effects.

Parameters

- ▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
  Window handle.
- ▷ **Row** (output_control) ..... rectangle.origin.y ⇝ *integer*
  Row index of upper left corner of the window.
- ▷ **Column** (output_control) ..... rectangle.origin.x ⇝ *integer*
  Column index of upper left corner of the window.
- ▷ **Width** (output_control) ..... rectangle.extent.x ⇝ *integer*
  Window width.
- ▷ **Height** (output_control) ..... rectangle.extent.y ⇝ *integer*
  Window height.

Example

```
open_window(100,100,200,200,'root','visible','',WindowHandle)
fwrite_string(FileHandle, 'Move the window with the mouse!')
fnew_line(FileHandle)
repeat
get_mbutton(WindowHandle,_,_,Button)
get_window_extents(WindowHandle,Row,Column,Width,Height)
fwrite_string(FileHandle, ['(',Row,',',Column,')'])
fnew_line(FileHandle)
until(Button == 4)
```

Result

If the window is valid get_window_extents returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_window_pointer3 (: : WindowHandle : ImageRed, ImageGreen, ImageBlue, Width, Height)

Access to a window's pixel data.

This operator does not work in an HDevelop graphics window opened with dev_open_window.

get_window_pointer3 enables (in some window systems) the direct access to the bitmap. Result values are the three pointers on the color extracts of a 24-bit window (ImageRed, ImageGreen, ImageBlue), as well as the window size (Width, Height). In the language C the type of the image points is unsigned char.

Attention

get_window_pointer3 is usable only for window type *'pixmap'*.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.
▷ **ImageRed** (output_control) . . . . . integer ⇝ *integer*
Pointer on red channel of pixel data.
▷ **ImageGreen** (output_control) . . . . . integer ⇝ *integer*
Pointer on green channel of pixel data.
▷ **ImageBlue** (output_control) . . . . . integer ⇝ *integer*
Pointer on blue channel of pixel data.
▷ **Width** (output_control) . . . . . extent.x ⇝ *integer*
Length of an image line.
▷ **Height** (output_control) . . . . . extent.y ⇝ *integer*
Number of image lines.

Result

If a window of type *'pixmap'* exists and it is valid `get_window_pointer3` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

`open_window`, `set_window_type`

Module

Foundation

get_window_type (: : WindowHandle : WindowType)

Get the window type.

`get_window_type` determines the type or the graphical software, respectively, of the output device for the window. You may query the available types of output devices with the operator `query_window_type`. A reasonable use for `get_window_type` might be in the field of the development of machine independent software. Possible values are:

'X-Window' X-Window Version 11.

'WIN32-Window' Microsoft Windows.

'pixmap' Windows are not shown, but managed in memory. By this means HALCON programs can be ported on computers without a graphical display. Note that windows of this type support only HALCON objects (images, regions and XLDs). Fonts, for example, are not available.

'PostScript' Objects are output to a PostScript File.

'default' Current window type.

'system_default' Default window type for current platform.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle* / string
Window handle.
Suggested values: `WindowHandle` ∈ {'default', 'system_default'}
▷ **WindowType** (output_control) . . . . . string ⇝ *string*
Window type

Example

```
open_window(100,100,200,200,'root','visible','',WindowHandle)
get_window_type(WindowHandle,WindowType)
fwrite_string(FileHandle, ['Window type: ',WindowType])
fnew_line(FileHandle)
```

Result

If the window is valid `get_window_type` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_window`

See also

`query_window_type`, `set_window_type`, `get_window_pointer3`, `open_window`

Module

Foundation

new_extern_window (: : WINHWnd, Row, Column, Width, Height : WindowHandle)

Create a virtual graphics window under Windows.

`new_extern_window` opens a new virtual window. Note that this only works on Windows systems and drawing objects are not supported.

Virtual means that a new window will not be created, but the window whose window handle is given in the parameter `WINHWnd` is used to perform output of gray value data, regions, graphics as well as to perform textual output.

All operators that allow the user to define graphical primitives through mouse interactions, like for example `draw_rectangle1`, do not work on external windows. The following operators can be used:

- Output of gray values: `set_paint`, `set_lut`
- Regions: `set_color`, `set_rgb`, `set_hsi`, `set_gray`, `set_shape`, `set_line_width`, `set_insert`, `set_line_style`, `set_draw`
- Image part: `set_part`
- Text: `set_font`

You may query current set values by calling operators like `get_shape`. As some parameters are specified through the hardware (Resolution/Colors), you may query current available resources by calling operators like `query_color`.

The parameter `WINHWnd` is used to pass the window handle of the window in which output should be done.

The origin of the coordinate system of the window resides in the upper left corner (coordinates: (0,0)). The row index grows downward (maximum: `Height`-1), the column index grows to the right (maximal: `Width`-1).

You may use the value *-1* for parameters `Width` and `Height`. This means, that the corresponding value is chosen automatically. In particular, this is important if the aspect ratio of the pixels is not 1.0 (see `set_system`). If one of the two parameters is set to *-1*, it will be chosen through the size which results out of the aspect ratio of the pixels. If both parameters are set to *-1*, they will be set to the current image format.

The position and size of a window may change during runtime of a program, e.g., through external influences (window manager). With the operator `set_window_extents`, you can change the size of the (external) widow

via the program. Note that set_window_extents offers to change the position as well, but you cannot change the position of an external window under Windows.

Opening a window causes the assignment of a default font. It is used in connection with operators like write_string and you may change it by performing set_font after calling open_window. On the other hand, you have the possibility to specify a default font by calling set_system(::'default_font',<Fontname>:) before opening a window (and all following windows; see also query_font).

You may set the color of graphics and font, which is used for output operators like disp_region or disp_circle, by calling set_rgb, set_hsi or set_gray. Calling set_insert specifies how graphics is combined with the content of the image repeat memory. Thereto you may achieve by calling, e.g., set_insert(::'not':) to eliminate the font after writing text twice at the same position.

The content of the window is not saved, if other windows overlap the window. This must be done in the program code that handles the window in the calling program.

For graphical output (disp_image,disp_region, etc.) you may adjust the window by calling the operator set_part in order to represent a logical clipping of the image format. In particular this implies that only this part (appropriately scaled) of images and regions is displayed. Before you close your window, you have to close the HALCON-window.

Attention

Note that parameters as Row, Column, Width and Height are constrained through the output device, i.e., the size of the Windows NT desktop. Furthermore, be aware that all operators that allow the user to define graphical primitives through mouse interactions, like for example draw_rectangle1, do not work on external windows.

Parameters

- ▷ **WINHWnd** (input_control) ..... pointer ⇝ *integer*
  Windows window handle of a previously created window.
  Restriction: WINHWnd != 0
- ▷ **Row** (input_control) ..... rectangle.origin.y ⇝ *integer*
  Row coordinate of upper left corner.
  Default: 0
  Restriction: Row >= 0
- ▷ **Column** (input_control) ..... rectangle.origin.x ⇝ *integer*
  Column coordinate of upper left corner.
  Default: 0
  Restriction: Column >= 0
- ▷ **Width** (input_control) ..... rectangle.extent.x ⇝ *integer*
  Width of the window.
  Default: 512
  Restriction: Width > 0 || Width == -1
- ▷ **Height** (input_control) ..... rectangle.extent.y ⇝ *integer*
  Height of the window.
  Default: 512
  Restriction: Height > 0 || Height == -1
- ▷ **WindowHandle** (output_control) ..... window ⇝ *handle*
  Window handle.

Example

```
// Needs to be embedded into an application framework,
// see examples/cpp/mfc/MatchingExtWin.
```

Result

If the values of the specified parameters are correct new_extern_window returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

Module

Foundation

open_window (: : Row, Column, Width, Height, FatherWindow, Mode, Machine : WindowHandle)

Open a graphics window.

open_window opens a new window, which can be used to perform output of gray value data, regions, graphics as well as to perform textual output. All output (disp_region, disp_image, etc.) is redirected to this window, if the same logical window number WindowHandle is used.

The background of the created window is set to black in advance and it has a white border, which is 2 pixels wide (see also set_window_attr(::'border_width',<Width>:)).

Certain parameters used for the editing of output data are assigned to a window. These parameters are considered during the output itself (e.g., with disp_image or disp_region). They are not specified by an output operator, but by "configuration operators". If you want to set, e.g., the color red for the output of regions, you have to call set_color(::WindowHandle,'red':) before calling disp_region. These parameters are always set for the window with the logical window number WindowHandle and remain assigned to a window as long as they will be overwritten. You may use the following configuration operators:

- Output of gray values: set_paint, set_lut
- Regions: set_color, set_rgb, set_hsi, set_gray, set_shape, set_line_width, set_insert, set_line_style, set_draw
- Image clipping: set_part
- Text: set_font

You may query current set values by calling operators like get_shape. As some parameters are specified through the hardware (Resolution/Colors), you may query current available resources by calling query_color.

The origin of the coordinate system of the window resides in the upper left corner (coordinates: (0,0)). The row index grows downward (maximal: Height-1), the column index grows to the right (maximal: Width-1). You have to keep in mind, that the range of the coordinate system is independent of the window size. It is specified only through the image format (see reset_obj_db).

The parameter Machine indicates the name of the computer, which has to open the window. In case of a X-window, TCP-IP only sets the name, DEC-Net sets in addition a colon behind the name. The "server" resp. the "screen" are not specified. If the empty string is passed the environment variable DISPLAY is used. It indicates the target computer. At this the name is indicated in common syntax

```
<Host>:0.0
```

.

For windows of type *'WIN32-Window'* and *'X-Window'* the parameter FatherWindow can be used to determine the father window for the window to be opened. In case the control 'father' is set via set_check, FatherWindow must be the ID of a HALCON window, otherwise (set_check(::'~father':)) it can also be the ID of an operating system window. If FatherWindow is passed the value 0 or 'root', then under Windows and Unix-like systems the desktop and the root window become the father window, respectively. In this case, the value of the control 'father' (set via set_check) is irrelevant. The caller must ensure that FatherWindow is a valid handle and not destroyed as long as the embedded HALCON window is used.

You may use the value "-1" for parameters Width and Height. This means, that the according value has to be specified automatically. In particular this is of importance, if the proportion of pixels is not 1.0 (see set_system): Is one of the two parameters set to "-1", it will be specified through the size which results out of the proportion of pixels. Are both parameters set to "-1", they will be set to the maximum image format, which is currently used (further information about the currently used maximum image format can be found in the description of get_system using "width" or "height").

Position and size of a window may change during runtime of a program. This may be achieved by calling set_window_extents, but also through external interferences (window manager). In the latter case the operator set_window_extents is provided.

Opening a window causes the assignment of a called default font. It is used in connection with operators like write_string and you may overwrite it by performing set_font after calling open_window. On the other hand you have the possibility to specify a default font by calling set_system(::'default_font',<Fontname>:) before opening a window (and all following windows; see also query_font).

You may set the color of graphics and font, which is used for output operators like disp_region or disp_circle, by calling set_rgb, set_hsi or set_gray. Calling set_insert specifies how graphics is combined with the content of the image repeat memory. Thereto you may achieve by calling, e.g., set_insert(::'not':) to eliminate the font after writing text twice at the same position.

Normally every output (e.g., disp_image, disp_region, disp_circle, etc.) in a window is terminated by a called "flush". This causes the data to be fully visible on the display after termination of the output operator. But this is not necessary in all cases, in particular if there are permanently output tasks or if there is a mouse procedure active. Therefore it is more favorable (i.e., more rapid) to store the data until sufficient data is available. You may stop this behavior by calling set_system(::'flush_graphic','false':).

The content of windows is saved (in case it is supported by special driver software); i.e., it is preserved, also if the window is hidden by other windows. But this is not necessary in all cases: If the content of a window is built up permanently new (copy_rectangle), you may suppress the security mechanism for that and hence you can save the necessary memory. This is done by calling set_system(::'backing_store','false':) before opening a window. In doing so you save not only memory but also time to compute. This is significant for the output of video clips (see copy_rectangle).

For graphical output (disp_image,disp_region, etc.) you may adjust the window by calling the operator set_part in order to represent a logical clipping of the image format. In particular this implicates that you obtain this clipping (with appropriate enlargement) of images and regions only.

Difference: graphical window - textual window

- Using graphical windows the layout is not as variable as concerned to textual windows.
- You may use textual windows for the input of user data only (read_string).
- During the output of images, regions and graphics a "zooming" is performed using graphical windows: Independent on size and side ratio of the window images are transformed in that way, that they are displayed in the window by filling it completely. On the opposite side using textual windows the output does not care about the size of the window (only if clipping is necessary).
- Using graphical windows the coordinate system of the window corresponds to the coordinate system of the image format. Using textual windows, its coordinate system is always equal to the display coordinates independent on image size.

The parameter Mode determines the mode of the window. It may have following values:

'visible': Normal mode for graphical windows: The window is created according to the parameters and all input and output are possible.

'invisible': Invisible windows are not displayed in the display. Parameters like Row, Column and FatherWindow do not have any meaning. Output to these windows has no effect. Input (read_string, mouse, etc.) is not possible. You may use these windows to query representation parameter for an output device without opening a (visible) window. Common queries are, e.g., query_color and get_string_extents.

'transparent': These windows are transparent: the window itself is not visible (edge and background), but all the other operations are possible and all output is displayed. A common use for this mode is the creation of mouse sensitive regions.

'buffer': These are also not visible windows. The output of images, regions and graphics is not visible on the display, but is stored in memory. Parameters like Row, Column and FatherWindow do not have any meaning. You may use buffer windows, if you prepare output (in the background) and copy it finally with copy_rectangle in a visible window. Another usage might be the rapid processing of image regions during interactive manipulations. Textual input and mouse interaction are not possible in this mode.

Attention

You may keep in mind that parameters as Row, Column, Width and Height are constrained by the output device. If you specify a father window (FatherWindow <> 'root') the coordinates are relative to this window.

Parameters

▷ **Row** (input_control) . . . . . rectangle.origin.y ⇝ *integer*
Row index of upper left corner.
Default: 0
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) . . . . . rectangle.origin.x ⇝ *integer*
Column index of upper left corner.
Default: 0
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Width** (input_control) . . . . . rectangle.extent.x ⇝ *integer*
Width of the window.
Default: 256
(lin)
Minimum increment: 1
Recommended increment: 1
Restriction: 0 <= Width <= 32768 || Width == -1

▷ **Height** (input_control) . . . . . rectangle.extent.y ⇝ *integer*
Height of the window.
Default: 256
(lin)
Minimum increment: 1
Recommended increment: 1
Restriction: 0 <= Height <= 32768 || Height == -1

▷ **FatherWindow** (input_control) . . . . . pointer ⇝ *integer* / string
Logical number of the father window. To specify the display as father you may enter 'root' or 0.
Default: 0
Restriction: FatherWindow >= 0

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Window mode.
Default: 'visible'
List of values: Mode ∈ {'visible', 'invisible', 'transparent', 'buffer'}

▷ **Machine** (input_control) . . . . . string ⇝ *string*
Name of the computer on which you want to open the window. Otherwise the empty string.
Default: ''

▷ **WindowHandle** (output_control) . . . . . window ⇝ *handle*
Window handle.

Example

```
open_window(0,0,400,-1,'root','visible','',WindowHandle)
read_image(Image,'fabrik')
disp_image(Image,WindowHandle)
write_string(WindowHandle,'File, fabrik')
new_line(WindowHandle)
get_mbutton(WindowHandle,_,_,_)
set_lut(WindowHandle,'temperature')
set_color(WindowHandle,'blue')
write_string(WindowHandle,'temperature')
new_line(WindowHandle)
write_string(WindowHandle,'Draw Rectangle')
new_line(WindowHandle)
draw_rectangle1(WindowHandle,Row1,Column1,Row2,Column2)
set_part(WindowHandle,Row1,Column1,Row2,Column2)
disp_image(Image,WindowHandle)
new_line(WindowHandle)
```

Result

If the values of the specified parameters are correct `open_window` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`reset_obj_db`

Possible Successors

`set_color`, `query_window_type`, `get_window_type`, `set_window_type`, `get_mposition`, `set_tposition`, `set_tshape`, `set_window_extents`, `get_window_extents`, `query_color`, `set_check`, `set_system`

Module

Foundation

query_window_type (: : : WindowTypes)

Query all available window types.

`query_window_type` returns a tuple which contains all devices or software systems, respectively, which are used to display image objects. You may use `query_window_type` usefully while developing machine independent programs. Possible values are:

'X-Window' X-Window Version 11.

'WIN32-Window' Microsoft Windows.

'pixmap' Windows are not displayed, but managed in memory. In this manner it is possible to port HALCON programs to computers without graphical display.

'PostScript' Objects are output to a PostScript File.

Parameters

▷ **WindowTypes** (output_control) . . . . . string-array ⇝ *string*
Names of available window types.

Result

`query_window_type` always returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`reset_obj_db`

Module

Foundation

set_window_attr (: : AttributeName, AttributeValue :)

Set window characteristics.

You may use `set_window_attr` to set specific characteristics of graphics windows. With it you may modify the following default parameters of a window:

'border_width' Width of the window border in pixels. Is not implemented under Windows.

'border_color' Color of the window border. Is not implemented under Windows.

'background_color' Background color of the window.

'window_title' Name of the window in the title bar.

Attention

You have to call `set_window_attr` *before* calling `open_window`.

Parameters

▷ **AttributeName** (input_control) . . . . . string ⇝ *string*
Name of the attribute that should be modified.
List of values: `AttributeName` ∈ {'border_width', 'border_color', 'background_color', 'window_title'}

▷ **AttributeValue** (input_control) . . . . . string ⇝ *string* / integer
Value of the attribute that should be set.
List of values: `AttributeValue` ∈ {0, 1, 2, 'white', 'black', 'MyName', 'default'}

Result

If the parameters are correct `set_window_attr` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window, set_draw, set_color, set_colored, set_line_width

See also

open_window, get_window_attr, set_window_param

Module

Foundation

set_window_dc (: : WindowHandle, WINHDC :)

Set the device context of a virtual graphics window (Windows NT).

set_window_dc sets the device context of a window previously opened with new_extern_window. All output (disp_region, disp_image, etc.) is done in the window with this device context.

The parameter WINHDC contains the device context of the window in which HALCON should output its data. This device context is used in all output routines of HALCON.

Attention

The window WindowHandle has to be created with new_extern_window beforehand.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **WINHDC** (input_control) ..... pointer ⇝ *integer*
device context of WINHWnd.
Restriction: WINHDC != 0

Result

If the values of the specified parameters are correct, set_window_dc returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

new_extern_window

Possible Successors

disp_image, disp_region

Module

Foundation

set_window_extents (: : WindowHandle, Row, Column, Width, Height :)

Modify position and size of a window.

set_window_extents positions the upper left corner of the output window at (Row,Column) and changes the size of the window to Width and Height at the same time. Negative values for Width and Height are ignored.

Adapting the size of the window to the size of the image part to be displayed will prevent slowing down the display due to necessary interpolations. Thus, the window preferably has the same size as the image part to be displayed, or otherwise half its size, quarter its size, etc.

Attention

Modifying the size of the window does not automatically redraw the window contents. This has to be done by the program by redisplaying the desired data.

Parameters

▷ **WindowHandle** (input_control) . . . . . window ⇝ *handle*
Window handle.

▷ **Row** (input_control) . . . . . rectangle.origin.y ⇝ *integer*
Row index of upper left corner in target position.
Default: 0
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) . . . . . rectangle.origin.x ⇝ *integer*
Column index of upper left corner in target position.
Default: 0
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Width** (input_control) . . . . . rectangle.extent.x ⇝ *integer*
Width of the window.
Default: 512
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Height** (input_control) . . . . . rectangle.extent.y ⇝ *integer*
Height of the window.
Default: 512
(lin)
Minimum increment: 1
Recommended increment: 1

Result

If the window is valid and the parameters are correct `set_window_extents` returns `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`get_window_extents`, `open_window`

Module

Foundation

set_window_type (: : WindowType :)

Specify a window type.

set_window_type determines on which type of output device the output is going to be displayed. This specification is going to be used by the operator open_window while opening the windows. You may open different windows on different types of output devices. Therefore you have to specify the wanted type before opening. You may request the available types of output devices by calling the operator query_window_type. Possible values are:

'X-Window' X-Window Version 11.

'WIN32-Window' Microsoft Windows.

'pixmap' Windows are not displayed, but managed in memory only. In this manner you may port HALCON programs to computers without graphical display.

'PostScript' Objects are output to a PostScript File.

'system_default' Default for current platform.

A useful usage of set_window_type could be the development of machine independent programs.

Parameters

▷ **WindowType** (input_control) . . . . . string ⇝ *string*
Name of the window type which has to be set.
Default: 'X-Window'
List of values: WindowType ∈ {'X-Window', 'WIN32-Window', 'pixmap', 'PostScript', 'system_default'}

Result

If the type of the output device is available, then set_window_type returns 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_window

unproject_coordinates (Image : : WindowHandle, Row, Column : ImageRow, ImageColumn, Height)

Calculates image coordinates for a point in a 3D plot window.

If Image is displayed in WindowHandle using a 3D plot (i.e., *'3d_plot'* was set using set_paint), unproject_coordinates calculates the image coordinates ImageRow, ImageColumn, and the Height for a given point Row,Column in window coordinates. The window coordinates Row, Column must be provided in respect to the current image part. As a consequence, this coordinates are subpixel coordinates. Given the current image part (row1,column1,row2, column2), the upper left corner corresponds to the coordinates (row1 - 0.5, col1 - 0.5). Accordingly, the bottom right corner corresponds to the coordinates (row2 - 0.5, col2 - 0.5). Use get_mposition_sub_pix or get_mbutton_sub_pix to obtain these coordinates directly.

One of the window parameters *'save_depth_buffer'* or *'interactive_plot'* must be set to *'true'* using set_window_param. Otherwise, unproject_coordinates cannot be used.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / real / complex / vector_field
Displayed image.

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **Row** (input_control) ..... integer ⇝ *real* / integer
Row coordinate in the window.

▷ **Column** (input_control) ..... integer ⇝ *real* / integer
Column coordinate in the window.

▷ **ImageRow** (output_control) ..... integer ⇝ *integer*
Row coordinate in the image.

▷ **ImageColumn** (output_control) ..... integer ⇝ *integer*
Column coordinate in the image.

▷ **Height** (output_control) ..... real ⇝ *integer* / real
Height value.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`get_mbutton_sub_pix`, `get_mposition_sub_pix`, `disp_image`

See also

`disp_obj`, `update_window_pose`, `set_paint`

Module

Foundation

update_window_pose (: : WindowHandle, LastRow, LastCol, CurrentRow, CurrentCol, Mode :)

Modify the pose of a 3D plot.

The operator `update_window_pose` provides an easy way to modify the pose of the height field displayed by `disp_obj` if the paint mode is set to *'3d_plot'* using `set_paint`.

Two window coordinates (`LastRow`,`LastCol`) and (`CurrentRow`, `CurrentCol`) are transformed into rotation, scaling, or movement depending on `Mode`. This window coordinates must be provided with respect to the current image part. As a consequence, this coordinates are subpixel coordinates. Given the current image part (row1,column1,row2,column2), the upper left corner corresponds to the coordinate (row1 - 0.5, col1 - 0.5). Accordingly, the bottom right corner corresponds to the coordinate (row2 - 0.5, col2 - 0.5). Use `get_mposition_sub_pix` or `get_mbutton_sub_pix` to obtain this coordinates directly.

If `Mode` is set to *'rotate'*, the height field is rotated using a virtual trackball model. Both points are projected on a sphere centered in the center of the window `WindowHandle`. The circular arc between this two projections corresponds to the rotation applied to the height field.

If `Mode` is set to *'scale'*, zooming is reduced if `CurrentRow` is greater than `LastRow` and increased if `CurrentRow` is smaller than `LastRow`.

If `Mode` is set to *'move'*, the input points are projected onto the plane through the center of the height field parallel to the viewing plane. The center of the height field is moved in this plane by the distance between both projections.

If `Mode` is set to *'move_plane'*, the input points are projected on the plane given by height zero. The height field is moved in this plane by the distance between both projections.

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window handle.

▷ **LastRow** (input_control) ..... point.y ⇝ *real* / integer
Row coordinate of the first point.

▷ **LastCol** (input_control) ..... point.x ⇝ *real* / integer
Column coordinate of the first point.

▷ **CurrentRow** (input_control) ..... point.y ⇝ *real* / integer
Row coordinate of the second point.

▷ **CurrentCol** (input_control) ..... point.x ⇝ *real* / integer
Column coordinate of the second point.

▷ **Mode** (input_control) ..... string ⇝ *string*
Navigation mode.
Default: 'rotate'
List of values: Mode ∈ {'rotate', 'scale', 'move', 'move_plane'}

