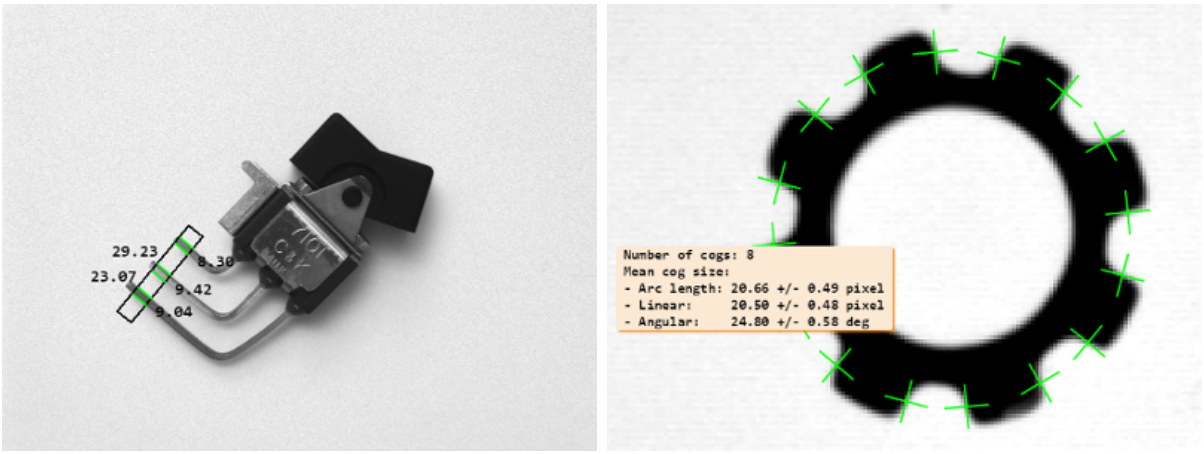
Chapter 1

1D Measuring

This chapter contains operators for 1D measuring.

Concept of 1D measuring

With 1D measuring, edges, i.e., transitions from light to dark or from dark to light, can be located along a predefined line or arc. This allows you to measure the dimension of parts fast and easily with high accuracy. Note that if you want to measure the dimensions of geometric primitives like circles, ellipses, rectangles, or lines, and approximate values for the positions, orientations, and geometric shapes are known, 2D Metrology may be a suitable alternative.



(1) (2)

Measure edges and the distances between them along a line (1) or along an arc (2). These images are from the example programs fuzzy_measure_pin.hdev and measure_ring.hdev.

In the following, the steps that are required to use 1D measuring are described briefly.

Generate measure object: First, a measure object must be generated that describes the region of interest for the measurement. If the measurement should be performed along a line, the measure object is defined by a rectangle. If it should be performed along an arc, the measure object is defined as an annular arc. The measure objects are generated by the operators

- `gen_measure_rectangle2` or
- `gen_measure_arc`.

Note that you can use shape-based matching (see chapter Matching / Shape-Based) to automatically align the measure objects.

Perform the measurement: Then, the actual measurement is performed. For this, typically one of the following operators is used:

- measure_pos extracts straight edges perpendicular to the main axis of the measure object and returns the positions of the edge centers, the edge amplitudes, and the distances between consecutive edges.
- measure_pairs extracts straight edge pairs perpendicular to the main axis of the measure object and returns the positions of the edge centers of the edge pairs, the edge amplitudes for the edge pairs, the distances between the edges of an edge pair, and the distances between consecutive edge pairs.
- measure_thresh extracts points with a particular gray value along the main axis of the measure object and returns their positions and the distances between consecutive points.

Alternatively, if there are extra edges that do not belong to the measurement, fuzzy measuring can be applied. Here, so-called fuzzy rules, which describe the features of good edges, must be defined. Possible features are, e.g., the position, the distance, the gray values, or the amplitude of edges. These functions are created with create_funct_1d_pairs and passed to the tool with set_fuzzy_measure or set_fuzzy_measure_norm_pair. Then, based on these rules, one of the following operators will extract the most appropriate edges:

- fuzzy_measure_pos extracts straight edges perpendicular to the main axis of the measure object and returns the positions of the edge centers, the edge amplitudes, the fuzzy scores, and the distances between consecutive edges.
- fuzzy_measure_pairs extracts straight edge pairs perpendicular to the main axis of the measure object and returns the positions of the first and second edges of the edge pairs, the edge amplitudes for the edge pairs, the positions of the centers of the edge pairs, the fuzzy scores, the distances between the edges of an edge pair, and the distances between consecutive edge pairs.
- fuzzy_measure_pairing is similar to fuzzy_measure_pairs with the exception that it is also possible to extract interleaving and included pairs using the parameter Pairing.

Alternatively to the automatic extraction of edges or points within the measure object, you can also extract a one-dimensional gray value profile perpendicular to the rectangle or annular arc and evaluate this gray value information according to your needs. The gray value profile within the measure object can be extracted with the operator

- measure_projection.

Destroy measure object handle: When you no longer need the measure object, you destroy it by passing the handle to

- close_measure.

Further operators

In addition to the operators mentioned above, you can use reset_fuzzy_measure to discard a fuzzy function of a fuzzy set that was set via set_fuzzy_measure or set_fuzzy_measure_norm_pair before, translate_measure to translate the reference point of the measure object to a specified position, write_measure and read_measure to write the measure object to file and read it from file again, and serialize_measure and deserialize_measure to serialize and deserialize the measure object.

Glossary

In the following, the most important terms that are used in the context of 1D Measuring are described.

measure object A data structure that contains a specific region of interest that is prepared for the extraction of straight edges which lie perpendicular to the major axis of a rectangle or an annular arc.

annular arc A circular arc with an associated width.

Further Information

See also the "Solution Guide Basics" and "Solution Guide on 1D Measuring" for further details about 1D Measuring.

Learn about 1D Measuring and many other topics in interactive online courses at our MVTec Academy .

close_measure (: : MeasureHandle :)

Delete a measure object.

close_measure deletes the measure object given by MeasureHandle. The memory used for the measure object is freed.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Parameters

▷ **MeasureHandle** (input_control) ..... measure ⇝ *handle*
Measure object handle.

Result

If the parameter values are correct the operator close_measure returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MeasureHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

gen_measure_rectangle2, gen_measure_arc, measure_pos, measure_pairs

Alternatives

clear_handle

clear_handle

Module

1D Metrology

deserialize_measure (: : SerializedItemHandle : MeasureHandle)

Deserialize a serialized measure object.

deserialize_measure deserializes a measure object, that was serialized by serialize_measure (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized measure object is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created measure object with the handle MeasureHandle.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **MeasureHandle** (output_control) ..... measure ⇝ *handle*
Measure object handle.

Result

If the parameters are valid, the operator deserialize_measure returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

1D Metrology

fuzzy_measure_pairing (Image : : MeasureHandle, Sigma, AmpThresh, FuzzyThresh, Transition, Pairing, NumPairs : RowEdgeFirst, ColumnEdgeFirst, AmplitudeFirst, RowEdgeSecond, ColumnEdgeSecond, AmplitudeSecond, RowPairCenter, ColumnPairCenter, FuzzyScore, IntraDistance)

Extract straight edge pairs perpendicular to a rectangle or an annular arc.

fuzzy_measure_pairing serves to extract *straight* edge pairs that lie *perpendicular* to the major axis of a rectangle or an annular arc.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

The extraction algorithm of fuzzy_measure_pairing is identical to fuzzy_measure_pairs (see there for details) with the exception, that it is also possible to extract interleaving and included pairs using the parameter Pairing. Currently only *'no_restriction'* is available, which returns all possible edge pairs, allowing interleaving and inclusion of pairs.

Only the best scored NumPairs edge pairs are returned, whereas 0 indicates to return all possible found edge combinations.

The selected edges are returned as single points, which lie on the major axis of the rectangle or annular arc. The corresponding edge amplitudes are returned in AmplitudeFirst and AmplitudeSecond, the fuzzy scores in FuzzyScore. In addition, the distance between each edge pair is returned in IntraDistance, corresponding to the distance between EdgeFirst[i] and EdgeSecond[i].

Attention

fuzzy_measure_pairing only returns meaningful results if the assumptions that the edges are straight and perpendicular to the major axis of the rectangle or annular arc are fulfilled. Thus, it should not be used to extract edges from curved objects, for example. Furthermore, the user should ensure that the rectangle or annular arc is as close to perpendicular as possible to the edges in the image. Additionally, Sigma must not become larger than approx. 0.5 * Length1 (for Length1 see gen_measure_rectangle2).

It should be kept in mind that fuzzy_measure_pairing ignores the domain of Image for efficiency reasons. If certain regions in the image should be excluded from the measurement a new measure object with appropriately modified parameters should be generated.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2 / real
Input image.

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **Sigma** (input_control) . . . . . number ⇝ *real*
Sigma of Gaussian smoothing.
Default: 1.0
Suggested values: Sigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ Sigma ≤ 100 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **AmpThresh** (input_control) ..... number ⇝ *real*
Minimum edge amplitude.
Default: 30.0
Suggested values: AmpThresh ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ AmpThresh ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **FuzzyThresh** (input_control) ..... number ⇝ *real*
Minimum fuzzy value.
Default: 0.5
Suggested values: FuzzyThresh ∈ {0.1, 0.3, 0.5, 0.7, 0.9}
Value range: 0.0 ≤ FuzzyThresh ≤ 1.0 (lin)
Recommended increment: 0.1

▷ **Transition** (input_control) ..... string ⇝ *string*
Select the first gray value transition of the edge pairs.
Default: 'all'
List of values: Transition ∈ {'all', 'positive', 'negative'}

▷ **Pairing** (input_control) ..... string ⇝ *string*
Constraint of pairing.
Default: 'no_restriction'
List of values: Pairing ∈ {'no_restriction'}

▷ **NumPairs** (input_control) ..... number ⇝ *integer*
Number of edge pairs.
Default: 10
Suggested values: NumPairs ∈ {0, 1, 10, 20, 50}
Value range: 0 ≤ NumPairs
Recommended increment: 1

▷ **RowEdgeFirst** (output_control) ..... point.y-array ⇝ *real*
Row coordinate of the first edge.

▷ **ColumnEdgeFirst** (output_control) ..... point.x-array ⇝ *real*
Column coordinate of the first edge.

▷ **AmplitudeFirst** (output_control) ..... real-array ⇝ *real*
Edge amplitude of the first edge (with sign).

▷ **RowEdgeSecond** (output_control) ..... point.y-array ⇝ *real*
Row coordinate of the second edge.

▷ **ColumnEdgeSecond** (output_control) ..... point.x-array ⇝ *real*
Column coordinate of the second edge.

▷ **AmplitudeSecond** (output_control) ..... real-array ⇝ *real*
Edge amplitude of the second edge (with sign).

▷ **RowPairCenter** (output_control) ..... point.y-array ⇝ *real*
Row coordinate of the center of the edge pair.

▷ **ColumnPairCenter** (output_control) ..... point.x-array ⇝ *real*
Column coordinate of the center of the edge pair.

▷ **FuzzyScore** (output_control) ..... real-array ⇝ *real*
Fuzzy evaluation of the edge pair.

▷ **IntraDistance** (output_control) ..... real-array ⇝ *real*
Distance between the edges of the edge pair.

Result

If the parameter values are correct the operator fuzzy_measure_pairing returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

fuzzy_measure_pairs (Image : : MeasureHandle, Sigma, AmpThresh, FuzzyThresh, Transition : RowEdgeFirst, ColumnEdgeFirst, AmplitudeFirst, RowEdgeSecond, ColumnEdgeSecond, AmplitudeSecond, RowEdgeCenter, ColumnEdgeCenter, FuzzyScore, IntraDistance, InterDistance)

Extract straight edge pairs perpendicular to a rectangle or an annular arc.

fuzzy_measure_pairs serves to extract *straight* edge pairs which lie *perpendicular* to the major axis of a rectangle or an annular arc. In addition to measure_pairs it uses fuzzy functions to evaluate and select the edge pairs.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

The extraction algorithm of fuzzy_measure_pairs is identical to fuzzy_measure_pos. In addition, neighboring edges are grouped to pairs. To extract pairs that intersect or include each other, use fuzzy_measure_pairing.

If Transition = *'positive'*, the edge points with a dark-to-light transition in the direction of the major axis of the rectangle or annular arc are returned in RowEdgeFirst and ColumnEdgeFirst. In this case, the corresponding edges with a light-to-dark transition are returned in RowEdgeSecond and ColumnEdgeSecond. If Transition = *'negative'*, the behavior is exactly opposite. If Transition = *'all'*, the first detected edge defines the transition for RowEdgeFirst and ColumnEdgeFirst. I.e., dependent on the positioning of the measure object, edge pairs with a light-dark-light transition or edge pairs with a dark-light-dark transition are returned. This is suited, e.g., to measure objects with different brightness relative to the background.

Having extracted subpixel edge locations, the edges are paired. The pairing algorithm groups the edges such that interleavings and inclusions of pairs are prohibited. The features of an edge pair are evaluated by a fuzzy function, which can be set by set_fuzzy_measure or set_fuzzy_measure_norm_pair. Which edge pairs are selected can be determined with the parameter FuzzyThresh, which constitutes a threshold on the weight over all fuzzy sets, i.e., the geometric mean of the weights of the defined fuzzy functions.

The selected edges are returned as single points, which lie on the major axis of the rectangle or annular arc. The corresponding edge amplitudes are returned in AmplitudeFirst and AmplitudeSecond, the fuzzy scores in FuzzyScore. In addition, the distance between each edge pair is returned in IntraDistance and the distance between consecutive edge pairs is returned in InterDistance. Here, IntraDistance[i] corresponds to the distance between EdgeFirst[i] and EdgeSecond[i], while InterDistance[i] corresponds to the distance between EdgeSecond[i] and EdgeFirst[i+1], i.e., the tuple InterDistance contains one element less than the tuples of the edge pairs.

Attention

fuzzy_measure_pairs only returns meaningful results if the assumptions that the edges are straight and perpendicular to the major axis of the rectangle or annular arc are fulfilled. Thus, it should not be used to extract edges from curved objects, for example. Furthermore, the user should ensure that the rectangle or a annular arc is as close to perpendicular as possible to the edges in the image. Additionally, Sigma must not become larger than approx. 0.5 * Length1 (for Length1 see gen_measure_rectangle2).

It should be kept in mind that fuzzy_measure_pairs ignores the domain of Image for efficiency reasons. If certain regions in the image should be excluded from the measurement a new measure object with appropriately modified parameters should be generated.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2 / real
Input image.

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **Sigma** (input_control) . . . . . number ⇝ *real*
Sigma of Gaussian smoothing.
Default: 1.0
Suggested values: `Sigma` ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ `Sigma` ≤ 100 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **AmpThresh** (input_control) . . . . . number ⇝ *real*
Minimum edge amplitude.
Default: 30.0
Suggested values: `AmpThresh` ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ `AmpThresh` ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **FuzzyThresh** (input_control) . . . . . number ⇝ *real*
Minimum fuzzy value.
Default: 0.5
Suggested values: `FuzzyThresh` ∈ {0.1, 0.3, 0.5, 0.7, 0.9}
Value range: 0.0 ≤ `FuzzyThresh` ≤ 1.0 (lin)
Recommended increment: 0.1

▷ **Transition** (input_control) . . . . . string ⇝ *string*
Select the first gray value transition of the edge pairs.
Default: 'all'
List of values: `Transition` ∈ {'all', 'positive', 'negative'}

▷ **RowEdgeFirst** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinate of the first edge point.

▷ **ColumnEdgeFirst** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinate of the first edge point.

▷ **AmplitudeFirst** (output_control) . . . . . real-array ⇝ *real*
Edge amplitude of the first edge (with sign).

▷ **RowEdgeSecond** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinate of the second edge point.

▷ **ColumnEdgeSecond** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinate of the second edge point.

▷ **AmplitudeSecond** (output_control) . . . . . real-array ⇝ *real*
Edge amplitude of the second edge (with sign).

▷ **RowEdgeCenter** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinate of the center of the edge pair.

▷ **ColumnEdgeCenter** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinate of the center of the edge pair.

▷ **FuzzyScore** (output_control) . . . . . real-array ⇝ *real*
Fuzzy evaluation of the edge pair.

▷ **IntraDistance** (output_control) . . . . . real-array ⇝ *real*
Distance between edges of an edge pair.

▷ **InterDistance** (output_control) . . . . . real-array ⇝ *real*
Distance between consecutive edge pairs.

Result

If the parameter values are correct the operator `fuzzy_measure_pairs` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

fuzzy_measure_pos, measure_pos

Module

1D Metrology

fuzzy_measure_pos (Image : : MeasureHandle, Sigma, AmpThresh, FuzzyThresh, Transition : RowEdge, ColumnEdge, Amplitude, FuzzyScore, Distance)

Extract straight edges perpendicular to a rectangle or an annular arc.

fuzzy_measure_pos extracts *straight* edges which lie *perpendicular* to the major axis of a rectangle or an annular arc. In addition to measure_pos it uses fuzzy functions to evaluate and select the edges.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

The algorithm of fuzzy_measure_pos works by averaging the gray values in "slices" perpendicular to the major axis of the rectangle or annular arc in order to obtain a one-dimensional edge profile. The sampling is done at subpixel positions in the image Image at integer row and column distances (in the coordinate frame of the rectangle) from the center of the rectangle. Since this involves some calculations which can be used repeatedly in several measurements, the operator gen_measure_rectangle2 is used to perform these calculations only once, thus increasing the speed of fuzzy_measure_pos significantly. Since there is a trade-off between accuracy and speed in the subpixel calculations of the gray values, and thus in the accuracy of the extracted edge positions, different interpolation schemes can be selected in gen_measure_rectangle2. (The interpolation only influences rectangles not aligned with the image axes and annular arcs.) The measure object generated with gen_measure_rectangle2 is passed in MeasureHandle.

After the one-dimensional edge profile has been calculated, subpixel edge locations are computed by convolving the profile with the derivatives of a Gaussian smoothing kernel of standard deviation Sigma. Salient edges can be selected with the parameter AmpThresh, which constitutes a threshold on the amplitude, i.e., the absolute value of the first derivative of the edge. Additionally, it is possible to select only positive edges, i.e., edges which constitute a dark-to-light transition in the direction of the major axis of the rectangle (Transition = *'positive'*), only negative edges, i.e., light-to-dark transitions (Transition = *'negative'*), or both types of edges (Transition = *'all'*). Finally, it is possible to select which edge points are returned.

Having extracted subpixel edge locations, features of these edges are evaluated by a corresponding fuzzy function, which can be set by set_fuzzy_measure. Which edges are selected can be determined with the parameter FuzzyThresh, which constitutes a threshold on the weight over all fuzzy sets, i.e., the geometric mean of the weights of the defined sets.

The selected edges are returned as single points, which lie on the major axis of the rectangle or annular arc, in (RowEdge, ColumnEdge). The corresponding edge amplitudes are returned in Amplitude, the fuzzy scores in FuzzyScore. In addition, the distance between consecutive edge points is returned in Distance. Here, Distance[i] corresponds to the distance between Edge[i] and Edge[i+1], i.e., the tuple Distance contains one element less than the tuples RowEdge and ColumnEdge.

Attention

fuzzy_measure_pos only returns meaningful results if the assumptions that the edges are straight and perpendicular to the major axis of the rectangle are fulfilled. Thus, it should not be used to extract edges from curved objects, for example. Furthermore, the user should ensure that the rectangle is as close to perpendicular as possible

to the edges in the image. Additionally, Sigma must not become larger than approx. 0.5 * Length1 (for Length1 see gen_measure_rectangle2).

It should be kept in mind that fuzzy_measure_pos ignores the domain of Image for efficiency reasons. If certain regions in the image should be excluded from the measurement a new measure object with appropriately modified parameters should be generated.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
Input image.

▷ **MeasureHandle** (input_control) ..... measure ⇝ *handle*
Measure object handle.

▷ **Sigma** (input_control) ..... number ⇝ *real*
Sigma of Gaussian smoothing.
Default: 1.0
Suggested values: Sigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ Sigma ≤ 100 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **AmpThresh** (input_control) ..... number ⇝ *real*
Minimum edge amplitude.
Default: 30.0
Suggested values: AmpThresh ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ AmpThresh ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **FuzzyThresh** (input_control) ..... number ⇝ *real*
Minimum fuzzy value.
Default: 0.5
Suggested values: FuzzyThresh ∈ {0.1, 0.3, 0.5, 0.6, 0.7, 0.9}
Value range: 0.0 ≤ FuzzyThresh ≤ 1.0 (lin)
Recommended increment: 0.1

▷ **Transition** (input_control) ..... string ⇝ *string*
Select light/dark or dark/light edges.
Default: 'all'
List of values: Transition ∈ {'all', 'positive', 'negative'}

▷ **RowEdge** (output_control) ..... point.y-array ⇝ *real*
Row coordinate of the edge point.

▷ **ColumnEdge** (output_control) ..... point.x-array ⇝ *real*
Column coordinate of the edge point.

▷ **Amplitude** (output_control) ..... real-array ⇝ *real*
Edge amplitude of the edge (with sign).

▷ **FuzzyScore** (output_control) ..... real-array ⇝ *real*
Fuzzy evaluation of the edges.

▷ **Distance** (output_control) ..... real-array ⇝ *real*
Distance between consecutive edges.

Result

If the parameter values are correct the operator fuzzy_measure_pos returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

1D Metrology

gen_measure_arc (: : CenterRow, CenterCol, Radius, AngleStart, AngleExtent, AnnulusRadius, Width, Height, Interpolation : MeasureHandle)

Prepare the extraction of straight edges perpendicular to an annular arc.

gen_measure_arc prepares the extraction of *straight* edges which lie *perpendicular* to an annular arc. Here, annular arc denotes a circular arc with an associated width. The center of the arc is passed in the parameters CenterRow and CenterCol, its radius in Radius, the starting angle in AngleStart, and its angular extent relative to the starting angle in AngleExtent. If AngleExtent > 0, an arc with counterclockwise orientation is generated, otherwise an arc with clockwise orientation. The radius of the annular arc, i.e., half its width, is determined by AnnulusRadius.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

The edge extraction algorithm is described in the documentation of the operator measure_pos. As discussed there, different types of interpolation can be used for the calculation of the one-dimensional gray value profile. For Interpolation = *'nearest_neighbor'*, the gray values in the measurement are obtained from the gray values of the closest pixel, i.e., by constant interpolation. For Interpolation = *'bilinear'*, bilinear interpolation is used, while for Interpolation = *'bicubic'*, bicubic interpolation is used.

To perform the actual measurement at optimal speed, all computations that can be used for multiple measurements are already performed in the operator gen_measure_arc. For this, an optimized data structure, a so-called measure object, is constructed and returned in MeasureHandle. The size of the images in which measurements will be performed must be specified in the parameters Width and Height.

The system parameter *'int_zooming'* (see set_system) affects the accuracy and speed of the calculations used to construct the measure object. If *'int_zooming'* is set to *'true'*, the internal calculations are performed using fixed point arithmetic, leading to much shorter execution times. However, the geometric accuracy is slightly lower in this mode. If *'int_zooming'* is set to *'false'*, the internal calculations are performed using floating point arithmetic, leading to the maximum geometric accuracy, but also to significantly increased execution times.

Attention

Note that when using bilinear or bicubic interpolation, not only the measurement rectangle but additionally the margin around the rectangle must fit into the image. The width of the margin (in all four directions) must be at least one pixel for bilinear interpolation and two pixels for bicubic interpolation. For projection lines that do not fulfill this condition, no gray value is computed. Thus, no edge can be extracted at these positions.

Please also note that the center coordinates of the arc are rounded internally, so that the center lies on the pixel grid. This is done to ensure consistency.

Parameters

▷ **CenterRow** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the center of the arc.
Default: 100.0
Suggested values: CenterRow ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
Value range: 0.0 ≤ CenterRow (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **CenterCol** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the center of the arc.
Default: 100.0
Suggested values: CenterCol ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
Value range: 0.0 ≤ CenterCol (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Radius** (input_control) . . . . . number ⇝ *real* / integer
Radius of the arc.
Default: 50.0
Suggested values: Radius ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: AnnulusRadius <= Radius

▷ **AngleStart** (input_control) . . . . . angle.rad ⇝ *real* / integer
Start angle of the arc in radians.
Default: 0.0
Suggested values: AngleStart ∈ {-3.14159, -2.35619, -1.57080, -0.78540, 0.0, 0.78540, 1.57080, 2.35619, 3.14159}
Value range: -3.14159 ≤ AngleStart ≤ 3.14159 (lin)
Minimum increment: 0.03142
Recommended increment: 0.31416

▷ **AngleExtent** (input_control) . . . . . angle.rad ⇝ *real* / integer
Angular extent of the arc in radians.
Default: 6.28318
Suggested values: AngleExtent ∈ {-6.28318, -5.49779, -4.71239, -3.92699, -3.14159, -2.35619, -1.57080, -0.78540, 0.78540, 1.57080, 2.35619, 3.14159, 3.92699, 4.71239, 5.49779, 6.28318}
Value range: -6.28318 ≤ AngleExtent ≤ 6.28318 (lin)
Minimum increment: 0.03142
Recommended increment: 0.31416

▷ **AnnulusRadius** (input_control) . . . . . number ⇝ *real* / integer
Radius (half width) of the annulus.
Default: 10.0
Suggested values: AnnulusRadius ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: AnnulusRadius > 0

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the image to be processed subsequently.
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768}
Value range: 0 ≤ Width (lin)
Minimum increment: 1
Recommended increment: 16

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the image to be processed subsequently.
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576}
Value range: 0 ≤ Height (lin)
Minimum increment: 1
Recommended increment: 16

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Type of interpolation to be used.
Default: 'nearest_neighbor'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear', 'bicubic'}

▷ **MeasureHandle** (output_control) . . . . . measure ⇝ *handle*
Measure object handle.

Result

If the parameter values are correct, the operator `gen_measure_arc` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

1D Metrology

gen_measure_rectangle2 (: : Row, Column, Phi, Length1, Length2, Width, Height, Interpolation : MeasureHandle)

Prepare the extraction of straight edges perpendicular to a rectangle.

`gen_measure_rectangle2` prepares the extraction of *straight* edges which lie *perpendicular* to the major axis of a rectangle. The center of the rectangle is passed in the parameters `Row` and `Column`, the direction of the major axis of the rectangle in `Phi`, and the length of the two axes, i.e., half the diameter of the rectangle, in `Length1` and `Length2`.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

The edge extraction algorithm is described in the documentation of the operator `measure_pos`. As discussed there, different types of interpolation can be used for the calculation of the one-dimensional gray value profile. For `Interpolation` = *'nearest_neighbor'*, the gray values in the measurement are obtained from the gray values of the closest pixel, i.e., by constant interpolation. For `Interpolation` = *'bilinear'*, bilinear interpolation is used, while for `Interpolation` = *'bicubic'*, bicubic interpolation is used.

To perform the actual measurement at optimal speed, all computations that can be used for multiple measurements are already performed in the operator `gen_measure_rectangle2`. For this, an optimized data structure, a so-called measure object, is constructed and returned in `MeasureHandle`. The size of the images in which measurements will be performed must be specified in the parameters `Width` and `Height`.

The system parameter *'int_zooming'* (see `set_system`) affects the accuracy and speed of the calculations used to construct the measure object. If *'int_zooming'* is set to *'true'*, the internal calculations are performed using fixed point arithmetic, leading to much shorter execution times. However, the geometric accuracy is slightly lower in this mode. If *'int_zooming'* is set to *'false'*, the internal calculations are performed using floating point arithmetic, leading to the maximum geometric accuracy, but also to significantly increased execution times.

Attention

Note that when using bilinear or bicubic interpolation, not only the measurement rectangle but additionally the margin around the rectangle must fit into the image. The width of the margin (in all four directions) must be at least one pixel for bilinear interpolation and two pixels for bicubic interpolation. For projection lines that do not fulfill this condition, no gray value is computed. Thus, no edge can be extracted at these positions.

Please also note that the center coordinates of the rectangle are rounded internally, so that the center lies on the pixel grid. This is done to ensure consistency.

Parameters

▷ **Row** (input_control) . . . . . rectangle2.center.y ⇝ *real* / integer
Row coordinate of the center of the rectangle.
Default: 300.0
Suggested values: Row ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
Value range: 0.0 ≤ Row ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Column** (input_control) . . . . . rectangle2.center.x ⇝ *real* / integer
Column coordinate of the center of the rectangle.
Default: 200.0
Suggested values: Column ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
Value range: 0.0 ≤ Column ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Phi** (input_control) . . . . . rectangle2.angle.rad ⇝ *real* / integer
Angle of longitudinal axis of the rectangle to horizontal (radians).
Default: 0.0
Suggested values: Phi ∈ {-1.178097, -0.785398, -0.392699, 0.0, 0.392699, 0.785398, 1.178097}
(lin)
Minimum increment: 0.001
Recommended increment: 0.1

▷ **Length1** (input_control) . . . . . rectangle2.hwidth ⇝ *real* / integer
Half width of the rectangle.
Default: 100.0
Suggested values: Length1 ∈ {3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0, 300.0, 500.0}
Value range: 1.0 ≤ Length1 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Length2** (input_control) . . . . . rectangle2.hheight ⇝ *real* / integer
Half height of the rectangle.
Default: 20.0
Suggested values: Length2 ∈ {1.0, 2.0, 3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0}
Value range: 0.0 ≤ Length2 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the image to be processed subsequently.
Default: 512
Suggested values: Width ∈ {128, 160, 192, 256, 320, 384, 512, 640, 768}
Value range: 0 ≤ Width (lin)
Minimum increment: 1
Recommended increment: 16

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the image to be processed subsequently.
Default: 512
Suggested values: Height ∈ {120, 128, 144, 240, 256, 288, 480, 512, 576}
Value range: 0 ≤ Height (lin)
Minimum increment: 1
Recommended increment: 16

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Type of interpolation to be used.
Default: 'nearest_neighbor'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear', 'bicubic'}

▷ **MeasureHandle** (output_control) . . . . . measure ⇝ *handle*
Measure object handle.

Result

If the parameter values are correct the operator gen_measure_rectangle2 returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

get_measure_param (: : MeasureHandle, GenParamName : GenParamValue)

Return the parameters and properties of a measure object.

The operator get_measure_param returns parameters and properties of the measure object MeasureHandle. The names of the desired properties are passed in the generic parameter GenParamName, the corresponding values are returned in GenParamValue.

The properties that can be passed to GenParamName depend on the kind of measure object as well as its parameters. If a property is not available, get_measure_param returns an error.

Properties for all measure objects

- *'type'*: Type of the measure object, either *'rectangle2'* if the object was created with gen_measure_rectangle2, or *'arc'* if it was created with gen_measure_arc.
- *'image_width'*, *'image_height'*: Image width and height, respectively, for which the measure object was created.
- *'interpolation'*: Used interpolation mode: *'nearest_neighbor'*, *'bilinear'* or *'bicubic'*.

Properties for rectangular measure objects

Properties for measure objects that were created with gen_measure_rectangle2.

- *'row'*, *'column'*: Row and column, respectively, of the center of the measurement rectangle.
- *'phi'*: Rotation angle of the measurement rectangle.
- *'length1'*, *'length2'*: Side lengths of the measurement rectangle.

Properties for annular-shaped measure objects

Properties for measure objects that were created with gen_measure_arc.

- *'row'*, *'column'*: Row and column, respectively, of the center of the annular arc.
- *'radius'*: Radius of the annular arc.

- *'angle_start'*, *'angle_extent'*: Starting angle and angular extent of annular arc.
- *'annulus_radius'*: Radius of the angular arc.

Properties for measure objects with fuzzy functions

Properties for measure objects, for which fuzzy functions have been set with `set_fuzzy_measure` or `set_fuzzy_measure_norm_pair`.