Example

```
* Interactive display of a height field
dev_set_paint ('3d_plot')
while (1)
  dev_set_check ('~give_error')
  get_mposition_sub_pix (WindowHandle, Row, Column, Button)
  dev_set_check ('give_error')
  if (ButtonDown and (Button == 0))
    ButtonDown := false
  endif
  if (not(Button == 0))
    if (ButtonDown)
      if (Button == 1)
        mode := 'rotate'
      endif
      if (Button == 4)
        mode := 'scale'
      endif
      if (Button == 5)
        mode := 'move'
      endif
      update_window_pose (WindowHandle, lastRow, lastCol, Row, Column, mode)
    else
      if (Button == 2)
        break
      endif
      ButtonDown := true
    endif
    lastCol := Column
    lastRow := Row
  endif
  dev_display (Image)
endwhile
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 14

Identification

14.1 Bar Code

This chapter provides an introduction to bar codes and the most important terms used when finding and reading bar codes in HALCON.

Structure of linear (1D) bar codes

A bar code consists of several dark bars and bright spaces. For every bar code there is a smallest possible element, the narrowest possible bar or the narrowest possible space, which is called module. In general, the width of the bars and spaces is different, but always a multiple of the module. Several bars and spaces together form a pattern. This pattern encodes a symbol defined in a decoding table. The conventions how such a binary pattern encodes a symbol and the corresponding decoding table lead to the respective bar code type. In addition to the patterns encoding the symbols, there are also patterns with special tasks. Depending on the type there are further patterns which can or must be part of the bar code:

- Quiet-zone: Zone in which no edges may occur. This zone is required before the start character and after the stop character to find the code.

Schematic representation of the quiet zone (orange) by means of an example bar code of type Code 128.

- Start and stop pattern: Define start, stop and direction. These patterns make it possible to read and decode the code from left to right as well as from right to left (and thus upside down).

Schematic representation of the start and stop pattern (orange) by means of an example bar code of type Code 128.

- Checksum: A digit which serves as a security check to ensure the code has been read correctly.

Schematic representation of the checksum (orange) by means of an example bar code of type Code 128.

- Guard pattern: Specific pattern, which can occur on the left, right, or in the center as additional symbol.

Schematic representation of a guard pattern (orange) by means of an example bar code of type UPC-A.

- Finder patterns: Pattern used to locate the symbol.

Schematic representation of a finder pattern (orange) by means of an example bar code of type GS1 Databar.

- Add-on symbol: Additional symbols for encoding of supplementary information. These symbols are encoded as bar codes with restricted length.

Schematic representation of an add-on symbol (orange) by means of an example bar code of type EAN-8 Add-On 2.

Structure of a composite bar code

Composite bar codes consist of the following elements:

- Linear bar code: As described above.
- 2D Code: For more information about 2D codes we refer to the "`Solution Guide II-C - 2D Data Codes`".
- Linking pattern: Combines the two codes mentioned before.

The following figure shows a schematic representation of a composite bar code.

Schematic representation of a composite bar code by means of an example bar code of type UPC-A Composite: Linear bar code (black), 2D code (light blue), and the linking pattern (orange).

Reading of a bar code

To be able to read a bar code in an image, it must be found first. The regions in which HALCON assumes a bar code are called candidates.

To read a candidate, different lines are laid through the region, called scanlines. Although theoretically a single scanline would be sufficient, one tries to decode the bar code along all scanlines. This increases the chance of decoding the code correctly. In addition, several successfully decoded scanlines allow additional plausibility checks, i.e., reading several scanlines equally decreases the chance of false positives.

Schematic representation of different scanlines of a candidate. Certain scanlines were read successfully (green), while the reading failed for others (red).

The workflow and various examples showing how to read bar codes in HALCON can be found in the "'Solution Guide I - Basics.

clear_bar_code_model (: : BarCodeHandle :)

Delete a bar code model and free the allocated memory

The operator clear_bar_code_model deletes a bar code model that was created by create_bar_code_model. All memory used by the model is freed. The handle of the model is passed in BarCodeHandle, which is invalid after the operator call.

Parameters

▷ **BarCodeHandle** (input_control) ..... barcode(-array) ⇝ *handle*
Handle of the bar code model.

Result

The operator clear_bar_code_model returns the value 2 (H_MSG_TRUE) if a valid handle was passed and the referred bar code model can be freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- BarCodeHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

See also

find_bar_code

Module

Bar Code

create_bar_code_model (: : GenParamName,
GenParamValue : BarCodeHandle)

Create a model of a bar code reader.

The operator create_bar_code_model creates a generic model for reading all types of supported bar code symbols. The result of this operator is a handle to the bar code model (BarCodeHandle), which is used for all further operations on the bar code, like modifying the model, reading a symbol, or accessing the results of the symbol search.

In general, bar codes will be found and decoded without any additional adjustment of the parameters. Therefore, GenParamName and GenParamValue are empty tuples by default. In the case of poor image quality or abnormal geometric characteristics of the bar code, which requires special parameter settings for a successful decoding of the bar code symbols, parameters can be adjusted already while creating the bar code model. Alternatively, parameters can be changed later on as well by applying the operator set_bar_code_param

or set_bar_code_param_specific. For a detailed description of the available model parameters see set_bar_code_param.

Parameters

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that can be adjusted for the bar code model.
Default: []
List of values: GenParamName ∈ {'check_char', 'composite_code', 'barcode_height_min', 'barcode_width_min', 'barcode_width_max', 'element_size_max', 'element_size_min', 'meas_thresh', 'meas_thresh_abs', 'min_identical_scanlines', 'num_scanlines', 'orientation', 'orientation_tol', 'persistence', 'start_stop_tolerance', 'stop_after_result_num', 'upce_encodation', 'upce1_enable', 'timeout', 'train', 'quiet_zone', 'element_size_variable', 'min_code_length', 'max_code_length'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string
Values of the generic parameters that can be adjusted for the bar code model.
Default: []
Suggested values: GenParamValue ∈ {0, 0.1, 1, 1.5, 2, 8, 32, 45, 'present', 'absent', 'none', 'CC-A/B', 'auto', 'high', 'low', 'true', 'false'}

▷ **BarCodeHandle** (output_control) . . . . . barcode ⇝ *handle*
Handle for using and accessing the bar code model.

Result

The operator create_bar_code_model returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

Module

Bar Code

decode_bar_code_rectangle2 (Image : : BarCodeHandle, CodeType, Row, Column, Phi, Length1, Length2 : DecodedDataStrings)

Decode bar code symbols within a rectangle.

The operator decode_bar_code_rectangle2 uses the bar code model specified by BarCodeHandle to decode a bar code at a given position within the image Image. BarCodeHandle must be created with create_bar_code_model, its parameters can be set with set_bar_code_param. The position of the bar code is given as an arbitrarily oriented rectangle. Contrary to find_bar_code, where the decoding is preceded by a time consuming search for candidate regions, decode_bar_code_rectangle2 scans the provided region directly for bar codes. The rectangular region is defined by the parameters Row and Column for the center, Phi for the orientation and Length1 and Length2 for the half edge lengths (see gen_rectangle2). The angle Phi also determines the reading direction and is defined as the angle between the reading direction of the bar code and the horizontal image axis. The angle is positive in counter clockwise direction and is given in radians as in gen_rectangle2. Note that the angle unit deviates from the conventions in get_bar_code_result and set_bar_code_param where angles are given in degrees. Phi can be in the range of $[-\pi, +\pi]$. The reading direction is perpendicular to the bars of the bar code. Bar codes with a reading direction Phi $+ \pi$ are also returned. Multiple regions for decoding can be given by supplying tuples for Row, Column, Phi, Length1 and Length2.

The rectangle should cover completely the bar code and the quiet zones. Regions that are too big will be decoded, if there is no disturbing pattern within these regions and the height (Length2) is small enough such that scanlines can be placed sufficiently dense. Rectangles that are too short in reading direction (Length1) cannot be decoded.

decode_bar_code_rectangle2 can be used if the position of the bar code is already known in advance. For example, the candidate regions found by find_bar_code and get_bar_code_object could be reused with a different code type (see the following example).

Multiple bar code types can be specified for CodeType. See section Autodiscrimination for find_bar_code.

Further aspects of the actual decoding are explained with the operator find_bar_code.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte
Input image.

▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

▷ **CodeType** (input_control) ..... string(-array) ⇝ *string*
Type of the searched bar code.
Default: ’EAN-13’
List of values: CodeType ∈ {’2/5 Industrial’, ’2/5 Interleaved’, ’Codabar’, ’Code 39’, ’Code 93’, ’Code 128’, ’EAN-13’, ’EAN-13 Add-On 2’, ’EAN-13 Add-On 5’, ’EAN-8’, ’EAN-8 Add-On 2’, ’EAN-8 Add-On 5’, ’UPC-A’, ’UPC-A Add-On 2’, ’UPC-A Add-On 5’, ’UPC-E’, ’UPC-E Add-On 2’, ’UPC-E Add-On 5’, ’MSI’, ’PharmaCode’, ’GS1 DataBar Omnidir’, ’GS1 DataBar Truncated’, ’GS1 DataBar Stacked’, ’GS1 DataBar Stacked Omnidir’, ’GS1 DataBar Limited’, ’GS1 DataBar Expanded’, ’GS1 DataBar Expanded Stacked’, ’GS1-128’, ’auto’}

▷ **Row** (input_control) ..... rectangle2.center.y(-array) ⇝ *real* / integer
Row index of the center.
Default: 50.0

▷ **Column** (input_control) ..... rectangle2.center.x(-array) ⇝ *real* / integer
Column index of the center.
Default: 100.0

▷ **Phi** (input_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real* / integer
Orientation of rectangle in radians.
Default: 0.0
Suggested values: Phi ∈ {0.0, 0.785398, 1.570796, 3.1415926}

▷ **Length1** (input_control) . . . . . rectangle2.hwidth(-array) ⇝ *real* / integer
Half of the length of the rectangle along the reading direction of the bar code.
Default: 200.0

▷ **Length2** (input_control) . . . . . rectangle2.hheight(-array) ⇝ *real* / integer
Half of the length of the rectangle perpendicular to the reading direction of the bar code.
Default: 100.0

▷ **DecodedDataStrings** (output_control) . . . . . string(-array) ⇝ *string*
Data strings of all successfully decoded bar codes.

Example

```
read_image (Image, 'barcode/ean13/ean1301.png')
create_bar_code_model ([], [], BHandle)
find_bar_code (Image, SymReg, BHandle, '2/5 Industrial', Dec)
if (|Dec| == 0)
*     A 2/5 Industrial code wasn't found. Try decoding an EAN-13 code.
    get_bar_code_object (CandReg, BHandle, 'all', 'candidate_regions')
    smallest_rectangle2 (CandReg, R, C, Phi, L1, L2)
    decode_bar_code_rectangle2 (Image, BHandle, 'EAN-13', R, C, Phi, \
                                L1, L2, Dec)
endif
```

Result

The operator decode_bar_code_rectangle2 returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- BarCodeHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_bar_code_model, set_bar_code_param, smallest_rectangle2

Possible Successors

get_bar_code_result, get_bar_code_object, clear_bar_code_model

Alternatives

find_bar_code

gen_rectangle2

Module

Bar Code

deserialize_bar_code_model (
: : SerializedItemHandle : BarCodeHandle)

Deserialize a bar code model.

deserialize_bar_code_model deserializes a bar code model that was serialized by serialize_bar_code_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized model is defined by the handle SerializedItemHandle. The deserialized values are stored in a new bar code model with the handle BarCodeHandle.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **BarCodeHandle** (output_control) . . . . . barcode ⇝ *handle*
Handle of the bar code model.

Result

The operator deserialize_bar_code_model returns the value 2 (H_MSG_TRUE) if the bar code can be correctly deserialized. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Bar Code

find_bar_code (Image : SymbolRegions : BarCodeHandle,
CodeType : DecodedDataStrings)

Detect and read bar code symbols in an image.

The operator find_bar_code finds and reads bar code symbols in a given image (Image) and returns the decoded data. In one image an arbitrary number of bar codes of a single type can be read. The type of the desired bar code symbology is given by CodeType. The decoded strings are returned in DecodedDataStrings and the corresponding bar code regions in SymbolRegions. For a total of n successfully read bar codes, the indices from 0 to (n-1) can be used as candidate handle in the operators get_bar_code_object and get_bar_code_result in order to retrieve the desired data of one specific bar code result.

Bar codes are expected to appear dark on a light background. To read light bar codes on a dark background, invert the input image using the operator invert_image beforehand.

Before calling find_bar_code a bar code model must be created by calling create_bar_code_model. This operator returns a bar code model BarCodeHandle, which is input to find_bar_code.

The output value DecodedDataStrings contains the decoded string of the symbol for each bar code result. The contents of the strings are conform to the appropriate standard of the symbology. Typically, DecodedDataStrings contains only data characters. For bar codes with a mandatory check character the check character is not included in the string. For bar codes with an optional check character, like for example Code 39, Codabar, 2/5 Industrial or 2/5 Interleaved, the result depends on the value of the *'check_char'* parameter, which can be set in create_bar_code_model, set_bar_code_param or set_bar_code_param_specific: The default setting of *'absent'* assumes that no check character is present. In this case, no check is performed and all characters are returned as data. When set to *'present'*, a check character is expected and used to verify the correctness of the bar code. The bar code is graded as unreadable if the check sum does not match. Accordingly, the symbol region and the decoded string do not appear in the

list of resulting strings (DecodedDataStrings) and in the list of resulting regions (SymbolRegions). The check character itself is stripped from the data. If this stripping is undesired, the mode *'preserved'* allows to verify the bar code while still keeping the check character in the data.

The underlying decoded reference data, including start/stop and check characters, can be queried by using the get_bar_code_result operator with the option *'decoded_reference'*.

Following bar code symbologies are supported:

2/5 Industrial	EAN-8	GS1-128
2/5 Interleaved	EAN-8 Add-On 2	GS1 DataBar Omnidirectional
Codabar	EAN-8 Add-On 5	GS1 DataBar Truncated
Code 39	EAN-13	GS1 DataBar Stacked
Code 32 (converted from Code 39)	EAN-13 Add-On 2	GS1 DataBar Stacked Omnidirectional
Code 93	EAN-13 Add-On 5	GS1 DataBar Limited
Code 128	UPC-A	GS1 DataBar Expanded
MSI	UPC-A Add-On 2	GS1 DataBar Expanded Stacked
PharmaCode	UPC-A Add-On 5	
	UPC-E	
	UPC-E Add-On 2	
	UPC-E Add-On 5	

Note that the PharmaCode can be read in forward and backward direction, both yielding a valid result. Therefore, both strings are returned and concatenated into a single string in DecodedDataStrings by a separating comma.

Note that the GS1 DataBar bar codes may contain an additional composite code component. To find and decode this component, set the parameter *'composite_code'* to *'CC-A/B'* using the operator set_bar_code_param.

Note that also a bar code of type 'Code 32' can be read by using find_bar_code with CodeType set to *'Code 39'* in combination with the external procedure convert_decoded_string_code39_to_code32.

The list of available GS1 Application Identifiers can be updated using set_system (see the parameter *'gs1_syntax_dictionary'*).

Autodiscrimination

Autodiscrimination describes the simultaneous decoding of multiple bar code types in one call of find_bar_code. For this purpose a tuple of bar code types is specified for the parameter CodeType. Using the generic value *'auto'* all known bar code types are decoded - except *'PharmaCode'* and *'MSI'* because these codes don't have enough features to be reliably separated from other bar code types. The tuple can also contain bar code types with the tilde prefix (~) which won't be decoded. For example

['auto', '~EAN-8', '~EAN-8 Add-On 2', '~EAN-8 Add-On 5']

describes all bar code types without *'PharmaCode'*, *'MSI'* and all kinds of *'EAN-8'*. Please note that each additionally allowed bar code type increases the run-time of the operator. Using too many bar code types the reliability of the decoding could decrease because not all bar code types can be discriminated reliably. To improve autodiscrimination compatibility bar codes with a check character or check sum should be used.

The bar code reader tries to decode the bar code types in the following order:

'GS1 DataBar Omnidir', *'GS1 DataBar Truncated'*, *'GS1 DataBar Limited'*, *'GS1 DataBar Expanded'*, *'GS1 DataBar Expanded Stacked'*, *'GS1 DataBar Stacked Omnidir'*, *'GS1 DataBar Stacked'*, *'GS1-128'*, *'Code 128'*, *'EAN-13 Add-On 5'*, *'EAN-13 Add-On 2'*, *'EAN-13'*, *'UPC-A Add-On 5'*, *'UPC-A Add-On 2'*, *'UPC-A'*, *'EAN-8 Add-On 5'*, *'EAN-8 Add-On 2'*, *'EAN-8'*, *'UPC-E Add-On 5'*, *'UPC-E Add-On 2'*, *'UPC-E'*, *'Code 93'*, *'Code 39'*, *'Codabar'*, *'2/5 Interleaved'*, *'2/5 Industrial'*

Therefore you should exclude at least all definitely not occurring bar code types that are scanned before the first of the bar code types you expect to find or, better, just scan for the explicit list of bar code types you expect.

Note that *'UPC-A'* codes have the same structure as *'EAN-13'* codes, except that they always start with a zero. If one wants to read *'UPC-A'*, *'UPC-A Add-On 2'*, or *'UPC-A Add-On 5'* codes explicitly, then the corresponding EAN-13 bar code type must be excluded (*'EAN-13'*, *'EAN-13 Add-On 2'*, or *'EAN-13 Add-On 5'*, respectively). Otherwise, the results will be returned as EAN codes because of the decoding order. For UPC-A codes with Add-On, *'EAN-13'* must be excluded in addition to the corresponding EAN-13 type with Add-On.

Especially for the autodiscrimination there is the operator set_bar_code_param_specific. With it some parameters of the bar code model can be set specifically for certain bar code types.

Training

If the bar code reader is in training mode, the operator find_bar_code executes a training cycle. The training mode is described with the operator set_bar_code_param.

Timeout and Abort

The operator find_bar_code can be aborted by a timeout and dynamically. With the operator set_bar_code_param you can specify a timeout. If find_bar_code reaches this timeout, it returns all codes decoded so far. Alternatively, you can call set_bar_code_param with *'abort'* from another thread to abort find_bar_code dynamically.

The information whether the operator was aborted or not can be queried by calling get_bar_code_result with the parameter *'aborted'*.

Furthermore, the operator find_bar_code can be canceled, which means no result is returned but instead an error is returned. This can be done with the operator set_operator_timeout or interrupt_operator. If find_bar_code is canceled by set_operator_timeout, H_ERR_TIMEOUT (9400) is returned. If find_bar_code is canceled by interrupt_operator, H_ERR_CANCEL (22) is returned. Note: Both mentioned operators are only supported in cancel mode.

Advice on low resolution bar code imaging systems

This advice applies to bar code applications that use low resolution images, i.e., images in which a single bar is between 0.6 and 2 pixels wide.

In these cases, one should optimize the bar code imaging system in order to eliminate noise and focal blur because a combination of these optical distortions lead to problems in the decodability of low resolution bar codes.

See set_bar_code_param documentation entry on *'small_elements_robustness'* for more advice.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object : byte*
  Input image. If the image has a reduced domain, the bar code search is reduced to that domain. This usually reduces the runtime of the operator. However, if the bar code is not fully inside the domain, the bar code cannot be decoded correctly.
- ▷ **SymbolRegions** (output_object) ..... region(-array) ⇝ *object*
  Regions of the successfully decoded bar code symbols.
- ▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
  Handle of the bar code model.
- ▷ **CodeType** (input_control) ..... string(-array) ⇝ *string*
  Type of the searched bar code.
  Default: 'auto'
  List of values: CodeType ∈ {'auto', '2/5 Industrial', '2/5 Interleaved', 'Codabar', 'Code 39', 'Code 93', 'Code 128', 'EAN-13', 'EAN-13 Add-On 2', 'EAN-13 Add-On 5', 'EAN-8', 'EAN-8 Add-On 2', 'EAN-8 Add-On 5', 'UPC-A', 'UPC-A Add-On 2', 'UPC-A Add-On 5', 'UPC-E', 'UPC-E Add-On 2', 'UPC-E Add-On 5', 'MSI', 'PharmaCode', 'GS1 DataBar Omnidir', 'GS1 DataBar Truncated', 'GS1 DataBar Stacked', 'GS1 DataBar Stacked Omnidir', 'GS1 DataBar Limited', 'GS1 DataBar Expanded', 'GS1 DataBar Expanded Stacked', 'GS1-128'}
- ▷ **DecodedDataStrings** (output_control) ..... string(-array) ⇝ *string*
  Data strings of all successfully decoded bar codes.

Example

```
* Small example for aborting bar code search:
read_image (Image, 'barcode/ean13/tea_box_10.png')

* Decode normally:
create_bar_code_model ([], [], BarCodeHandle)
find_bar_code (Image, SymbolRegions, BarCodeHandle, 'auto', \
    DecodedDataStrings)
stop ()
```

```
* Start bar code search in separate thread.
par_start<ThreadID>: find_bar_code (Image, SymbolRegions1, BarCodeHandle, \
    'auto', DecodedDataStrings1)

* Let some time pass.
wait_seconds (0.002)

* Abort the data code search.
set_bar_code_param (BarCodeHandle, 'abort', 'true')

* Wait for the thread, it should finish very fast.
par_join(ThreadID)

* We can determine that the search in fact was aborted.
get_bar_code_result (BarCodeHandle, 'all', 'aborted', Aborted)
```

Result

The operator `find_bar_code` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- BarCodeHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_bar_code_model`, `set_bar_code_param`

Possible Successors

`get_bar_code_result`, `get_bar_code_object`, `clear_bar_code_model`

Alternatives

`decode_bar_code_rectangle2`

Module

Bar Code

get_bar_code_object (: BarCodeObjects : BarCodeHandle, CandidateHandle, ObjectName :)

Access iconic objects that were created during the search or decoding of bar code symbols.

With the operator `get_bar_code_object`, iconic objects created during the last call of the operator `find_bar_code` can be accessed. Besides the name of the object (`ObjectName`), the bar code model (`BarCodeHandle`) must be passed to `get_bar_code_object`. In addition, in `CandidateHandle` an index to a single decoded symbol or a single symbol candidate must be passed. Alternatively, `CandidateHandle` can be set to *'all'* and then all objects of the decoded symbols or symbol candidates are returned.

Depending on the option selected in `ObjectName` parameter the following objects are returned:

'symbol_regions': The regions of successfully decoded symbols are returned. When choosing *'all'* as `CandidateHandle`, the regions of all decoded symbols are retrieved. The order of the returned objects is the same as in `find_bar_code`.

'candidate_regions': The regions of potential bar codes are returned. If there is a total of n decoded symbols out of a total of m candidates then CandidateHandle can be chosen between 0 and (m-1). With CandidateHandle between 0 and (n-1) the original segmented region of the respective decoded symbol is retrieved. With CandidateHandle between n and (m-1) the region of the potential or undecodable symbol is returned. In addition, CandidateHandle can be set to *'all'* to retrieve all candidate regions at the same time.

'scanlines_all', *'scanlines_valid'*, *'scanlines_all_plain'*, *'scanlines_valid_plain'*, *'scanlines_merged_edges'*: XLD contours representing the particular detected bars in the scanlines applied on the candidate regions are returned. Note that the scanlines can be only be returned if the bar code was decoded by find_bar_code or decode_bar_code_rectangle2 in *'persistence'* mode (see set_bar_code_param for further details).

'scanlines_all' represents all scanlines that find_bar_code could potentially create in order to decode a bar code.

'scanlines_valid' represents only those scanlines that could be successfully decoded. The number of scanlines that has to be valid can be adjusted with set_bar_code_param with the parameter *'min_identical_scanlines'*. There will be no *'scanlines_valid'* if the symbol was not decoded. For stacked bar codes (e.g., *'GS1 DataBar Stacked'* and *'GS1 DataBar Expanded Stacked'*) this rule applies similarly, but on a per-symbol-row basis rather then per-symbol.

'scanlines_merged_edges' shows the scanlines and edges which were used for the merged scanlines (see *'merge_scanlines'* in set_bar_code_param).

get_bar_code_object returns each scanline as separate XLD contour. Please note that the XLD contours returned by *'scanlines_all'*, *'scanlines_valid'* and *'scanlines_merged_edges'* are meant for visualization purposes and hence consist of many XLD points. Double lines are used between edges that the bar code reader recognized as bar, whereas single lines are used for white spaces. Additional information about each scanline can be obtained with get_bar_code_result with the parameter *'status'*.

The *'_plain'* variants *'scanlines_all_plain'* and *'scanlines_valid_plain'* return the described scanlines in a plain format. Every edge found is returned as a point of an XLD contour. For every scanline a new XLD contour is created. Scanlines for which no edges could be found are omitted.

Parameters

▷ **BarCodeObjects** (output_object) ..... object(-array) ⇝ *object*
Objects that are created as intermediate results during the detection or evaluation of bar codes.

▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

▷ **CandidateHandle** (input_control) ..... integer ⇝ *string* / integer
Indicating the bar code results respectively candidates for which the data is required.
Default: 'all'
Suggested values: CandidateHandle ∈ {0, 1, 2, 'all'}

▷ **ObjectName** (input_control) ..... string ⇝ *string*
Name of the iconic object to return.
Default: 'candidate_regions'
List of values: ObjectName ∈ {'symbol_regions', 'candidate_regions', 'scanlines_all', 'scanlines_valid', 'scanlines_merged_edges', 'scanlines_all_plain', 'scanlines_valid_plain'}

Result

The operator get_bar_code_object returns the value 2 (H_MSG_TRUE) if the given parameters are correct and the requested objects are available for the last symbol search. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_bar_code_result

Module

Bar Code

```
get_bar_code_param ( : : BarCodeHandle,
    GenParamName : GenParamValue )
```

Get one or several parameters that describe the bar code model.

The operator `get_bar_code_param` allows to query parameters of a bar code model, which are of relevance for a successful search and decoding of a respective class of bar codes.

The names of the desired parameters are passed in the generic parameter `GenParamName` and the corresponding values are returned in `GenParamValue`. All of these parameters can be set and changed at any time with the operator `set_bar_code_param`.

Parameters that have been set bar code type specifically by `set_bar_code_param_specific` or by automatic parameter training cannot be read with `get_bar_code_param`, but must be read with `get_bar_code_param_specific`. All parameters listed with the operator `get_bar_code_param_specific` can always be set specifically. Which parameters are actually set specifically can be determined at runtime with the operator `query_bar_code_params`.

The following parameters can be queried – ordered by different categories:

Size of the bar code elements:

'element_size_min': Minimal size of the base bar code elements, i.e., the minimal width of the narrowest bars and spaces for the specific bar code type.

'element_size_max': Maximal size of the base bar code elements, i.e., the maximal width of the narrowest bars and spaces for the specific bar code type.

'element_size_variable': Specifies if the element size varies across a single bar code.

'barcode_height_min': Minimal height of the bar code.

'barcode_width_min': Minimal bar code width.

'barcode_width_max': Maximal bar code width.

Scanning settings:

'num_scanlines': Maximal number of scans per (candidate) bar code.

'min_identical_scanlines': Minimal number of decoded scanlines which return identical data to read the bar code successfully.

'majority_voting': Decode result selection mode. Specifies whether majority voting is used in the selection of different scanline results.

'stop_after_result_num': Number of successfully decoded bar codes after which the decoding will stop. *0* is the default where the reader tries to decode all candidates.

'orientation': Accepted orientation of the decoded bar codes.

'orientation_tol': Tolerance of the accepted orientation.

'quiet_zone': Quiet zone verification mode.

'start_stop_tolerance': Start/Stop search criteria tolerance.

'min_code_length': Minimal number of decoded characters.

'max_code_length': Maximum number of decoded characters.

'merge_scanlines': Determines whether merged scanlines are computed if not enough scanlines could be decoded individually. Thus, occluded or damaged bar codes can be read.

Appearance of the bar code in the image:

'meas_thresh': Relative threshold for the detection of edges in the bar code region.

'meas_thresh_abs': Absolute threshold for the detection of edges in the bar code region.

'contrast_min': Minimal contrast between the foreground and the background of the bar code elements.

Print quality inspection-specific values:

'quality_isoiec15416_reflectance_reference': Reference gray value to normalize the reflectances used to assess the quality grades Symbol Contrast, Minimal Reflectance, and Minimal Edge Contrast.

Values that only apply to certain code types:

'check_char': Handling of an optional check character.

'composite_code': Presence and type of a 2D composite code appended to the bar code.

'upce_encodation': Output format for UPC-E bar codes (with number system 0 or 1).

'upce1_enable': Enables the decoding of UPC-E bar codes with number system 1.

Miscellaneous:

'timeout': Timeout for `find_bar_code`

'persistence': Persistence mode of the bar code model.

'train': Returns the *names* of the trained parameters. The returned tuple can be passed as `GenParamName` to a further call to `get_bar_code_param` to get the *values* of the trained parameters.

Further details on these parameters can be found with the description of the operator `set_bar_code_param`.

Parameters

▷ **`BarCodeHandle`** (input_control) . . . . . barcode ⇝ *handle*
Handle of the bar code model.

▷ **`GenParamName`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that are to be queried for the bar code model.
Default: 'element_size_min'
List of values: `GenParamName` ∈ {'check_char', 'composite_code', 'barcode_height_min', 'barcode_width_min', 'barcode_width_max', 'element_size_max', 'element_size_min', 'contrast_min', 'meas_thresh', 'meas_thresh_abs', 'min_identical_scanlines', 'majority_voting', 'num_scanlines', 'orientation', 'orientation_tol', 'persistence', 'quality_isoiec15416_reflectance_reference', 'start_stop_tolerance', 'stop_after_result_num', 'timeout', 'train', 'upce_encodation', 'upce1_enable', 'quiet_zone', 'element_size_variable', 'min_code_length', 'max_code_length', 'merge_scanlines', 'small_elements_robustness'}

▷ **`GenParamValue`** (output_control) . . . . . attribute.name(-array) ⇝ *real* / integer / string
Values of the generic parameters.

Result

The operator `get_bar_code_param` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_bar_code_model`, `set_bar_code_param`

Possible Successors

`set_bar_code_param`

Alternatives

`get_bar_code_param_specific`

Module

Bar Code

get_bar_code_param_specific (: : BarCodeHandle, CodeTypes, GenParamName : GenParamValue)

Get parameters that are used by the bar code reader when processing a specific bar code type.

The operator get_bar_code_param_specific allows to query parameters of a bar code model, which are of relevance for a successful search and decoding of a respective class of bar codes. Contrary to get_bar_code_param, get_bar_code_param_specific allows a bar code type specific query for the following parameters. This is useful when searching different code types in one image. The bar code types are specified in CodeTypes. The names of the desired parameters are passed in the generic parameter GenParamName and the corresponding values are returned in GenParamValue. All of these parameters can be set and changed selectively with the operator set_bar_code_param_specific or for all bar code types with the operator set_bar_code_param. Which parameters are set specifically can be determined at runtime with the operator query_bar_code_params. These parameters cannot be read with get_bar_code_param, but must be read with get_bar_code_param_specific.

The following parameters can be queried:

'num_scanlines': Maximal number of scanlines used during the scanning of a (candidate) bar code.

'min_identical_scanlines': Minimal number of decoded scanlines which return identical data to read the bar code successfully.

'stop_after_result_num': Number of successfully decoded bar codes of the given code type after which the decoding will stop. *0* is the default where the reader tries to decode all candidates.

'orientation': Accepted orientation of the decoded bar codes.

'orientation_tol': Tolerance of the accepted orientation.

'quiet_zone': Quiet zone verification mode.

'start_stop_tolerance': Start/stop search criteria tolerance. Currently it is implemented only for Code 128 and GS1-128.

'check_char': Handling of an optional check character.

'composite_code': Presence and type of a 2D composite code appended to the bar code.

'min_code_length': Minimal number of decoded characters.

'max_code_length': Maximum number of decoded characters.

Further details on the above parameters can be found with the description of set_bar_code_param operator.

Parameters

▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

▷ **CodeTypes** (input_control) ..... string(-array) ⇝ *string*
Names of the bar code types for which parameters should be queried.
Default: 'EAN-13'
List of values: CodeTypes ∈ {'2/5 Industrial', '2/5 Interleaved', 'Codabar', 'Code 39', 'Code 93', 'Code 128', 'EAN-13', 'EAN-13 Add-On 2', 'EAN-13 Add-On 5', 'EAN-8', 'EAN-8 Add-On 2', 'EAN-8 Add-On 5', 'UPC-A', 'UPC-A Add-On 2', 'UPC-A Add-On 5', 'UPC-E', 'UPC-E Add-On 2', 'UPC-E Add-On 5', 'MSI', 'PharmaCode', 'GS1 DataBar Omnidir', 'GS1 DataBar Truncated', 'GS1 DataBar Stacked', 'GS1 DataBar Stacked Omnidir', 'GS1 DataBar Limited', 'GS1 DataBar Expanded', 'GS1 DataBar Expanded Stacked', 'GS1-128'}

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Names of the generic parameters that are to be queried for the bar code model.
Default: 'check_char'
List of values: GenParamName ∈ {'check_char', 'composite_code', 'min_identical_scanlines', 'num_scanlines', 'orientation', 'orientation_tol', 'start_stop_tolerance', 'stop_after_result_num', 'quiet_zone', 'min_code_length', 'max_code_length'}

▷ **GenParamValue** (output_control) ..... attribute.name(-array) ⇝ *real* / integer / string
Values of the generic parameters.

Result

The operator get_bar_code_param_specific returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_bar_code_model, set_bar_code_param, set_bar_code_param_specific

Alternatives

get_bar_code_param

Module

Bar Code

get_bar_code_result (: : BarCodeHandle, CandidateHandle, ResultName : BarCodeResults)

Get the alphanumerical results that were accumulated during the decoding of bar code symbols.

The operator get_bar_code_result returns alphanumeric results of the reading process in BarCodeResults. In order to obtain a result, the bar code model (BarCodeHandle) and the index of the resulting symbol or candidate (CandidateHandle) are needed. ResultName determines what kind of result is to be returned.

CandidateHandle refers to the read candidates in the order as returned by the operator find_bar_code. This implies, the possible values for CandidateHandle depend on the queried result:

- Referring to decoded symbols, values from 0 to (n-1) are possible (with n as the total number of successfully decoded symbols).
- Referring to candidates, values from 0 to (m-1) are possible (with m as the total number of candidates).

In case the asked result is single valued, CandidateHandle can also be set to *'all'* to return the results of all symbols or candidates.

The following values are supported for ResultName:

'decoded_strings': returns the decoded result as a string in a human-readable format. Note that only data characters are contained in the decoded string. Start, stop, and check characters are excluded. For optional check characters the behavior depends on the value of the *'check_char'* (see set_bar_code_param for details) parameter.
The returned result is a single value.

'decoded_types': returns the bar code type of the decoded result as a string. This is especially important in the context of autodiscrimination (see find_bar_code).
The returned result is a single value.

'decoded_data': returns the decoded result as a tuple of byte values. In contrast to *'decoded_reference'*, this contains the same high level processed data that is also returned for *'decoded_strings'*. However, if the data contains binary non-printable characters, this parameter is more convenient. Also, for Code 128 or Code 93, the decoded data may contain NULL characters. In this case, the data can only be fully retrieved using this parameter, as the NULL character will otherwise terminate the string.

'decoded_reference': returns the underlying decoded reference data. It comprises all original characters of the symbol, i.e., data characters, potential start or stop characters and check characters if present. The specific result depends on the code type:

- For codes taking only numeric data, like, e.g., the EAN/UPC codes, the GS1 DataBar codes (except the GS1 DataBar Expanded variants), or the 2/5 codes, the decoded reference data takes the same values as the decoded string data including check characters.

- For codes with alphanumeric data, like for example Code 128 or Code 39 the decoded reference data are the indices of the respective decoding table.
- For GS1-128, the decoded reference data are the indices of the respective decoding table. The special character FNC1 appears with value 102.
- For GS1 DataBar Expanded and GS1 DataBar Expanded Stacked, the reference values are the ASCII codes of the decoded data (see also Tuple / String Operations), where the special character FNC1 appears with value 29.
- Furthermore, for all codes from the GS1 DataBar family the first reference value represents a linkage flag with value of 1 if the flag is set and 0 otherwise.

The result is returned as a tuple.

'composite_strings': returns the decoded string of a GS1 Composite component. For further details see the description of the parameter *'composite_code'* of `set_bar_code_param`.

The returned result is a single value.

'composite_reference': returns the decoded string of a GS1 Composite component as a tuple of byte values. If the data contains binary non-printable characters, this parameter is more convenient than *'composite_strings'*.

'orientation': returns the orientation for the specified result. The *'orientation'* of a bar code is defined as the angle between its reading direction and the horizontal image axis. The angle is positive in counter clockwise direction and is given in degrees. Note that the reading direction is perpendicular to the bars of the bar code. In cases where the orientation of the bars can not be determined reliably, e.g., for distorted codes, the orientation of the scanlines is returned.

The returned result is a single value.

Value range: *-180.0 ... 180.0*.

'element_size': returns the size of bar code elements for the specified result.

The returned result is a single value.

'aborted': returns a value indicating whether `find_bar_code` was aborted or not:

0 - *completed* `find_bar_code` completed.

1 - *aborted* `find_bar_code` was aborted by a timeout, see `set_bar_code_param`.

2 - *aborted* `find_bar_code` was aborted using `set_bar_code_param` with *'abort'*.

The returned result is a single value.

'quality_isoiec15416': returns a tuple with the assessment of print quality in compliance with the international standard ISO/IEC 15416:2016. Note that the print quality of a bar code can only be evaluated if the bar code was decoded by `find_bar_code` in *'persistence'* mode (see `set_bar_code_param` for further details).

The first tuple element always contains the overall print quality of the symbol. The length of the tuple and the interpretation of the remaining elements depend on whether a simple 1D bar code is evaluated (e.g., EAN-13, Code 128, GS1 DataBar) or a composite bar code (e.g., GS1 DataBar Omnidirectional CC-A, GS1 DataBar Limited CC-B). The names of the grades can be queried by setting `ResultName` to *'quality_isoiec15416_labels'*, see below.

For the print quality assessment a set of scan reflectance profiles (scan lines) is generated across the symbol. For each scan line a grade for each of the evaluated parameters is allocated.

For compatibility reasons these grades are numbers from 0 to 4, where 0 is the worst and 4 the best possible grade. Setting `ResultName` to *'quality_isoiec15416_float_grades'*, the grades are returned in accordance with the standard with one decimal place. The worst of all parameter grades of a scan line is defined as the scan reflectance profile grade. Thus, each scan line has an own grade representing the respective minimal grade of all parameter grades of this scan line. The arithmetic mean of all those scan line grades is then returned as the overall symbol grade.

If a grade is not defined for the bar code type of the decoded symbol, *'N/A'* is returned. In this case, the overall symbol grade is also *'N/A'*.

It is important to note that, even though the implementation is strictly based on the standard, the computation of the print quality grades depends on the decoding algorithm used. Thus, different bar code readers (of different vendors) can potentially produce slightly different results in the print quality assessment.

The tuple describing the print quality depends on whether the bar code is simple or composite:

simple 1D bar codes:

The valuation of the print quality is described in a tuple with the following nine elements:

0 - *overall quality*: The arithmetic mean of the scan reflectance profile grade of each scan line. Note, that this value is, in most cases, not the minimum of the other symbol grades, because it depends on the individual scan reflectance profile grades.

1 - *decode*: Set to *4* when the reflectance profile of the symbol could be decoded according to the reference decode algorithm for the symbology and *0*, otherwise. Note that HALCON's decode algorithm differs from the reference decode algorithm. Thus, in many cases HALCON can decode the symbol although the *decode* grade according to the standard is *0*.

2 - *symbol contrast*: The range between the minimal and the maximal value in the reflectance profile. A strong contrast results in a good grading.

3 - *minimal reflectance*: Set to *4* if the lowest reflectance value in the scan reflectance profile is lower or equal to 0.5 of the maximal reflectance value. Otherwise a value of *0* is assigned.

4 - *minimal edge contrast*: The contrast between any two adjacent elements, both bar-to-space or space-to-bar. The *minimal edge contrast* grades the minimum of the edge contrast values measured in the reflectance profile.

5 - *modulation*: Indicates how strong the amplitudes of the bar code elements are. Big amplitudes make the assignment of the elements to bars or spaces more certain, resulting in a high modulation grade.

6 - *defects*: Reflects irregularities in the gray value profile found within elements and quiet zones.

7 - *decodability*: Reflects deviations of the element widths from the nominal widths defined for the corresponding symbology.

8 - *additional requirements*: A grade concerning symbology specific requirements of the bar code. It mostly regards the required quiet zones, but sometimes it can also be related to e.g., wide/narrow ratio, inter-character gaps, guarding patterns. For the following code types the conformity to the corresponding ISO/IEC standard cannot be guaranteed. This is mainly because the computation of the *additional requirements* requires the availability of metrical information.

Code 39: the grade of the inter-character gap depends on the measured narrow element width given in millimeters. Since in `find_bar_code` neither metric information is available nor can be calculated, `get_bar_code_result` will only return the grade for the inter-character gap assuming that the measured narrow element width is less than 0.287mm.

EAN-13, EAN-8, UPC-A, UPC-E (including all add-on variants): ISO/IEC 15420:2009 specifies the magnification factors as an additional criterion. A computation of this criterion is not possible since this would require knowledge of the metrical size of the bar code.

While *overall quality* is the final symbol grade to be reported, the rest of the grades give information for possible causes for poor quality of a symbol. A detailed list of frequently appearing defects and their effect on the individual grades can be found with the ISO/IEC 15416:2016 standard.

composite bar codes:

The valuation of the print quality is described in a tuple with 24 elements, which we organize for better clarity in three groups: `OVERALL`, `LINEAR`, and `COMPOSITE`, the latter one including a sub group. The overall grades that are listed in the group `OVERALL`. The grades in the groups `LINEAR` and `COMPOSITE` give information of possible causes for poor quality of the symbol.
In the following, the individual tuple elements with their corresponding index and definition are listed in groups.

- The group `OVERALL`:
  These grades represent the respective minimum of all individual grades of each group.

  0 - *overall quality*: The final symbol grade to be reported. It returns the minimum of all grades.

  1 - *overall linear*: The overall grade for the symbols of the group `LINEAR`, the linear 1D symbols. This grade returns the minimum of all grades belonging to the group.

  2 - *overall composite*: The overall grade for the symbols of the group `COMPOSITE`, the composite 2D symbols. This grade returns the minimum of all grades belonging to the group.

- The group `LINEAR`:
  The interpretation of the grades in the `LINEAR` group correspond to those for simple 1D bar codes described above.

  3 - *decode*

  4 - *symbol contrast*

  5 - *minimal reflectance*

  6 - *minimal edge contrast*

7 - *modulation*

8 - *defects*

9 - *decodability*

10 - *additional requirements*

- The group COMPOSITE:
  these grades are equivalent to the quality grades for PDF 417 data code symbols, thus of two-dimensional symbols according to ICO/IEC 15415:2011 (see *'quality_isoiec15415'* in get_data_code_2d_results). However, there is a difference: For PDF 417 data code symbols a start/stop pattern is used for the evaluation concerning the quality of the reflectance profile. In contrast, for composite bar codes so-called Raw Address Patterns (RAP) are used instead of a start/stop pattern. The grades of the respective RAP symbols are organized in the sub group COMPOSITE RAP and are consistent with the grades for simple 1D bar codes.

  11 - *decode*: Grade for the decodability of the composite symbol part. Its meaning and determination is equivalent to the one for simple 1D bar codes described above.

  12 - *RAP overall*: Minimum of all individual grades of the sub group COMPOSITE RAP.

  13 - *RAP contrast*: Grade of the COMPOSITE RAP sub group, corresponds to the one for simple 1D bar codes as described above.

  14 - *RAP minimal reflectance*: Grade of the COMPOSITE RAP sub group, corresponds to the one for simple 1D bar codes as described above.

  15 - *RAP minimal edge contrast*: Grade of the COMPOSITE RAP sub group, corresponds to the one for simple 1D bar codes as described above.

  16 - *RAP modulation*: Grade of the COMPOSITE RAP sub group, corresponds to the one for simple 1D bar codes as described above.

  17 - *RAP defects*: Grade of the COMPOSITE RAP sub group, corresponds to the one for simple 1D bar codes as described above.

  18 - *RAP decodability*: Grade of the COMPOSITE RAP sub group, corresponds to the one for simple 1D bar codes as described above.

  19 - *codeword yield*: Counts and evaluates the relative number of correct decoded words acquired by the set of scan profiles.

  20 - *unused error correction*: Counts and evaluates the relative number of false decoded words within the error correction blocks.

  21 - *modulation*: Grades the ratio of the minimum edge contrast to the symbol contrast. indicates how strong the amplitudes, i.e., the extremal intensities, of the bars and spaces are.

  22 - *decodability*: Grades the uniformity of reflectance of the dark and light modules, respectively.

  23 - *defects*: Refers to a measurement of how perfect the reflectance profiles of bars and spaces are.

'quality_isoiec15416_float_grades': returns a tuple with the same assessment of print quality like *'quality_isoiec15416'*. In compliance with the international standard ISO/IEC 15416:2016 the grades are returned with one decimal place. The names of the grades can be queried by setting ResultName to *'quality_isoiec15416_labels'*, see below.

Note that the print quality of a bar code can only be evaluated if the bar code was decoded by find_bar_code in *'persistence'* mode (see set_bar_code_param for further details).

'quality_isoiec15416_values': returns a tuple with the raw values for all *'directly measurable'* grades (returned with ResultName to *'quality_isoiec15416'*). These are the grades, whose definition in the ISO/IEC 15416:2016 standard is a *'direct derivative'* of the reflectance (i.e., the gray values) properties of the symbol or grades that are the result of a *'direct counting'*. Additionally the three overall grades *overall quality*, *overall linear*, and *overall composite* are returned (see their explanation above in *'quality_isoiec15416'*). Note that the print quality of a bar code can only be evaluated if the bar code was decoded by find_bar_code in *'persistence'* mode (see set_bar_code_param for further details).

The names of the tuple elements can be queried by setting ResultName to *'quality_isoiec15416_labels'*, see below.

All values (not grades) are normalized between *0.0* and *1.0*. Hence, for example, a *symbol contrast* value of *0.75* will correspond to a gray value of *191.25* (for byte images).

Which values make up the tuple depends on whether the bar code is a simple 1D or a composite bar code:

simple 1D bar codes:

The following values are returned by the respective index:

0 - *overall quality*
2 - *symbol contrast*
3 - *minimal reflectance*
4 - *minimal edge contrast*
5 - *modulation*
6 - *defects*
7 - *decodability*

composite bar codes:
The following values are returned by the respective index:
0 - *overall quality*
1 - *overall linear*
2 - *overall composite*
4 - *symbol contrast*
5 - *minimal reflectance*
6 - *minimal edge contrast*
7 - *modulation*
8 - *defects*
9 - *decodability*
13 - *RAP contrast*
14 - *RAP minimal reflectance*
15 - *RAP minimal edge contrast*
16 - *RAP modulation*
17 - *RAP defects*
18 - *RAP decodability*
19 - *codeword yield*
20 - *unused error correction*

These tuples have the same length as the tuple with the grades returned when setting `ResultName` to *'quality_isoiec15416'* and *'quality_isoiec15416_float_grades'*, respectively. For the entries not listed above, the operator reports *'N/A'*. In case of simple 1D bar codes, the grades *decode* and *additional requirements* do not have any interpretation in the reflectance profile and as a consequence the value *'N/A'* is returned. For composite bar codes this is the case for the grades *decode* (`LINEAR`), *additional requirements* (`LINEAR`), *decode* (`COMPOSITE`), and *RAP overall* (`COMPOSITE`). Note that although the grades *modulation* (`COMPOSITE`), *decodability* (`COMPOSITE`), and *defects* (`COMPOSITE`) are grading the gray value reflectance profile of a composite symbol, *'N/A'* is reported for them as well. This is because they are computed in a complicated scheme involving the symbology decoding routine and the error correction mechanism. As a consequence they do not have a direct raw measurement interpretation.

If a grade is not defined for the bar code type of the decoded symbol, *'N/A'* is returned as its value. In this case, the value of the overall symbol grade is also *'N/A'*.

'quality_isoiec15416_labels': returns convenience grade labels of the elements of the tuple returned when calling `get_bar_code_result` with *'quality_isoiec15416'*. Note, that in order to be able to discriminate the composite from the linear grading case, the operator needs a handle of a valid result to be passed in `CandidateHandle`.

'gs1_lint_passed': If the symbol contains a GS1 formatted string, additional linting can be performed on the contained string. *'gs1_lint_passed'* will return *'true'*, if this is successful. Otherwise, *'false'* is returned. Linting checks that

- one AI (Application Identifier) does not occur multiple times with different contents,
- AIs required by other AIs are contained,
- AIs excluded by other AIs are not included, and that
- specific formatting rules for AIs are respected.

'gs1_lint_result': *'gs1_lint_result'* performs the linting tests documented in *'gs1_lint_passed'*. If the linting fails, a list of human-readable error messages is returned, if it is successful, *'ok'* is returned.

'status': determines and returns additional information about scanlines of a given candidate region in a human-readable format. Note in order to evaluate the status of the bar code scanlines the preceding call of the operator `find_bar_code` or `decode_bar_code_rectangle2` needs to be done in the mode *'persistence'*, see `set_bar_code_param`.

For the calculation of additional information the given candidate region is scanned again. In doing so, the bar code reader exits only after evaluation of all scanlines and not usual after a successful decoding. This is computationally expensive and should be queried only if additional information is needed. For further information on setting scanline parameters, see `set_bar_code_param`.

The operator returns for every scanline of the candidate region a status message and possible warning message, which will be added to the string containing the status message. These messages are sorted in the same order as the scanlines themselves are returned by `get_bar_code_object` with the parameter *'scanlines_all'*. The possible messages of these categories are listed below.

- Status messages:
  The following list shows the possible messages grouped into stages in which the message can appear. The numbers are the corresponding status codes returned by *'status_id'* (see below).

  0 - *'unknown status.'* The status of this scanline is unknown. The scanline will be ignored.

  1 - *'success.'* The scanline could be decoded successfully.

  2 - *'edges: not enough edges detected.'* The number of edges in this scanline is too low for this bar code type.

  3 - *'edges: not enough edges for a start, a stop and at least one data character.'* The number of edges in this scanline is too low to find at least the start pattern, the stop pattern and a data character.

  4 - *'edges: too many edges detected.'* The number of edges in this scanline is too high for this bar code type.

  5 - *'edges: center of scanline not within image domain.'*

  6 - *'decoding: could not find stop character.'* The symbology specific stop character could not be found.

  7 - *'decoding: could not find start and stop characters.'* The symbology specific start and stop characters could not be found.

  8 - *'decoding: internal error when estimating the maximum string length.'* Internal error.

  9 - *'decoding: internal error when decoding a single character.'* Internal error.

  10 - *'decoding: number of wide bars of a single character is not equal to 2.'* For bar code types *'2/5 Industrial'* and *'2/5 Interleaved'*, the number of wide bars in a single character must be two.

  11 - *'decoding: invalid encoding pattern.'* The encoding pattern does not correspond to a character in the symbology specific decoding table.

  12 - *'decoding: invalid mix of character sets.'* For bar code types *'EAN-13'* and *'UPC-A'*, the left half of the symbol contains an invalid mix of the number sets A and B.

  13 - *'decoding: error decoding the reference to a human readable string.'* For example, this could happen if not enough characters (depending on whether a check character is expected) could be found.

  14 - *'decoding: could not detect center guard pattern.'* For bar code types *'EAN-13'*, *'EAN-8'*, and *'UPC-A'* (including add-on variants) the obligatory center guard pattern could not be found.

  15 - *'decoding: could not detect left and/or right guard patterns.'* For bar code types *'EAN-13'*, *'EAN-8'*, and *'UPC-A'* (including add-on variants) either the obligatory left or right normal guard patterns could not be found. For bar code types *'UPC-E'* (including add-on variants) either the left normal or right special guard patterns could not be found.

  16 - *'decoding: could not detect add-on guard pattern.'* For bar code types *'EAN-13'*, *'EAN-8'*, *'UPC-A'*, and *'UPC-E'* containing add-on symbols, the obligatory add-on guard pattern could not be found.

  17 - *'decoding: could not detect enough finder patterns.'* For bar code types of the GS1 DataBar family, not enough finder patterns could be found.

  18 - *'decoding: no segment found.'* For stacked bar code types no segment could be found.

  19 - *'check: checksum test failed.'* The check character test failed. For bar codes with an optional check character, it is possible to disable the check character testing with *'check_char'* in `set_bar_code_param`.

  20 - *'check: check of add-on symbol failed.'* For bar code types *'EAN-13'*, *'EAN-8'*, *'UPC-A'*, and *'UPC-E'* containing add-on symbols, the mix of the number sets A and B does not match the implicit check digit.

21 - *'check: detected EAN-13 bar code type instead of specified type.'* For the bar code type *'UPC-A'* and its add-on variants, the left half of the symbol must consist of six symbol characters of number set A, but a *'EAN-13'* compatible mix of number sets A and B has been found instead. Try decoding the bar code as *'EAN-13'*.

22 - *'check: symbol region overlaps with another symbol region'* The bar code could be decoded, but its symbol region intersects with the symbol region of another successfully decoded symbol.

23 - *'decoding: could not detect the bar code type.'* While scanning a candidate region in autodiscrimination mode (see `find_bar_code` with `CodeType`=*'auto'*), the decoder was unable to detect which bar code type the symbol belongs to.

24 - *'decoding: quiet zone is disturbed.'* The quiet zone check was not successful. See the section *'quiet_zone'* in `set_bar_code_param` for further information.

25 - *'check: symbol region detected outside of the candidate region.'* A bar code could be decoded, but the resulting symbol region does not intersect the original candidate region. This is an indication that random clutter or another candidate was detected by accident by the scanlines used to scan the original candidate.

26 - *'decoding: minimum code length not reached (see min_code_length).'* The number of characters in the found code is smaller than the required amount. See the section *'min_code_length'* in `set_bar_code_param` for further information about the minimal required code length.

27 - *'decoding: maximum code length exceeded (see max_code_length).'* The number of characters in the found code exceeds the maximum. See the section *'max_code_length'* in `set_bar_code_param` for further information about the maximum allowed code length.

28 - *'decoding: could not estimate bar width threshold.'* Specific to Pharmacode. It was not possible to estimate a threshold to distinguish between wide and narrow bars.

- Warning messages:
  The messages listed below are only warnings, not errors. They can appear in combination with a status message and are then added to the status message string. These messages are returned if the bar code reader detects possible quality issues in the input image. The messages 1000 to 1003 can appear only for successfully decoded scanlines and only for the following bar code types: *'Codabar'*, *'2/5 Industrial'*, *'2/5 Interleaved'*, *'Code 39'*, *'Code 93'*, *'GS1-128'*, *'Code 128'*, *'MSI'*, all *'EAN'*-, *'UPC-A'*- and *'UPC-E'*-variants. Note that in cases where scanlines were already decoded incorrectly but not recognized as invalid by the bar code reader, these warnings will be wrong and must be ignored.

  1000 - *'White spaces too wide.'* The measured width of the white spaces is bigger than internally expected. This is not a decoding error, but a warning that increasing white spaces could lead to undecodable symbols.

  1001 - *'White spaces too narrow.'* The measured width of the white spaces is smaller than internally expected. This is not a decoding error, but a warning that decreasing white spaces could lead to undecodable symbols.

  1002 - *'Bars too wide.'* The measured width of the bars is bigger than internally expected. This is not a decoding error, but a warning that increasing the width of the bars could lead to undecodable symbols.

  1003 - *'Bars too narrow.'* The measured width of the bars is smaller than internally expected. This is not a decoding error, but a warning that decreasing the width of the bars could lead to undecodable symbols.

  1004 - *'Possible saturation of gray values.'* Internal algorithms show that the white pixels in the symbol region could be saturated. This warning is not bar code type specific. This warning is returned for each scanline. For example, the combination of the status messages 1001/1004 or 1003/1004 is a hint, that the input images might be overexposed.

  1005 - *'No composite component found.'* The linkage flag in the linear bar code component indicates that there should be a composite component, but the composite component could not be found. The decoder returned the linear component only. This warning is returned for each scanline.

  1006 - *'Used for merging.'* This message is an information that some edges of the current scanline were used to compute the merged scanline.

'status_id': returns additional information about scanlines in a numeric format that can be easily parsed. The description of this functionality and the message numbers are described with the parameter *'status'* above. The numbers of the warnings can be returned together with other status numbers. The single status message and warning numbers for each scanline are returned as a string, separated by a semicolon, e.g., `'1;1000;1004'`.

'status_small_elements_robustness': determines the status of an optional decoding attempt, which is described in the section about *'small_elements_robustness'* in `set_bar_code_param`. Additionally to the messages listed for *'status'*, *'status_small_elements_robustness'* can return the status *'small_elements_robustness: no scan.'* if for some reason the algorithm was not executed or failed.

'decode_feature': returns the feature that is used for the successful symbol decoding.

The returned result is a single value.

Suggested values: *'standard'*, *'merge_scanlines'*, *'small_elements_robustness'*.

Parameters

▷ **BarCodeHandle** (input_control) . . . . . barcode ⇝ *handle*
Handle of the bar code model.

▷ **CandidateHandle** (input_control) . . . . . integer ⇝ *string* / integer
Indicating the bar code results respectively candidates for which the data is required.
Default: 'all'
Suggested values: `CandidateHandle` ∈ {0, 1, 2, 'all'}

▷ **ResultName** (input_control) . . . . . attribute.name ⇝ *string*
Names of the resulting data to return.
Default: 'decoded_types'
Suggested values: `ResultName` ∈ {'decoded_types', 'decoded_strings', 'decoded_data', 'decoded_reference', 'element_size', 'orientation', 'composite_strings', 'composite_reference', 'aborted', 'gs1_lint_result', 'gs1_lint_passed', 'quality_isoiec15416', 'quality_isoiec15416_labels', 'quality_isoiec15416_values', 'quality_isoiec15416_float_grades', 'status', 'status_id', 'status_small_elements_robustness', 'decode_feature'}

▷ **BarCodeResults** (output_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
List with the results.

Result

The operator `get_bar_code_result` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct and the requested results are available for the last symbol search. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Bar Code

```
query_bar_code_params ( : : BarCodeHandle,
    Properties : GenParamName )
```

Get the names of the parameters that can be used in set_bar_code and get_bar_code* operators for a given bar code model*

The operator `query_bar_code_params` returns parameter names of the bar code model that correspond to the selection given in `Properties`. To explain this, here first some background: After creating a bar code model, all parameters are initially set *'general'*, i.e., they have the same values set for each supported bar code type. During automatic parameter training or after calling the operator `set_bar_code_param_specific` some parameters might become bar code type specific at runtime. These parameters can not be read with the general operator `get_bar_code_param` but must be read for a given bar code type with `get_bar_code_param_specific`. To make this access easy and generic, the output `GenParamName` of

query_bar_code_params can be used as input parameter GenParamName in get_bar_code_param or get_bar_code_param_specific, depending on Properties='*general' or Properties='*specific'.

Please note that you could alternatively use a static tuple of parameter names for get_bar_code_param or get_bar_code_param_specific (e.g., the parameter names described with these operators), but this is inflexible and therefore not recommended.

Possible values for Properties are:

'all': Returns the names of all parameters supported by the bar code reader. The names are independent of the bar code model given in BarCodeHandle.

'general': Returns the names of the parameters that contain the same values for all supported bar code types, i.e., there are no specific values set for certain bar code types, e.g., with set_bar_code_param_specific. The values of only these parameters can be read with get_bar_code_param.

Please note that the parameter name *'train'* is explicitly excluded here. *'train'* in a following call to get_bar_code_param would return a multivalue tuple and therefore couldn't be used within one tuple in combination with other parameter names.

'specific': Returns the names of the parameters that contain specific values for certain bar code types. The values of these parameters must be read with get_bar_code_param_specific instead of get_bar_code_param. Bar code type specific values can occur in conjunction with bar code autodiscrimination, described with the operator find_bar_code or automatic parameter training.

'trained_general': Returns the names of parameters that have already been trained and contain the same values for all supported bar code types. The training mode is described with the operator set_bar_code_param.

'trained_specific': Returns the names of the parameters that have already been trained and contain specific values for certain bar code types. The training mode is described with the operator set_bar_code_param.

Parameters

▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

▷ **Properties** (input_control) ..... attribute.name ⇝ *string*
Properties of the parameters.
Default: 'trained_general'
List of values: Properties ∈ {'general', 'specific', 'trained_general', 'trained_specific', 'all'}

▷ **GenParamName** (output_control) ..... attribute.name(-array) ⇝ *string*
Names of the generic parameters.

Example