- *'fuzzy_contrast'*: Fuzzy function for evaluation of the edge amplitudes.
- *'fuzzy_position'*, *'fuzzy_position_center'*, *'fuzzy_position_end'*, *'fuzzy_position_first_edge'*, *'fuzzy_position_last_edge'*: Fuzzy function for evaluation of the distance of edge candidates to the reference point on the measure object.
- *'fuzzy_position_pair'*, *'fuzzy_position_pair_center'*, *'fuzzy_position_pair_end'*, *'fuzzy_position_first_pair'*, *'fuzzy_position_last_pair'*: Fuzzy function for evaluation of of the distance of edge pairs to the reference point on the measure object.
- *'fuzzy_size'*, *'fuzzy_size_diff'*, *'fuzzy_size_abs_diff'*: Fuzzy function for evaluation of the distance between two edges of a pair.
- *'fuzzy_gray'*: Fuzzy function for weighting the mean projected gray value between two edges of a pair.

Parameters

▷ **`MeasureHandle`** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **`GenParamName`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the parameter to be returned.
Default: 'type'
List of values: `GenParamName` ∈ {'type', 'image_width', 'image_height', 'interpolation', 'row', 'column', 'phi', 'length1', 'length2', 'radius', 'angle_start', 'angle_extent', 'annulus_radius', 'fuzzy_contrast', 'fuzzy_gray', 'fuzzy_position', 'fuzzy_position_center', 'fuzzy_position_end', 'fuzzy_position_first_edge', 'fuzzy_position_last_edge', 'fuzzy_position_pair', 'fuzzy_position_pair_center', 'fuzzy_position_pair_end', 'fuzzy_position_first_pair', 'fuzzy_position_last_pair', 'fuzzy_size', 'fuzzy_size_diff', 'fuzzy_size_abs_diff'}

▷ **`GenParamValue`** (output_control) . . . . . attribute.value(-array) ⇝ *real* / string / integer
Value of the parameter.

Result

If the parameter values are correct the operator `get_measure_param` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Module

1D Metrology

```
measure_pairs ( Image : : MeasureHandle, Sigma, Threshold,
    Transition, Select : RowEdgeFirst, ColumnEdgeFirst,
    AmplitudeFirst, RowEdgeSecond, ColumnEdgeSecond, AmplitudeSecond,
    IntraDistance, InterDistance )
```

Extract straight edge pairs perpendicular to a rectangle or annular arc.

measure_pairs serves to extract *straight* edge pairs which lie *perpendicular* to the major axis of a rectangle or annular arc.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

The extraction algorithm of measure_pairs is identical to measure_pos. In addition the edges are grouped to pairs: If Transition = *'positive'*, the edge points with a dark-to-light transition in the direction of the major axis of the rectangle are returned in RowEdgeFirst and ColumnEdgeFirst. In this case, the corresponding edges with a light-to-dark transition are returned in RowEdgeSecond and ColumnEdgeSecond. If Transition = *'negative'*, the behavior is exactly opposite. If Transition = *'all'*, the first detected edge defines the transition for RowEdgeFirst and ColumnEdgeFirst. I.e., dependent on the positioning of the measure object, edge pairs with a light-dark-light transition or edge pairs with a dark-light-dark transition are returned. This is suited, e.g., to measure objects with different brightness relative to the background.

If more than one consecutive edge with the same transition is found, the first one is used as a pair element. This behavior may cause problems in applications in which the threshold Threshold cannot be selected high enough to suppress consecutive edges of the same transition. For these applications, a second pairing mode exists that only selects the respective strongest edges of a sequence of consecutive rising and falling edges. This mode is selected by appending *'_strongest'* to any of the above modes for Transition, e.g., *'negative_strongest'*. Finally, it is possible to select which edge pairs are returned. If Select is set to *'all'*, all edge pairs are returned. If it is set to *'first'*, only the first of the extracted edge pairs is returned, while it is set to *'last'*, only the last one is returned.

The extracted edges are returned as single points which lie on the major axis of the rectangle. The corresponding edge amplitudes are returned in AmplitudeFirst and AmplitudeSecond. In addition, the distance between each edge pair is returned in IntraDistance and the distance between consecutive edge pairs is returned in InterDistance. Here, IntraDistance[i] corresponds to the distance between EdgeFirst[i] and EdgeSecond[i], while InterDistance[i] corresponds to the distance between EdgeSecond[i] and EdgeFirst[i+1], i.e., the tuple InterDistance contains one element less than the tuples of the edge pairs.

Attention

measure_pairs only returns meaningful results if the assumptions that the edges are straight and perpendicular to the major axis of the rectangle are fulfilled. Thus, it should not be used to extract edges from curved objects, for example. Furthermore, the user should ensure that the rectangle is as close to perpendicular as possible to the edges in the image. Additionally, Sigma must not become larger than approx. 0.5 * Length1 (for Length1 see gen_measure_rectangle2).

It should be kept in mind that measure_pairs ignores the domain of Image for efficiency reasons. If certain regions in the image should be excluded from the measurement a new measure object with appropriately modified parameters should be generated.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2 / real
Input image.

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **Sigma** (input_control) . . . . . number ⇝ *real*
Sigma of gaussian smoothing.
Default: 1.0
Suggested values: Sigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ Sigma ≤ 100 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Threshold** (input_control) . . . . . number ⇝ *real*
Minimum edge amplitude.
Default: 30.0
Suggested values: Threshold ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ Threshold ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **Transition** (input_control) . . . . . string ⇝ *string*
Type of gray value transition that determines how edges are grouped to edge pairs.
Default: 'all'
List of values: Transition ∈ {'all', 'positive', 'negative', 'all_strongest', 'positive_strongest',

'negative_strongest'}

▷ **Select** (input_control) ..... string ⇝ *string*
Selection of edge pairs.
Default: 'all'
List of values: Select ∈ {'all', 'first', 'last'}

▷ **RowEdgeFirst** (output_control) ..... point.y-array ⇝ *real*
Row coordinate of the center of the first edge.

▷ **ColumnEdgeFirst** (output_control) ..... point.x-array ⇝ *real*
Column coordinate of the center of the first edge.

▷ **AmplitudeFirst** (output_control) ..... real-array ⇝ *real*
Edge amplitude of the first edge (with sign).

▷ **RowEdgeSecond** (output_control) ..... point.y-array ⇝ *real*
Row coordinate of the center of the second edge.

▷ **ColumnEdgeSecond** (output_control) ..... point.x-array ⇝ *real*
Column coordinate of the center of the second edge.

▷ **AmplitudeSecond** (output_control) ..... real-array ⇝ *real*
Edge amplitude of the second edge (with sign).

▷ **IntraDistance** (output_control) ..... real-array ⇝ *real*
Distance between edges of an edge pair.

▷ **InterDistance** (output_control) ..... real-array ⇝ *real*
Distance between consecutive edge pairs.

Result

If the parameter values are correct the operator measure_pairs returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

measure_pos (Image : : MeasureHandle, Sigma, Threshold, Transition, Select : RowEdge, ColumnEdge, Amplitude, Distance)

Extract straight edges perpendicular to a rectangle or annular arc.

measure_pos extracts *straight* edges which lie *perpendicular* to the major axis of a rectangle or annular arc.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

The algorithm of measure_pos works by averaging the gray values in "slices" perpendicular to the major axis of the rectangle or annular arc in order to obtain a one-dimensional edge profile. The sampling is done at sub-pixel positions in the image Image at integer row and column distances (in the coordinate frame of the rectangle) from the center of the rectangle. Since this involves some calculations which can be used repeatedly in several measurements, the operator gen_measure_rectangle2 or gen_measure_arc is used to perform

these calculations only once, thus increasing the speed of measure_pos significantly. Since there is a trade-off between accuracy and speed in the subpixel calculations of the gray values, and thus in the accuracy of the extracted edge positions, different interpolation schemes can be selected in gen_measure_rectangle2. (The interpolation only influences rectangles not aligned with the image axes.) The measure object generated with gen_measure_rectangle2 is passed in MeasureHandle.

After the one-dimensional edge profile has been calculated, subpixel edge locations are computed by convolving the profile with the derivatives of a Gaussian smoothing kernel of standard deviation Sigma. Salient edges can be selected with the parameter Threshold, which constitutes a threshold on the amplitude values (Amplitude), i.e., the absolute value of the first derivative of the edge. Note that the amplitude values are scaled by the factor $\text{Sigma} \cdot \sqrt{2\pi}$. Additionally, it is possible to select only positive edges, i.e., edges which constitute a dark-to-light transition in the direction of the major axis of the rectangle or the arc (Transition = *'positive'*), only negative edges, i.e., light-to-dark transitions (Transition = *'negative'*), or both types of edges (Transition = *'all'*). Finally, it is possible to select which edge points are returned. If Select is set to *'all'*, all edge points are returned. If it is set to *'first'*, only the first of the extracted edge points is returned, while it is set to *'last'*, only the last one is returned.

The extracted edges are returned as single points which lie on the major axis of the rectangle or arc in (RowEdge, ColumnEdge). The corresponding edge amplitudes are returned in Amplitude. In addition, the distance between consecutive edge points is returned in Distance. Here, Distance[i] corresponds to the distance between Edge[i] and Edge[i+1], i.e., the tuple Distance contains one element less than the tuples RowEdge and ColumnEdge.

Attention

measure_pos only returns meaningful results if the assumptions that the edges are straight and perpendicular to the major axis of the rectangle or arc are fulfilled. Thus, it should not be used to extract edges from curved objects, for example. Furthermore, the user should ensure that the rectangle or arc is as close to perpendicular as possible to the edges in the image. Additionally, Sigma must not become larger than approx. 0.5 * Length1 (for Length1 see gen_measure_rectangle2).

It should be kept in mind that measure_pos ignores the domain of Image for efficiency reasons. If certain regions in the image should be excluded from the measurement a new measure object with appropriately modified parameters should be generated.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
Input image.

▷ **MeasureHandle** (input_control) ..... measure ⇝ *handle*
Measure object handle.

▷ **Sigma** (input_control) ..... number ⇝ *real*
Sigma of gaussian smoothing.
Default: 1.0
Suggested values: Sigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ Sigma ≤ 100 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Threshold** (input_control) ..... number ⇝ *real*
Minimum edge amplitude.
Default: 30.0
Suggested values: Threshold ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ Threshold ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **Transition** (input_control) ..... string ⇝ *string*
Light/dark or dark/light edge.
Default: 'all'
List of values: Transition ∈ {'all', 'positive', 'negative'}

▷ **Select** (input_control) ..... string ⇝ *string*
Selection of end points.
Default: 'all'
List of values: Select ∈ {'all', 'first', 'last'}

▷ **RowEdge** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinate of the center of the edge.

▷ **ColumnEdge** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinate of the center of the edge.

▷ **Amplitude** (output_control) . . . . . real-array ⇝ *real*
Edge amplitude of the edge (with sign).

▷ **Distance** (output_control) . . . . . real-array ⇝ *real*
Distance between consecutive edges.

Result

If the parameter values are correct the operator `measure_pos` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

measure_projection (Image : : MeasureHandle : GrayValues)

Extract a gray value profile perpendicular to a rectangle or annular arc.

`measure_projection` extracts a one-dimensional gray value profile perpendicular to a rectangle or annular arc. This is done by averaging the gray values in "slices" perpendicular to the major axis of the rectangle or arc. The sampling is done at subpixel positions in the image `Image` at integer row and column distances (in the coordinate frame of the rectangle) from the center of the rectangle. Since this involves some calculations which can be used repeatedly in several projections, the operator `gen_measure_rectangle2` is used to perform these calculations only once, thus increasing the speed of `measure_projection` significantly. Since there is a trade-off between accuracy and speed in the subpixel calculations of the gray values, different interpolation schemes can be selected in `gen_measure_rectangle2` (the interpolation only influences rectangles not aligned with the image axes). The measure object generated with `gen_measure_rectangle2` is passed in `MeasureHandle`.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Attention

It should be kept in mind that `measure_projection` ignores the domain of `Image` for efficiency reasons. If certain regions in the image should be excluded from the measurement a new measure object with appropriately modified parameters should be generated.

Parameters

Module

1D Metrology

measure_thresh (Image : : MeasureHandle, Sigma, Threshold, Select : RowThresh, ColumnThresh, Distance)

Extracting points with a particular gray value along a rectangle or an annular arc.

`measure_thresh` extracts points for which the gray value within an one-dimensional gray value profile is equal to the specified threshold `Threshold`. The gray value profile is projected onto the major axis of the measure rectangle which is passed with the parameter `MeasureHandle`, so the threshold points calculated within the gray value profile correspond to certain image coordinates on the rectangle's major axis. These coordinates are returned as the operator results in `RowThresh` and `ColumnThresh`.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

If the gray value profile intersects the threshold line for several times, the parameter `Select` determines which values to return. Possible settings are *'first'*, *'last'*, *'first_last'* (first and last) or *'all'*. For the last two cases `Distance` returns the distances between the calculated points.

The gray value profile is created by averaging the gray values along all line segments, which are defined by the measure rectangle as follows:

1. The segments are perpendicular to the major axis of the rectangle,
2. they have an integer distance to the center of the rectangle,
3. the rectangle bounds the segments.

For every line segment, the average of the gray values of all points with an integer distance to the major axis is calculated. Due to translation and rotation of the measure rectangle with respect to the image coordinates the input image `Image` is in general sampled at subpixel positions.

Since this involves some calculations which can be used repeatedly in several projections, the operator `gen_measure_rectangle2` is used to perform these calculations only once in advance. Here, the measure object `MeasureHandle` is generated and different interpolation schemes can be selected.

Attention

`measure_thresh` only returns meaningful results if the assumptions that the edges are straight and perpendicular to the major axis of the rectangle are fulfilled. Thus, it should not be used to extract edges from curved objects, for example. Furthermore, the user should ensure that the rectangle is as close to perpendicular as possible to the edges in the image. Additionally, `Sigma` must not become larger than approx. 0.5 * Length1 (for Length1 see `gen_measure_rectangle2`).

It should be kept in mind that `measure_thresh` ignores the domain of `Image` for efficiency reasons. If certain regions in the image should be excluded from the measurement a new measure object with appropriately modified parameters should be generated.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2 / real
Input image.

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **Sigma** (input_control) . . . . . number ⇝ *real*
Sigma of gaussian smoothing.
Default: 1.0
Suggested values: `Sigma` ∈ {0.0, 0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.0 ≤ `Sigma` ≤ 100 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Threshold** (input_control) . . . . . number ⇝ *real*
Threshold.
Default: 128.0
Value range: 0 ≤ `Threshold` ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 1

▷ **Select** (input_control) . . . . . string ⇝ *string*
Selection of points.
Default: 'all'
List of values: `Select` ∈ {'all', 'first', 'last', 'first_last'}

▷ **RowThresh** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinates of points with threshold value.

▷ **ColumnThresh** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinates of points with threshold value.

▷ **Distance** (output_control) . . . . . real-array ⇝ *real*
Distance between consecutive points.

Result

If the parameter values are correct the operator `measure_thresh` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

1D Metrology

read_measure (: : FileName : MeasureHandle)

Read a measure object from a file.

`read_measure` reads a measure object, which has been written with `write_measure` from the file `FileName`. The default HALCON file extension for a measure object is 'msr'. The values contained in the read measure object are stored in a measure object with the handle `MeasureHandle`.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
File extension: .msr

▷ **MeasureHandle** (output_control) . . . . . measure ⇝ *handle*
Measure object handle.

Result

If the parameters are valid, the operator read_measure returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

measure_pos, measure_pairs

reset_fuzzy_measure (: : MeasureHandle, SetType :)

Reset a fuzzy function.

reset_fuzzy_measure discards a fuzzy function of the fuzzy set SetType. This function should have been set by set_fuzzy_measure before.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Parameters

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **SetType** (input_control) . . . . . string ⇝ *string*
Selection of the fuzzy set.
Default: 'contrast'
List of values: SetType ∈ {'position', 'position_pair', 'size', 'gray', 'contrast'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MeasureHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

serialize_measure (: : MeasureHandle : SerializedItemHandle)

Serialize a measure object.

serialize_measure serializes the data of a measure object (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_measure is converted to a serialized item. The measure object is defined by the handle MeasureHandle. The serialized measure object is returned by the handle SerializedItemHandle and can be deserialized by deserialize_measure.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Parameters

▷ **MeasureHandle** (input_control) ..... measure ⇝ *handle*
Measure object handle.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_measure returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MeasureHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

1D Metrology

set_fuzzy_measure (: : MeasureHandle, SetType, Function :)

Specify a fuzzy function.

set_fuzzy_measure specifies a fuzzy function passed in Function. The specified fuzzy functions enable fuzzy_measure_pos and fuzzy_measure_pairs / fuzzy_measure_pairing to evaluate and select the detected edge candidates. For this purpose, weighting characteristics for different edge features can be defined by one function each. Such a specified feature is called fuzzy set. Specifying no function for a fuzzy set means not to use this feature for the final edge evaluation. Setting a second fuzzy function to a set means to discard the first defined function and replace it by the second one. A previously defined fuzzy function can be discarded completely by reset_fuzzy_measure.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Functions for five different fuzzy set types selected by the SetType parameter can be defined, the sub types of a set being mutual exclusive:

- *'contrast'* will use the fuzzy function to evaluate the amplitudes of the edge candidates. When extracting edge pairs, the fuzzy evaluation is obtained by the geometric average of the fuzzy contrast scores of both edges.
- The fuzzy function of *'position'* evaluates the distance of each edge candidate to the reference point of the measure object, generated by gen_measure_arc or gen_measure_rectangle2. The reference point is located at the beginning whereas *'position_center'* or *'position_end'* sets the reference point to the middle or the end of the one-dimensional gray value profile instead. If the fuzzy position evaluation depends on the position of the object along the profile, *'position_first_edge'* / *'position_last_edge'* sets the reference point at the position of the first/last extracted edge. When extracting edge pairs the position of a pair is referenced by the geometric average of the fuzzy position scores of both edges.
- Similar to *'position'*, *'position_pair'* evaluates the distance of each edge pair to the reference point of the measure object. The position of a pair is defined by the center point between both edges. The object's reference can be set by *'position_pair_center'*, *'position_pair_end'* and *'position_first_pair'*, *'position_last_pair'*, respectively. Contrary to *'position'*, this set is only used by fuzzy_measure_pairs/fuzzy_measure_pairing.
- *'size'* denotes a fuzzy set that evaluates the normed distance of the two edges of a pair in pixels. This set is only used by fuzzy_measure_pairs/fuzzy_measure_pairing. Specifying an upper bound for the size by terminating the function with a corresponding fuzzy value of 0.0 will speed up fuzzy_measure_pairs / fuzzy_measure_pairing because not all possible pairs need to be considered.
- *'gray'* sets a fuzzy function to weight the mean projected gray value between two edges of a pair. This set is only used by fuzzy_measure_pairs / fuzzy_measure_pairing.

A fuzzy function is defined as a piecewise linear function by at least two pairs of values, sorted in an ascending order by their x value. The x values represent the edge feature and must lie within the parameter space of the set type, i.e., in case of *'contrast'* and *'gray'* feature and, e.g., byte images within the range $0.0 \leq x \leq 255.0$. In case of *'size'* x has to satisfy $0.0 \leq x$ whereas in case of *'position'* x can be any real number. The y values of the fuzzy function represent the weight of the corresponding feature value and have to satisfy the range of $0.0 \leq y \leq 1.0$. Outside of the function's interval, defined by the smallest and the greatest x value, the y values of the interval borders are continued constantly. Such Fuzzy functions can be generated by create_funct_1d_pairs.

If more than one set is defined, fuzzy_measure_pos / fuzzy_measure_pairs / fuzzy_measure_pairing yield the overall fuzzy weighting by the geometric middle of the weights of each set.

Parameters

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **SetType** (input_control) . . . . . string ⇝ *string*
Selection of the fuzzy set.
Default: 'contrast'
List of values: SetType ∈ {'position', 'position_center', 'position_end', 'position_first_edge', 'position_last_edge', 'position_pair_center', 'position_pair_end', 'position_first_pair', 'position_last_pair', 'size', 'gray', 'contrast'}

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Fuzzy function.

Example

```
* how to use a fuzzy function
* ...
gen_measure_rectangle2 (50, 100, 0, 200, 100, 512, 512, 'nearest_neighbor', \
                        MeasureHandle)
* create a generalized fuzzy function to evaluate edge pairs
* * (30% uncertainty).
create_funct_1d_pairs ([0.7,1.0,1.3], [0.0,1.0,0.0], SizeFunction)
* and transform it to expected size of 13.45 pixels
transform_funct_1d (SizeFunction, [1.0,0.0,13.45,0.0], TransformedFunction)
set_fuzzy_measure (MeasureHandle, 'size', TransformedFunction)

fuzzy_measure_pairs (Image, MeasureHandle, 1, 30, 0.5, 'all', RowEdgeFirst, \
                     ColumnEdgeFirst, AmplitudeFirst, RowEdgeSecond, \
                     ColumnEdgeSecond, AmplitudeSecond, RowEdgeCenter, \
                     ColumnEdgeCenter, FuzzyScore, IntraDistance, \
                     InterDistance)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MeasureHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

reset_fuzzy_measure

Module

1D Metrology

set_fuzzy_measure_norm_pair (: : MeasureHandle, PairSize, SetType, Function :)

Specify a normalized fuzzy function for edge pairs.

set_fuzzy_measure_norm_pair specifies a normalized fuzzy function passed in Function. The specified fuzzy functions enables fuzzy_measure_pos, fuzzy_measure_pairs and fuzzy_measure_pairing to evaluate and select the detected candidates of edges and edge pairs. For this purpose, weighting characteristics for different edge features can be defined by one function each. Such a specified feature is called fuzzy set. Specifying no function for a fuzzy set means not to use this feature for the final edge evaluation. Setting a second fuzzy function to a fuzzy set means to discard the first defined function and replace it by the second one. In difference to set_fuzzy_measure, the abscissa x of these functions must be defined relative to the desired size s of the edge pairs (passed in PairSize). This enables a generalized

usage of the defined functions. A previously defined normalized fuzzy function can be discarded completely by reset_fuzzy_measure.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Functions for three different fuzzy set types selected by the SetType parameter can be defined, the sub types of a set being mutual exclusive:

- *'size'* denotes a fuzzy set that valuates the normalized distance of two edges of a pair in pixels:

$$x = \frac{d}{s}(x \geq 0) \ .$$

  .

  Specifying an upper bound x_{max} for the size by terminating the function with a corresponding fuzzy value of 0.0 will speed up fuzzy_measure_pairs / fuzzy_measure_pairing because not all possible pairs must be considered. Additionally, this fuzzy set can also be specified as a normalized size difference by *'size_diff'*

$$x = \frac{s - d}{s}(x \leq 1)$$

  and a absolute normalized size difference by *'size_abs_diff'*

$$x = \frac{|s - d|}{s}(0 \leq x \leq 1) \ .$$

  .

- The fuzzy function of *'position'* evaluates the signed distance p of each edge candidate to the reference point of the measure object, generated by gen_measure_arc or gen_measure_rectangle2:

$$x = \frac{p}{s} \ .$$

  .

  The reference point is located at the beginning whereas *'position_center'* or *'position_end'* sets the reference point to the middle or the end of the one-dimensional gray value profile, instead. If the fuzzy position valuation depends on the position of the object along the profile *'position_first_edge'* / *'position_last_edge'* sets the reference point at the position of the first/last extracted edge. When extracting edge pairs, the position of a pair is referenced by the geometric average of the fuzzy position scores of both edges.
- Similar to *'position'*, *'position_pair'* evaluates the signed distance of each edge pair to the reference point of the measure object. The position of a pair is defined by the center point between both edges. The object's reference can be set by *'position_pair_center'*, *'position_pair_end'* and *'position_first_pair'*, *'position_last_pair'*, respectively. Contrary to *'position'*, this set is only used by fuzzy_measure_pairs/fuzzy_measure_pairing.

A normalized fuzzy function is defined as a piecewise linear function by at least two pairs of values, sorted in an ascending order by their x value. The y values of the fuzzy function represent the weight of the corresponding feature value and must satisfy the range of $0.0 \leq y \leq 1.0$. Outside of the function's interval, defined by the smallest and the greatest x value, the y values of the interval borders are continued constantly. Such Fuzzy functions can be generated by create_funct_1d_pairs.

If more than one set is defined, fuzzy_measure_pos / fuzzy_measure_pairs / fuzzy_measure_pairing yield the overall fuzzy weighting by the geometric mean of the weights of each set.

Parameters

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **PairSize** (input_control) . . . . . number ⇝ *real* / integer
Favored width of edge pairs.
Default: 10.0
Suggested values: PairSize ∈ {4.0, 6.0, 8.0, 10.0, 15.0, 20.0, 30.0}
Value range: 0.0 ≤ PairSize
Minimum increment: 0.1
Recommended increment: 1.0

▷ **SetType** (input_control) . . . . . string ⇝ *string*
Selection of the fuzzy set.
Default: 'size_abs_diff'
List of values: SetType ∈ {'size', 'size_diff', 'size_abs_diff', 'position', 'position_center', 'position_end', 'position_first_edge', 'position_last_edge', 'position_pair_center', 'position_pair_end', 'position_first_pair', 'position_last_pair'}

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Fuzzy function.

Example

```
* how to use a fuzzy function
* ...
gen_measure_rectangle2 (50, 100, 0, 200, 100, 512, 512, 'nearest_neighbor', \
                        MeasureHandle)
* create a generalized fuzzy function to evaluate edge pairs
* * (30% uncertainty).
create_funct_1d_pairs ([0.7,1.0,1.3], [0.0,1.0,0.0], SizeFunction)
* and set it for an expected pair size of 13.45 pixels
set_fuzzy_measure_norm_pair (MeasureHandle, 13.45, 'size', SizeFunction)

fuzzy_measure_pairs (Image, MeasureHandle, 1, 30, 0.5, 'all', RowEdgeFirst, \
                     ColumnEdgeFirst, AmplitudeFirst, RowEdgeSecond, \
                     ColumnEdgeSecond, AmplitudeSecond, RowEdgeCenter, \
                     ColumnEdgeCenter, FuzzyScore, IntraDistance, \
                     InterDistance)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MeasureHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

reset_fuzzy_measure

Module

1D Metrology

translate_measure (: : MeasureHandle, Row, Column :)

Translate a measure object.

translate_measure translates the reference point of the measure object given by MeasureHandle to the point (Row, Column). If the measure object and the translated measure object lie completely within the image,

the measure object is shifted to the new reference point in an efficient manner. Otherwise, the measure object is generated anew with gen_measure_rectangle2 or gen_measure_arc using the parameters that were specified when the measure object was created and the new reference point.

For an explanation of the concept of 1D measuring see the introduction of chapter 1D Measuring.

Parameters

▷ **MeasureHandle** (input_control) . . . . . measure ⇝ *handle*
Measure object handle.

▷ **Row** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the new reference point.
Default: 50.0
Suggested values: Row ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
Value range: 0.0 ≤ Row ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Column** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the new reference point.
Default: 100.0
Suggested values: Column ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
Value range: 0.0 ≤ Column ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

Result

If the parameter values are correct the operator translate_measure returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MeasureHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

1D Metrology

Chapter 2

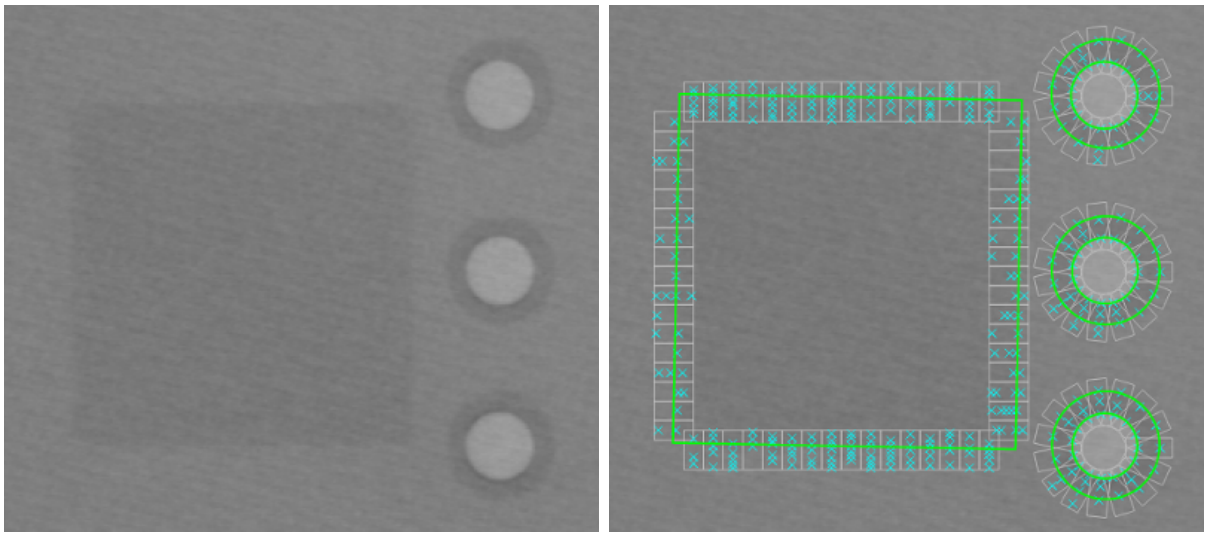
2D Metrology

This chapter contains operators for 2D metrology.

Concept of 2D Metrology

With 2D metrology, you can measure the dimensions of objects that can be represented by specific geometric primitives. The geometric shapes that can be measured comprise circles, ellipses, rectangles, and lines. You need approximate values for the positions, orientations, and dimensions of the objects to measure. Then, the real edge positions of the objects in the image are located near the boundaries of the approximate objects. With these edge positions, the parameters of the geometric shapes are optimized to better fit to the image data and are returned as measurement result.

The approximate values for the shape parameters of an object as well as some parameters that control the measurement are stored in a data structure that is called metrology object. The edges of the object in the image are located within so-called measure regions. These are rectangular regions that are arranged perpendicular to the boundaries of the metrology objects. Parameters that adjust the dimension and distribution of the measure regions are specified together with the approximate shape parameters for each metrology object. When the measurement is applied, the edge positions inside all measure regions are determined and fitted to geometric shapes using a RANSAC algorithm. All metrology objects, all further information that is necessary for the measurement, and the measurement results are stored in a data structure that is called metrology model.



(1) (2)

The geometric shapes in (1) are measured using 2D Metrology (2): A metrology model with 4 metrology objects (blue contours) is created. Using the edge positions (cyan crosses) located within the measure regions (gray rectangles) for each metrology object, the geometric shapes (green contours) are fitted and their parameters can be queried. As shown for the circles, more than one instance per object can be found. This image is from the example program `apply_metrology_model.hdev`.

In the following, the steps that are required to use 2D metrology are described briefly.

Create the metrology model and specify the image size: First, a metrology model must be created using

- create_metrology_model.

The metrology model is used as a container for one or more metrology objects. For an efficient measurement, after creating the metrology model, the image size of the image in which the measurements will be performed should be specified using

- set_metrology_model_image_size.

Provide approximate values: Then, metrology objects are added to the metrology model. Each metrology object consists of the approximate shape parameters for the corresponding object in the image and of the parameters that control the measurement. The parameters that control the measurement comprise, e.g., parameters that specify the dimension and distribution of the measure regions. Furthermore, several generic parameters can be adjusted for each metrology object. The metrology objects are specified with

- add_metrology_object_circle_measure for circles,
- add_metrology_object_ellipse_measure for ellipses,
- add_metrology_object_rectangle2_measure for rectangles, and
- add_metrology_object_line_measure for lines.
- add_metrology_object_generic allows to create metrology objects of different shapes (e.g., ellipse, circle, etc.) using one operator.

To visually inspect the defined metrology objects, you can access their XLD contours with the operator get_metrology_object_model_contour. To visually inspect the created measure regions, you can access their XLD contours with the operator get_metrology_object_measures.

Modify the model parameters: If a camera calibration has been performed, the camera parameters and the pose of the measurement plane can be set with

- set_metrology_model_param.