```
TrainParams := ['element_size_min', 'element_size_max', 'orientation']
Train3times := gen_tuple_const(|TrainParams|,'train')
create_bar_code_model (Train3times, TrainParams, BarCodeHandle)
find_bar_code (Image, SymbolRegions, BarCodeHandle, 'EAN-13', \
               DecodedDataStrings)
query_bar_code_params (BarCodeHandle, 'trained_general', NamesGen)
* returns NamesGen = ['element_size_max', 'element_size_min']
get_bar_code_param (BarCodeHandle, NamesGen, ValGen)
* returns e.g., ValGen = [4.0, 1.5]
query_bar_code_params (BarCodeHandle, 'trained_specific', NamesSpec)
* returns NamesSpec = ['orientation', 'orientation_tol']
get_bar_code_param_specific (BarCodeHandle, 'EAN-13', NamesSpec, ValSpec)
* returns e.g., ValSpec = [89.9127, 0.5]
```

Result

The operator query_bar_code_params returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

find_bar_code, decode_bar_code_rectangle2

Possible Successors

get_bar_code_param, get_bar_code_param_specific

Module

Bar Code

read_bar_code_model (: : FileName : BarCodeHandle)

Read a bar code model from a file and create a new model.

The operator read_bar_code_model reads the bar code model from the file FileName and creates a new model that is an identical copy of the saved model. The parameter BarCodeHandle returns the handle of the new model. The model file FileName must have been created by the operator write_bar_code_model. The default HALCON file extension for bar code model is 'bcm'.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the bar code model file.
Default: 'bar_code_model.bcm'
File extension: .bcm

▷ **BarCodeHandle** (output_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

Result

The operator read_bar_code_model returns the value 2 (H_MSG_TRUE) if the named bar code file was found and correctly read. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

write_bar_code_model, clear_bar_code_model

Module

Bar Code

serialize_bar_code_model (
: : BarCodeHandle : SerializedItemHandle)

Serialize a bar code model.

serialize_bar_code_model serializes a bar code model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by

write_bar_code_model is converted to a serialized item. The bar code model is defined by the handle BarCodeHandle. The serialized model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_bar_code_model.

Parameters

▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

The operator serialize_bar_code_model returns the value 2 (H_MSG_TRUE) if the passed handle of the bar code model is valid and if the model can be serialized into the serialized item. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Bar Code

set_bar_code_param (: : BarCodeHandle, GenParamName, GenParamValue :)

Set selected parameters of the bar code model.

The operator set_bar_code_param is used to set or change the different parameters of a bar code model in order to adapt to special properties of the bar codes or to a particular appearance in the image. All parameters can also be set while creating the bar code model with create_bar_code_model. The current configuration of the bar code model can be queried with get_bar_code_param.

The following overview lists the different generic parameters with the respective value ranges and default values:

Size of bar code elements:

The first two parameters, *'element_size_min'* and *'element_size_max'*, influence the search for candidate regions and the decoding of the bar code. But note that these values are not used as strict limits for the size of the elements of found bar codes, i.e., also bar codes with elements that are smaller than *'element_size_min'* or larger than *'element_size_max'* may be found.

Attention: When the size is changed by calling the operator set_bar_code_param, the consistency of the parameters *'element_size_min'* and *'element_size_max'* is verified. Both parameters should be set in the same call.

'element_size_min': Minimal size of the base bar code elements (also called 'modules' or 'narrow bars', depending on the specific bar code type), i.e., the minimal width of the narrowest bars and spaces for the specific bar code type. The value of this parameter is defined in pixels. For low resolution bar codes, the value should be reduced to *1.5*, and in some cases even as low as *0.6*. If the *'element_size_min'* is specified below *2.0* pixels an additional decoding attempt is made (see *'small_elements_robustness'* for more details on this attempt). In the case of huge bar codes, the value should be increased, which results in a shorter execution time and fewer candidates.

Suggested values: [*1.2*, ..., *10.0*]

Value range: [*0.6*, ..., *64*]

Default: *2.0*

'element_size_max': Maximal size of the base bar code elements (also called 'modules' or 'narrow bars', depending on the specific bar code type), i.e., the maximal width of the narrowest bars and spaces for the specific bar code type. The value of *'element_size_max'* is defined in pixels. It should be adequately low such that two neighboring bar codes are not fused into a single one. On the other hand the value should be sufficiently high in order to find the complete bar code region.

Suggested values: [*4.0*, ..., *60.0*]

Value range: [*1*, ..., *256*]

Default: *8.0*

'element_size_variable': In some bar code images, the smallest element size may vary across a given bar code object. These deformations might be caused by perspective projection or by deformations of the surface on which the bar code is printed (e.g., barrel distortion on a bottle). By default, the bar code reader cannot handle such distortions. However, if *'element_size_variable'* is set to *'true'*, the bar code reader tries to compensate for such distortions. Please note that in some situations it is still not possible to undistort the bar code image.

The parameter *'element_size_variable'* applies to the following bar code types only:

- GS1 DataBar Limited
- GS1 DataBar Expanded
- GS1 DataBar Expanded Stacked

Any other bar code type is unaffected by this parameter.

List of values: *'false'*, *'true'*

Default: *'false'*

'barcode_height_min': Minimal bar code height. The value of this parameter is defined in pixels. The default value is *-1*, meaning that the bar code reader automatically derives a reasonable height from the other parameters. Just for very flat and very high bar codes a manual adjustment of this parameter can be necessary. In the case of a bar code with a height of less than 16 pixels the respective height should be set by the user. Note, that the minimal value is 8 pixels. If the bar code is very high, i.e. 70 pixels and more, manually adjusting to the respective height can lead to a speed-up of the subsequent finding and reading operation.

Suggested values: *-1*, *8*, *64*

Default: *-1*

'barcode_width_min': Minimal bar code width. The value of this parameter is defined in pixels. The width of a bar code depends on many factors:

- resolution of the camera
- distance between camera and bar code
- bar code type
- number of encoded characters

If these properties are constant throughout the application, this parameter should be set in order to increase both speed and robustness. The default value is *-1*, meaning that the reader estimates a minimal bar code width based on symbology specifications and the parameter *'element_size_min'*.

Suggested values: *-1*, *40*, *50*, *60*

Default: *-1*

'barcode_width_max': Maximal bar code width. The value of this parameter is defined in pixels. The width of a bar code depends on many factors:

- resolution of the camera
- distance between camera and bar code
- bar code type
- number of encoded characters

If the maximal bar code width is known, this parameter can increase the robustness. Especially the unintended merging of bar codes lying close to each other can be avoided reliably. In general it should not be necessary to set this parameter. The default value is *-1*, meaning that the maximal bar code width is not restricted.

Suggested values: *-1*, *300*, *400*, *500*

Default: *-1*

Scanning settings:

'num_scanlines': Maximum number of scanlines used during the scanning of a (candidate) bar code. If *'num_scanlines'* is not set (the parameter has a value of *0*), the maximum number of scanlines is determined internally and it will be *10* for all single-row bar codes, *20* for GS1 DataBar Stacked and GS1 DataBar Stacked Omnidirectional, and *55* for GS1 DataBar Expanded Stacked. With this parameter, you can improve performance in two cases. In the first case, the image contains many false candidates. While the bar code itself is usually decoded after one or two scans (except for stacked bar codes, see below), a false candidate is scanned with the default value of 10 scanlines, which increases the runtime unnecessarily. Reducing the number of scanlines can therefore improve performance in images with many false candidates. As a rule of thumb, images with higher quality need less scanlines than images of lower quality. For an average image, a value between 2 and 5 should be sufficient. If a bar code can, however, not be detected after reducing the number of scanlines, the number has to be increased again. The second case concerns stacked bar codes (currently GS1 DataBar Stacked, GS1 DataBar Stacked Omnidirectional, and GS1 DataBar Expanded Stacked). Here, all scanlines are evaluated, in contrast to single-row bar codes (e.g., Code 128, EAN 13, or GS1 DataBar Limited) where the scanning stops after the code is decoded successfully. Since the scanning of the scanlines is actually one of the most time consuming parts of the `find_bar_code` algorithm, adjusting *'num_scanlines'* might result in essential performance improvements. This is especially valid for GS1 DataBar Expanded Stacked. A GS1 DataBar Expanded Stacked symbol might have up to 11 rows and therefore 55 scanlines are required to robustly detect all of them. If only symbols with smaller number of rows are expected, you can reduce *'num_scanlines'*, leaving 1.5 to 5 scanlines per row.

If this parameter is set to a value that is smaller than the specified *'min_identical_scanlines'* value, the value of the parameter *'min_identical_scanlines'* is automatically reduced to the value of the specified *'num_scanlines'*.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

Suggested values: *0*, *5*, *10*, *20*

Default: *0*

'min_identical_scanlines': With this parameter, the probability can be lowered to read bar codes wrongly or in places where no bar codes is present. The parameter specifies the minimal number of decoded scanlines which return identical data to read the bar code successfully.

If this parameter is set to 0 (which is the default for all code types, except for '2/5 Industrial' and '2/5 Interleaved'), a bar code is considered decoded with the first successfully decoded scanline (in the case of stacked codes, there must be a successful scanline per symbol row). If *'majority_voting'* is enabled, a different scheme applies (see the section on *'majority_voting'* for more details). Increasing this parameter to 2 or more is particularly useful, to prevent that a bar code is detected accidentally. This can typically happen if a scanline extracted erroneous or false edges out of a low quality image or in a very noisy image fragment. This parameter can be used to reduce the number of false detections also in cases where a specific bar code type is searched for in an image containing symbols from other bar code symbologies.

Note that the default value of this parameter is *0* for most code types. However, the default value is *2* for *'2/5 Industrial'* and *'2/5 Interleaved'* bar code types. The reason for this is that these bar code types are easily misread in other structures like clutter and text with a *'min_identical_scanlines'* setting of *1*.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

If merged scanlines (see *'merge_scanlines'*) are used, *'min_identical_scanlines'* specifies in how many scanlines each edge must be recognized successfully (see `get_bar_code_object`, *'scanlines_merged_edges'*).

For *'GS1 DataBar Expanded Stacked'*, *'min_identical_scanlines'* specifies in how many scanlines each segment must be recognized successfully.

Suggested values: *0*, *2*, *3*

Default:

Bar code Type	*'min_identical_scanlines'*
2/5 Industrial	2
2/5 Interleaved	2
all others	0

'majority_voting': This parameter controls the decode result selection mode. If this parameter is *'false'*, a successful decode result is returned if the minimal number of identically decoded scanlines are found (see section on *'min_identical_scanlines'* for more details). By setting this parameter to *'true'* a majority voting scheme is used to select between different scanline results. The result which is decoded by the majority of all scanlines is selected as the overall result. Please note that setting this parameter to *'true'* leads to a slightly increased runtime since nearly all scanlines have to be considered instead of just the minimal identical ones.

In order to reduce false decode results this parameter should be enabled.

This parameter is only supported for non-stacked bar code types.

List of values: *'false'*, *'true'*

Default: *'false'*

'stop_after_result_num': Number of successfully decoded bar codes after which the decoding will stop. If this parameter is not set (has a value of *0*), all bar code candidates are decoded. Typically, this parameter is set if the number of expected bar codes is known in advance. Then the bar code reader can abort further decoding of candidates after a certain number of bar codes has been found and the overall decoding time will decrease.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

Suggested values: *0*, *1*, *2*

Default: *0*

'orientation': Expected bar code orientation. A potential (candidate) bar code contains bars with similar orientation. The *'orientation'* and *'orientation_tol'* parameters are used to specify the range [*'orientation'*-*'orientation_tol'*, *'orientation'*+*'orientation_tol'*]. `find_bar_code` processes a candidate bar code only when the average orientation of its bars lies in this range. If the bar codes are expected to appear only in certain orientations in the processed images, you can reduce the orientation range adequately. This enables an early identification of false candidates and hence shorter execution times. This adjustment can be used for images with a lot of texture, which includes fragments tending to result in false bar code candidates.

The actual orientation angle of a bar code is explained with `get_bar_code_result`(...,*'orientation'*,...) with the only difference that for the early identification of false candidates the reading direction of the bar codes is ignored, which results in relevant orientation values only in the range [*-90.0 ... 90.0*]. The only exception to this rule constitutes the bar code symbol PharmaCode, which possesses a forward and a backward reading direction at the same time: here, *'orientation'* can take values in the range [*-180.0 ... 180.0*] and the decoded result is unique corresponding to just one reading direction.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

Suggested values: [*-90.0*, ..., *90.0*]

Default: *0.0*

'orientation_tol': Orientation tolerance. Please refer to the explanation of *'orientation'* parameter for further information. As explained there, relevant orientation values are only in the range of [*-90.0 ... 90.0*], which means that with *'orientation_tol'* = *90* the whole range is spanned. Therefore, valid values for *'orientation_tol'* are only in the range of [*0.0 ... 90.0*]. The default value *90.0* means that no restriction on the bar code candidates is performed.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

Suggested values: [*0.0*, ..., *90.0*]

Default: *90.0*

'quiet_zone': Enforces the verification of the quiet zones of a bar code symbol. When enabled, scanlines are rejected when unexpected bars are detected within the quiet zones both left or right of a detected bar code sequence. Possible values:

- *'false'*: The quiet zones verification is disabled.
- *'true'*: The quiet zones must be at least as wide as specified by the corresponding bar code standard. The following values apply (in X units, where X stands for "module width" and corresponds to the smallest width of a bar in the sequence):
- An integer value (>= *1*): The quiet zones must be at least as wide as *'quiet_zone'*×X.
- *'tolerant'*: A limited number of edges are allowed in the quiet zones, but at most 1 per 4 module widths. The intent of this is to prevent detecting only part of a bar code, while still allowing to read bar codes with simple quiet zone violations.

Bar code Type	Left QZ	Right QZ	Bar code Type	Left QZ	Right QZ
2/5 Industrial	10	10	UPC-A	9	9
2/5 Interleaved	10	10	UPC-A Add-On 2	9	5
Codabar	10	10	UPC-A Add-On 5	9	5
Code 39	10	10	UPC-E	9	7
Code 93	10	10	UPC-E Add-On 2	9	5
Code 128	10	10	UPC-E Add-On 5	9	5
MSI	10	10	GS1-128	10	10
PharmaCode	5	5	GS1 DataBar Omnidir	1	1
EAN-8	7	7	GS1 DataBar Truncated	1	1
EAN-8 Add-On 2	7	5	GS1 DataBar Stacked	1	1
EAN-8 Add-On 5	7	5	GS1 DataBar Stacked Omnidir	1	1
EAN-13	11	7	GS1 DataBar Limited	1	5
EAN-13 Add-On 2	11	5	GS1 DataBar Expanded	1	1
EAN-13 Add-On 5	11	5	GS1 DataBar Expanded Stacked	1	1

Note: Even for code types with a specified quiet zone smaller than four module widths, the edges are checked within a range of four module widths around the code. In this case, this criterion can be stricter than the verification with *'quiet_zone'='true'*.

The quiet zone verification is very useful when using the bar code reader in multi-type or 'auto' reading mode. It prevents that simple bar code types are detected inside of a bar sequence representing a longer bar code or inside another, typically more complex bar code type. Usually, values between *2* and *4* achieve optimal results by effectively suppressing false bar codes, but still tolerating small disturbances, textures, label edges, etc. next to the symbol.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

Note: The quiet zones serve as a check, that no bar is detected within this zones, but it is not required that the quiet zones are contained as a whole in the image. This means, if a set quiet zone is not contained as a whole, only the part within the image is assessed and the part outside the image is assumed to be free of defects.

Suggested values: *'false'*, *'true'*, *'tolerant'*, *1*, ..., *100*

Default: *'false'*

'start_stop_tolerance': Enforces a tolerant (*'high'*) or strict (*'low'*) searching criteria while inspecting a scanline for a start or stop pattern, respectively. A more tolerant criteria will generally increase the detection chances of a bar code, provided that a clear symbol is imaged in the processed image. On the other side, it might result in false detections in noisy images or images containing symbols from other symbologies. Less tolerant criteria increase the robustness against false detections, but might reduce the general detection rate. Currently, there are two distinct criteria implemented only for Code 128 and GS1-128.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`. As already mentioned, currently this makes a difference only for Code 128 and GS1-128.

List of values: *'high'*, *'low'*

Default: *'high'*

'min_code_length': Minimal number of decoded characters. If a bar code is found with a code length below *'min_code_length'*, the result is discarded and not returned by `find_bar_code` or `decode_bar_code_rectangle2`. This parameter is useful to reduce the number of false reads in applications where the minimal number of characters is known in advance.

Note that the default value of this parameter is *0* for most code types. However, the default value is *3* for *'2/5 Industrial'* and *'2/5 Interleaved'* bar code types. The reason for this is that these bar code types are easily misread in other structures like clutter and text with a code length of *2*.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

Suggested values: *0*, *1*, *2*

Default:

Bar code Type	*'min_code_length'*
2/5 Industrial	3
2/5 Interleaved	3
all others	0

'max_code_length': Maximum number of decoded characters. If a bar code is found with a code length exceeding *'max_code_length'*, the result is discarded and not returned by `find_bar_code` or `decode_bar_code_rectangle2`. This parameter is useful to reduce the number of false reads in applications where the maximum number of characters is known in advance.

Value range: *1* ... *2147483647*

Default: *2147483647*

'merge_scanlines': If not enough scanlines (see *'min_identical_scanlines'*) can be read successfully, i.e., because the bar code is partly occluded or damaged, an attempt is being made to merge the existing scanlines. Then, these merged scanlines are decoded again. This additional decoding step is only performed for non-stacked bar code types and can be disabled for performance reasons.

List of values: *'true'*, *'false'*

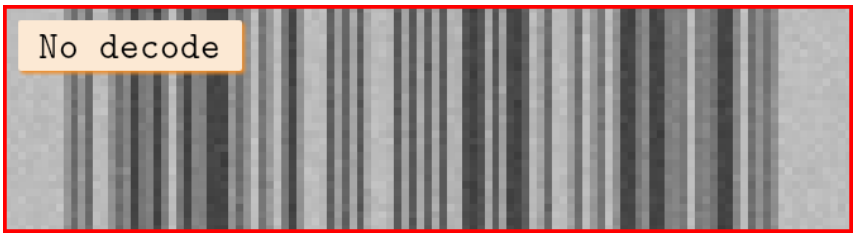
Default: *'true'*

'small_elements_robustness': If not enough scanlines (see *'min_identical_scanlines'*) can be read successfully, i.e., because the bar code contains small elements (smaller than *2.0* pixels in element size), an attempt is being made to read the code with an advanced algorithm which tries to solve the low resolution problem.

This additional decoding attempt is only performed for non-stacked bar code types and if the specified *'element_size_min'* is smaller than *2.0* pixels.

The status result of this attempt can be retrieved by calling the operator `get_bar_code_result` with *'status_small_elements_robustness'*.

In case of very small elements (smaller than *1.3* pixels in element size) it is beneficial if the camera sensor is rotated slightly with respect to the bar code (e.g., around 7 degrees). This is important because in such low resolution cases the bar code information is contained in multiple rows/columns of the perceived image only if it is rotated. See the following two figures for examples.



A bar code at *0.9* element size without sensor rotation. The relevant information of the bar code is not present in the image.

The same bar code as in the previous figure with sensor rotation. The rows of the image contain more information about the code and thus it can be decoded successfully.

Another important advice is to reduce the amount of blur introduced by the optical system.

The input image should not be preprocessed with filter operations such as `emphasize`, `zoom_image_size` or `mean_image`. Those operators would remove important information.

Note, if optical conditions are optimal (small amount of blur and slight rotation with respect to the bar code) it is possible to read bar codes as small as *0.6* pixels in element size.

This feature is only compatible with byte input images and can be disabled for performance reasons.

List of values: *'true'*, *'false'*
Default: *'true'*

Appearance of the bar code in the image:

'meas_thresh': *'meas_thresh'* defines a threshold which is a relative value with respect to the dynamic range of the scanline pixels. The bar-space-sequence of a bar code is determined with a scanline measuring the position of the edges. Finding these edges requires the mentioned threshold. In the case of disturbances in the bar code region or a high noise level, the value of *'meas_thresh'* should be increased.
Suggested values: [*0.05*, ..., *0.2*]
Value range: (*0.0*, ..., *1.0*] - without *0.0*
Default: *0.05*

'meas_thresh_abs': If a scanline is laid in an image region with no or just very small gray value dynamic range (e.g., in a white region with all gray values near 255), the edge detection threshold based on *'meas_thresh'* would be computed unreasonably small. This leads typically to the detection of a big amount of false edges. *'meas_thresh_abs'* is used to prevent such misdetections. If the threshold value based on *'meas_thresh'* gets smaller than the value of *'meas_thresh_abs'*, the latter is used as threshold instead. By default, *'meas_thresh_abs'* is set to *5.0*. A greater value might be more appropriate for images with high noise levels. On the other hand, in noise-free images with very weak contrast, this parameter might disturb the detection of real edges, so it might be necessary to reduce it or even completely disable it by setting it to *0.0*.
Suggested values: [*0.0*, ..., *10.0*]
Value range: [*0.0*, ..., *65535*]
Default: *5.0*

'contrast_min': Minimal contrast between the foreground and the background of the bar code elements. Setting this parameter to values greater than 5 will help the operator `find_bar_code` to optimize the candidate region search. `find_bar_code` will reject all candidate regions with a contrast value below *'contrast_min'*. Hence, setting a high *'contrast_min'* value will improve the runtime performance of `find_bar_code`. However, please note, that all bar codes with a contrast value below *'contrast_min'* will not be read. The calculated contrast value is an approximation in order to speed up the execution time. Try to set a lower threshold for *'contrast_min'* in order to find bar codes which might get rejected and have a contrast value that is close to the specified *'contrast_min'*.
Suggested values: *0*, *40*, *90*, *120*
Default: *0*

Values specific for print quality inspection:

'quality_isoiec15416_reflectance_reference': The reflectances used to assess the quality grades Symbol Contrast, Minimal Reflectance, and Minimal Edge Contrast is normalized with a reference gray value for reflectance. This value can be obtained with barium sulphate or magnesium oxide samples, i.a., see ISO/IEC 15416:2016 section 5.2. **Value range:** [*1* ... *255*]
Default: *255*

Values that only apply to certain code types:

'check_char': Bar codes with an optional check character are interpreted according to this parameter. These bar code types include, e.g., Code 39, Codabar, 2/5 Industrial and 2/5 Interleaved. The default setting of *'absent'* assumes that no check character is present. In this case, no check is performed and all characters are returned as data.
When set to *'present'*, a check character is expected and used to verify the correctness of the bar code. If the check sum matches, the check character itself is stripped from the data. If this stripping is undesired, the mode *'preserved'* allows to verify the bar code while still keeping the check character in the data. In the case the check sum does not match, no bar code result is returned.
For bar code types with a mandatory check character the parameter *'check_char'* is set to *'present'*. However, if the check character is removed from the data or stays, depends on the standard of the specific code type. Such code types include, e.g., Code 128, EAN-8, EAN-13, and UPC-A.
This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.
List of values: *'absent'*, *'present'*, *'preserved'*
Default: *'absent'*

'composite_code': Most of the GS1 conform bar codes can have an additional 2D GS1 Composite code component appended. If *'composite_code'* is set to *'CC-A/B'* the composite component will be found and decoded. By default, *'composite_code'* is set to *'none'* and thus it is disabled. If the searched bar code symbol has no attached composite component, just the result of the bar code itself is returned by `find_bar_code`. Currently, composite codes are supported only for bar codes of the GS1 DataBar family.

This parameter can be set specifically for different types of bar codes by using the operator `set_bar_code_param_specific`.

List of values: *'none'*, *'CC-A/B'*

Default: *'none'*

'upce_encodation': For UPC-E bar codes, different output formats can be used. By default, *'upce_encodation'* is set to *'ucc-12'* and the decoded string will be returned in UCC-12 format (consisting of 12 digits). If *'upce_encodation'* is set to *'zero-suppressed'*, the result will be returned in zero-suppressed format (with suppressed zeros at defined places). This format consists of a leading zero (or a leading one, see *'upce1_enable'*), six encoded digits, and an implicitly encoded check digit. This corresponds to the format demanded by ISO/IEC 15420:2009 standard.

List of values: *'ucc-12'*, *'zero-suppressed'*

Default: *'ucc-12'*

'upce1_enable': The parameter *'upce1_enable'* enables the decoding of UPC-E bar codes with number system 1, if the parameter is set to *'true'*. UPC-E bar codes with number system 1 are an extension of UPC-E bar codes with number system 0, but are not documented in the underlying standard ISO/IEC 15420:2009. UPC-E bar codes with number system 1 also support the different output formats mentioned in *'upce_encodation'*, noting that the formats contain a leading one instead of a leading zero in UPC-E bar codes with number system 0.

List of values: *'true'*, *'false'*

Default: *'false'*

Training:

Besides setting the model parameters manually with `set_bar_code_param`, the model can also be trained with `find_bar_code` based on one or several sample images. For this, a bar code model must be created in training mode or an existing bar code model must be put into training mode by passing the generic parameter *'train'* in `GenParamName` of `set_bar_code_param`. The corresponding value passed in `GenParamValue` determines the model parameters that should be learned. The following values are possible:

'all': Train all possible model parameters.

'element_size_min': Minimal size of the base bar code elements. This setting activates the training mode for the parameter *'element_size_min'*.

'element_size_max': Maximal size of the base bar code elements. This setting activates the training mode for the parameter *'element_size_max'*.

'barcode_width_min': Minimal bar code width. This setting activates the training mode for the parameter *'barcode_width_min'*.

'barcode_width_max': Maximal bar code width. This setting activates the training mode for the parameter *'barcode_width_max'*.

'meas_thresh': Relative threshold for measuring the edge position within a scanline. This setting activates the training mode for the parameter *'meas_thresh'*.

'meas_thresh_abs': Absolute threshold for measuring the edge position within a scanline. This setting activates the training mode for the parameter *'meas_thresh_abs'*.

'orientation': Orientation of the bar code. This setting activates the training mode for the parameters *'orientation'* and *'orientation_tol'*. After ending the training the value for *'orientation_tol'* can be increased by a tolerance value to be able to find bar codes with orientations slightly beyond the trained orientations.

It is possible to train several of these parameters in one call of `find_bar_code` by passing the generic parameter *'train'* in `set_bar_code_param` in a tuple more than once in conjunction with the appropriate parameters: e.g., `GenParamName` = *['train','train']* and `GenParamValue` = *['element_size_min','element_size_max']*. Furthermore, in conjunction with *'train'* = *'all'* it is possible to exclude single parameters from training explicitly again by passing *'train'* more than once. The names of the parameters to exclude, however, must be prefixed by *'~'*: `GenParamName` = *['train','train']* and `GenParamValue` =

['all','~orientation'], e.g., trains all parameters except the orientation.

Afterwards, the operator find_bar_code has to be called for every image to be trained.

For training the model, the following aspects should be considered:

- Additionally needed, non-trained parameters (e.g., *'check_char'*) must be set manually before the training.
- To use several images for the training, the operator find_bar_code must be called once for every sample image.
- On a single training image there may be multiple bar codes of the selected code type visible.
- Please check the output of find_bar_code during training. Every decoded bar code will contribute to the trained bar code model. Hence, please make sure, that there are no false decodes. If you encounter false decodes, you may have to discard the image or set appropriate parameters in advance (e.g., you may need to increase the value of the parameter *'min_identical_scanlines'* or you may try to reduce the domain of the image appropriately).
- In an application with very similar images, *one* image for the training may be sufficient for the parameters *'element_size_min'*, *'element_size_max'*, *'meas_thresh'*, and *'meas_thresh_abs'*.

  For the training of the parameter *'orientation'*, at least two images are needed showing the bar code at its minimum and maximum orientations.
- In applications where the element size is not fixed, the smallest as well as the biggest symbols should be used for the training. If this can not be guaranteed, the limits for the element size should be adapted manually after the training or the element sizes should entirely be excluded from the training.
- During the first call of find_bar_code in the training mode, the trained model parameters are restricted to the properties of the detected bar code. Any successive training call will, where necessary, extend the parameter range to cover the already trained bar codes as well as the new bar code.
- The training can be stopped when enough images have been trained. Before this, the trained parameters should be retrieved. With the operator query_bar_code_params the names of the trained parameters - split into specific and general parameters - can be determined. The values of the parameters can then be retrieved with the operators get_bar_code_param_specific and get_bar_code_param.

  To stop the training, all trained parameters are excluded from the training by calling the operator set_bar_code_param with the parameters GenParamName = *'train'* and GenParamValue = *'~all'*.

  Alternatively, the existing bar code model can simply be cleared with the operator clear_bar_code_model.
- The value of any trained parameter should not be set explicitly with set_bar_code_param or set_bar_code_param_specific during training mode. If this is done, the complete internal training data is being reset and training will be started again at the beginning with the next call of find_bar_code.
- If find_bar_code is not able to read the bar code in the training image, this will produce no error or exception handling. It can simply be tested in the program by checking the output parameter DecodedDataStrings or SymbolRegions. These tuples will then be empty and the parameters of the model (especially the trained parameters) will not be modified.
- Timeouts are disabled during the training.

Miscellaneous:

'timeout': By the use of this parameter, it is possible to abort find_bar_code after a defined period in milliseconds. This is especially useful in cases where a maximum cycle time has to be ensured. All results gained before the timeout can be accessed by get_bar_code_result. Passing values less or equal zero implies a deactivation of the timeout (default).

The temporal accuracy of this timeout is about 10 ms. It depends on several factors including the speed of your computer and the *'timer_mode'* set via set_system.

find_bar_code does not raise an exception if a timeout occurs. To check whether find_bar_code has been aborted, check the parameter *'aborted'* in get_bar_code_result.

Note that the timeout is ignored if find_bar_code runs in training mode.

Suggested values: *'false'*, *-1*, *20*, *100*

Default: *'false'*

'abort': Using this option, it is possible to abort `find_bar_code` from another thread. When `set_bar_code_param` is called with *'abort'*, an instance of `find_bar_code` with the model `BarCodeHandle` running in another thread is requested to abort. If there is no `find_bar_code` running with this model, nothing happens.

The operator `find_bar_code` might not return immediately. It has to reach a cancellation point to ensure a proper cleanup. Depending on different factors like the computer performance this may take up to 10 ms.

All decoded results until this moment, are still returned. Note that the parameter is ignored if `find_bar_code` runs in training mode.

Note: This is the only action with a bar code handle, which can be used from different threads without requiring additional synchronization.

Default: *'true'* (The value is not processed.)

'persistence': Setting the model in persistence mode to *1*, makes it store some intermediate results during bar code decoding. These results are required if the bar code print quality has to be assessed (`get_bar_code_result` with *'quality_isoiec15416'*) or the decoding scanlines have to be inspected (`get_bar_code_object` with *'scanlines_all'* or *'scanlines_valid'*). Yet, enabling the *'persistence'* mode results in increased memory requirements for the bar code model structures.

List of values: *0*, *1*

Default: *0*

Parameters

▷ **BarCodeHandle** (input_control) . . . . . barcode ⇝ *handle*
Handle of the bar code model.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that shall be adjusted for finding and decoding bar codes.
Default: 'element_size_min'
List of values: `GenParamName` ∈ {'check_char', 'composite_code', 'barcode_height_min', 'barcode_width_min', 'barcode_width_max', 'element_size_max', 'element_size_min', 'contrast_min', 'meas_thresh', 'meas_thresh_abs', 'min_identical_scanlines', 'majority_voting', 'num_scanlines', 'orientation', 'orientation_tol', 'persistence', 'quality_isoiec15416_reflectance_reference', 'start_stop_tolerance', 'stop_after_result_num', 'upce_encodation', 'upce1_enable', 'timeout', 'train', 'quiet_zone', 'element_size_variable', 'min_code_length', 'max_code_length', 'merge_scanlines', 'small_elements_robustness', 'abort'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string
Values of the generic parameters that are adjusted for finding and decoding bar codes.
Default: 8
Suggested values: `GenParamValue` ∈ {0, 0.1, 1, 1.5, 2, 8, 32, 45, 'true', 'false', 'present', 'absent', 'none', 'CC-A/B', 'auto', 'high', 'low', 'ucc-12', 'zero-suppressed'}

Result

The operator `set_bar_code_param` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- BarCodeHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_bar_code_model`

Possible Successors

`find_bar_code`

Alternatives

set_bar_code_param_specific

Module

Bar Code

set_bar_code_param_specific (: : BarCodeHandle, CodeTypes, GenParamName, GenParamValue :)

Set selected parameters of the bar code model for selected bar code types

The operator set_bar_code_param_specific is used to set or change the different parameters of a bar code model for selected bar code types in order to adapt to special properties of the bar codes. Contrary to set_bar_code_param, only parameters for selected bar code types will be changed with set_bar_code_param_specific. This is useful when searching different code types within one image (see section Autodiscrimination in find_bar_code).

The current configuration of the bar code model for a specified bar code type can be queried with get_bar_code_param_specific.

The following generic parameters can be set for specific bar code types:

'num_scanlines': Maximal number of scanlines used during the scanning of a (candidate) bar code.

Suggested values: [*0*, *5*, *10*, *20*, ...]

Default: *0*

'min_identical_scanlines': Minimal number of decoded scanlines which return identical data to read the bar code successfully.

Suggested values: [*0*, *2*, *3*, ...]

Default:

Bar code Type	*'min_identical_scanlines'*
2/5 Industrial	2
2/5 Interleaved	2
all others	0

'stop_after_result_num': Number of successfully decoded bar codes of the given code type after which the decoding will stop.

Suggested values: [*0*, *1*, *2*, ...]

Default: *0*

'orientation': Expected bar code orientation.

Suggested values: [*-90.0* ... *90.0*]

Default: *0.0*

'orientation_tol': Orientation tolerance.

Suggested values: [*0.0* ... *90.0*]

Default: *90.0*

'quiet_zone': Enforces the verification of quiet zones of a bar code symbol.

Suggested values: *'false'*, *'true'*, *1*, *2*, *3*, *4*, *5*

Default: *'false'*

'start_stop_tolerance': Start/stop search criteria tolerance. Currently this is implemented only for Code 128 and GS1-128.

List of values: *'high'*, *'low'*

Default: *'high'*

'check_char': Handling of an optional check character.

List of values: *'absent'*, *'present'*, *'preserved'*

Default: *'absent'*

'composite_code': Find and decode a composite component.

List of values: *'none'*, *'CC-A/B'*

Default: *'none'*

'min_code_length': Minimal number of decoded characters.

Default:

Bar code Type	*'min_code_length'*
2/5 Industrial	3
2/5 Interleaved	3
all others	0

'max_code_length': Maximum number of decoded characters.

Value range: [*1* ... *2147483647*]

Default: *2147483647*

Further details on these parameters can be found with the description of the operator `set_bar_code_param`.

It is possible to supply multivalue tuples for `CodeTypes`, `GenParamName`, and `GenParamValue`. The n-th entry of one multivalue tuple corresponds to the n-th entry of the other multivalue tuple. The following combinations are allowed:

CodeTypes	**GenParamName**	**GenParamValue**
single-valued	single-valued	single-valued
single-valued	multi-valued	multi-valued
multi-valued	single-valued	multi-valued
multi-valued	single-valued	single-valued

Parameters

▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

▷ **CodeTypes** (input_control) ..... string(-array) ⇝ *string*
Names of the bar code types for which parameters should be set.
Default: 'EAN-13'
List of values: `CodeTypes` ∈ {'2/5 Industrial', '2/5 Interleaved', 'Codabar', 'Code 39', 'Code 93', 'Code 128', 'EAN-13', 'EAN-13 Add-On 2', 'EAN-13 Add-On 5', 'EAN-8', 'EAN-8 Add-On 2', 'EAN-8 Add-On 5', 'UPC-A', 'UPC-A Add-On 2', 'UPC-A Add-On 5', 'UPC-E', 'UPC-E Add-On 2', 'UPC-E Add-On 5', 'MSI', 'PharmaCode', 'GS1 DataBar Omnidir', 'GS1 DataBar Truncated', 'GS1 DataBar Stacked', 'GS1 DataBar Stacked Omnidir', 'GS1 DataBar Limited', 'GS1 DataBar Expanded', 'GS1 DataBar Expanded Stacked', 'GS1-128'}

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Names of the generic parameters that shall be adjusted for finding and decoding bar codes.
Default: 'check_char'
List of values: `GenParamName` ∈ {'check_char', 'composite_code', 'min_identical_scanlines', 'num_scanlines', 'orientation', 'orientation_tol', 'start_stop_tolerance', 'stop_after_result_num', 'quiet_zone', 'min_code_length', 'max_code_length'}

▷ **GenParamValue** (input_control) ..... attribute.name-array ⇝ *real* / integer / string
Values of the generic parameters that are adjusted for finding and decoding bar codes.
Default: 'absent'
Suggested values: `GenParamValue` ∈ {0, 1, 2, 4, 45, 90, 'true', 'false', 'present', 'absent', 'none', 'CC-A/B', 'high', 'low'}

Result

The operator `set_bar_code_param_specific` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- BarCodeHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_bar_code_model

Possible Successors

find_bar_code

Alternatives

set_bar_code_param

Module

Bar Code

write_bar_code_model (: : BarCodeHandle, FileName :)

Write a bar code model to a file.

The operator write_bar_code_model writes the bar code model BarCodeHandle to the file FileName. The model can be read again with read_bar_code_model. The stored data contains all generic and all specific model parameters (see set_bar_code_param and set_bar_code_param_specific, respectively). If the model is in training mode (see set_bar_code_param with parameter *'train'*), the current training state is stored as well. After restoring the model, the training can be proceeded.

Besides the training state no other results of find_bar_code are stored in the file.

The default HALCON file extension for bar code model is 'bcm'.

Parameters

▷ **BarCodeHandle** (input_control) ..... barcode ⇝ *handle*
Handle of the bar code model.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Name of the bar code model file.
Default: 'bar_code_model.bcm'
File extension: .bcm

Example

```
*
* Create the bar code model in the training mode
create_bar_code_model ('train', 'all', BarCodeHandle)
*
* Set all additional, non-trained parameters in advance:
* Here, we specify that the training images have check characters
set_bar_code_param (BarCodeHandle, 'check_char', 'present')
*
* Train the model with several images
for I := 1 to 7 by 1
    FileName := 'barcode/25interleaved/25interleaved' + I$'.02'
    read_image (Image, FileName)
    *
    * Apply the training
    find_bar_code (Image, SymbolRegion, BarCodeHandle, '2/5 Interleaved', \
```

```
                    DecodedDataStrings)
endfor
*
* The training may be interrupted and the intermediate state
* of the model can be stored in a file
write_bar_code_model (BarCodeHandle, 'bar_code_model.bcm')
*
* RESTORE TRAINING:
* Later, when, e.g., new images are available, the training
* may be restored
read_bar_code_model ('bar_code_model.bcm', BarCodeHandle)
FileName := 'barcode/25interleaved/25interleaved08'
read_image (Image, FileName)
*
* Apply the training to the new image
find_bar_code (Image, SymbolRegion, BarCodeHandle, '2/5 Interleaved', \
               DecodedDataStrings)
*
* Finally, the training can be completed
set_bar_code_param (BarCodeHandle, 'train', '~all')
*
* The trained model can be stored for ONLINE use
write_bar_code_model (BarCodeHandle, 'trained_bar_code_model.bcm')
*
* ONLINE USE:
read_bar_code_model ('trained_bar_code_model.bcm', BarCodeHandle)
* ...
```

Result

The operator `write_bar_code_model` returns the value `2` (`H_MSG_TRUE`) if the passed handle is valid and if the model can be written into the named file. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

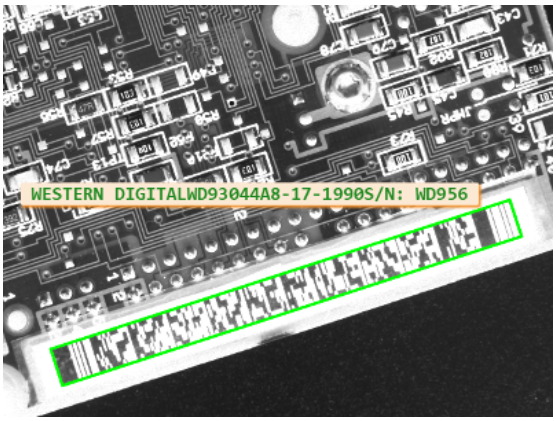
14.2 Data Code

This chapter contains operators for reading 2D data codes.

Concept of reading 2D data codes

2D data code symbols are a special kind of two-dimensional patterns that encode text and numbers. HALCON is able to read the most popular 2D data codes: Data Matrix ECC 200, QR Code, Micro QR Code, Aztec Code, PDF417, and DotCode. Except for DotCodes all these codes contain a finder pattern and a data pattern. The finder pattern is used to locate the pattern of the symbol and get basic information about the geometric properties, e.g., the orientation of the symbol. The data pattern contains the code itself and consists of multiple dots, bars, or small squares, the so-called modules. Because of the special design of the codes, they can be decoded even if some parts are disturbed.



Reading a 2D data code of type PDF417. This image is from the example program 2d_data_codes_default_settings.hdev.

In the following, the steps that are required to read 2D data codes are described briefly.

Create 2D data code model: First, a 2D data code model must be created using

- `create_data_code_2d_model`.

This model provides the reader with all necessary information about the structure of the code. For normal printed codes only the name needs to be provided and HALCON will select suitable default parameters. For special cases, you can modify the model parameters either when creating the 2D data code model or in a later step to adapt the model to a particular symbol appearance.

Modify the model parameters for non-standard codes: Using the default parameters, the 2D data code reader is able to read a wide range of codes. For non-standard codes the parameters can be modified using

- `set_data_code_2d_param`.

Here, you can either select an enhanced set of default parameters using the generic parameter *'default_parameters'*, e.g., with the value *'enhanced_recognition'*, or you specify the parameter values separately to adapt the model optimally to the conditions of the used print style. Note that `query_data_code_2d_params` can be used to query the parameters that are valid for the specific data code type. To obtain the currently set values of parameters, `get_data_code_2d_param` can be used.

Instead of modifying the model parameters manually, you can also let HALCON train the model using

- `find_data_code_2d`

with the generic parameter *'train'*. Then, HALCON will search for the best parameters needed to extract the given code. It is recommended to apply this to multiple example images to ensure that all variations are covered.

Read 2D data code: The 2D data code is located and its content is decoded using

- `find_data_code_2d`.

The operator returns for every successfully decoded symbol the surrounding XLD contour, a handle to a result structure, which contains additional information about the symbol as well as about the search and decoding process, and the string that is encoded in the symbol. With the result handles and the operators `get_data_code_2d_results` and `get_data_code_2d_objects`, additional data about the extraction process can be accessed that can be used both for process analysis and for displaying. In particular, `get_data_code_2d_results` allows to access several alphanumerical results that were calculated while searching and reading the symbols and `get_data_code_2d_objects` allows to access iconic objects that were created during the last call of `find_data_code_2d`.

Further operators

In addition to the operators mentioned above, write_data_code_2d_model allows to write the model into a file that can be used later to create (e.g., in a different application) an identical copy of the model. Such a model copy is created directly by read_data_code_2d_model (without calling create_data_code_2d_model). Furthermore, you can use serialize_data_code_2d_model and deserialize_data_code_2d_model to serialize and deserialize the 2D data code model.

Glossary

2D data code symbol Two-dimensional graphical symbol that encodes characters and numbers. It is constructed by dark and light dots, bars, or small squares that are called modules. There are different types of 2D data codes. Two common types are the so-called stacked codes and the so-called matrix codes.

stacked code Type of 2D data code symbol that contains a stack of 1D bar codes arranged in rows and columns. To ensure that the complete stack of 1D bar codes is processed, the symbol contains a start and a stop pattern. Additionally, the symbol is framed by a quiet zone.

matrix code Type of 2D data code symbol that uses graphical patterns consisting of dark and light modules arranged in two dimensions. The symbol consists of three components: a finder pattern, a data pattern, and a quiet zone.

modules Dark and light dots, bars, or small squares that are used to build a 2D data code symbol.

quiet zone Homogeneous frame around the symbol's border that makes the symbol better distinguishable from the background or from other objects in the image.

finder pattern Pattern that is used to find the symbol and its orientation in the image. The pattern differs depending on the used data code type.

Further Information

See also the "Solution Guide Basics" and the "Solution Guide on 2D Data Codes" for further details about 2D data codes.

clear_data_code_2d_model (: : DataCodeHandle :)

Delete a 2D data code model and free the allocated memory.

The operator clear_data_code_2d_model deletes a 2D data code model that was created by create_data_code_2d_model or read_data_code_2d_model. All memory used by the model is freed. The handle of the model is passed in DataCodeHandle. After the operator call it is invalid.

For an explanation of the concept of the 2D data code reader see the introduction of chapter Identification / Data Code.

Parameters

▷ **DataCodeHandle** (input_control) ..... datacode_2d ⇝ *handle*
Handle of the 2D data code model.

Result

The operator clear_data_code_2d_model returns the value 2 (H_MSG_TRUE) if a valid handle was passed and the referred 2D data code model can be freed correctly. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DataCodeHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Data Code

create_data_code_2d_model (: : SymbolType, GenParamName, GenParamValue : DataCodeHandle)

Create a model of a 2D data code class.

The operator create_data_code_2d_model creates a model for a certain class of 2D data codes. In DataCodeHandle the operator returns a handle to the 2D data code model, which is used for all further operations on the data code, like modifying the model, reading a symbol, or accessing the results of the symbol search.

For an explanation of the concept of the 2D data code reader see the introduction of chapter Identification / Data Code.

Supported symbol types

The parameter SymbolType is used to determine the type of data codes to process. Presently, six main types are supported: *'Data Matrix ECC 200'*, *'QR Code'*, *'Micro QR Code'*, *'PDF417'*, *'Aztec Code'*, and *'DotCode'*. Additionally, four GS1 types are supported: *'GS1 DataMatrix'*, *'GS1 QR Code'*,*'GS1 Aztec Code'*, and *'GS1 DotCode'*. Data Matrix codes of type ECC 000-140 are not supported. For the QR Code the older Model 1 as well as the new Model 2 can be read. The PDF417 can be read in its conventional as well as in its compact form ('Compact/Truncated PDF417'). The Aztec code can be read in compact, full-range, and rune (see Annex E of ISO/IEC 24778:2008 (E)) form. The structure of the four GS1 symbologies is basically identical to their non-GS1 counterparts - Data Matrix ECC 200, QR Code Aztec Code, and DotCode, respectively. In the following, all parameters, settings, and rules applying to any particular data code type apply to its GS1 variant as well. The GS1 symbologies enforce merely additional rules for the format of the data carried by the codes. It has to be organized in so called GS1 application element strings according to the GS1 General Specifications. To update the list of available GS1 Application Identifiers, see the parameter *'gs1_syntax_dictionary'* in set_system.

For all symbol types, the data code reader supports the Extended Channel Interpretation (ECI) protocol. If the symbol contains an ECI code, all characters with ASCII code 92 (backslash, '\') that occur in the normal data stream are, in compliance with the standard, doubled ('\\') for the output. This is necessary in order to distinguish data backslashes from the ECI sequence *'\nnnnnn'*.

The information whether the symbol contains ECI codes (and consequently doubled backslashes) or not is stored in the Symbology Identifier number that can be obtained for every successfully decoded symbol with the help of the operator get_data_code_2d_results passing the generic parameter *'symbology_ident'*. How the code number encodes additional information about the symbology and the data code reader, like the ECI support, is defined in the different symbology specifications. For more information see the corresponding standards and the operator get_data_code_2d_results.

The Symbology Indentifier code will not be preceded by the data code reader to the output data, even if the symbol contains an ECI code. If this is needed, e.g., by a subsequent processing unit, the *'symbology_ident'* number (obtained by the operator get_data_code_2d_results with the parameter *'symbology_ident'*) can be added to the data stream manually together with the symbology flag and the symbol code: ']d', ']Q', ']L', ']z', or ']J' for DataMatrix codes, QR Codes, PDF417 Codes, Aztec Codes, or DotCodes, respectively. In particular, for GS1 symbologies the parameter *'symbology_ident'* returns 2 for GS1 DataMatrix, 3 for GS1 QR Code, and 1 for GS1 Aztec Code and GS1 DotCode. This corresponds to symbol codes: ']d2', ']Q3', ']z1', and ']J1', respectively.

Standard default settings of the data code model

The default settings of the model were chosen to read a wide range of common symbols within a reasonable amount of time. However, for runtime reasons some restrictions apply to the symbol (see the following table). If the model was modified (as described later), it is at any time possible to reset it to these default settings by passing the generic parameter *'default_parameters'* together with the value *'standard_recognition'* to the operator set_data_code_2d_param.

For some model parameters the default values depend on the chosen recognition approach. Those parameters are listed in the table below. Further parameter details and the remaining model parameters can be found in the reference of set_data_code_2d_param.

Model parameter	*'standard_recognition'*	*'enhanced_recognition'*	*'maximum_recognition'*
'polarity'	'dark_on_light' (dark symbols on a light background)	'any' (dark symbols on a light background and vice versa)	'any' (dark symbols on a light background and vice versa)
'contrast_min' (Aztec Code, Micro QR Code, QR Code, PDF417)	30	10	10
'symbol_cols_min', *'symbol_cols_max'* (PDF417)	1 ... 20	1 ... 30	1 ... 30
'symbol_rows_min', *'symbol_rows_max'* (PDF417)	5 ... 45	3 ... 90	3 ... 90
'module_size_min', *'module_size_max'* (Aztec Code, Data Matrix ECC 200, Micro QR Code, QR Code)	6 ... 20 pixels	4 (2 for sharp images) ... 100 pixels	4 (1 for sharp images) ... 100 pixels
'module_size_min', *'module_size_max'* (DotCode)	4 ... 100 pixels	2 ... 100 pixels	2 ... 100 pixels
'module_width_min', *'module_width_max'* (PDF417)	3 ... 15 pixels	3 (2 for sharp images) ... 100 pixels	3 (1 for sharp images) ... 100 pixels
'module_aspect_min', *'module_aspect_max'* (PDF417)	1 ... 4	1 ... 10	1 ... 10
'small_modules_robustness' (All code types except DotCode)	'low'	'low'	'high'
'module_gap_max' (Aztec Code)	'small' (< 10% of the module size)	'big' (< 50% of the module size)	'big' (< 50% of the module size)
'module_gap_max' (Data Matrix ECC 200, Micro QR Code, QR Code)	'no'	'small' (< 10% of the module size)	'big' (< 50% of the module size)
'module_gap_max' (DotCode)	'no'	'small' (< 10% of the module size)	'small' (< 10% of the module size)
'slant_max' (Data Matrix ECC 200)	0.1745 (10 degree)	0.5235 (30 degree)	0.5235 (30 degree)
'module_grid' (Data Matrix ECC 200)	'fixed'	'any' (fixed or variable)	'any' (fixed or variable)
'finder_pattern_tolerance' (Aztec Code)	'low'	'high'	'high'
'finder_pattern_tolerance' (Data Matrix ECC 200)	'low'	'low'	'any'
'alternating_pattern_tolerance' (Data Matrix ECC 200)	'low'	'medium'	'high'
'contrast_tolerance' (Data Matrix ECC 200, Micro QR Code, QR Code)	'low'	'low'	'any'
'candidate_selection' (Data Matrix ECC 200)	'default'	'extensive'	'extensive'
'candidate_selection' (DotCode, Micro QR Code, QR Code)	'default'	'extensive'	'all'
'position_pattern_min' (QR Code)	3	2	2
'model_type' (QR Code)	2	2	'any'

Modify the data code model

If it is known that the symbol does not or may not comply with all of these restrictions (e.g., the symbol is brighter than the background or the contrast is very low), or if first tests show that some of the symbols cannot be read with the default settings, it is possible to adapt single model parameters – while others are kept to the default – or the whole model can be extended in a single step by setting the generic parameter *'default_parameters'* to the value *'enhanced_recognition'*. This will lead to a more general model that covers a wider range of 2D data code symbols. However, the symbol search with such a general model is more extensive, hence the runtime of the operator `find_data_code_2d` may increase significantly. This is true especially in the following cases: *no* readable data code is detected, the symbol is printed light on dark, or the modules are very small.

By setting the generic parameter *'default_parameters'* to the value *'maximum_recognition'* the model is further extended in comparison to *'enhanced_recognition'*, so that data codes with very small module sizes can be decoded more robustly (see *'small_modules_robustness'*). For the Data Matrix ECC 200, the mode *'maximum_recognition'* differs from the mode *'enhanced_recognition'* in a way that even symbols with defect or partially occluded finder patterns can be read (see *'finder_pattern_tolerance'*). Using this mode may lead to a further increased runtime and memory usage of the operator `find_data_code_2d` during symbol search and decoding.

For these reasons, the model should always be specified as exactly as possible by setting all known parameters. The model parameters can be set directly during the creation of the model or later with the help of the operator `set_data_code_2d_param`. Both operators provide the generic parameters `GenParamName` and `GenParamValue` for this purpose. For the Data Matrix ECC 200, for example, the symbol size should be specified as exactly as possible if the mode *'maximum_recognition'* was chosen. A detailed description of all supported generic parameters can be found with the operator `set_data_code_2d_param`.

Another way for adapting the model is to train it based on sample images. Passing the parameter *'train'* to the operator `find_data_code_2d` will cause the find operator to look for a symbol, determine its parameters, and modify the model accordingly. More details can be found with the description of the operator `find_data_code_2d`.

It is possible to query the model parameters with the operator `get_data_code_2d_param`. The names of all supported parameters for setting or querying the model are returned by the operator `query_data_code_2d_params`.

Parameters

▷ **`SymbolType`** (input_control) . . . . . string ⇝ *string*
Type of the 2D data code.
Default: 'Data Matrix ECC 200'
List of values: `SymbolType` ∈ {'Data Matrix ECC 200', 'QR Code', 'Micro QR Code', 'PDF417', 'Aztec Code', 'DotCode', 'GS1 DataMatrix', 'GS1 QR Code', 'GS1 Aztec Code', 'GS1 DotCode'}

▷ **`GenParamName`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that can be adjusted for the 2D data code model.
Default: []
List of values: `GenParamName` ∈ {'default_parameters', 'strict_model', 'persistence', 'polarity', 'mirrored', 'contrast_min', 'candidate_selection', 'model_type', 'version', 'version_min', 'version_max', 'symbol_size', 'symbol_size_min', 'symbol_size_max', 'symbol_cols', 'symbol_cols_min', 'symbol_cols_max', 'symbol_rows', 'symbol_rows_min', 'symbol_rows_max', 'symbol_shape', 'module_size', 'module_size_min', 'module_size_max', 'small_modules_robustness', 'module_width', 'module_width_min', 'module_width_max', 'module_aspect', 'module_aspect_min', 'module_aspect_max', 'module_gap', 'module_gap_min', 'module_gap_max', 'slant_max', 'module_grid', 'position_pattern_min', 'strict_quiet_zone', 'timeout', 'finder_pattern_tolerance', 'contrast_tolerance', 'additional_levels'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Values of the generic parameters that can be adjusted for the 2D data code model.
Default: []
Suggested values: `GenParamValue` ∈ {'standard_recognition', 'enhanced_recognition', 'maximum_recognition', 'yes', 'no', 'any', 'dark_on_light', 'light_on_dark', 'square', 'rectangle', 'small', 'big', 'fixed', 'variable', 'low', 'high', 'default', 'extensive', 0, 1, 2, 3, 4, 5, 6, 7, 8, 10, 30, 50, 70, 90, 12, 14, 16, 18, 20, 22, 24, 26, 32, 36, 40, 44, 48, 52, 64, 72, 80, 88, 96, 104, 120, 132, 144}

▷ **`DataCodeHandle`** (output_control) . . . . . datacode_2d ⇝ *handle*
Handle for using and accessing the 2D data code model.

Example

```
* Two simple examples that show the use of create_data_code_2d_model
* to detect a Data matrix ECC 200 code and a QR Code.
```

```
* (1) Create a model for reading simple QR Codes
*     (only dark symbols on a light background will be read)
create_data_code_2d_model ('QR Code', [], [], DataCodeHandle)
* Read an image
read_image (Image, 'datacode/qrcode/qr_workpiece_01')
* Read the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, [], [], \
                   ResultHandles, DecodedDataStrings)
* Clear the model
clear_data_code_2d_model (DataCodeHandle)