Then, the result of the measurements returned by get_metrology_object_result will be in world coordinates. The reference coordinate system in which the metrology objects are defined can also be changed with set_metrology_model_param.

Modify object parameters: Many parameters can be set when adding the metrology objects to the metrology model. Some of them can also be modified afterwards using the operator

- set_metrology_object_param.

Align the metrology model: To translate and rotate the metrology model before the next measurement is performed, you can use the operator

- align_metrology_model.

An alignment is temporary and is replaced by the next alignment. The metrology model itself is not changed. Note that typically the alignment parameters are obtained using shape-based matching.

Apply the measurement: The actual measurement in the image is performed with

- apply_metrology_model.

The operator locates the edges within the measure regions and fits the specified geometric shape to the edge positions using a RANSAC algorithm. The edges are located internally using the operator measure_pos or fuzzy_measure_pos (see also chapter 1D Measuring). The latter uses fuzzy methods and is used only if at least one fuzzy function was set via set_metrology_object_fuzzy_param before applying the measurement. If more than one instance of the returned object shape is needed (compare image above), the generic parameter *'num_instances'* must be set to the number of instances that should be returned. The parameter can be set when adding the individual metrology objects or afterwards with the operator set_metrology_object_param.

Access the results: After the measurement, the results can be accessed. The parameters of the adapted geometric shapes of the objects are queried with the operator

- get_metrology_object_result.

Querying only the edges used for the returned result and their amplitudes is also done using get_metrology_object_result.

The row and column coordinates of all located edges can be accessed with

- get_metrology_object_measures.

To visualize the adapted geometric shapes, you can access their XLD contours with

- get_metrology_object_result_contour.

Further operators

In addition to the operators mentioned above, you can copy the metrology handle with copy_metrology_model, write the metrology model to file with write_metrology_model, read a model from file again using read_metrology_model, and serialize or deserialize a metrology model using serialize_metrology_model or deserialize_metrology_model.

Furthermore, you can query various information from the metrology model. For example, you can query the indices of the metrology objects with get_metrology_object_indices, query parameters that are valid for the entire metrology model with get_metrology_model_param, query a fuzzy parameter of a metrology model with get_metrology_object_fuzzy_param, query the number of instances of the metrology objects of a metrology model with get_metrology_object_num_instances, and query the current configuration of the metrology model with get_metrology_object_param.

Additionally, you can reset all parameters of a metrology model using reset_metrology_object_param or reset only all fuzzy parameters and fuzzy functions of a metrology model using reset_metrology_object_fuzzy_param.

Glossary

In the following, the most important terms that are used in the context of 2D Metrology are described.

metrology model Data structure that contains all metrology objects, all information needed for the measurement, and the measurement results.

metrology object Data structure for the object to be measured with 2D metrology. The metrology object is represented by a specific geometric shape for which the shape parameters are approximately known. Additionally, it contains parameters that control the measurement, e.g., parameters that specify the dimension and distribution of the measure regions.

measure regions Rectangular regions that are arranged perpendicular to the boundaries of the approximate objects. Within these regions the edges that are used to get the exact shape parameters of the metrology objects are extracted.

returned instance of a metrology object For each metrology object, different instances of the object can be returned by the measurement, e.g., if parallel structures of the same shape exist near to the boundaries of the approximated geometric shape (see image above). The sequence of the returned instances is arbitrary, i.e., it is no measure for the quality of the fitting.

Further Information

See also the "Solution Guide on 2D Measuring" for further details about 2D metrology.

```
add_metrology_object_circle_measure ( : : MetrologyHandle, Row,
    Column, Radius, MeasureLength1, MeasureLength2, MeasureSigma,
    MeasureThreshold, GenParamName, GenParamValue : Index )
```

Add a circle or a circular arc to a metrology model.

add_metrology_object_circle_measure adds a metrology object of type circle or circular arc to a metrology model and prepares the rectangular measure regions. The handle of the model is passed in MetrologyHandle.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The geometric shape of the metrology object of type circle is specified by its center (Row, Column) and Radius. The rectangular measure regions lie *perpendicular* to the boundary of the circle. The half edge lengths of the measure regions are set in MeasureLength1 and MeasureLength2. The centers of the measure regions lie on the boundary of the circle. The parameter MeasureSigma specifies the standard deviation that is used by operator apply_metrology_model to smooth the gray values of the image. Salient edges can be selected with the parameter MeasureThreshold, which constitutes a threshold on the amplitude, i.e., the absolute value of the first derivative of the edge. The operator add_metrology_object_circle_measure returns the index of the added metrology object in parameter Index.

Furthermore, you can adjust some generic parameters with GenParamName and GenParamValue. The following values for GenParamName and GenParamValue are available:

'start_phi': The parameter specifies the angle at the start point of a circular arc. To create a closed circle the value of the parameter *'start_phi'* is set to 0 and the value of the parameter *'end_phi'* is set to 2π (with positive point order). The input value is mapped automatically to the interval $[0, 2\pi]$.

Suggested values: *0.0*, *0.78*, *6.28318*

Default: *0.0*

'end_phi': The parameter specifies the angle at the end point of a circular arc. To create a closed circle the value of the parameter *'start_phi'* is set to 0 and the value of the parameter *'end_phi'* is set to 2π (with positive point order). The input value is mapped internally automatically to the interval $[0, 2\pi]$.

Suggested values: *0.0*, *0.78*, *6.28318*

Default: *6.28318*

'point_order': The parameter specifies the direction of the circular arc. For the value *'positive'*, the circular arc is defined between *'start_phi'* and *'end_phi'* in mathematically positive direction (counterclockwise). For the value *'negative'*, the circular arc is defined between *'start_phi'* and *'end_phi'* in mathematically negative direction (clockwise).

List of values: *'positive'*, *'negative'*

Default: *'positive'*

Additionally all generic parameters, that are available for the operator set_metrology_object_param can be set. But note that for a lot of applications the default values are sufficient and no adjustment is necessary.

Parameters

▷ **MetrologyHandle** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Row** (input_control) ..... circle.center.y(-array) ⇝ *real* / integer
Row coordinate (or Y) of the center of the circle or circular arc.

▷ **Column** (input_control) ..... circle.center.x(-array) ⇝ *real* / integer
Column (or X) coordinate of the center of the circle or circular arc.

▷ **Radius** (input_control) ..... circle.radius(-array) ⇝ *real* / integer
Radius of the circle or circular arc.

▷ **MeasureLength1** (input_control) ..... number ⇝ *real* / integer
Half length of the measure regions perpendicular to the boundary.
Default: 20.0
Suggested values: MeasureLength1 ∈ {10.0, 20.0, 30.0}
Value range: 1.0 ≤ MeasureLength1
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: MeasureLength1 < Radius

▷ **MeasureLength2** (input_control) . . . . . number ⇝ *real* / integer
Half length of the measure regions tangential to the boundary.
Default: 5.0
Suggested values: MeasureLength2 ∈ {3.0, 5.0, 10.0}
Value range: 1.0 ≤ MeasureLength2
Minimum increment: 1.0
Recommended increment: 10.0

▷ **MeasureSigma** (input_control) . . . . . number ⇝ *real* / integer
Sigma of the Gaussian function for the smoothing.
Default: 1.0
Suggested values: MeasureSigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ MeasureSigma ≤ 100.0
Minimum increment: 0.01
Recommended increment: 0.1

▷ **MeasureThreshold** (input_control) . . . . . number ⇝ *real* / integer
Minimum edge amplitude.
Default: 30.0
Suggested values: MeasureThreshold ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ MeasureThreshold ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'distance_threshold', 'end_phi', 'instances_outside_measure_regions', 'max_num_iterations', 'measure_distance', 'measure_interpolation', 'measure_select', 'measure_transition', 'min_score', 'num_instances', 'num_measures', 'point_order', 'rand_seed', 'start_phi'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {1, 2, 3, 4, 5, 10, 20, 'all', 'true', 'false', 'first', 'last', 'positive', 'negative', 'uniform', 'nearest_neighbor', 'bilinear', 'bicubic'}

▷ **Index** (output_control) . . . . . integer ⇝ *integer*
Index of the created metrology object.

Example

```
read_image (Image, 'rings_and_nuts')
create_metrology_model (MetrologyHandle)
get_image_size (Image, Width, Height)
set_metrology_model_image_size (MetrologyHandle, Width, Height)
add_metrology_object_circle_measure (MetrologyHandle, 120, 130, 35, 10, 2, \
                                     1, 30, ['measure_distance'], [40], Index)
apply_metrology_model (Image, MetrologyHandle)
get_metrology_object_result (MetrologyHandle, Index, 'all', 'result_type', \
                             'all_param', Circle)
get_metrology_object_result_contour (Contour, MetrologyHandle, Index, \
                                     'all', 1.5)
```

Result

If the parameters are valid, the operator add_metrology_object_circle_measure returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

set_metrology_model_image_size

Possible Successors

align_metrology_model, apply_metrology_model

Alternatives

add_metrology_object_generic

See also

get_metrology_object_model_contour, set_metrology_model_param, add_metrology_object_ellipse_measure, add_metrology_object_line_measure, add_metrology_object_rectangle2_measure

Module

2D Metrology

add_metrology_object_ellipse_measure (: : MetrologyHandle, Row, Column, Phi, Radius1, Radius2, MeasureLength1, MeasureLength2, MeasureSigma, MeasureThreshold, GenParamName, GenParamValue : Index)

Add an ellipse or an elliptic arc to a metrology model.

add_metrology_object_ellipse_measure adds a metrology object of type ellipse or elliptic arc to a metrology model and prepares the rectangular measure regions. The handle of the model is passed in MetrologyHandle.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The geometric shape of the metrology object of type ellipse is specified by its center (Row, Column), the orientation of the main axis Phi, the length of the larger half axis Radius1, and the length of the smaller half axis Radius2. The input value for Phi is mapped automatically to the interval $]-\pi,\pi]$. The rectangular measure regions lie *perpendicular* to the boundary of the ellipse. The half edge lengths of the measure regions perpendicular and tangential to the boundary of the ellipse are set in MeasureLength1 and MeasureLength2. The centers of the measure regions lie on the boundary of the geometric shape. The parameter MeasureSigma specifies the standard deviation that is used by the operator apply_metrology_model to smooth the gray values of the image. Salient edges can be selected with the parameter MeasureThreshold, which constitutes a threshold on the amplitude, i.e., the absolute value of the first derivative of the edge. The operator add_metrology_object_ellipse_measure returns the index of the added metrology object in the parameter Index.

Furthermore, you can adjust some generic parameters within GenParamName and GenParamValue. The following values for GenParamName and GenParamValue are available:

'start_phi': The parameter specifies the angle at the start point of an elliptic arc. The angle at the start point is measured relative to the positive main axis specified with Phi and corresponds to the smallest surrounding circle of the ellipse. The actual start point of the ellipse is the intersection of the ellipse with the orthogonal projection of the corresponding circle point onto the main axis. The angle refers to the coordinate system of the ellipse, i.e., it is specified relative to the main axis and in a mathematical positive direction. Thus, the two main poles correspond to the angles 0 and π, the two minor poles to the angle $\pi/2$ and $3\pi/2$. To create a closed ellipse the value of the parameter *'start_phi'* is set to 0 and the value of the parameter *'end_phi'* is set to 2π (with positive point order). The input value is mapped internally automatically to the interval $[0, 2\pi]$.

Suggested values: *0.0*, *0.78*, *6.28318*

Default: *0.0*

'end_phi': The parameter specifies the angle at the end point of an elliptic arc. The angle at the end point are measured relative to the positive main axis specified with Phi and corresponds to the smallest surrounding

circle of the ellipse. The actual end point of the ellipse is the intersection of the ellipse with the orthogonal projection of the corresponding circle point onto the main axis. The angle refers to the coordinate system of the ellipse, i.e., it is specified relative to the main axis and in a mathematical positive direction. Thus, the two main poles correspond to the angles 0 and π, the two minor poles to the angle $\pi/2$ and $3\pi/2$. To create a closed ellipse the value of the parameter *'start_phi'* is set to 0 and the value of the parameter *'end_phi'* is set to 2π (with positive point order). The input value is mapped automatically to the interval $[0, 2\pi]$.

Suggested values: *0.0*, *0.78*, *6.28318*

Default: *6.28318*

'point_order': The parameter specifies the direction of the elliptic arc. For the value *'positive'*, the elliptic arc is defined between *'start_phi'* and *'end_phi'* in mathematically positive direction (counterclockwise). For the value *'negative'*, the elliptic arc is defined between *'start_phi'* and *'end_phi'* in mathematically negative direction (clockwise).

List of values: *'positive'*, *'negative'*

Default: *'positive'*

Additionally, all generic parameters that are available for the operator `set_metrology_object_param` can be set. But note that for a lot of applications the default values are sufficient and no adjustment is necessary.

Parameters

▷ **`MetrologyHandle`** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **`Row`** (input_control) . . . . . ellipse.center.y(-array) ⇝ *real* / integer
Row (or Y) coordinate of the center of the ellipse.

▷ **`Column`** (input_control) . . . . . ellipse.center.x(-array) ⇝ *real* / integer
Column (or X) coordinate of the center of the ellipse.

▷ **`Phi`** (input_control) . . . . . ellipse.angle.rad(-array) ⇝ *real* / integer
Orientation of the main axis [rad].

▷ **`Radius1`** (input_control) . . . . . ellipse.radius1(-array) ⇝ *real* / integer
Length of the larger half axis.

▷ **`Radius2`** (input_control) . . . . . ellipse.radius2(-array) ⇝ *real* / integer
Length of the smaller half axis.

▷ **`MeasureLength1`** (input_control) . . . . . number ⇝ *real* / integer
Half length of the measure regions perpendicular to the boundary.
Default: 20.0
Suggested values: `MeasureLength1` ∈ {10.0, 20.0, 30.0}
Value range: 1.0 ≤ MeasureLength1
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: MeasureLength1 < Radius1 && MeasureLength1 < Radius2

▷ **`MeasureLength2`** (input_control) . . . . . number ⇝ *real* / integer
Half length of the measure regions tangential to the boundary.
Default: 5.0
Suggested values: `MeasureLength2` ∈ {3.0, 5.0, 10.0}
Value range: 1.0 ≤ MeasureLength2
Minimum increment: 1.0
Recommended increment: 10.0

▷ **`MeasureSigma`** (input_control) . . . . . number ⇝ *real* / integer
Sigma of the Gaussian function for the smoothing.
Default: 1.0
Suggested values: `MeasureSigma` ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ `MeasureSigma` ≤ 100.0
Minimum increment: 0.01
Recommended increment: 0.1

▷ **MeasureThreshold** (input_control) ..... number ⇝ *real* / integer
Minimum edge amplitude.
Default: 30.0
Suggested values: MeasureThreshold ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ MeasureThreshold ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **GenParamName** (input_control) ..... attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'distance_threshold', 'end_phi', 'instances_outside_measure_regions', 'max_num_iterations', 'measure_distance', 'measure_interpolation', 'measure_select', 'measure_transition', 'min_score', 'num_instances', 'num_measures', 'point_order', 'rand_seed', 'start_phi'}

▷ **GenParamValue** (input_control) ..... attribute.value-array ⇝ *real* / integer / string
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {1, 2, 3, 4, 5, 10, 20, 'all', 'true', 'false', 'first', 'last', 'positive', 'negative', 'uniform', 'nearest_neighbor', 'bilinear', 'bicubic'}

▷ **Index** (output_control) ..... integer ⇝ *integer*
Index of the created metrology object.

Result

If the parameters are valid, the operator add_metrology_object_ellipse_measure returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

set_metrology_model_image_size

Possible Successors

Module

2D Metrology

add_metrology_object_generic (: : MetrologyHandle, Shape, ShapeParam, MeasureLength1, MeasureLength2, MeasureSigma, MeasureThreshold, GenParamName, GenParamValue : Index)

Add a metrology object to a metrology model.

add_metrology_object_generic adds a metrology object of type Shape to a metrology model and prepares the rectangular measure regions.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The handle of the model is passed in MetrologyHandle.