* (2) Create a model for reading a wide range of Data matrix ECC 200 codes
*     (this model will also read light symbols on dark background)
create_data_code_2d_model ('Data Matrix ECC 200', 'default_parameters', \
                           'enhanced_recognition', DataCodeHandle)
* Read an image
read_image (Image, 'datacode/ecc200/ecc200_cpu_010')
* Read the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, [], [], \
                   ResultHandles, DecodedDataStrings)
* Clear the model
clear_data_code_2d_model (DataCodeHandle)
```

Result

The operator `create_data_code_2d_model` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`set_data_code_2d_param`, `find_data_code_2d`

Alternatives

`read_data_code_2d_model`

Module

Data Code

deserialize_data_code_2d_model (
: : SerializedItemHandle : DataCodeHandle)

Deserialize a serialized 2D data code model.

deserialize_data_code_2d_model deserializes a 2D data code model, that was serialized by serialize_data_code_2d_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized 2D data code model is defined by the handle SerializedItemHandle. The deserialized values are stored in a new 2D data code model with the handle DataCodeHandle.

For an explanation of the concept of the 2D data code reader see the introduction of chapter Identification / Data Code.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **DataCodeHandle** (output_control) ..... datacode_2d ⇝ *handle*
Handle of the 2D data code model.

Result

The operator deserialize_data_code_2d_model returns the value 2 (H_MSG_TRUE) if the 2D data code can be correctly deserialized. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Data Code

find_data_code_2d (Image : SymbolXLDs : DataCodeHandle,
GenParamName, GenParamValue : ResultHandles, DecodedDataStrings)

Detect and read 2D data code symbols in an image or train the 2D data code model.

The operator find_data_code_2d detects 2D data code symbols in the input image (Image) and reads the data that is encoded in the symbol. Before calling find_data_code_2d, a model of a class of 2D data codes that matches the symbols in the images must be created with create_data_code_2d_model or read_data_code_2d_model. The handle returned by these operators is passed to find_data_code_2d in DataCodeHandle. To look for more than one symbol in an image, the generic parameter *'stop_after_result_num'* can be passed to GenParamName together with the number of requested symbols as GenParamValue.

As a result the operator returns for every successfully decoded symbol the surrounding XLD contour (SymbolXLDs), a result handle, which refers to a candidate structure that stores additional information about the symbol as well as the search and decoding process (ResultHandles), and the string that is encoded in the symbol (DecodedDataStrings). Passing the candidate handle from ResultHandles together with the generic parameter *'decoded_data'*, get_data_code_2d_results returns a tuple with the ASCII code of all characters of the string (see also Tuple / String Operations).

For an explanation of the concept of the 2D data code reader see the introduction of chapter Identification / Data Code.

The symbol structure of GS1 DataMatrix, GS1 QR Code, GS1 Aztec Code, and GS1 DotCode is identical to the structure of Data Matrix ECC 200, QR Code, Aztec Code, and DotCode, respectively. Therefore, all parameters, settings, and rules applying to Data Matrix ECC 200, QR Code, Aztec Code, or DotCode apply to their GS1 variants as well. The GS1 symbologies enforce merely additional rules for the format of the data carried by the codes. The data has to be organized in so called GS1 application element strings according to the GS1 General Specifications. For example, if the data code model `DataCodeHandle` is created as GS1 DataMatrix, then `find_data_code_2d` only returns a result if the underlying symbol is a valid Data Matrix ECC 200 symbol, and only if its data conforms to the GS1 application element strings rules. For the GS1 application element strings it is only checked if the application identifiers exist in the GS1 General Specifications. In contrast, `find_data_code_2d` will return no results for Data Matrix ECC 200 containing general data. The same is valid for GS1 QR Code, GS1 Aztec Code, and GS1 DotCode Code.

Adjusting the model

If there is a symbol in the image that cannot be read, it should be verified, whether the properties of the symbol fit the model parameters. Special attention should be paid to

- the correct polarity (*'polarity'*, light-on-dark or dark-on-light),
- the symbol size (*'symbol_size'* for Data Matrix ECC 200, Aztec Code, and DotCode),
- *'version'* for QR Code,
- *'format'* for Aztec Code,
- the module size (*'module_size'* for Data Matrix ECC 200, QR Code, Micro QR Code, Aztec Code, and DotCode, *'module_width'* and *'module_aspect'* for PDF417),
- the possibility of a mirroring of the symbol (*'mirrored'*),
- and the specified minimum contrast (*'contrast_min'* for Aztec Code, QR Code, and PDF417).

Further relevant parameters are the gap between neighboring foreground modules and, for Data Matrix ECC 200, the maximum slant of the L-shaped finder pattern (*'slant_max'*). The current settings for these parameters are returned by the operator `get_data_code_2d_param`. If necessary, the corresponding model parameters can be adjusted with `set_data_code_2d_param`.

It is recommended to adjust the model as well as possible to the symbols in the images also for runtime reasons. In general, the runtime of `find_data_code_2d` is higher for a more general model than for a more specific model. One should take into account that a general model leads to a high runtime especially if *no* valid data code can be found.

Train the model

Besides setting the model parameters manually with `set_data_code_2d_param`, the model can also be trained with `find_data_code_2d` based on one or several sample images. For this, the generic parameter *'train'* must be passed in `GenParamName`. The corresponding value passed in `GenParamValue` determines the model parameters that should be learned. The following values are possible:

- All data code types:

  'all': All model parameters that can be trained.

  'symbol_size': Size of the data code symbol.
  The model parameters trained for Data Matrix ECC200, PDF417, and DotCode are *'symbol_cols_min'*, *'symbol_cols_max'*, *'symbol_rows_min'*, and *'symbol_rows_max'*. Additionally, the model parameter *'symbol_shape'* (square or rectangular) is trained for Data Matrix ECC 200 only.
  For QR Code and Micro QR Code it is also possible to pass *'version'*. The model parameters trained hereby are *'symbol_size_min'*, *'symbol_size_max'*, *'version_min'*, and *'version_max'*.
  The model parameters trained for Aztec Code are *'symbol_size_min'* and *'symbol_size_max'*.

  'module_size': Size of the modules. The model parameters trained are *'module_size_min'* and *'module_size_max'*.
  For PDF417 this includes the module width and the module aspect ratio, so thereby the respective model parameters are *'module_width_min'*, *'module_width_max'*, *'module_aspect_min'*, and *'module_aspect_max'*.

  'polarity': Polarity of the symbols, i.e. they may appear dark on a light background or light on a dark background. The model parameter trained is *'polarity'*.

'mirrored': Whether the symbols in the image are mirrored or not. The model parameter trained is *'mirrored'*.

- Data Matrix ECC 200, Aztec Code, PDF417, QR Code, and Micro QR Code only:

  'small_modules_robustness': Robustness of the decoding of data codes with very small module sizes. This parameter is not trained for DotCode. The model parameter trained is *'small_modules_robustness'*. Note that the training of the parameter is deactivated internally if the training image exceeds the maximum image size (see `get_system` *'halcon_xl'*).

- Aztec Code, PDF417, QR Code, and Micro QR Code only:

  'contrast': Minimum contrast for detecting the symbols. The model parameter trained is *'contrast_min'*.

- Data Matrix ECC 200, Micro QR Code, and QR Code only:

  'contrast_tolerance': The tolerance of the symbol search with respect to strong local contrast variations. The model parameter trained is *'contrast_tolerance'*.

- All data code types except PDF417::

  'module_shape': Whether there is a gap between neighboring foreground modules or whether they are connected. The model parameters trained are *'module_gap_min'* and *'module_gap_max'*.

- Data Matrix ECC 200 and Aztec Code only:

  'finder_pattern_tolerance': The allowed tolerance of the symbol search with respect to a defect or partially occluded finder pattern. The model parameter trained is *'finder_pattern_tolerance'*.

- Data Matrix ECC 200, DotCode, Micro QR Code, and QR Code only:

  'candidate_selection': Selection of candidate regions to be processed. The model parameter trained is *'candidate_selection'*.

- Data Matrix ECC 200 only:

  'alternating_pattern_tolerance': The tolerance of the symbol search with respect to a variation of the module widths along the two sides with the alternating pattern. The model parameter trained is *'alternating_pattern_tolerance'*.

  'module_grid': Algorithm for calculating the module positions (fixed or variable grid). The model parameter trained is *'module_grid'*.

  'image_proc': Adjusting different internal image processing parameters. Until now, only the maximum slant of the L-shaped finder pattern of the Data Matrix ECC 200 symbols is set (more parameters may follow in future). The model parameter trained is *'slant_max'*.

- QR Code only:

  'model_type': Whether the QR Code symbols follow the Model 1 or Model 2 specification. The model parameter trained is *'model_type'*.

  'position_pattern_min': Number of position detection patterns that have to be visible for generating a new symbol candidate. The model parameter trained is *'position_pattern_min'*.

- Aztec Code only

  'additional_levels': The number of additional pyramid levels. The model parameter trained is *'additional_levels'*.

It is possible to train several of these parameters in one call of `find_data_code_2d` by passing the generic parameter *'train'* in a tuple more than once in conjunction with the corresponding parameters: e.g., `GenParamName` = *['train','train']* and `GenParamValue` = *['polarity','module_size']*. Furthermore, in conjunction with *'train'* = *'all'* it is possible to exclude single parameters from training explicitly again by passing *'train'* more than once. The names of the parameters to exclude, however, must be prefixed by *'~'*: `GenParamName` = *['train','train']* and `GenParamValue` = *['all','~contrast']*, e.g., trains all parameters except the minimum contrast.

For training the model, the following aspects should be considered:

- To use several images for the training, the operator `find_data_code_2d` must be called with the parameter *'train'* once for every sample image.
- It is also possible to train the model with several symbols in one image. Here, the generic parameter *'stop_after_result_num'* must be passed as a tuple to `GenParamName` together with *'train'*. The number of symbols in the image is passed in `GenParamValue` together with the training parameters.

- If the training image contains more symbols than the one that shall be used for the training the domain of the image should be reduced to the symbol of interest with reduce_domain.
- In an application with very similar images, *one* image for training may be sufficient if the following assumptions are true: The symbol size (in modules) is the same for all symbols used in the application, foreground and background modules are of the same size and there is no gap between neighboring foreground modules, the background has no distinct texture; and the contrast of all images is almost the same. Otherwise, several images should be used for training.
- In applications where the symbol size (in modules) is not fixed, the smallest as well as the biggest symbols should be used for the training. If this can not be guaranteed, the limits for the symbol size should be adapted manually after the training, or the symbol size should entirely be excluded from the training.
- During the first call of find_data_code_2d in the training mode, the trained model parameters are restricted to the properties of the detected symbol. Any successive training call will, where necessary, extend the parameter range to cover the already trained symbols as well as the new symbols. Resetting the model with set_data_code_2d_param to one of its default settings (*'default_parameters'* = *'standard_recognition'*, *'enhanced_recognition'*, or *'maximum_recognition'*) will also reset the training state of the model. With set_data_code_2d_param and *'trained'* the training state of parameters can be set to trained. Subsequent training of this parameter will not reset its value, but extend it, so symbols readable by the previous value can still be read after training.
- If find_data_code_2d is not able to read the symbol in the training image, this will produce no error or exception handling. This can simply be tested in the program by checking the results of find_data_code_2d: SymbolXLDs, ResultHandles, DecodedDataStrings. These tuples will be empty, and the model will not be modified.

Note that during training, a possibly set timeout is ignored (see set_data_code_2d_param).

Functionality of the symbol search

- All data code types:

  Depending on the current settings of the 2D data code model (see set_data_code_2d_param), the operator find_data_code_2d performs several passes for searching the data code symbols. The search starts at the highest pyramid level, where – according to the maximum module size defined in the data code model – the modules can be separated. In addition, in every pyramid level the preprocessing can vary depending on the presets for the module gap. If the data code model enables dark symbols on a light background as well as light symbols on a dark background, within the current pyramid level, the dark symbols are searched first. Then the passes for searching light symbols follow. A pass consists of two phases: The search phase is used to look for the finder patterns and to generate a symbol candidate for every detected finder pattern, and the evaluation phase, where in a lower pyramid level all candidates are investigated and – if possible – read.

  The operator call is either terminated after successfully decoding the requested number of symbols, after processing all search passes, or due to a timeout (see set_data_code_2d_param). The number of requested symbols can be specified via the generic parameter GenParamName = *'stop_after_result_num'*. Without specifying this number the search stops as soon as one symbol could be decoded.
- Data Matrix ECC 200, QR Code, and Micro QR Code:

  The complexity of the symbol search can be controlled with the generic parameter GenParamName = *'symbol_search'*. Per default, *'symbol_search'* is set to GenParamValue = *'default'*.

  – For simple images, i.e. images that:
    * only contain symbols with high contrast and a large quiet zone and
    * show a homogeneous background

    a less complex and (in simple cases) faster symbol search method can be used by setting *'symbol_search'* to *'rudimental'*. Please note that in this case the following parameters do not have any effect: *'module_gap_min'*, *'module_gap_max'*, *'module_gap'*, *'finder_pattern_tolerance'*,*'contrast_tolerance'*, and *'candidate_selection'*. Further, no parameters can be trained with this method.

  – For large images with many codes and a highly structured background, the number of code candidates can be very high for certain parameter settings, e.g. for *'maximum_recognition'*. For performance reasons, the ECC 200 reader, the QR Code reader, and the Micro QR Code reader stop by default after 10000 processed candidates.

    For cases, where more candidates need to be considered in order to decode all codes in the image the *'symbol_search'* can be set to *'exhaustive'*. This will stop the search only when

'stop_after_result_num' codes have been decoded or all candidates have been processed. Please note that this may increase the runtime accordingly. The actual number of candidates can be queried with `get_data_code_2d_results`.

Query results of the symbol search

With the result handles and the operators `get_data_code_2d_results` and `get_data_code_2d_objects`, additional data can be requested about the search process, e.g., the number of internal search passes or the number of investigated candidates, and – together with the `ResultHandles` – about the symbols, like the symbol and module size, the contrast, or the raw data coded in the symbol. In addition, these operators provide information about all investigated candidates that could not be read. In particular, this helps to determine if a candidate was actually generated at the symbol's position during the preprocessing and – by the value of a status variable – why the search or reading was aborted. Further information about the parameters can be found with the operators `get_data_code_2d_results` and `get_data_code_2d_objects`.

Timeout and Abort

The operator `find_data_code_2d` can be aborted by a timeout and dynamically. With the operator `set_data_code_2d_param` you can specify a timeout. If `find_data_code_2d` reaches this timeout, it returns all codes decoded so far. Alternatively, you can call `set_data_code_2d_param` with *'abort'* from another thread to abort `find_data_code_2d` dynamically.

The information whether the operator was aborted or not can be queried by calling `get_data_code_2d_results` with the parameter *'aborted'*.

Furthermore, the operator `find_data_code_2d` can be canceled, which means no result is returned but instead an error is returned. This can be done with the operator `set_operator_timeout` or `interrupt_operator`. If `find_data_code_2d` is canceled by `set_operator_timeout`, H_ERR_TIMEOUT (9400) is returned. If `find_data_code_2d` is canceled by `interrupt_operator`, H_ERR_CANCEL (22) is returned. Note: Both mentioned operators are only supported in cancel mode.

Special parallelization for Data Matrix ECC 200

The operator `find_data_code_2d` supports special parallelization features for Data Matrix ECC 200. This additional internal parallelization can lead to a significantly shorter execution time under certain circumstances. In general, faster calculation times can be expected if, e.g., `set_data_code_2d_param` is used to set the value *'any'* for one or more of the parameters *'polarity'*, *'contrast_tolerance'* and *'finder_pattern_tolerance'*, or if the set values for *'module_gap_min'* and *'module_gap_max'* differ. In all these cases, a series of parameter values must be taken into account. This applies in particular if *'default_parameters'* has been set to *'enhanced_recognition'* or *'maximum_recognition'*.

Please note, that the memory consumption increases with the number of parallel running threads. To reduce the memory consumption `set_system` can be used to either set the number of threads with the parameter *'thread_num'*, or to switch off the temporary memory cache with the parameter *'temporary_mem_cache'*. The Data Matrix ECC 200 specific parallelization can also be easily disabled by setting the generic parameter `GenParamName` = *'specific_parallelization'* to *'disable'*. Note that this will only switch off the additional internal parallelization for Data Matrix ECC 200. Certain sub-tasks might be still processed in parallel. For more information on how to disable the entire parallelization, see the operator reference of `set_system` with its parameters *'thread_num'* and *'parallelize_operators'*. In general, however, it should not be necessary to switch off the specific parallelization. Per default, *'specific_parallelization'* is set to *'enable'*.

Chinese characters

If a QR Code contains Chinese characters encoded according to the Chinese national standard GBT 18284-2000, `find_data_code_2d` returns these characters UTF-8 encoded in `DecodedDataStrings`, if the system parameter *'filename_encoding'* is set to *'utf8'*. The contents of *'decoded_data'*, which can be retrieved with `get_data_code_2d_results`, are never converted to UTF-8.

Parameters

▷ **`Image`** (input_object) ..... singlechannelimage ⇝ *object :* byte
Input image. If the image has a reduced domain, the data code search is reduced to that domain. This usually reduces the runtime of the operator. However, if the datacode is not fully inside the domain, the datacode might not be found correctly. In rare cases, data codes may be found outside the domain. If these results are undesirable, they have to be subsequently eliminated.

▷ **SymbolXLDs** (output_object) ..... xld_cont(-array) ⇝ *object*
XLD contours that surround the successfully decoded data code symbols. The order of the contour points reflects the orientation of the detected symbols. The contours begin in the top left corner (see *'orientation'* in the reference of `get_data_code_2d_results`) and continue clockwise.

Order of points of `SymbolXLDs`

▷ **DataCodeHandle** (input_control) ..... datacode_2d ⇝ *handle*
Handle of the 2D data code model.

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Names of (optional) parameters for controlling the behavior of the operator.
Default: []
List of values: `GenParamName` ∈ {'train', 'stop_after_result_num', 'symbol_search', 'specific_parallelization'}

▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *integer* / real / string
Values of the optional generic parameters.
Default: []
Suggested values: `GenParamValue` ∈ {'all', 'model_type', 'symbol_size', 'version', 'module_size', 'small_modules_robustness', 'module_shape', 'polarity', 'mirrored', 'contrast', 'candidate_selection', 'module_grid', 'alternating_pattern_tolerance', 'finder_pattern_tolerance', 'contrast_tolerance', 'position_pattern_min', 'additional_levels', 'image_proc', 'rudimental', 'default', 'exhaustive', 1, 2, 3, 'enable', 'disable'}

▷ **ResultHandles** (output_control) ..... integer(-array) ⇝ *integer*
Handles of all successfully decoded 2D data code symbols.

▷ **DecodedDataStrings** (output_control) ..... string(-array) ⇝ *string*
Decoded data strings of all detected 2D data code symbols in the image.

Example

```
* Examples showing the use of find_data_code_2d.
* First, the operator is used to train the model, afterwards it is used to
* read the symbol in another image.

* Create a model for reading Data matrix ECC 200 codes
create_data_code_2d_model ('Data Matrix ECC 200', [], [], DataCodeHandle)
* Read a training image
read_image (Image, 'datacode/ecc200/ecc200_cpu_007')
* Train the model with the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, 'train', 'all', \
                   ResultHandles, DecodedDataStrings)
*
* End of training / begin of normal application
*

* Read an image
read_image (Image, 'datacode/ecc200/ecc200_cpu_010')
* Read the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, [], [], \
```

```
                    ResultHandles, DecodedDataStrings)

* Display all symbols, the strings encoded in them, and the module size
dev_set_color ('green')
for i := 0 to |ResultHandles| - 1 by 1
    select_obj (SymbolXLDs, SymbolXLD, i+1)
    dev_display (SymbolXLD)
    get_contour_xld (SymbolXLD, Row, Col)
    set_tposition (WindowHandle, max(Row), min(Col))
    write_string (WindowHandle, DecodedDataStrings[i])
    get_data_code_2d_results (DataCodeHandle, ResultHandles[i], \
                              ['module_height','module_width'], ModuleSize)
    new_line (WindowHandle)
    write_string (WindowHandle, 'module size = ' + ModuleSize[0] + 'x' + \
                                 ModuleSize[1])
endfor

* Clear the model
clear_data_code_2d_model (DataCodeHandle)
```

Result

The operator `find_data_code_2d` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- DataCodeHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_data_code_2d_model`, `read_data_code_2d_model`, `set_data_code_2d_param`

Possible Successors

`get_data_code_2d_results`, `get_data_code_2d_objects`, `write_data_code_2d_model`

Module

Data Code

get_data_code_2d_objects (: DataCodeObjects : DataCodeHandle, CandidateHandle, ObjectName :)

Access iconic objects that were created during the search for 2D data code symbols.

The operator `get_data_code_2d_objects` facilitates to access iconic objects that were created during the last call of `find_data_code_2d` while searching and reading the 2D data code symbols. Besides the name of the object (`ObjectName`), the 2D data code model (`DataCodeHandle`) must be passed

to get_data_code_2d_objects. In addition, in CandidateHandle a handle of a result or candidate structure or a string identifying a group of candidates (see get_data_code_2d_results) must be passed. These handles are returned by find_data_code_2d for all successfully decoded symbols and by get_data_code_2d_results for a group of candidates. If these operators return several handles in a tuple, the individual handles can be accessed by normal tuple operations.

For an explanation of the concept of the 2D data code reader see the introduction of chapter Identification / Data Code.

If *'discard_undecoded_candidates'* was set to *'yes'* with set_data_code_2d_param, only results of successfully decoded candidates can be accessed.

Some objects are not accessible without setting the model parameter *'persistence'* to *1* (see set_data_code_2d_param). The persistence must be set before calling find_data_code_2d, either while creating the model with create_data_code_2d_model or with set_data_code_2d_param.

Currently, the following iconic objects can be retrieved:

Regions of the modules

- All data code types:

  'module_1_rois': All modules that were classified as foreground (set).

- All data code types except DotCode:

  'module_0_rois': All modules that were classified as background (not set).

These region arrays correspond to the areas that were used for the classification. The returned object is a region array. Hence it cannot be requested for a group of candidates. Therefore, a single result handle must be passed in CandidateHandle. The model persistence must be *1* for this object. In addition, requesting the module ROIs makes sense only for symbols that were detected as valid symbols. For other candidates, whose processing was aborted earlier, the module ROIs are not available.

XLD contour

'candidate_xld': An XLD contour that surrounds the candidate or decoded symbol.

This object can be requested for any group of results or for any single candidate or symbol handle. The persistence setting is of no relevance.

Pyramid images

'search_image': Pyramid image, in which the candidate was found.

'process_image': Pyramid image, in which the candidate was investigated more closely.

The persistence setting is also not relevant here.

Parameters

▷ **DataCodeObjects** (output_object) ..... object(-array) ⇝ *object*
Objects that are created as intermediate results during the detection or evaluation of 2D data codes.

▷ **DataCodeHandle** (input_control) ..... datacode_2d ⇝ *handle*
Handle of the 2D data code model.

▷ **CandidateHandle** (input_control) ..... integer ⇝ *integer* / string
Handle of the 2D data code candidate. Either an integer (usually the ResultHandle of find_data_code_2d) or a string representing a group of candidates.
Default: 'all_candidates'
Suggested values: CandidateHandle ∈ {0, 1, 2, 'all_candidates', 'all_results', 'all_undecoded', 'all_aborted'}

▷ **ObjectName** (input_control) ..... string ⇝ *string*
Name of the iconic object to return.
Default: 'candidate_xld'
List of values: ObjectName ∈ {'module_1_rois', 'module_0_rois', 'candidate_xld', 'search_image', 'process_image'}

Example

```
* Example demonstrating how to access the iconic objects of the data code
* search.

* Create a model for reading Data matrix ECC 200 codes
create_data_code_2d_model ('Data Matrix ECC 200', [], [], DataCodeHandle)
set_data_code_2d_param (DataCodeHandle, 'default_parameters', \
                        'maximum_recognition')
set_data_code_2d_param (DataCodeHandle, 'persistence', 1)
* Read an image
read_image (Image, 'datacode/ecc200/ecc200_disturbed_012')
* Read the symbol in the image
find_data_code_2d (Image, SymbolXLDs, DataCodeHandle, [], [], \
                   ResultHandles, DecodedDataStrings)

* Get the handles of all candidates that were detected as a symbol but
* could not be read
get_data_code_2d_results (DataCodeHandle, 'all_undecoded', 'handle', \
                          HandlesUndecoded)

* For every undecoded symbol, get the contour and the classified
* module regions
for I := 0 to |HandlesUndecoded| - 1 by 1
  * Display image.
  dev_display (Image)
  dev_set_draw ('margin')
  * Get the contour of the symbol.
  dev_set_color ('blue')
  get_data_code_2d_objects (SymbolXLD, DataCodeHandle, \
                            HandlesUndecoded[I], 'candidate_xld')
  dev_display (SymbolXLD)
  * Get the module regions of the foreground modules
  dev_set_color ('green')
  get_data_code_2d_objects (ModuleFG, DataCodeHandle, \
                            HandlesUndecoded[I], 'module_1_rois')
  dev_display (ModuleFG)
  * Get the module regions of the background modules
  dev_set_color ('red')
  get_data_code_2d_objects (ModuleBG, DataCodeHandle, \
                            HandlesUndecoded[I], 'module_0_rois')
  dev_display (ModuleBG)
  * Stop for inspecting the image.
  stop ()
endfor

* Clear the model
clear_data_code_2d_model (DataCodeHandle)
```

Result

The operator `get_data_code_2d_objects` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct and the requested objects are available for the last symbol search. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

find_data_code_2d, query_data_code_2d_params

Possible Successors

get_data_code_2d_results

Module

Data Code

get_data_code_2d_param (: : DataCodeHandle, GenParamName : GenParamValue)

Get one or several parameters that describe the 2D data code model.

The operator get_data_code_2d_param allows to query the parameters that are used to describe the 2D data code model. The names of the desired parameters are passed in the generic parameter GenParamName, the corresponding values are returned in GenParamValue. All these parameters can be set and changed at any time with the operator set_data_code_2d_param. A list with the names of all parameters that are valid for the used 2D data code type is returned by the operator query_data_code_2d_params.

For an explanation of the concept of the 2D data code reader see the introduction of chapter Identification / Data Code.

Note that the symbol structure of GS1 DataMatrix, GS1 QR Code, GS1 Aztec Code, and GS1 DotCode is identical to the structure of Data Matrix ECC 200, QR Code, Aztec Code, and DotCode, respectively. Therefore, all symbology specific parameters applying to Data Matrix ECC 200, QR Code, Aztec Code, or DotCode apply to their corresponding GS1 variant as well. In the following, the explicit enumeration of the parameters for any particular GS1 code is omitted for sake of readability. Instead, the relevant parameters names are to be inferred from the parameters for the corresponding non-GS1 code type or can be explicitly queried by query_data_code_2d_params with parameter *'get_model_params'*.

The following parameters can be queried – ordered by different categories and data code types:

Size and shape of the symbol:

- Data Matrix ECC 200 (including the finder pattern):

  'symbol_cols_min': Minimum number of module columns in the symbol.

  'symbol_cols_max': Maximum number of module columns in the symbol.

  'symbol_rows_min': Minimum number of module rows in the symbol.

  'symbol_rows_max': Maximum number of module rows in the symbol.

  'symbol_shape': Possible restrictions concerning the module shape (rectangle and/or square)
  List of values: *'square'*, *'rectangle'*, *'any'*.

- QR Code (including the finder pattern):

  'model_type': Type of the QR Code model specification: *1*, *2*, *0* (for *'any'*)

  'version_min': Minimum symbol version to be read: [*1*...*40*] (Model 1: [*1*...*14*])

  'version_max': Maximum symbol version to be read: [*1*...*40*] (Model 1: [*1*...*14*])

  'symbol_size_min': Minimum symbol size (this value is directly linked to the version *'version_min'*): [*21*...*177*] (Model 1: [*21*...*73*])

  'symbol_size_max': Maximum symbol size (this value is directly linked to the version *'version_max'*): [*21*...*177*] (Model 1: [*21*...*73*])

- Micro QR Code:

  'version_min': Minimum symbol version to be read: [*1*...*4*]

  'version_max': Maximum symbol version to be read: [*1*...*4*]

  'symbol_size_min': Minimum symbol size (this value is directly linked to the version *'version_min'*): [*11*...*17*]

'symbol_size_max': Maximum symbol size (this value is directly linked to the version *'version_max'*): [*11*...*17*]

- PDF417:

  'symbol_cols_min': Minimum number of data columns in the symbol in codewords, i.e., excluding the codewords of the start/stop pattern and of the two row indicators.

  'symbol_cols_max': Maximum number of data columns in the symbol in codewords, i.e., excluding the codewords of the start/stop pattern and of the two row indicators.

  'symbol_rows_min': Minimum number of module rows in the symbol.

  'symbol_rows_max': Maximum number of module rows in the symbol.

- Aztec Code (including the finder pattern):

  'format': Format of the Aztec Code: space separated list with the values *'compact'*, *'full_range'*, or *'rune'*

  'symbol_size_min': Minimum symbol size [*11*...*151*]

  'symbol_size_max': Maximum symbol size [*11*...*151*]

- DotCode:

  'symbol_cols_min': Minimum number of module columns in the symbol.

  'symbol_cols_max': Maximum number of module columns in the symbol.

  'symbol_rows_min': Minimum number of module rows in the symbol.

  'symbol_rows_max': Maximum number of module rows in the symbol.

Appearance of the modules in the image:

- All data code types:

  'polarity': Possible restrictions concerning the polarity of the modules, i.e., if they are printed dark on a light background or vice versa: *'dark_on_light'*, *'light_on_dark'*, *'any'*.

  'discard_undecoded_candidates' Controls whether candidates that could not be successfully decoded are stored in the model: *'yes'*, *'no'*.

  'mirrored': Describes whether the symbol is or may be mirrored (which is equivalent to swapping the rows and columns of the symbol): *'yes'*, *'no'*, *'any'*.

- All data code types except Data Matrix ECC 200 and DotCode:

  'contrast_min': Minimum contrast between the foreground and the background of the symbol (specified as gray value difference). This measure corresponds to the minimum gradient between the symbol's foreground and the background.

- Data Matrix ECC 200, Micro QR Code, and QR Code:

  'contrast_tolerance': Describes the tolerance of the search with respect to local contrast variations (e.g., in the presence of glare or reflections). Depending on the value of the parameter two different algorithms are applied. If *'contrast_tolerance'* is set to *'high'* the robustness in the presence of strong local contrast variations is improved. In the case where *'contrast_tolerance'* is set to *'low'* the algorithm used is less robust to strong local contrast variations, however, it is faster and still able to handle contrast variations under normal circumstances and therefore *'low'* should be used in most cases. If *'contrast_tolerance'* is set to *'any'* both algorithms are applied.

- All data code types except PDF417:

  'module_size_min': Minimum module size in the image in pixels.

  'module_size_max': Maximum module size in the image in pixels.

  With the following parameters it is possible to specify whether neighboring foreground modules are connected or whether there is or may be a gap between them (possible values are *'no'* (no gap) $<$ *'small'* $<$ *'big'*) (for DotCode, only *'no'* and *'small'* are available):

  'module_gap_min': Minimum gap.

  'module_gap_max': Maximum gap.

- All data code types except DotCode:

'small_modules_robustness': Robustness of the decoding of data codes with very small module sizes. Setting the parameter *'small_modules_robustness'* to *'high'* increases the likelihood of being able to decode data codes with very small module sizes. Additionally, in that case the minimum module size should also be adapted accordingly, thus *'module_size_min'* and *'module_width_min'* (PDF417) should be set to the expected minimum module size and width, respectively. Setting *'small_modules_robustness'* to *'high'* can significantly increase the internal memory usage of `find_data_code_2d`. Thus, in the default case *'small_modules_robustness'* should be set to *'low'*.
List of values: *'low'*, *'high'*
Default: *'low'* (enhanced: *'low'*, maximum: *'high'*)

- PDF417:

  'module_width_min': Minimum module width in the image in pixels.

  'module_width_max': Maximum module width in the image in pixels.

  'module_aspect_min': Minimum module aspect ratio (module height to module width).

  'module_aspect_max': Maximum module aspect ratio (module height to module width).

- Aztec Code:

  'finder_pattern_tolerance': Tolerance of the search with respect to a defect or partially occluded finder pattern. Depending on this parameter, different algorithms are used during the symbol search in `find_data_code_2d`. In one case (*'low'*), it is assumed that all rings of the finder pattern can be extracted. In the other case (*'high'*) it is assumed that at least one of the rings of the finder pattern can be extracted.

  'additional_levels': To increase the robustness of the Aztec Code reader, a number of additional search levels (in addition to the search levels derived from the minimum and maximum module dimensions) can be specified via this parameter. [*0*...*2*]

- Data Matrix ECC 200:

  'slant_max': Maximum slant of the L-shaped finder pattern (the angle is returned in radians and corresponds to the distortion that occurs when the symbol is printed or during the image acquisition).

  'finder_pattern_tolerance': Tolerance of the search with respect to a defect or partially occluded finder pattern. The finder pattern includes the L-shaped side as well as the opposite alternating side. Depending on this parameter, different algorithms are used during the symbol search in `find_data_code_2d`. In one case (*'low'*), it is assumed that the finder pattern is present to a high degree and shows almost no disturbances. In the other case (*'high'*), the finder pattern may be defect or partially occluded without influencing the recognition and the reading of the symbol. Note, however, that in this mode the parameters for the symbol search should be restricted as narrow as possible by using `set_data_code_2d_param` because otherwise the runtime of `find_data_code_2d` may increase significantly. Also note that the two algorithms slightly differ from each other in terms of robustness. This may lead to different results depending on the value of *'finder_pattern_tolerance'* even if the finder pattern of the symbol is not disturbed. For example, if *'high'* is chosen, only symbols with an equidistant module grid can be found (see below), and hence the robustness to perspective distortions is decreased. Finally, if *'finder_pattern_tolerance'* is set to *'any'* both algorithms are applied.

  'alternating_pattern_tolerance': Tolerance of the search with respect to the variation of the module widths along the two sides with the alternating pattern. The alternating pattern analysis is decisive if *'finder_pattern_tolerance'* is set to *'low'* (or *'any'* which includes *'low'*). Note, however, that this parameter has no effect if *'finder_pattern_tolerance'* has been set to *'high'*. A total of three different values are allowed for this parameter, with a higher setting always including the lower values: *'low'* allows only a small variation of the module widths along the sides with the alternating pattern. *'medium'* first tries to meet the strict requirements of *'low'*, and if this fails, a larger variation of the module widths along the sides with the alternating pattern is allowed. Finally, *'high'* includes everything that *'medium'* allowed and additionally expands the parameter space for the symbol's outer boundaries through further attempts. It also softens the relation between the number of edges detected and the symbol type used for subsequent decoding. The greater robustness in difficult cases comes with the disadvantage that *'high'* in particular can lead to a significant runtime increase. To counteract this, the parameter space should be reduced in total by using `set_data_code_2d_param`, e.g., by setting the expected symbol sizes as tight as possible.

  'module_grid': Describes whether the size of the modules may vary (in a specific range) or not. Dependent on the parameter different algorithms are used for the calculation of the module's center positions. If it is set to *'fixed'*, an equidistant grid is used. Allowing a variable module size (*'variable'*), the grid is

aligned only to the alternating side of the finder pattern. With *'any'* both approaches are tested one after the other. Please note that the value of *'module_grid'* is ignored if *'finder_pattern_tolerance'* is set to *'high'*. In this case, an equidistant grid is assumed.

- QR Code:

  'position_pattern_min': Number of position detection patterns that have to be visible for generating a new symbol candidate (2 or 3).

General model behavior:

- All data code types:

  'persistence': Controls whether certain intermediate results of the symbol search with `find_data_code_2d` are stored only temporarily or persistently in the model: *0* (temporary), *1* (persistent).

  'strict_model': Controls the behavior of `find_data_code_2d` while detecting symbols that could be read but that do not fit the model restrictions concerning the size of the symbols: *'yes'* (strict: such symbols are rejected), *'no'* (not strict: all readable symbols are returned as a result independent of their size and the size specified in the model). Please note that for DotCode symbols the module size restrictions (*'module_size_min'* and *'module_size_max'*) are not checked even if *'strict_model'* is set to *'yes'*.

  'string_encoding': Returns the expected encoding of the string that is encoded in the symbol: *'utf8'*, *'locale'*, *'latin1'*, *'shiftjis'*, or *'raw'*.

  'symbol_type': Returns symbol type which was set with `create_data_code_2d_model`.

  'timeout': Enables aborting `find_data_code_2d` after a defined period in milliseconds: *'false'*, *-1*, *20 ... 100*.

- All data code types except Aztec Code:

  'strict_quiet_zone': Controls the behavior of `find_data_code_2d` while detecting symbols that could be read but show defects in their quiet zone. Possible values:

  'yes': Decoded symbols with poor grades for their quiet zone are not returned as a result. The quiet zone is validated similar to the method used for print quality inspection, but regarded as being only one module large. The *'status'* for rejected symbols is set to *'quiet zone is missing'*.

  'no' **(default):** All readable symbols are returned as a result.

- All data code types except DotCode:

  'quality_isoiec15415_aperture_size': Defines the aperture sizes for ISO/IEC 15415:2011 print quality inspection as fraction of the module width (see ISO/IEC 15415:2011 section 7.3.3).

  'quality_isoiec15415_reflectance_reference': Defines the reference reflectance for ISO/IEC 15415:2011 print quality inspection as grayvalue (see ISO/IEC 15415:2011 section 7.3).

  'quality_isoiec15415_smallest_module_size': Defines the module size used to obtain the synthetic aperture for ISO/IEC 15415:2011 print quality inspection (see ISO/IEC 15415:2011 section 7.3.3).

- Data Matrix ECC 200, DotCode, Micro QR Code, and QR Code:

  'candidate_selection': Controls the selection of candidate regions that are used for symbol detection. Setting this parameter to *'extensive'* increases the number of generated candidate regions and thus the likelihood of detecting a code. When this parameter is set to *'all'*, all possible candidates are used. If *'candidate_selection'* is set to *'default'*, less candidate regions are used.

- DotCode:

  'max_allowed_error_correction': Controls the maximum allowed error correction. Due to the high error correction capacity, it is possible to successfully decode false positive DotCode candidates. Especially candidates which only cover a small part of a real DotCode may be decoded successfully because of the error correction capabilities. This is the case because DotCode symbols can consist of almost every size. So there are fewer criteria to decide whether the candidate is valid or not. In order to tackle this problem, the parameter *'max_allowed_error_correction'* can be used to specify the percentage of maximum allowed error correction. Per default the value is set to *'0.9'*, which means 90%. Setting the value to e.g., *'0.5'* means, only candidates which could be decoded with maximum 50% used error correction, will be returned as successfully decoded results.
  Value range: [*0.0 ... 1.0*]
  Default: *'0.9'*

It is possible to query the values of several or all parameters with a single operator call by passing a tuple containing the names of all desired parameters to GenParamName. As a result a tuple of the same length with the corresponding values is returned in GenParamValue.

Parameters

▷ **DataCodeHandle** (input_control) . . . . . datacode_2d ⇝ *handle*
Handle of the 2D data code model.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that are to be queried for the 2D data code model.
Default: 'polarity'
List of values: GenParamName ∈ {'strict_model', 'persistence', 'polarity', 'mirrored', 'contrast_min', 'candidate_selection', 'discard_undecoded_candidates', 'model_type', 'version_min', 'version_max', 'format', 'string_encoding', 'symbol_size_min', 'symbol_size_max', 'symbol_cols_min', 'symbol_cols_max', 'symbol_rows_min', 'symbol_rows_max', 'symbol_shape', 'module_size_min', 'module_size_max', 'module_width_min', 'module_width_max', 'small_modules_robustness', 'module_aspect_min', 'module_aspect_max', 'module_gap_min', 'module_gap_max', 'slant_max', 'module_grid', 'position_pattern_min', 'strict_quiet_zone', 'timeout', 'alternating_pattern_tolerance', 'finder_pattern_tolerance', 'additional_levels', 'contrast_tolerance', 'quality_isoiec15415_aperture_size', 'quality_isoiec15415_decode_algorithm', 'quality_isoiec15415_reflectance_reference', 'quality_isoiec15415_smallest_module_size', 'decoding_scheme', 'symbol_type', 'max_allowed_error_correction'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Values of the generic parameters.

Result

The operator get_data_code_2d_param returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

query_data_code_2d_params, set_data_code_2d_param, find_data_code_2d

Possible Successors

find_data_code_2d, write_data_code_2d_model

Alternatives

write_data_code_2d_model

See also

Module

Data Code

get_data_code_2d_results (: : DataCodeHandle, CandidateHandle, ResultNames : ResultValues)

Get the alphanumerical results that were accumulated during the search for 2D data code symbols.

The operator get_data_code_2d_results allows to access several alphanumerical results that were calculated while searching and reading the 2D data code symbols. These results describe the search process in general or one of the investigated candidates – independently of whether it could be read or not. The results are in most cases not related to the symbol with the highest resolution but depend on the pyramid level that was investigated when the reading process was aborted. To access a result, the name of the parameter (ResultNames) and the 2D data code model (DataCodeHandle) must be passed. In addition, in CandidateHandle a handle of a result

or candidate structure or a string identifying a group of candidates must be passed. These handles are returned by find_data_code_2d for all successfully decoded symbols and by get_data_code_2d_results for a group of candidates. If these operators return several handles in a tuple, the individual handles can be accessed by normal tuple operations.

For an explanation of the concept of the 2D data code reader see the introduction of chapter Identification / Data Code.

If *'discard_undecoded_candidates'* was set to *'yes'* with set_data_code_2d_param, only results of successfully decoded candidates can be accessed.

Most results consist of one value. Several of these results can be queried for a specific candidate in a single call. The values returned in ResultValues correspond to the appropriate parameter names in the ResultNames tuple. As an alternative, these results can also be queried for a group of candidates (see below). In this case, only one parameter can be requested per call, and ResultValues contains one value for every candidate.

Furthermore, there exists another group of results that consist of more than one value (e.g., *'bin_module_data'*), which are returned as a tuple. These parameters must always be queried exclusively: one result for one specific candidate.

Apart from the candidate-specific results there are a number of results referring to the search process in general. This is indicated by passing the string *'general'* in CandidateHandle instead of a candidate handle.

Note that the symbol structure of GS1 DataMatrix, GS1 QR Code, GS1 Aztec Code, and GS1 DotCode is identical to the structure of Data Matrix ECC 200, QR Code, Aztec Code, or DotCode, respectively. Therefore, all type specific results for Data Matrix ECC 200, QR Code, Aztec Code, and DotCode can be queried for their corresponding GS1 variant as well. In the following, the explicit enumeration of the type specific results for any particular GS1 code is omitted for sake of readability. Instead, the relevant result names are to be inferred from the result names for the corresponding non-GS1 code type and or be explicitly queried by query_data_code_2d_params with parameter *'get_result_params'*.

Candidate groups

The following candidate group names are predefined and can be passed as CandidateHandle instead of a single handle:

'general': This value is used for results that refer to the last find_data_code_2d call in general but not to a specific candidate.

'all_candidates': All candidates (including the successfully decoded symbols) that were investigated during the last call of find_data_code_2d.

'all_results': All symbols that were successfully decoded during the last call of find_data_code_2d.

'all_undecoded': All candidates of the last call of find_data_code_2d that were detected as 2D data code symbols, but could not be decoded. For these candidates the error correction detected too many errors, or there was an failure while decoding the error-corrected data because of inconsistent data.

'all_aborted': All candidates of the last call of find_data_code_2d that could not be identified as valid 2D data code symbols and for which the processing was aborted.

Supported results

Currently, the access to the following results, which are returned in ResultValues, is supported:

General results that do not depend on specific candidates – *'general'*:

- All data code types:

  'min_search_level': Lowest pyramid level that is searched for symbols. A pyramid level of 0 corresponds to the original image.

  'max_search_level': Highest pyramid level that is searched for symbols. A pyramid level of 0 corresponds to the original image.

  'result_num': Number of successfully decoded symbols.

  'candidate_num': Number of all investigated candidates.

  'undecoded_num': Number of candidates that were identified as symbols but could not be read.

  'aborted_num': Number of candidates that could not be identified as valid 2D data code symbols.

  'aborted': returns whether find_data_code_2d was aborted. This might be caused by a timeout (see *'timeout'* in set_data_code_2d_param) or an explicit abort (see *'abort'* in set_data_code_2d_param).

Value	Description
0	find_data_code_2d completed
1	find_data_code_2d was aborted by a timeout
2	find_data_code_2d was aborted using set_data_code_2d_param with *'abort'*

- Data Matrix ECC 200, Aztec Code, QR Code, and Micro QR Code:

  'quality_isoiec29158_labels' **and** *'quality_aimdpm_1_2006_labels'*: Labels of grades for all tuple elements returned when calling get_data_code_2d_results with *'quality_isoiec29158'* or *'quality_aimdpm_1_2006'*.

- Data Matrix ECC 200, Aztec Code, PDF417, QR Code, and Micro QR Code:

  'pass_num': Number of passes that were completed, see also find_data_code_2d (Functionality of the symbol search).

  'quality_isoiec15415_labels': Labels of grades for all tuple elements returned when calling get_data_code_2d_results with *'quality_isoiec15415'*. The labels are different depending on the type of the evaluated data code symbol.

- Data Matrix ECC 200:

  'quality_semi_t10_labels': Convenience value labels of the elements of the tuple returned when calling get_data_code_2d_results with *'quality_semi_t10_values'*.

Results associated with a specific candidate - one value results:

Results that contain exactly **one value** and hence can be applied to a **candidate group** or a **specific candidate**. Please consider that some of the following results will only be meaningful if the candidate could be successfully decoded (see *'status'*).

- All data code types:

  'handle': Handle to the candidate. This parameter is used to receive the handles of all candidates of the specified group.

  'status': Indicates whether the decoding was successful or why the processing was aborted.

  'search_level': Pyramid level on which the finder pattern was found.

  'process_level': Pyramid level on which the candidate was processed and decoded.

  'polarity': Polarity of the symbol. This is the assumption about the polarity that was used for searching the candidate.

  'mirrored': Indicates whether a successfully decoded symbol is mirrored or not. For ECC 200, PDF417, QR and Micro QR Codes *'no'* or *'yes'* is returned. For Aztec Codes *'false'* or *'true'* is returned. For candidates that could not be read, the parameter returns the mirroring specification of the model.

  'orientation': Indicates the orientation of a successfully decoded symbol. The orientation is an angle relative to the orientation described in the figure below. The angle is positive in counter clockwise direction and is given in degrees. It can be in the range of [-180.0 .. 180.0] degrees.

(1) (2) (3)

(4) (5)

Orientation at zero degree of a Aztec symbol (1), ECC200 symbol (2), QR code symbol (3), PDF417 symbol (4) and DotCode symbol (5). The respective finder patterns or characteristic points are highlighted.

'symbol_rows', *'symbol_cols'*: Data Matrix ECC 200, QR Code, Micro QR Code, Aztec Code, and DotCode:
detected size of the symbol in modules: number of rows and columns including the finder pattern;
PDF417:
detected number of rows and data columns (each 17 modules wide) within the symbol (excluding the start/stop patterns and the row indicators).

'module_height', *'module_width'*: Height and width of the modules in pixels.

'decoded_string': Result string that is encoded in the symbol – this query is useful only for successfully decoded strings. It returns the same string as `find_data_code_2d`.

'decoding_error': Decoding error – for successfully decoded symbols this is the number of errors that were detected and corrected by the error correction. The number of errors corresponds here to the number of code words that lead to errors when trying to read them. For PDF417 this number includes erasures, i.e. errors with known locations. If the error correction failed, a negative error code is returned.

- Data Matrix ECC 200, Aztec Code, PDF417 QR Code, and Micro QR Code:

  'pass': Number of the pass in which the candidate was generated and processed, see also `find_data_code_2d` (Functionality of the symbol search).

  'small_modules_robustness': Robustness of the decoding of data codes with very small module sizes. For *'low'* the data code was decoded with a method that has only a small robustness regarding very small module sizes. For *'high'* the data code was decoded with a method that has a high robustness in this regard.

  'contrast': Estimation of the symbol's contrast. This value is based on the gradient of the edge between the finder pattern and the background.

- Data Matrix ECC 200, Micro QR Code, and QR Code:

  'contrast_tolerance': This parameter informs about the algorithm that was used to correct local contrast variations in the symbol search. For *'high'* the symbol was found using an algorithm to correct strong local contrast variations. For *'low'* the symbol was found with the faster algorithm, which however is less robust with respect to local contrast variations.

- Data Matrix ECC 200, Aztec Code, QR Code, Micro QR Code, and DotCode:

  'module_gap': Assumption about the module gap that was used for searching the candidate.

- Data Matrix ECC 200, Aztec Code, QR Code, PDF417, and DotCode:

  'symbology_ident': The *Symbology Identifier* is used to indicate that the data code contains the FNC1 and/or ECI characters.
  FNC1 (*Function 1 Character*) is used if the data formatting conforms to specific predefined industry standards.
  The ECI protocol (*Extended Channel Interpretation*) is used to change the default interpretation of the encoded data. A 6-digit code number after the ECI character switches the interpretation of the following characters from the default to a specific code page like an international character set. In the output stream the ECI switch is coded as *'\nnnnnn'*. Therefore all backslashes (*'\'*, ASCII code 92), that occur in the normal output stream have to be doubled.
  The *'symbology_ident'* parameter returns only the actual identifier value m ($m \in [0,6]$ (QR-Code), $m \in [0,12]$ (Data Matrix ECC 200 and Aztec Code), $m \in [0,2]$ (PDF417) bzw. $m \in [0,5]$ (DotCode)) according to the specification of Data Matrix, QR Codes, Aztec Code, PDF417, and DotCode but not the identifier prefixes ']d', ']Q', ']z', ']L', and ']J' for Data Matrix, QR Codes, Aztec Codes, PDF417, and DotCode, respectively. If required, this *Symbology Identifier* composed of the prefix and the value m has to be preceded the decoded string (normally only if $m > 1$) manually (for Data Matrix ECC 200 and Aztec Codes, the values 10, 11, and 12 have to be converted to A, B, and C, respectively).
  GS1 symbologies have the following identifiers: ']d2' for GS1 DataMatrix, ']Q3' for GS1 QR Code, ']z1' for GS1 Aztec Code, and ']J1' for GS1 DotCode. Therefore, the *'symbology_ident'* parameter returns the values 2, 3, and 1, respectively.
  Symbols that contain ECI codes (and hence doubled backslashes) can be recognized by the following identifier values: Data Matrix ECC 200: 4, 5, 6, 10, 11 and 12, QR Code: 2, 4, and 6, PDF417: 1, Aztec Code: 3, 4, 5, 9, 10, and 11, DotCode: 3, 4, and 5.

- Data Matrix ECC 200 and DotCode:

  'reader_programming': If the symbol contains a Reader Programming character that indicates that the symbol encodes a message used to program the reader system, this parameter returns *'yes'*, otherwise this parameter returns *'no'*. The decoded message does not contain the Reader Programming character.

- Data Matrix ECC 200:

  'slant': Slant of the L-shaped finder pattern in radians. This is the difference between the angle of the 'L' and the right angle.

  'finder_pattern_tolerance': This parameter informs about the algorithm that found the symbol. For *'low'* the symbol was found with the algorithm that has only a small tolerance with respect to a defect or partially occluded finder pattern. For *'high'* the symbol was found with the algorithm that has a high tolerance in this regard. Please note that when using both algorithms simultaneously it may happen that symbols with an undisturbed finder pattern are found from the algorithm of high tolerance.

  'alternating_pattern_tolerance': This parameter informs about the algorithm that was used to detect and analyze the two sides with the alternating pattern. Based on this analysis, the associated symbol type is derived and the grid for the module classification is created. For *'low'*, the analysis was performed with a small tolerance to variations in the module widths. *'medium'*, when successfully decoded, signals that an acceptance of greater variations with respect to the module widths along the sides with the alternating pattern was necessary. Finally, *'high'* means that not only a larger variation has to be accepted, but additionally the parameter space for the symbol's outer boundaries had to be expanded or the relation between the number of edges and the symbol type had to be softened. In addition, *'undefined'* signals that the candidate either did not reach the alternating pattern analysis or was part of the search pass that is based on *'finder_pattern_tolerance'* set to *'high'*. In the latter case, the *'alternating_pattern_tolerance'* parameter has no effect.

  'module_grid': For symbols that could be decoded, this parameter informs about the algorithm that was used for calculating the module grid: If a variable grid was used it returns *'variable'*, and otherwise *'fixed'*. For symbols that could not be decoded, it returns the method that was used during the last decoding trial or, if the candidate was rejected before the decoding, the corresponding model setting.

- QR Codes:

  'version': Version number that corresponds to the size of the symbol (version 1 = 21 $\times$ 21, version 2 = 25 $\times$ 25, ..., version 40 = 177 $\times$ 177).

  'symbol_size': Detected size of the symbol in modules.

  'model_type': Type of the QR Code Model. In HALCON the older, original specification for QR Codes Model 1 as well as the newer, enhanced form Model 2 are supported.

  'error_correction_level': If a candidate is recognized as a QR Code, the first step is to read the format information encoded in the symbol. This includes the level of error correction (*'error_correction_level'* $\in$ [*'L'* (Low), *'M'* (Medium), *'Q'* (Quartile), *'H'* (High)]).

  'mask_pattern_ref': Additionally, the format information encoded in the symbol include a code for the pattern that was used for masking the data modules ($0 \leq$ *'mask_pattern_ref'* ≤ 7).

- Micro QR Codes:

  'version': Version number that corresponds to the size of the symbol (version M1 = 11 $\times$ 11, version M2 = 13 $\times$ 13, version M3 = 15 $\times$ 15, version M4 = 17 $\times$ 17).

  'symbol_size': Detected size of the symbol in modules.

  'error_correction_level': If a candidate is recognized as a Micro QR Code, the first step is to read the format information encoded in the symbol. This includes the level of error correction (*'error_correction_level'* $\in$ [*'N'* (None), *'L'* (Low), *'M'* (Medium), *'Q'* (Quartile)]).

  'mask_pattern_ref': Additionally, the format information encoded in the symbol include a code for the pattern that was used for masking the data modules ($0 \leq$ *'mask_pattern_ref'* ≤ 7).

- PDF417:

  'module_aspect': Module aspect ratio; this corresponds to the ratio of *'module_height'* to *'module_width'*.

  'error_correction_level': If a candidate is recognized as a PDF417 the first step is to read the format information encoded in the symbol. This includes the error correction level, which was used during encoding (*'error_correction_level'* $\in$ [*0*, *8*]).

'macro_exist': Symbols that are part of a group of symbols are called *"Macro PDF417"* symbols. These symbols contain additional information within a control block. For macro symbols *'macro_exist'* returns the value *1* while for conventional symbols *0* is returned.

'macro_segment_index': Returns the index of the symbol in the group. For macro symbols this information is obligatory.

'macro_file_id': Returns the group identifier as a string. For macro symbols this information is obligatory.

'macro_segment_count': Returns the number of symbols that belong to the group. For macro symbols this information is optional.

'macro_time_stamp': Returns the time stamp on the source file expressed as the elapsed time in seconds since 1970:01:01:00:00:00 GMT as a string. For macro symbols this information is optional.

'macro_checksum': Returns the CRC checksum computed over the entire source file using the CCITT-16 polynomial. For macro symbols this information is optional.

'macro_last_symbol': Returns *1* if the symbol is the last one within the group of symbols. Otherwise *0* is returned. For macro symbols this information is optional.

'quality_isoiec15415_float_grades': returns a tuple with the same assessment of print quality like *'quality_isoiec15415'*. For a PDF417 some grades are assessed with the international standard ISO/IEC 15416:2016. In compliance with the standard the grades are returned with one decimal place.

- Aztec Codes:

  'format': String that corresponds to the format of the decoded symbol: *'compact'*, *'full_range'*, or *'rune'*.

  'symbol_size': Detected size of the symbol in modules.

  'layer_num': The number of layers as encoded in the mode message of the symbol.

  'codeword_num': The number of codewords as encoded in the mode message of the symbol.

Results associated with a specific candidate - tuple of values results:

Results that return a **tuple of values** and hence can be requested only separately and only for a **single candidate**. Please consider that some of the following results will not return a useful value if the investigation of the candidate was aborted.

- All data code types:

  'bin_module_data': Binary symbol data that corresponds to the classification results of the individual modules – a value of 0 means that the module was classified as background and 100 indicates that the module belongs to the foreground. Values between 0 and 100 can be interpreted as foreground or background. The model persistence must be 1 for this result (see `set_data_code_2d_param`). For DotCodes the model persistence does not matter. It shall be noted that the order of *'bin_module_data'* does not necessarily match the order of the modules, which can be retrieved using *'module_1_rois'* and *'module_0_rois'* via `get_data_code_2d_objects`. Instead, the order for successfully decoded symbols depends on the actual *'mirrored'* status of the result, or the *'mirrored'* setting specified via `set_data_code_2d_param` for failed candidates.