Shape specifies which type of object is added to the metrology model. The operator add_metrology_object_generic returns the index of the added metrology object in the parameter Index. Note that add_metrology_object_generic provides the functionality of the operators add_metrology_object_circle_measure, add_metrology_object_ellipse_measure, add_metrology_object_rectangle2_measure and add_metrology_object_line_measure in one operator.

Possible shapes

Depending on the object specified in Shape the following values are expected:

'circle': The geometric shape of the metrology object of type circle is specified by its center (Row, Column) and radius.
ShapeParam=*[Row, Column, Radius]*

'rectangle2': The geometric shape of the metrology object of type rectangle is specified by its center (Row, Column), the orientation of the main axis Phi, and the half edge lengths Length1 and Length2. The input value for Phi is mapped automatically to the interval $]-\pi, \pi]$.
ShapeParam=*[Row, Column, Phi, Length1, Length2]*

'ellipse': The geometric shape of the metrology object of type ellipse is specified by its center (Row, Column), the orientation of the main axis Phi, the length of the larger half axis Radius1, and the length of the smaller half axis Radius2. The input value for Phi is mapped automatically to the interval $]-\pi, \pi]$.
ShapeParam=*[Row, Column, Phi, Radius1, Radius2]*

'line': The geometric shape of the metrology object of type line is described by the coordinates of its start point (RowBegin, ColumnBegin) and the coordinates of its end point (RowEnd, ColumnEnd).
ShapeParam=*[RowBegin, ColumnBegin, RowEnd, ColumnEnd]*

Definition of measure regions

add_metrology_object_generic also prepares the rectangular measure regions. The rectangular measure regions lie *perpendicular* to the boundary of the object. The half edge lengths of the measure regions perpendicular and tangential to the boundary of the object are set in MeasureLength1 and MeasureLength2. The centers of the measure regions lie on the boundary of the object. The parameter MeasureSigma specifies a standard deviation that is used by the operator apply_metrology_model to smooth the gray values of the image. Salient edges can be selected with the parameter MeasureThreshold, which constitutes a threshold on the amplitude, i.e., the absolute value of the first derivative of the edge.

Generic parameters

Generic parameters and their values can be specified using GenParamName and GenParamValue. All generic parameters that are available in the operator set_metrology_object_param can also be set in add_metrology_object_generic. But note that for a lot of applications the default values are sufficient and no adjustment is necessary. Furthermore, the following values for GenParamName and GenParamValue are available only for Shape = *'circle'* and *'ellipse'*:

'start_phi': The parameter specifies the angle at the start point of a circular or elliptic arc. For an ellipse, the angle at the start point is measured relative to the positive main axis and corresponds to the smallest surrounding circle of the ellipse. The actual start point of the ellipse is the intersection of the ellipse with the orthogonal projection of the corresponding circle point onto the main axis. To create a closed circle or ellipse the value of the parameter *'start_phi'* is set to 0 and the value of the parameter *'end_phi'* is set to 2π (with positive point order). The input value is mapped automatically to the interval $[0, 2\pi]$.
Suggested values: *0.0*, *0.78*, *6.28318*
Default: *0.0*

'end_phi': The parameter specifies the angle at the end point of a circular or elliptic arc. For an ellipse, the angle at the end point is measured relative to the positive main axis and corresponds to the smallest surrounding circle of the ellipse. The actual end point of the ellipse is the intersection of the ellipse with the orthogonal projection of the corresponding circle point onto the main axis. To create a closed circle or ellipse the value of the parameter *'start_phi'* is set to 0 and the value of the parameter *'end_phi'* is set to 2π (with positive point order). The input value is mapped internally automatically to the interval $[0, 2\pi]$.
Suggested values: *0.0*, *0.78*, *6.28318*
Default: *6.28318*

'point_order': The parameter specifies the direction of the circular or elliptic arc. For the value *'positive'*, the arc is defined between *'start_phi'* and *'end_phi'* in mathematically positive direction (counterclockwise). For the value *'negative'*, the arc is defined between *'start_phi'* and *'end_phi'* in mathematically negative direction (clockwise).

List of values: *'positive'*, *'negative'*

Default: *'positive'*

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Shape** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Type of the metrology object to be added.
Default: 'circle'
List of values: Shape ∈ {'circle', 'ellipse', 'rectangle2', 'line'}

▷ **ShapeParam** (input_control) . . . . . attribute.value-array ⇝ *real* / integer
Parameters of the metrology object to be added.

▷ **MeasureLength1** (input_control) . . . . . number ⇝ *real* / integer
Half length of the measure regions perpendicular to the boundary.
Default: 20.0
Suggested values: MeasureLength1 ∈ {10.0, 20.0, 30.0}
Value range: 1.0 ≤ MeasureLength1 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **MeasureLength2** (input_control) . . . . . number ⇝ *real* / integer
Half length of the measure regions tangential to the boundary.
Default: 5.0
Suggested values: MeasureLength2 ∈ {3.0, 5.0, 10.0}
Value range: 1.0 ≤ MeasureLength2 ≤ 511.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **MeasureSigma** (input_control) . . . . . number ⇝ *real* / integer
Sigma of the Gaussian function for the smoothing.
Default: 1.0
Suggested values: MeasureSigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ MeasureSigma ≤ 100 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **MeasureThreshold** (input_control) . . . . . number ⇝ *real* / integer
Minimum edge amplitude.
Default: 30.0
Suggested values: MeasureThreshold ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ MeasureThreshold ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'distance_threshold', 'end_phi', 'instances_outside_measure_regions', 'max_num_iterations', 'measure_distance', 'measure_interpolation', 'measure_select', 'measure_transition', 'min_score', 'num_instances', 'num_measures', 'point_order', 'rand_seed', 'start_phi'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {1, 2, 3, 4, 5, 10, 20, 'all', 'true', 'false', 'first', 'last', 'positive', 'negative', 'uniform', 'nearest_neighbor', 'bilinear', 'bicubic'}

▷ **Index** (output_control) . . . . . integer ⇝ *integer*
Index of the created metrology object.

Example

```
create_metrology_model (MetrologyHandle)
read_image (Image, 'fabrik')
get_image_size (Image, Width, Height)
set_metrology_model_image_size (MetrologyHandle, Width, Height)
LinePar := [45,360,415,360]
RectPar1 := [270,232,rad(0),30,25]
RectPar2 := [360,230,rad(0),30,25]
LinePar := [45,360,415,360]
RectPar3 := [245,320,rad(-90),70,35]
* Add two rectangles
add_metrology_object_generic (MetrologyHandle, 'rectangle2', \
                              [RectPar1,RectPar2], 20, 5, 1, 30, [], [], \
                              Indices)
* Add a rectangle and a line
add_metrology_object_generic (MetrologyHandle, ['rectangle2','line'], \
                              [RectPar3,LinePar], 20, 5, 1, 30, [], [], \
                              Index)
get_metrology_object_model_contour (Contour, MetrologyHandle, 'all', 1.5)
apply_metrology_model (Image, MetrologyHandle)
get_metrology_object_result_contour (Contour1, MetrologyHandle, 'all', \
                                     'all', 1.5)
```

Result

If the parameters are valid, the operator `add_metrology_object_generic` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

2D Metrology

add_metrology_object_line_measure (: : MetrologyHandle, RowBegin, ColumnBegin, RowEnd, ColumnEnd, MeasureLength1, MeasureLength2, MeasureSigma, MeasureThreshold, GenParamName, GenParamValue : Index)

Add a line to a metrology model.

add_metrology_object_line_measure adds a metrology object of type line to a metrology model and prepares the rectangular measure regions. The handle of the model is passed in MetrologyHandle.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The geometric shape of the metrology object of type line is described by the coordinates of the start point (RowBegin, ColumnBegin) and the coordinates of the end point (RowEnd, ColumnEnd). The rectangular measure regions lie *perpendicular* to the line. The half edge lengths of the measure regions perpendicular and tangential to the line are set in MeasureLength1 and MeasureLength2. The centers of the measure regions lie on the line. The parameter MeasureSigma specifies a standard deviation that is used by the operator apply_metrology_model to smooth the gray values of the image. Salient edges can be selected with the parameter MeasureThreshold, which constitutes a threshold on the amplitude, i.e., the absolute value of the first derivative of the edge.

Furthermore, you can adjust some generic parameters within GenParamName and GenParamValue. In particular, all generic parameters that are available in the operator set_metrology_object_param can be set. But note that for a lot of applications the default values are sufficient and no adjustment is necessary.

The operator add_metrology_object_line_measure returns the index of the added metrology object in the parameter Index.

Parameters

▷ **MetrologyHandle** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **RowBegin** (input_control) ..... line.begin.y(-array) ⇝ *real* / integer
Row (or Y) coordinate of the start of the line.

▷ **ColumnBegin** (input_control) ..... line.begin.x(-array) ⇝ *real* / integer
Column (or X) coordinate of the start of the line.

▷ **RowEnd** (input_control) ..... line.end.y(-array) ⇝ *real* / integer
Row (or Y) coordinate of the end of the line.

▷ **ColumnEnd** (input_control) ..... line.end.x(-array) ⇝ *real* / integer
Column (or X) coordinate of the end of the line.

▷ **MeasureLength1** (input_control) ..... number ⇝ *real* / integer
Half length of the measure regions perpendicular to the boundary.
Default: 20.0
Suggested values: MeasureLength1 ∈ {10.0, 20.0, 30.0}
Value range: 1.0 ≤ MeasureLength1
Minimum increment: 1.0
Recommended increment: 10.0

▷ **MeasureLength2** (input_control) ..... number ⇝ *real* / integer
Half length of the measure regions tangential to the boundary.
Default: 5.0
Suggested values: MeasureLength2 ∈ {3.0, 5.0, 10.0}
Value range: 1.0 ≤ MeasureLength2
Minimum increment: 1.0
Recommended increment: 10.0

▷ **MeasureSigma** (input_control) ..... number ⇝ *real* / integer
Sigma of the Gaussian function for the smoothing.
Default: 1.0
Suggested values: MeasureSigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ MeasureSigma ≤ 100.0
Minimum increment: 0.01
Recommended increment: 0.1

▷ **MeasureThreshold** (input_control) ..... number ⇝ *real* / integer
Minimum edge amplitude.
Default: 30.0
Suggested values: MeasureThreshold ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ MeasureThreshold ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'distance_threshold', 'instances_outside_measure_regions', 'max_num_iterations', 'measure_distance', 'measure_interpolation', 'measure_select', 'measure_transition', 'min_score', 'num_instances', 'num_measures', 'rand_seed'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {1, 2, 3, 4, 5, 10, 20, 'all', 'true', 'false', 'first', 'last', 'positive', 'negative', 'uniform', 'nearest_neighbor', 'bilinear', 'bicubic'}

▷ **Index** (output_control) . . . . . integer ⇝ *integer*
Index of the created metrology object.

Result

If the parameters are valid, the operator add_metrology_object_line_measure returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

set_metrology_model_image_size

Possible Successors

align_metrology_model, apply_metrology_model

Alternatives

add_metrology_object_generic

Module

2D Metrology

add_metrology_object_rectangle2_measure (: : MetrologyHandle, Row, Column, Phi, Length1, Length2, MeasureLength1, MeasureLength2, MeasureSigma, MeasureThreshold, GenParamName, GenParamValue : Index)

Add a rectangle to a metrology model.

add_metrology_object_rectangle2_measure adds a metrology object of type rectangle to a metrology model and prepares the rectangular measure regions. The handle of the model is passed in MetrologyHandle.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The geometric shape of the metrology object of type rectangle is specified by its center (Row, Column), the orientation of the main axis Phi, and the half edge lengths Length1 and Length2. The input value for Phi is mapped automatically to the interval $]-\pi,\pi]$. The rectangular measure regions lie *perpendicular* to the boundary

of the rectangle. The half edge lengths of the measure regions perpendicular and tangential to the boundary of the rectangle are set in MeasureLength1 and MeasureLength2. The centers of the measure regions lie on the boundary of the rectangle. The parameter MeasureSigma specifies a standard deviation that is used by the operator apply_metrology_model to smooth the gray values of the image. Salient edges can be selected with the parameter MeasureThreshold, which constitutes a threshold on the amplitude, i.e., the absolute value of the first derivative of the edge.

Furthermore, you can adjust some generic parameters within GenParamName and GenParamValue. In particular, all generic parameters that are available in the operator set_metrology_object_param can be set. But note that for a lot of applications the default values are sufficient and no adjustment is necessary.

The operator add_metrology_object_rectangle2_measure returns the index of the added metrology object within the metrology model in the parameter Index.

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Row** (input_control) . . . . . rectangle2.center.y(-array) ⇝ *real* / integer
Row (or Y) coordinate of the center of the rectangle.

▷ **Column** (input_control) . . . . . rectangle2.center.x(-array) ⇝ *real* / integer
Column (or X) coordinate of the center of the rectangle.

▷ **Phi** (input_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real* / integer
Orientation of the main axis [rad].

▷ **Length1** (input_control) . . . . . rectangle2.hwidth(-array) ⇝ *real* / integer
Length of the larger half edge of the rectangle.

▷ **Length2** (input_control) . . . . . rectangle2.hheight(-array) ⇝ *real* / integer
Length of the smaller half edge of the rectangle.

▷ **MeasureLength1** (input_control) . . . . . number ⇝ *real* / integer
Half length of the measure regions perpendicular to the boundary.
Default: 20.0
Suggested values: MeasureLength1 ∈ {10.0, 20.0, 30.0}
Value range: 1.0 ≤ MeasureLength1
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: MeasureLength1 < Length1 && MeasureLength1 < Length2

▷ **MeasureLength2** (input_control) . . . . . number ⇝ *real* / integer
Half length of the measure regions tangential to the boundary.
Default: 5.0
Suggested values: MeasureLength2 ∈ {3.0, 5.0, 10.0}
Value range: 1.0 ≤ MeasureLength2
Minimum increment: 1.0
Recommended increment: 10.0

▷ **MeasureSigma** (input_control) . . . . . number ⇝ *real* / integer
Sigma of the Gaussian function for the smoothing.
Default: 1.0
Suggested values: MeasureSigma ∈ {0.4, 0.6, 0.8, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 7.0, 10.0}
Value range: 0.4 ≤ MeasureSigma ≤ 100.0
Minimum increment: 0.01
Recommended increment: 0.1

▷ **MeasureThreshold** (input_control) . . . . . number ⇝ *real* / integer
Minimum edge amplitude.
Default: 30.0
Suggested values: MeasureThreshold ∈ {5.0, 10.0, 20.0, 30.0, 40.0, 50.0, 60.0, 70.0, 90.0, 110.0}
Value range: 1 ≤ MeasureThreshold ≤ 255 (lin)
Minimum increment: 0.5
Recommended increment: 2

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'distance_threshold', 'instances_outside_measure_regions',

'max_num_iterations', 'measure_distance', 'measure_interpolation', 'measure_select', 'measure_transition', 'min_score', 'num_instances', 'num_measures', 'rand_seed'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {1, 2, 3, 4, 5, 10, 20, 'all', 'true', 'false', 'first', 'last', 'positive', 'negative', 'uniform', 'nearest_neighbor', 'bilinear', 'bicubic'}

▷ **Index** (output_control) . . . . . integer ⇝ *integer*
Index of the created metrology object.

Result

If the parameters are valid, the operator add_metrology_object_rectangle2_measure returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

align_metrology_model (: : MetrologyHandle, Row, Column, Angle :)

Alignment of a metrology model.

align_metrology_model moves and rotates the whole metrology model MetrologyHandle relative to the image coordinate system which has its origin in the top left corner.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

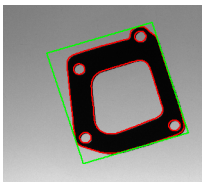
An alignment ensures, that the position and orientation of the metrology model is adapted to the objects to be measured in the current image. The alignment is then used by apply_metrology_model to perform the measurement. First the metrology model is rotated by Angle, then the metrology model is translated by Row and Column. The values of the alignment are overwritten by the next call of align_metrology_model.