  'raw_coded_data': Data obtained by mapping the binary data to data words according to the particular coding scheme of the symbol type. Single bits may still be erroneous, and the words that are used for the error correction are still included.

  'corr_coded_data': Data obtained after applying the error correction: erroneous bits are corrected and all redundant words are removed, but the words are still encoded according to the coding scheme that is specific for the data code type.

  'decoded_data': Tuple with the decoded data words (= characters of the decoded data string) as Latin-1 or ASCII code (see also Tuple / String Operations). Additionally, decoded words can be encoded as JIS8 or Shift JIS characters (QR Code and Micro QR Code only) or GB2312 characters (QR Code only). Note that for QR Code and Micro QR Code the Kanji characters are not returned as single (Shift JIS) code points by `get_data_code_2d_results`, but split into individual bytes.

- All data code types except DotCode:

  'quality_isoiec15415': Tuple with the assessment of print quality in compliance with the international standard ISO/IEC 15415:2011. The first element always contains the overall print quality of the symbol; the length of the tuple and the denotation of the remaining elements depend on the specific data code type. According to the standard, the grades are whole numbers from 0 to 4, where 0 is the lowest and 4 the

highest grade. It is important to note what, even though the implementation is based on the parts of the standard which are applicable to software, the computation of the print quality grades depends on the preceding decoding algorithm. Thus, different data code readers (of different vendors) can potentially produce slightly different results in the print quality assessment. See `set_data_code_2d_param` for how to set the algorithm used to determine the module grid for *Data Matrix ECC 200* codes with *'quality_isoiec15415_decode_algorithm'*.

Using these values requires a thorough understanding of the underlying algorithms, and we recommend to read ISO/IEC 15415:2011 along with this documentation.

We recommend to use high quality images without artifacts like defocus, noise, overexposure, or inhomogeneous illumination. Such artifacts influence the result of the print quality grading. Further, to obtain robust grading results, an effective resolution of at least ten pixels per module in width and height is required (see ISO/IEC 15415:2011, Chapter 7.3.3). The quality grades are only computed when the symbol region including the quiet zone is fully in the image, elsewise -1 is returned for the quality grades. For the reference decoding algorithm, more cases lead to quality grades equal to -1. Please refer to *'quality_isoiec15415_decode_algorithm'* for more information.

For the 2D data codes *ECC 200*, *Aztec Code*, *QR Code*, and *Micro QR Code* the print quality is described in a tuple with twelve elements:(*overall quality, contrast, modulation, fixed pattern damage, decode, axial non-uniformity, grid non-uniformity, unused error correction, reflectance margin, print growth, contrast uniformity, aperture*). For *QR Code* and *Micro QR Code* also the *format information* and *version information* are returned as additional grading parameters.

The definition of the respective elements is as follows: The *overall quality* is the minimum of all individual grades. The *contrast* is the range between the minimal and the maximal pixel intensity in the data code domain, and a strong contrast results in a good grading. The *modulation* indicates how strong the amplitudes of the data code modules are. Big amplitudes make the assignment of the modules to black or white more certain, resulting in a high modulation grade. It is to note that the computation of the modulation grade is influenced by the specific level of error correction capacity, meaning that the modulation degrades less for codes with higher error correction capacity. The *contrast uniformity* is the minimum modulation value found in any module. This value is no grade, therefore, it can have real values. It does not affect the *overall quality*. According to ISO/IEC15415:2011, the *print growth* is no grade and is therefore not used for calculating the *overall quality*. Instead, it can be used as an additional information to find out, if the graphical features comprising the symbol have not shrunk or grown from their nominal size. This means that the *print growth* gives some indication to which extent the dark and light modules fill out their module boundaries. The calculation of the print growth does not follow the scheme as specified by ISO/IEC 15415:2011, but instead it considers the specifications as stated by the ISO/IEC standard of the 2D data code to be examined. This means that the computation of the *print growth* for *Aztec Codes* is implemented as described in ISO/IEC 24778:2008. For *ECC 200* the corresponding standard is ANSI/AIM International Specification Data Matrix and for *QR Codes* as well as for *Micro QR Codes* the implementation follows ISO/IEC 18004:2006. For all 2D data codes described above, the *print growth* is calculated in horizontal and vertical direction. The reported grade is the lower rated of the pair.

The *reflectance margin* also indicates (like the modulation) how strong the amplitudes of the data code modules are. The difference to *modulation* is that *reflectance margin* assessed the correct classification of the modules. The fixed pattern of both ECC 200, Aztec Code, QR Code, and Micro QR Code is of high importance for detecting and decoding the codes. Degradation or damage of the fixed pattern, or the respective quiet zones, is assessed with the *fixed pattern damage* quality, which is based on the modulation values.

The *decode* grade indicates if a code was successfully decoded. The *decode* quality is graded *4* when the code could be decoded according to the reference decode algorithm defined in the standard, and *0*, otherwise. Note that HALCON's decode algorithm differs from the reference decode algorithm. Thus, in many cases HALCON can decode the symbol although the decode grade according to the standard is *0*.

Originally, data codes have squared modules, i.e., the width and height of the modules are the same. Due to a potentially oblique view of the camera onto the data code or a defective fabrication of the data code itself, the width to height ratio can be distorted. This deterioration results in a degraded *axial non-uniformity*. If apart from an affine distortion the data code is subject to perspective or any other distortions too this degrades the *grid non-uniformity* quality. As data codes are redundant codes, errors in the modules or codewords can be corrected. The amount of error correcting capacities which is not already used by the present data code symbol is expressed in the *unused error correction* quality. In a way, this grade reflects the reliability of the decoding process. Note, that even codes with an unused

error correction grading of 0, which could possibly mean a false decoding result, can be decoded by the find_data_code_2d operator in a reliable way, because the implemented decoding functionality is more sophisticated and robust compared to the reference decode algorithm proposed by the standard.
For *QR Codes* and *Micro QR Codes* the additional grading parameters *format information* and *version information* are graded in a similar way to *fixed pattern damage*. If no *version information* exists, *'N/A'* is returned.
For the 2D stacked code *PDF417* the print quality is described in a tuple with eight elements: (overall quality, start/stop pattern, codeword yield, unused error correction, modulation, decodability, defects, aperture).
The definition of the respective elements is as follows: The *overall quality* is the minimum of all individual grades. As the PDF417 data code is a stacked code, which can be read by line scan devices as well, print quality assessment is mainly based on techniques for linear bar codes: a set of scan reflectance profiles is generated across the symbol followed by the evaluation of the respective print qualities within each scan, which are finally subsumed as overall print qualities. For more details, the user is referred to the standard for linear symbols ISO/IEC 15416:2016. In *start/stop pattern*, the start and stop patterns are assessed concerning the quality of the reflectance profile and the correctness of the bar and space sequence. The grade *codeword yield* counts and evaluates the relative number of correct decoded words acquired by the set of scan profiles. For the grade *unused error correction*, the relative number of false decoded words within the error correction blocks are counted. As for 2D data codes, the *modulation* grade indicates how strong the amplitudes, i.e., the extremal intensities, of the bars and spaces are. The grade *decodability* measures the deviation of the nominal length of bars and spaces with respect to their reference length. And finally, the grade *defects* refers to a measurement of how perfect the reflectance profiles of bars and spaces are.
The *aperture* is the size of the synthesized aperture in units of the module size of the symbol. This aperture is used to obtain the reference gray scale image during the grading procedure. It is defined in ISO/IEC 15415:2011, Chapter 7.3.3.
To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter *'persistence'* (see set_data_code_2d_param) is set to a value greater than or equal to *0*. For Data Matrix ECC 200, quality grading can also be performed with a *'persistence'* value of *-1*.

'quality_isoiec15415_values': returns a tuple with the raw values for all *'directly measurable'* grades (reported by *'quality_isoiec15415'*). These are grades, whose definition in the ISO/IEC 15415:2011 standard is a *'direct derivative'* of the reflectance (i.e., the gray values) or of geometrical properties of the symbol, or grades that are the result of a *'direct counting'*.
The returned tuple has the same order of elements as the corresponding result with *'quality_isoiec15415'*. For the grades, which are excluded from these lists, the operator reports *'N/A'*. For the 2D data codes *ECC 200*, *Aztec Code*, *QR Code*, and *Micro QR Code* the excluded grades are *overall quality*, *modulation*, *fixed pattern damage*, *decode* and *reflectance margin*. For the 2D stacked code *PDF417* the excluded grades are *overall quality*, *start/stop pattern*, *modulation*, *decodability*, *defects*.
Although the grades *modulation* (for *ECC 200*, *QR Code*, and *Micro QR Code*) and *modulation*, *decodability*, *defects* (for *PDF417*) generally are grading the reflectance properties of the symbol, the standard procedures for their computation involve the symbology decoding routine and error correction mechanism. Therefore there is no *'direct'* raw measurement underlying these grades. The grade *start/stop pattern* (for *PDF417*) is excluded because it is a complex grade, which does not correspond to a single raw measurement value.
All values except the *print growth* are normalized between *0.0* and *1.0*. Hence, for example, a *contrast* value of *0.75* will correspond to a gray value of *191.25* (for BYTE images). For the *print growth*, values between approximately *-0.9* and *0.9* are possible as an output. A negative value corresponds to a *print shrinkage* whereas a positive value reflects a *print growth*. The values can be interpreted as the percentage share that a dark module occupies too little (*print shrinkage*) or too much (*print growth*) of its nominal module size. A value of *-0.50* indicates for example that a dark module is 50% smaller as the nominal module size. If the *print growth* could not be calculated, the value is set to *'N/A'*.
To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter *'persistence'* (see set_data_code_2d_param) is set to a value greater than or equal to *0*. For Data Matrix ECC 200, quality grading can also be performed with a *'persistence'* value of *-1*.

- Data Matrix ECC 200:

'quality_isoiec15415_additional_reflectance_check': Returns the result of the additional reflectance check

described in ISO/IEC 15415:2011 7.7. If the check is successful or one of the grades for Modulation, Decode, or Fixed Pattern Damage is smaller than 1, *'passed'* is returned. If the reflectance interval in the extended area is within the reflectance interval of the code area including the quiet zone, *'passed'* is returned, as well. If the extended region required for this check is not completely contained within the image, *'fov_too_small'* is returned. If the check fails, *'failed'* is returned. In the exceptional case that the quality assessment fails and all grades are -1, *'unchecked'* will be returned.

'quality_isoiec15415_intermediate': Tuple with intermediate results that are determined during the assessment of print quality for ECC 200 codes in compliance with the international standard ISO/IEC 15415: 2011 and ISO/IEC 16022:2006. Using these values requires a thorough understanding of the underlying algorithms, and we strongly recommend to read ISO/IEC 15415:2011 and ISO/IEC 16022:2006 along with this documentation.

A description of the intermediate results is given below. The returned intermediate grades (*'quality_isoiec15415_intermediate'*) and values (*'quality_isoiec15415_intermediate_values'*) are the minimal grades and values for the code under inspection. The names of the available intermediate results can be queried with *'quality_isoiec15415_intermediate_labels'*.

- *'Rmin'* and *'Rmax'*: The minimum and maximum reflectance value in the sample area of the symbol (see Chapter 7.6, ISO/IEC 15415:2011). There are no corresponding grades for these values.
- *'L1'* and *'L2'*: The grades of the vertical and horizontal portions of the outside L of the fixed pattern as defined in Chapter M.1.2, ISO/IEC 16022:2006. The corresponding number of damaged modules is returned as value.
- *'QZL1'* and *'QZL2'*: The grades of the vertical and horizontal portions of the quiet zone adjacent to L1 and L2, respectively (see Chapter M.1.2, ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
- *'Transition Ratio'*: The grade for the transition ratio test described in Chapter M.1.3 b), ISO/IEC 16022:2006. The transition ratio TR is returned as value. It measures the ratio between the number of transitions on the clock track and the associated solid area.
- *'Clock track regularity'*: The grade for the clock track regularity test as described in Chapter M.1.3 e), ISO/IEC 16022:2006. If for any group of five adjacent modules more than two modules are considered as errors, this grade is 0, otherwise its 4. There is no corresponding value.
- *'Clock track damage'*: The grade for the clock track damage (see Chapter M.1.3 f), ISO/IEC 16022: 2006). The corresponding number of damaged modules is returned as value.
- *'Solid fix pattern'*: The grade for the solid fixed pattern (see Chapter M.1.3 g), ISO/IEC 16022: 2006). The corresponding number of damaged modules is returned as value.
- *'Clock track and adjacent solid pattern'*: The overall grade for the clock track and adjacent solid pattern (see Chapter M.1.3 k), ISO/IEC 16022:2006). There is no corresponding value.
- *'Average grade'*: The average grade for the for the fixed pattern. It is based on the grades for the L1, L2, QZL1, QZL2, and the overall grade for the clock track and adjacent solid pattern (see Chapter M.1.4, ISO/IEC 16022:2006). There is no corresponding value.

The grade for *fixed pattern damage* for the symbol is given by the minimum of the grades for *'L1'*, *'L2'*, *'QZL1'*, *'QZL2'*, *'Clock track and adjacent solid pattern'* and *'Average grade'* (see Chapter M1.4, ISO/IEC 16022:2006).

'quality_semi_t10_values': Tuple with the assessment of the print quality in compliance with the international standard SEMI T10-0701.

We recommend to use high quality images without artifacts like defocus, noise, overexposure, or inhomogeneous illumination. Such artifacts influence the result of the print quality grading. Further, to obtain robust grading results, an effective resolution of at least ten pixels per module in width and height is required. The quality grades are only computed when the symbol is fully in the image, elsewise -1 is returned for the quality grades.

The direct mark quality is described in a tuple with 21 elements: [P1 Row, P1 Column, P2 Row, P2 Column, P3 Row, P3 Column, P4 Row, P4 Column, Rows, Columns, Symbol Contrast, Symbol Contrast SNR, Horizontal Mark Growth, Vertical Mark Growth, Data Matrix Cell Width, Data Matrix Cell Height, Horizontal Mark Misplacement, Vertical Mark Misplacement, Cell Defects, Finder Pattern Defects, Unused Error Correction]. Note that the *Unused Error Correction* is returned for each Reed-Solomon block. Therefore, the actual length of the returned tuple depends on the number of Reed-Solomon blocks.

The definition of the respective elements is as follows: The first eight entries contain the coordinates of the four corners. The first corner is located at the vertical finder pattern. The remaining corners follow contour clockwise (for non mirrored codes). With *Rows* and *Columns* the numbers of rows and columns of the code are reported.

The value for *Symbol Contrast* reports the contrast between light and dark classified symbol pixels with respect to the full gray value range (255 for byte images) in percent. *Symbol Contrast SNR* is the corresponding signal-to-noise ratio. If the value is infinite, *'N/A'* is returned.
The values for *Horizontal Mark Growth* and *Vertical Mark Growth* represent the width and height, respectively, of marked modules with respect to the sum of the width and height, respectively, of a marked module and a space module in percent. A value of 50% is optimal. If some parts of the alternating pattern are hidden, *'N/A'* is returned.
The values for *Data Matrix Cell Width* and *Data Matrix Cell Height* report the average module width and height. They are computed from the four corner points and the number of rows and columns of the code.
The values for *Horizontal Mark Misplacement* and *Vertical Mark Misplacement* report the displacement of the alternating pattern marks' centers in horizontal and vertical direction, respectively. These values are given in percent with respect to *Data Matrix Cell Width* and *Data Matrix Cell Height*, respectively. If some parts of the alternating pattern are hidden, *'N/A'* is returned.
The value for *Cell Defects* reports the percentage of incorrectly classified symbol pixels.
The value for *Finder pattern Defects* reports the percentage of finder pattern pixels that would be classified incorrectly.
The value for *Unused Error Correction* reports the error correction capacities that are not already used by each Reed-Solomon block.

'quality_semi_t10_labels': Convenience value labels of the elements of the tuple returned when calling `get_data_code_2d_results` with *'quality_semi_t10_values'*. If the ECC 200 code has more than one Reed-Solomon block, the label tuple is extended by the corresponding values.

'quality_isoiec15415_reflectance_margin_module_grades': Tuple with the reflectance margin module grades that are determined during the assessment of print quality according to the ISO/IEC 15415:2011 standard Chapter 7.8.4.3. This includes the finder pattern modules and the 4 quiet zones adjacent to the symbol (2 horizontal and 2 vertical).
If the symbol size is $Rows \cdot Columns$, the tuple size is $(Rows + 2) \cdot (Columns + 2)$ as the 4 quiet zones are included. The tuple is sorted row by row, where the first row is the upper quiet zone and the last row is the bottom one (or QZL2 as described in ISO/IEC 16022:2006 Annex M.1.2, Figure M.1).
The computed grades for each module will be in the range 0 to 4. For unused data modules the module grade is not computed, in this case the corresponding tuple value will be -1.

'quality_isoiec15415_rows': Tuple with the image row coordinates of the points within the symbol modules for which the module grades are computed with the parameter *'quality_isoiec15415_reflectance_margin_module_grades'*.
The returned tuple has the same number and order of elements as the corresponding result with *'quality_isoiec15415_reflectance_margin_module_grades'*.

'quality_isoiec15415_cols': Tuple with the image column coordinates of the points within the symbol modules for which the module grades are computed with the parameter *'quality_isoiec15415_reflectance_margin_module_grades'*.
The returned tuple has the same number and order of elements as the corresponding result with *'quality_isoiec15415_reflectance_margin_module_grades'*.

'quality_isoiec29158_reflectance_margin_module_grades': Similar to *'quality_isoiec15415_reflectance_margin_module_grades'* but in compliance with the ISO/IEC TR 29158 (AIM DPM-1-2006) print quality standard.

'quality_aimdpm_1_2006_reflectance_margin_module_grades': See the entry for *'quality_isoiec29158_reflectance_margin_module_grades'*.

'quality_isoiec29158_reflectance_margin_module_float_grades': Similar to *'quality_isoiec29158_reflectance_margin_module_grades'* but in compliance with the ISO/IEC 29158: 2020 print quality standard. The underlying grades are returned with one decimal place.

'quality_isoiec29158_rows' **and** *'quality_aimdpm_1_2006_rows'*: Similar to *'quality_isoiec15415_rows'* but related to *'quality_isoiec29158_reflectance_margin_module_grades'* and *'quality_aimdpm_1_2006_reflectance_margin_module_grades'*.

'quality_isoiec29158_cols' **and** *'quality_aimdpm_1_2006_cols'*: Similar to *'quality_isoiec15415_cols'* but related to *'quality_isoiec29158_reflectance_margin_module_grades'* and *'quality_aimdpm_1_2006_reflectance_margin_module_grades'*.

- Data Matrix ECC 200, Aztec Code, QR Code and Micro QR Code:

'quality_isoiec29158' **and** *'quality_aimdpm_1_2006'***:** Tuple with the assessment of print quality in compliance with ISO/IEC TR 29158. This standard was previously established by the Automatic Identification Manufacturers as AIM DPM-1-2006. ISO/IEC TR 29158 is an extension to ISO/IEC 15415:2011 standard, which defines certain requirements for the gray-scale properties of the data code image and in doing so improves the reproducibility of the grading results among different vendors.
Using these values requires a thorough understanding of the underlying algorithms, and we recommend to read ISO/IEC TR 29158 (AIM DPM-1-2006) and ISO/IEC 15415:2011 along with this documentation.
It is very important to note that an ISO/IEC TR 29158 (AIM DPM-1-2006) standard conforming print quality assessment requires interactive image acquisition! No images of a data code symbol should be regarded if there is no information for the camera-lighting setup used to acquire these images. In most cases this implies that the user should set up and use her/his own camera-lighting configuration. Refer to ISO/IEC TR 29158 (AIM DPM-1-2006) for some prescribed camera-lighting configurations and general configuration principles that are relevant for the standard. Note also that, even though the implementation is strictly based on the standard, the computation of the print quality grades depends on the decoding algorithm used. Thus, the print quality inspection results are relevant only for the 2D data code reader implemented with HALCON.
Calling `get_data_code_2d_results` with argument *'quality_isoiec29158'* or *'quality_aimdpm_1_2006'* assumes that the image being processed fulfills the two criteria explained in detail below. The returned tuple represents the 13 print quality elements: [overall quality, cell contrast, cell modulation, fixed pattern damage, decode, axial non-uniformity, grid non-uniformity, unused error correction, mean light, reflectance margin, print growth, contrast uniformity, aperture]. The first eight as well as the last four grades have the same meaning as the ISO/IEC 15415:2011 grades with two exceptions: *contrast* and *modulation* are renamed to *cell contrast* and *cell modulation*, respectively, to reflect differences in the methods specified with both standards for estimating those values. The value of *mean light* is not a grade specified with ISO/IEC TR 29158 (AIM DPM-1-2006) standard. It is an estimation for the quality of the processed image computed as the mean gray-scale value of the centers of the light data code modules. It is a value between 0.0 and 1.0, corresponding to 0% to 100% of the maximum gray-scale value (255 for byte images). For *QR Code* and *Micro QR Code* also the *format information* and *version information* are returned as additional grading parameters.
The essence of the standard is a procedure for the adjustment of the camera system response (SR): *exposure time*, *gain* and/or another specific setting of the user's camera-lighting setup. The goal is to obtain an image of the inspected data code symbol with optimal gray-scale properties. In the image processing context, which is in the main focus of the standard, this is also the key to reproducibility of the grading results. An image has the required gray-scale properties when its *'mean light'* value is between 70% and 86% (*0.70* and *0.86*, respectively). Trying to achieve this condition for images of physically low-contrast data code symbols results usually in very high SR levels. Therefore, the standard defines additionally a calibration routine, which identifies for comparison purposes the normal (calibrated) system response settings (SRcal) by evaluating images of an object with well-known reflectance properties (such as NIST traceable calibrated conformance test card). Finally, the **two image acquisition criteria** for an image read: **first**, the image must have a *mean light* value between 70% and 86% (*0.70* and *0.86*, respectively); **second**, it has to be obtained with system response (SR) settings fulfilling: SR/SRcal ≤ 16. If no image of the data code symbol can be obtained to fulfill both criteria, the symbol must be graded with 0.
As neither the adjustment of the system response nor the verification of the SR criterion can be carried out from within a HALCON operator, the assessment of the AIM DPM-1-2006 quality grades should be performed in an appropriate program setup. The user is referred to two example programs provided with her/his installation of HALCON (calibration_aimdpm_1_2006.hdev and print_quality_aimdpm_1_2006.hdev in the directory HALCONEXAMPLES/hdevelop/Identification/Data-Code), which demonstrate the calibration and the grade evaluation routines, respectively. Both image criteria, as well as further details regarding the general camera setup and image acquisition are also explained and demonstrated there. Everyone who intends to use the AIM DPM-1-2006 grading standard can use the programs as a starting point and adapt them for her/his own camera-lighting setup.
The *aperture* is the size of the synthesized aperture in units of the module size of the symbol. This aperture is used to obtain the reference gray scale image during the grading procedure and selected by the procedure described in ISO/IEC TR 29158 (AIM DPM-1-2006), Chapter 7.3.
To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter *'persistence'* (see `set_data_code_2d_param`) is set to a value greater than or equal to *0*. For Data Matrix ECC 200, quality grading can also be performed with a *'persistence'*

value of *-1*.

'quality_isoiec29158_values' **and** *'quality_aimdpm_1_2006_values'***:** Similar to *'quality_isoiec15415_values'*, the raw values for all *'directly measurable'* grades are reported but in compliance with the ISO/IEC TR 29158 (AIM DPM-1-2006) print quality standard. The list of the reported and the excluded raw measurement values is the same as with *'quality_isoiec15415_values'*. The auxiliary ISO/IEC TR 29158 (AIM DPM-1-2006) grade *mean light* is reported in the same format (between 0.0 and 1.0) both by *'quality_isoiec29158'* and *'quality_isoiec29158_values'* (*'quality_aimdpm_1_2006'* and *'quality_aimdpm_1_2006_values'*).
To be able to compute the quality values for QR Code, Micro QR Code, PDF417, and Aztec Code, it is necessary that the parameter *'persistence'* (see `set_data_code_2d_param`) is set to a value greater than or equal to *0*. For Data Matrix ECC 200, quality grading can also be performed with a *'persistence'* value of *-1*.

'quality_isoiec29158_float_grades' Similar to *'quality_isoiec29158'*, but with continuous grading following ISO/IEC 29158:2020. The underlying grades are returned with one decimal place.
To be able to compute the quality values for QR Code, Micro QR Code, and Aztec Code, it is necessary that the parameter *'persistence'* (see `set_data_code_2d_param`) is set to a value greater than or equal to *0*. For Data Matrix ECC 200, quality grading can also be performed with a *'persistence'* value of *-1*.

- Data Matrix ECC 200:

'quality_isoiec29158_intermediate' **and** *'quality_aimdpm_1_2006_intermediate'***:** Tuple with intermediate results that are determined during the assessment of print quality of ECC 200 codes in compliance with the international standards ISO/IEC TR 29158 (or AIM DPM-1-2006), ISO/IEC 15415:2011 and ISO/IEC 16022:2006. Using these values requires a thorough understanding of the underlying algorithms, and we strongly recommend to read ISO/IEC TR 29158 (AIM DPM-1-2006), ISO/IEC 15415:2011 and ISO/IEC 16022:2006 along with this documentation.
A description of the intermediate results is given below. The returned intermediate grades (*'quality_isoiec29158_intermediate'* or *'quality_aimdpm_1_2006_intermediate'*) and values (*'quality_isoiec29158_intermediate_values'* or *'quality_aimdpm_1_2006_intermediate_values'*) are the minimal grades and values for the code under inspection. The names of the available intermediate results can be queried with *'quality_isoiec29158_intermediate_labels'* or *'quality_aimdpm_1_2006_intermediate_labels'*.

  - *'T2'*: The threshold created using the histogram of the reference gray-scale image pixel values at each intersection point of the grid using the method defined in Annex A, ISO/IEC TR 29158 (AIM DPM-1-2006).
  - *'MD'*: The value for MeanDark corresponding to T2, which is determined using the method defined in Annex A, ISO/IEC TR 29158 (AIM DPM-1-2006).
  - *'MLtarget'*: The value for MeanLight corresponding to T2, which is determined using the method defined in Annex A, ISO/IEC TR 29158 (AIM DPM-1-2006).
  - *'L1'* and *'L2'*: The grades of the vertical and horizontal portions of the outside L of the fixed pattern as defined in Chapter M.1.2, ISO/IEC 16022:2006. The corresponding number of damaged modules is returned as value.
  - *'QZL1'* and *'QZL2'*: The grades of the vertical and horizontal portions of the quiet zone adjacent to L1 and L2, respectively (see Chapter M.1.2, ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
  - *'Transition Ratio'*: The grade for the transition ratio test described in Chapter M.1.3 b), ISO/IEC 16022:2006. The transition ratio TR is returned as value. It measures the ratio between the number of transitions on the clock track and the associated solid area.
  - *'Clock track regularity'*: The grade for the clock track regularity test as described in Chapter M.1.3 e), ISO/IEC 16022:2006. If for any group of five adjacent modules more than two modules are considered as errors, this grade is 0, otherwise its 4. There is no corresponding value.
  - *'Clock track damage'*: The grade for the clock track damage (see Chapter M.1.3 f), ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
  - *'Solid fix pattern'*: The grade for the solid fixed pattern (see Chapter M.1.3 g), ISO/IEC 16022:2006). The corresponding number of damaged modules is returned as value.
  - *'Clock track and adjacent solid pattern'*: The overall grade for the clock track and adjacent solid pattern (see Chapter M.1.3 k), ISO/IEC 16022:2006). There is no corresponding value.

  - *'Distributed damage grade'*: The average grade for the for the fixed pattern. It is based on the grades for the L1, L2, QZL1, QZL2, and the overall grade for the clock track and adjacent solid pattern (see Chapter M.1.4, ISO/IEC 16022:2006, and Chapter 9.4, ISO/IEC TR 29158 (AIM DPM-1-2006)). There is no corresponding value.

  The grade for *fixed pattern damage* for the symbol is given by the minimum of the grades for *'L1'*, *'L2'*, *'QZL1'*, *'QZL2'*, *'Clock track and adjacent solid pattern'* and *'Distributed damage grade'* (see Chapter M1.4, ISO/IEC 16022:2006).

'quality_isoiec29158_intermediate_float_grades': Similar to *'quality_isoiec29158_intermediate'* but in compliance with the ISO/IEC 29158 print quality standard. The underlying grades are returned with one decimal place.

- Data Matrix ECC 200, QR Code, Aztec Code, and DotCode:

  'structured_append': If the symbol is part of a group of symbols ("Structured Append"), this parameter contains (1) the index of the symbol in the group, (2) the number of symbols that belong to the group, and (3) a number that serves as a group identifier. For Aztec Codes the group identifier is a string. If the symbol is not part of a group of symbols ("Structured Append") a empty tuple is returned in case of Aztec Codes.

  'gs1_lint_passed': If the symbol contains a GS1 formatted string and the data code model was created to read GS1 codes, additional linting can be performed on the contained string. *'gs1_lint_passed'* will return *'true'*, if this is successful. Otherwise, *'false'* is returned. Linting checks that
  - one AI (Application Identifier) does not occur multiple times with different contents,
  - AIs required by other AIs are contained,
  - AIs excluded by other AIs are not included, and that
  - specific formatting rules for AIs are respected.

  'gs1_lint_result': *'gs1_lint_result'* performs the linting tests documented in *'gs1_lint_passed'*. If the linting fails, a list of human-readable error messages is returned, if it is successful, *'ok'* is returned.

- DotCode:

  DotCodes are able to encode separate data messages in one single DotCode symbol. According to the AIM International Symbology Specification for DotCode, such separated messages should be treated as if they come from different symbols. In the following list, all results are listed which can be queried for DotCodes and need a dedicated result for each separated message segment. They are all postfixed with *'_separated'*. They return a tuple with the results separated for each separated message segment. In case of a symbol with separated messages the correspondent results without *'_separated'* postfix returns the result for the first separated message segment. Note: If one of the separated messages can not be decoded, no results are returned.

  'symbology_ident_separated': see *'symbology_ident'* for details.

  'decoded_string_separated': see *'decoded_string'* for details.

  'structured_append_separated': see *'structured_append'* for details.

  'reader_programming_separated': see *'reader_programming'* for details.

  'decoded_data_separated': see *'decoded_data'* for details.

  'segment_num': Number of separated message segments.

Status message

The status parameter that can be queried for all candidates reveals why and where in the evaluation phase a candidate was discarded. The following list shows the most important status messages in the order of their generation during the evaluation phase:

- Data Matrix ECC 200:

  'aborted: too close to image border': The symbol candidate is too close to the border. Only symbols that are completely within the image can be read.

  'aborted adjusting: ...': It is not possible to determine the exact position of the finder pattern in the processing image.

  'aborted finder pattern: ...': It is not possible to determine the width of one of the two legs of the L-shaped finder pattern.

'aborted leg widths: widths of the finder pattern legs differ too much': The widths of the two legs of the L-shaped finder pattern differ too much.

'aborted alternating side: ...': For one dimension of the candidate, two opposite borders were found during the symbol search phase. However, it is not possible to determine which is the alternating and which the solid side of the finder pattern.

'aborted border search: ...': For one dimension of the candidate, only the border that belongs to the solid side of the finder pattern was found during the symbol search phase. Searching the opposite (the alternating) side failed.

'aborted symbol: invalid size': The number of rows and columns of the symbol that was deduced from the alternating pattern does not yield in a valid ECC 200 code.

'aborted symbol: size does not fit strict model definition': Although the deduced symbol size is a valid ECC 200 size, it is not inside the range predefined by the model.