Computation of the parameters of the alignment

The parameters of the alignment can be determined using diverse methods. Here, three possibilities to determine the parameters are listed:

Using region analysis:

If the metrology model can be extracted using region processing and if the pose of the Region changes only slightly in subsequent images, the parameters of the reference system of the metrology model and of the alignment can be derived using region analysis. In the following picture `threshold` and `smallest_rectangle2` were used to obtain these parameter.

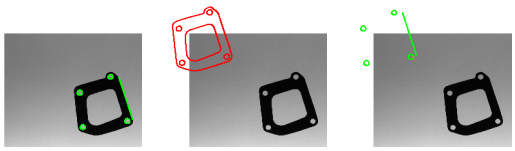


The region extracted with `threshold` is shown in red. The rectangle computed with `smallest_rectangle2` is shown in green.

1. Setting the reference system
   In the image in which the metrology model was defined, extract a region containing the metrology objects. The pose of this region with respect to the image coordinate system is determined and set as the reference system of the metrology model using `set_metrology_model_param`. This step is only performed once when setting up the metrology model.
   Example:
   ```
   threshold(Image, Region, 0, 50)
   smallest_rectangle2(Region, RowOrig, ColumnOrig, AngleOrig, Length1,
   Length2)
   set_metrology_model_param(MetrologyHandle, 'reference_system',
   [RowOrig, ColumnOrig, AngleOrig])
   ```
2. Determining the alignment
   In an image where the metrology model occurs in a different Pose, the current pose if the extracted region is determined. This pose is then used to align the metrology model.
   Example:
   ```
   threshold(CurrentImage, Region, 0, 50)
   smallest_rectangle2(Region, RowAlign, ColumnAlign, AngleAlign,
   Length1, Length2)
   align_metrology_model(MetrologyHandle, RowAlign, ColumnAlign,
   AngleAlign)
   ```

Using a shape model:

If a shape model is used to align the metrology model, the reference system with respect to which the metrology objects are given has to be set so that it coincides with the coordinate system used by the shape model. Only then, the results (*'row'*, *'column'*, *'angle'*) of `get_generic_shape_model_result` can be used directly in `align_metrology_model` to align the metrology model in the current image. The individual steps that are needed, are shown below.



(1) (2) (3)

(1) The contours of the metrology model (2) The contours of the shape model (3) The contours of the metrology model after setting the correct reference system.

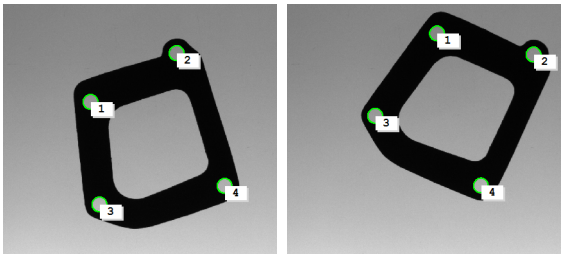
1. Setting the reference system
   In the image in which the metrology model was defined, the pose of the origin of the shape model is determined and set as the reference system of the metrology model using `set_metrology_model_param`. This step is only performed once when setting up the metrology model.
   Example:
   ```
   train_generic_shape_model(Image, ModelID)
   area_center(Image, Area, RowOrig, ColumnOrig)
   set_metrology_model_param(MetrologyHandle, 'reference_system',
   [RowOrig,ColumnOrig,0])
   ```

2. Determining the alignment
   In an image, in which the object to be measured occurs in a different pose, the current pose of the shape model is determined and set in the metrology model using `align_metrology_model`.
   Example:

```
find_generic_shape_model(CurrentImage, ModelID, MatchResultID,
NumMatchResult)
get_generic_shape_model_result(MatchResultID, 'all', 'row', RowAlign)
get_generic_shape_model_result(MatchResultID, 'all', 'column',
ColumnAlign)
get_generic_shape_model_result(MatchResultID, 'all', 'angle',
AngleAlign)
align_metrology_model(MetrologyHandle, RowAlign, ColumnAlign,
AngleAlign)
```

Using a rigid 2D transformation:

If certain model points (given as [PRowModel], [PColumnModel]) can be clearly identified and if they can still be clearly identified in further images in which the objects to be measured can occur shifted or rotated, a rigid transformation can be calculated between those points. The transformation parameters can then directly be used for aligning the model. In this case, the reference point of the metrology model does not have to be changed.



(1) (2)

(1) The contours of the metrology object and the four corresponding points in the image that was used for the creation of the metrology model. (2) The contours of the metrology object and the four corresponding points in a new image.

1. Determine the point correspondences
2. Estimate the model pose
   The following operator sequence calculates the parameters of the model pose (`Row`, `Column`, `Angle`) from corresponding points in the model image and one other image.
   Example:

```
vector_to_rigid(PRowModel, PColumnModel, PRowCurrent, PColumnCurrent,
HomMat2D)
hom_mat2d_to_affine_par(HomMat2D, Sx, Sy, Angle, Theta, Row, Column)
align_metrology_model(MetrologyHandle, Row, Column, Angle)
```

Parameters

▷ **`MetrologyHandle`** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **`Row`** (input_control) . . . . . real ⇝ *real* / integer
Row coordinate of the alignment.
Default: 0

▷ **`Column`** (input_control) . . . . . real ⇝ *real* / integer
Column coordinate of the alignment.
Default: 0

▷ **`Angle`** (input_control) . . . . . angle.rad ⇝ *real* / integer
Rotation angle of the alignment.
Default: 0

Example

```
read_image (Image, 'metal-parts/circle_plate_01')
```

```
create_metrology_model (MetrologyHandle)
get_image_size (Image, Width, Height)
set_metrology_model_image_size (MetrologyHandle, Width, Height)
CircleParam := [354,274,53]
CircleParam := [CircleParam,350,519,53]
add_metrology_object_generic (MetrologyHandle, 'circle', CircleParam, 20,\
                              5, 1, 30, [], [], CircleIndices)
create_generic_shape_model (ModelID)
set_generic_shape_model_param (ModelID, 'metric', 'use_polarity')
set_generic_shape_model_param (ModelID, 'min_contrast', 20)
train_generic_shape_model (Image, ModelID)
* Determine location of shape model origin
area_center (Image, Area, RowOrigin, ColOrigin)
set_metrology_model_param (MetrologyHandle, 'reference_system', \
                           [RowOrigin,ColOrigin,0])
read_image (CurrentImage, 'metal-parts/circle_plate_02')
find_generic_shape_model (CurrentImage, ModelID, MatchResultID, \
                          NumMatchResult)
get_generic_shape_model_result (MatchResultID, 'all', 'row', Row)
get_generic_shape_model_result (MatchResultID, 'all', 'column', Col)
get_generic_shape_model_result (MatchResultID, 'all', 'angle', Angle)
align_metrology_model (MetrologyHandle, Row, Col, Angle)
apply_metrology_model (CurrentImage, MetrologyHandle)
get_metrology_object_result (MetrologyHandle, CircleIndices, 'all', \
                             'result_type', 'all_param', Rectangle)
get_metrology_object_result_contour (Contour, MetrologyHandle, \
                                     CircleIndices, 'all', 1.5)
```

Result

If the parameters are valid, the operator `align_metrology_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

apply_metrology_model (Image : : MetrologyHandle :)

Measure and fit the geometric shapes of all metrology objects of a metrology model.

apply_metrology_model locates the edges inside the measure regions of the metrology objects of the metrology model MetrologyHandle within Image and fits the corresponding geometric shapes to the resulting edge positions.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The measurements are performed as follows:

Determining the edge positions

Within the measure regions of the metrology objects, the positions of the edges are determined. The edge location is calculated internally with the operator measure_pos or fuzzy_measure_pos. The latter is used if at least one fuzzy function was set for the metrology objects with set_metrology_object_fuzzy_param.

Fitting geometric shapes to the edge positions

The geometric shapes of the metrology objects are adapted to fit optimally to the resulting edge positions. In particular, a RANSAC algorithm is used to select a set of initial edge positions that is necessary to create an instance of the specific geometric shape, e.g., three edge positions are selected for a metrology object of type circle. Then, those edge positions that are near the corresponding instance of the geometric shape are determined and, if the number of suitable edge positions is sufficient (see the generic parameter *'min_score'* of set_metrology_object_param), are selected for the final fitting of the geometric shape. If the number of suitable edge positions is not sufficient, another set of initial edge positions is tested until a suitable selection of edge positions is found. Into the edge positions that are selected for the final fitting, the geometric shape is fitted and its parameters are stored in the metrology model. Note that more than one instance for each metrology object is returned if the generic parameter *'num_instances'* is set to value larger than 1. This and other parameters can be set when adding the metrology objects to the metrology model or separately with the operator set_metrology_object_param. Note that for each instance of the metrology object different initial edge positions are used, i.e., a second instance is based on edge positions that were not already used for the fitting of the first instance. The algorithm stops either when *'num_instances'* instances were found or if the remaining number of suitable initial edge positions is too low for a further fitting of the geometric shape.

Accessing the results

The results of the measurements can be accessed from the metrology model using get_metrology_object_result. Note that if more than one instance of an object is returned, the order of the returned instances is arbitrary and therefore no measure for the quality of the fitting. Note further that if the parameters *'camera_param'* and *'plane_pose'* were set for the metrology model using set_metrology_model_param, world coordinates are used for the fitting. Otherwise, image coordinates are used. The XLD contours for the measured objects can be obtained using get_metrology_object_result_contour.

Attention

Note that all measure regions of all metrology objects must be recomputed if the width or the height of the input Image is not equal to the width and height stored in the metrology object (e.g., set with set_metrology_model_image_size). This leads to longer execution times of the operator.

Note further that apply_metrology_model ignores the domain of Image for efficiency reasons (see also measure_pos).

Parameters

- ▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
  Handle of the metrology model.

Result

If the parameters are valid, the operator apply_metrology_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

set_metrology_object_fuzzy_param, read_metrology_model, write_metrology_model

Module

2D Metrology

clear_metrology_model (: : MetrologyHandle :)

Delete a metrology model and free the allocated memory.

clear_metrology_model deletes a metrology model that was created by create_metrology_model, copy_metrology_model, read_metrology_model, or deserialize_metrology_model. Note that by deleting the model also the including metrology objects are deleted. All memory used by the metrology model and the metrology objects is freed. The handle of the model is passed in MetrologyHandle. After the operator call, the metrology model is invalid.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

Parameters

▷ **MetrologyHandle** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

Result

The operator clear_metrology_model returns the value 2 (H_MSG_TRUE) if a valid handle was passed and the referred metrology model can be freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

get_metrology_object_result, write_metrology_model

Module

2D Metrology

clear_metrology_object (: : MetrologyHandle, Index :)

Delete metrology objects and free the allocated memory.

clear_metrology_object deletes in a metrology model metrology objects created, e.g, by add_metrology_object_circle_measure, add_metrology_object_ellipse_measure, add_metrology_object_line_measure, or add_metrology_object_rectangle2_measure.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

All memory used by the metrology objects is freed. The handle of the metrology model is passed in MetrologyHandle. The index of the metrology objects is passed in Index. If Index is set to *'all'*, all metrology objects are deleted. After the operator call the metrology objects are invalid.

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index ∈ {'all', 0, 1, 2}

Result

If the parameters are valid, the operator clear_metrology_object returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

copy_metrology_model (: : MetrologyHandle,
Index : CopiedMetrologyHandle)

Copy a metrology model.

copy_metrology_model creates a new metrology model and copies the selected metrology objects of the input metrology model to this new output metrology model.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The input metrology model is defined by a handle MetrologyHandle. The parameter Index determines the metrology objects that are copied. With Index set to *'all'*, all metrology objects are copied. The operator returns the handle CopiedMetrologyHandle of the new metrology model. It can be used to save memory space. Access to the parameters of the metrology objects is possible, e.g., with the operator get_metrology_object_param.

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index ∈ {'all', 0, 1, 2}

▷ **CopiedMetrologyHandle** (output_control) . . . . . integer ⇝ *integer*
Handle of the copied metrology model.

Result

If the parameters are valid, the operator `copy_metrology_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

create_metrology_model (: : : MetrologyHandle)

Create the data structure that is needed to measure geometric shapes.

`create_metrology_model` creates a metrology model, i.e., the data structure that is needed to measure objects with a specific geometric shape (metrology object) via 2D metrology, and returns it in the handle `MetrologyHandle`.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

Attention

Note, that after calling the operator `create_metrology_model` the operator `set_metrology_model_image_size` should be called for efficiency reasons.

Parameters

▷ **MetrologyHandle** (output_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

Example

```
read_image (Image, 'fabrik')
create_metrology_model (MetrologyHandle)
get_image_size (Image, Width, Height)
set_metrology_model_image_size (MetrologyHandle, Width, Height)
add_metrology_object_rectangle2_measure (MetrologyHandle, 270, 230, 0, 30, \
                                         25, 10, 2, 1, 30, [], [], Index)
apply_metrology_model (Image, MetrologyHandle)
get_metrology_object_result (MetrologyHandle, Index, 'all', 'result_type', \
                             'all_param', Rectangle)
get_metrology_object_result_contour (Contour, MetrologyHandle, \
                                     Index, 'all', 1.5)
```

Result

If the parameters are valid, the operator `create_metrology_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`set_metrology_model_image_size`

Module

2D Metrology

deserialize_metrology_model (: : SerializedItemHandle : MetrologyHandle)

Deserialize a serialized metrology model.

deserialize_metrology_model deserializes a metrology model, that was serialized by serialize_metrology_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized metrology model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created metrology model with the handle MetrologyHandle. Access to the parameters of the metrology model is possible, e.g., with the operators get_metrology_object_param or get_metrology_object_fuzzy_param.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **MetrologyHandle** (output_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

Result

If the parameters are valid, the operator deserialize_metrology_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

get_metrology_model_param (: : MetrologyHandle, GenParamName : GenParamValue)

Get parameters that are valid for the entire metrology model.

get_metrology_model_param queries parameters that are valid for the entire metrology model.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle.

The following generic parameter names for GenParamName are possible:

'camera_param': The internal camera parameters that are set for the metrology model.

'plane_pose': The 3D pose of the measurement plane that is set for the metrology model. The 3D pose is given in camera coordinates.

'reference_system': The rotation and translation of the current reference coordinate system with respect to the image coordinate system. The tuple returned in GenParamValue contains [row, column, angle].

'scale': The scaling factor or unit of the results of the measurement returned by `get_metrology_object_result`.

Parameters

▷ **`MetrologyHandle`** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **`GenParamName`** (input_control) ..... attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'camera_param'
List of values: `GenParamName` ∈ {'camera_param', 'plane_pose', 'scale', 'reference_system'}

▷ **`GenParamValue`** (output_control) ..... attribute.value(-array) ⇝ *string* / real / integer
Value of the generic parameter.

Result

If the parameters are valid, the operator `get_metrology_model_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

`get_metrology_object_fuzzy_param` (: : `MetrologyHandle`, `Index`, `GenParamName` : `GenParamValue`)

Get a fuzzy parameter of a metrology model.

`get_metrology_object_param` allows to access the fuzzy parameters of metrology objects.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle `MetrologyHandle`. The parameter `Index` specifies for which metrology objects the information is accessed. With `Index` set to *'all'*, the parameters of all metrology objects are accessed. The names of the desired parameters are passed in the generic parameter `GenParamName`, the corresponding values are returned in `GenParamValue` in the same order. All these fuzzy parameters can be set and changed at any time with the operator `set_metrology_object_fuzzy_param`.

The following parameters can be accessed:

'fuzzy_thresh': The meaning and the use of this parameter is equivalent to the parameter `FuzzyThresh` of the operator `fuzzy_measure_pos` and is described there.

'function_contrast': With this parameter the fuzzy function of type contrast that is set in the operator `set_metrology_object_param` can be queried. The meaning and the use of this parameter is equivalent to the parameter `SetType` with the value *'contrast'* of the operator `set_fuzzy_measure` and is described there. The return value `GenParamValue` contains the function of the metrology object.

'function_position': With this parameter the fuzzy function of type position that is set in the operator `set_metrology_object_param` can be queried. Because only one fuzzy function of a type can be set, only the last set function can be returned. The type can be *'function_position'*, *'function_position_center'*, *'function_position_end'*, *'function_position_first_edge'*, or *'function_position_last_edge'*.

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index ∈ {'all', 0, 1, 2}

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: 'fuzzy_thresh'
List of values: GenParamName ∈ {'function_contrast', 'function_position', 'fuzzy_thresh'}

▷ **GenParamValue** (output_control) . . . . . attribute.value-array ⇝ *real* / integer
Values of the generic parameters.

Result

If the parameters are valid, the operator get_metrology_object_fuzzy_param returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

get_metrology_object_indices (: : MetrologyHandle : Indices)

Get the indices of the metrology objects of a metrology model.

get_metrology_object_indices allows to access the indices of the metrology objects.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle. The operator get_metrology_object_indices returns the indices of the metrology object in the parameter Indices. Access to the parameters of the metrology object is possible, e.g., with the operator get_metrology_object_param.

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Indices** (output_control) . . . . . integer(-array) ⇝ *integer*
Indices of the metrology objects.

Result

If the parameters are valid, the operator get_metrology_object_indices returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

get_metrology_object_num_instances

Module

2D Metrology

get_metrology_object_measures (: Contours : MetrologyHandle, Index, Transition : Row, Column)

Get the measure regions and the results of the edge location for the metrology objects of a metrology model.

get_metrology_object_measures allows to access the measure regions of the metrology objects that were created with add_metrology_object_generic, add_metrology_object_circle_measure, etc. as XLD contours and the results of the edge location in image coordinates that was performed by apply_metrology_model.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle. The parameter Index determines for which metrology objects the information is accessed. With Index set to *'all'*, the measure regions and the results of the edge location for all metrology objects are accessed.

If positive and negative edges are available in the measure regions (see the generic parameter value *'measure_transition'* of the operator set_metrology_object_param), with the parameter Transition the desired edges (positive or negative) can be selected. If Transition is set to *'positive'*, only positive edges are returned. If Transition is set to *'negative'*, only negative edges are returned. All edges are returned if the parameter Transition is set to *'all'*.

The operator get_metrology_object_measures returns for each measure region one rectangular XLD contour with the boundary of the measure region in the parameter Contours. After calling apply_metrology_model, additionally the image coordinates of the results of the edge location are returned as single points in the parameters Row and Column. Note that the order for the values of these points is not defined. Furthermore, there is no possibility to assign the results of the edge location to specific measure regions. If get_metrology_object_measures is called before apply_metrology_model, the parameters Row and Column remain empty.

Parameters

▷ **Contours** (output_object) ..... xld_cont-array ⇝ *object*
Rectangular XLD Contours of measure regions.

▷ **MetrologyHandle** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) ..... integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index ∈ {'all', 0, 1, 2}

▷ **Transition** (input_control) ..... string ⇝ *string*
Select light/dark or dark/light edges.
Default: 'all'
List of values: Transition ∈ {'all', 'negative', 'positive'}

▷ **Row** (output_control) ..... point.y-array ⇝ *real*
Row coordinates of the measured edges.

▷ **Column** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinates of the measured edges.

Result

If the parameters are valid, the operator `get_metrology_object_measures` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

get_metrology_object_model_contour (: Contour : MetrologyHandle, Index, Resolution :)

Query the model contour of a metrology object in image coordinates.

`get_metrology_object_model_contour` returns the contours for the chosen metrology objects in image coordinates.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle `MetrologyHandle`. The parameter `Index` specifies for which metrology objects the contours are queried. For `Index` set to *'all'*, the contours of all metrology objects are returned.

The form and pose of each contour is determined by the parameters set when adding the object using e.g., `add_metrology_object_generic`, `add_metrology_object_circle_measure`, etc. If a different reference coordinate system was set for the metrology model using `set_metrology_model_param` or an alignment of the metrology model was performed using `align_metrology_model`, these values influence the current pose of the metrology objects and thus the pose of the contours returned in `Contour`.

The resolution of the returned `Contour` is controlled via `Resolution` containing the Euclidean distance (in pixel) between neighboring contour points. If the input value falls below the minimal possible value (1.192e-7), the resolution is set internally to the smallest valid value.

Parameters

▷ **Contour** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Model contour.

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *integer* / string
Index of the metrology object.
Default: 0
Suggested values: `Index` ∈ {'all', 0, 1, 2}

▷ **Resolution** (input_control) . . . . . real ⇝ *real*
Distance between neighboring contour points.
Default: 1.5
Restriction: Resolution >= 1.192e-7

Result

If the parameters are valid, the operator `get_metrology_object_model_contour` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

`get_metrology_object_num_instances` (: : `MetrologyHandle`, `Index` : `NumInstances`)

Get the number of instances of the metrology objects of a metrology model.

`get_metrology_object_num_instances` allows to access the number of instances (results) of measurements applied by `apply_metrology_model` for the metrology objects. Note that by default, the maximum number of instances of each metrology object is set to *1*. Thus, by default, the result of `get_metrology_object_num_instances` will typically be *1* as well. To allow more instances, before applying the measurement with `apply_metrology_model` you have to explicitly set the parameter *'num_instances'* to a higher value or to *'all'* using `set_metrology_object_param`.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle `MetrologyHandle`. The parameter `Index` specifies for which metrology object the instances are queried. For `Index` set to *'all'*, the number of instances of all metrology objects are returned. The number of instances is returned in `NumInstances` for each metrology object that was passed in `Index`.

Parameters

▷ **`MetrologyHandle`** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **`Index`** (input_control) ..... integer(-array) ⇝ *integer* / string
Index of the metrology objects.
Default: 0
Suggested values: `Index` ∈ {'all', 0, 1, 2}

▷ **`NumInstances`** (output_control) ..... integer(-array) ⇝ *real* / integer
Number of Instances of the metrology objects.

Result

If the parameters are valid, the operator `get_metrology_object_num_instances` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

get_metrology_object_indices

Module

2D Metrology

get_metrology_object_param (: : MetrologyHandle, Index, GenParamName : GenParamValue)

Get one or several parameters of a metrology model.

get_metrology_object_param allows to access the parameters that are used by a metrology object.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle. The parameter Index determines for which metrology objects the information is accessed. With Index set to *'all'*, the parameters of all metrology objects are accessed. The names of the desired parameters are passed in the generic parameter GenParamName, the corresponding values are returned in GenParamValue in the same order. All these general parameters can be set and changed at any time with the operator set_metrology_object_param. Parameters that describe the geometry of an object can only be set by creating the metrology object with the operators add_metrology_object_circle_measure, add_metrology_object_ellipse_measure, add_metrology_object_line_measure, or add_metrology_object_rectangle2_measure.

The following parameters can be accessed:

- Valid for all types of metrology objects:

  'min_score', *'num_instances'*, *'instances_outside_measure_regions'*: The meaning and the use of these parameters is described with the operator set_metrology_object_param.

  'rand_seed', *'distance_threshold'*, *'max_num_iterations'*: The meaning and the use of these parameters is described with the operator set_metrology_object_param.

  'measure_length1', *'measure_length2'*: The meaning and the use of these parameters is described with the operator set_metrology_object_param.

  'measure_sigma', *'measure_threshold'*, *'measure_transition'*, *'measure_select'*: The meaning and the use of these parameters is described with the operator measure_pos by the parameters Sigma, Threshold, Transition, and Select.

  'measure_interpolation': The meaning and the use of this parameter is described with the operator gen_measure_rectangle2 by the parameter Interpolation.

  'measure_distance_min': Returns the minimum distance between the centers of the generated measure regions, which depends on the geometry of the object and the value of the input parameter *'measure_distance'* or the value of the input parameter *'num_measures'* of the operator set_metrology_object_param. For a metrology object circle or a metrology object line the distances between measure regions are uniformly distributed. Therefore, *'measure_distance_min'* and *'measure_distance_max'* return the same value.

  'measure_distance_max': Returns the maximum distance between the centers of the generated measure regions, which depends on the geometry of the object and the value of the input parameter *'measure_distance'* or the value of the input parameter *'num_measures'* of the operator set_metrology_object_param. For a metrology object circle or a metrology object line the distances between measure regions are uniformly distributed. Therefore, *'measure_distance_min'* and *'measure_distance_max'* return the same value.

  'num_measures': Returns the number of generated measure regions, which depends on the geometry of the object and the value of the input parameter *'measure_distance'* or the value of the input parameter *'num_measures'* of the operator set_metrology_object_param.

'object_type': Type of the geometric shape of the metrology object. For a metrology object of type circle, the output parameter GenParamValue contains the value *'circle'*. For a metrology object of type ellipse, the output parameter GenParamValue contains the value *'ellipse'*. For a metrology object of type line, the output parameter GenParamValue contains the value *'line'*. For a metrology object of type rectangle, the output parameter GenParamValue contains the value *'rectangle'*.

'object_params': The parameters of the geometric shape of the metrology object. For a metrology object of type circle, the output parameter GenParamValue contains the geometry of the circle in the following order: *'row'*, *'column'*, *'radius'*. The meaning and the use of these parameters is described with the operator add_metrology_object_circle_measure. For a metrology object of type ellipse, the output parameter GenParamValue contains the geometry of the ellipse in the following order: *'row'*, *'column'*, *'phi'*, *'radius1'*, *'radius2'*. The meaning and the use of these parameters is described with the operator add_metrology_object_ellipse_measure. For a metrology object of type line, the output parameter GenParamValue contains the geometry of the line in the following order: *'row_begin'*, *'column_begin'*, *'row_end'*, *'column_end'*. The meaning and the use of these parameters is described with the operator add_metrology_object_line_measure. For a metrology object of type rectangle, the output parameter GenParamValue contains the geometry of the rectangle in the following order: *'row'*, *'column'*, *'phi'*, *'length1'*, *'length2'*. The meaning and the use of these parameters is described with the operator add_metrology_object_rectangle2_measure.

- Only valid for a metrology object of type circle:

  'row', *'column'*, *'radius'*: These are parameters for a metrology object of type circle. The meaning and the use of these parameters is described with the operator add_metrology_object_circle_measure.

- Only valid for a metrology object of type ellipse:

  'row', *'column'*, *'phi'*, *'radius1'*, *'radius2'*: These are parameters for a metrology object of type ellipse. The meaning and the use of these parameters is described with the operator add_metrology_object_ellipse_measure.

- Only valid for a metrology object of type line:

  'row_begin', *'column_begin'*, *'row_end'*, *'column_end'*: These are parameters for a metrology object of type line. The meaning and the use of these parameters is described with the operator add_metrology_object_line_measure.

- Only valid for a metrology object of type rectangle:

  'row', *'column'*, *'phi'*, *'length1'*, *'length2'*: These are parameters for a metrology object of type rectangle. The meaning and the use of these parameters is described with the operator add_metrology_object_rectangle2_measure.

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index ∈ {'all', 0, 1, 2}

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: 'num_measures'
List of values: GenParamName ∈ {'column', 'column_begin', 'column_end', 'distance_threshold', 'end_phi', 'instances_outside_measure_regions', 'length1', 'length2', 'max_num_iterations', 'measure_distance_min', 'measure_distance_min', 'measure_interpolation', 'measure_length1', 'measure_length2', 'measure_select', 'measure_sigma', 'measure_threshold', 'measure_transition', 'min_score', 'num_instances', 'num_measures', 'object_params', 'object_type', 'phi', 'point_order', 'radius', 'radius1', 'radius2', 'rand_seed', 'row', 'row_begin', 'row_end', 'start_phi', 'x', 'y', 'x_begin', 'y_begin', 'x_end', 'y_end'}

▷ **GenParamValue** (output_control) . . . . . attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters.

Result

If the parameters are valid, the operator `get_metrology_object_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

`get_metrology_object_result` `( : : MetrologyHandle, Index, Instance, GenParamName, GenParamValue : Parameter )`

Get the results of the measurement of a metrology model.

`get_metrology_object_result` allows to access the results of a measurement obtained by `apply_metrology_model` for the metrology objects of the metrology model `MetrologyHandle`.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The parameter `Index` specifies for which metrology objects the results are queried. For `Index` set to *'all'*, the results of all metrology objects are returned. With the parameter `Instance` it can be specified, which instances of the results are returned in `Parameter`. The results for all instances are returned by setting `Instance` to *'all'*. Different generic parameters can be used to control the returned values in `Parameter`. The generic parameter names are passed in `GenParamName`. The corresponding values are passed in `GenParamValue`. The following parameters and values are possible:

'result_type': If `GenParamName` is set to *'result_type'*, then `GenParamValue` allows to control how and what results are returned for a metrology object. All measured parameters of the queried metrology object can be queried at once, specific parameters can be queried individually or the score for the metrology object can be queried.

'Obtaining all parameters': If `GenParamValue` is set to *'all_param'*, then all measured parameters of a metrology object are returned. If camera parameters and a pose have been set (see `set_metrology_model_param`), the results are returned in metric coordinates, otherwise in pixels.
For a *circle*, the return values are the coordinates of the center and the radius of the circle. The order is [*'row'*, *'column'*, *'radius'*] or [*'x'*, *'y'*, *'radius'*] respectively.
For an *ellipse*, the return values are the coordinates of the center, the orientation of the major axis *'phi'*, the length of the larger half axis *'radius1'*, and the length of the smaller half axis *'radius2'* of the ellipse. The order is [*'row'*, *'column'*, *'phi'*, *'radius1'*, *'radius2'*] or [*'x'*, *'y'*, *'phi'*, *'radius1'*, *'radius2'*] respectively.
For a *line*, the start and end point of the line is returned. The order is [*'row_begin'*, *'column_begin'*, *'row_end'*, *'column_end'*] or [*'x_begin'*, *'y_begin'*, *'x_end'*, *'y_end'*]
For a *rectangle*, the return values are the coordinates of the center, the orientation of the main axis *'phi'*, the length of the larger half edge *'length1'*, and the length of the smaller half edge *'length2'* of the rectangle. The order is [*'row'*, *'column'*, *'phi'*, *'length1'*, *'length2'*] or [*'x'*, *'y'*, *'phi'*, *'length1'*, *'length2'*] respectively.

'Obtaining specific parameters': Measured object parameters can also be queried individually by providing the desired parameter name in `GenParamName`.

When *no camera parameters* and no measurement plane are set, the following parameters can be queried individually, depending on whether they are available for the respective object. Note that for lines, additionally the 3 parameters of the hessian normal form can be queried, i.e., the unit normal vector *'nrow'*, *'ncolumn'* and the orthogonal distance *'distance'* of the line from the origin of the coordinate system. The sign of the distance determines the side of the line on which the origin is located.
List of values: *'row'*, *'column'*, *'radius'*, *'phi'* , *'radius1'*, *'radius2'*, *'length1'*, *'length2'*, *'row_begin'*, *'column_begin'*, *'row_end'*, *'column_end'*, *'nrow'*, *'ncolumn'*, *'distance'*
If *camera parameters* and a measurement plane was set, the parameters are returned in metric coordinates, the following parameters can be queried individually, depending on whether they are available for the respective object. Note that for lines, additionally the 3 parameters of the hessian normal form can be queried, i.e., the unit normal vector *'nx'*, *'ny'* and the orthogonal distance *'distance'* of the line from the origin of the coordinate system. The sign of the distance determines the side of the line on which the origin is located.
List of values: *'x'*, *'y'*, *'radius'*, *'phi'* , *'radius1'*, *'radius2'*, *'length1'*, *'length2'*, *'radius1'*, *'radius2'*, *'length1'*, *'length2'*, *'x_begin'*, *'y_begin'*, *'x_end'*, *'y_end'*, *'nx'*, *'ny'*, *'distance'*

***'Obtaining the score'*:** If `GenParamName` is set to the *'score'*, the fitting scores are returned. The score represents the number of measurements that are used for the calculation of the results divided by the maximum number of measure regions.

'used_edges': To query the edge points, that were actually used for a fitted metrology object, you can choose between following values for `GenParamValue`:

'row': Return the row coordinate of the edges that were used to fit the metrology object.

'column': Return the column coordinate of the edges that were used to fit the metrology object.

'amplitude': Return the edge amplitude of the edges that were used to fit the metrology object.

List of values: *'row'*, *'column'*, *'amplitude'*

'angle_direction': The parameter determines the rotation direction for angles that result from the fitting. Setting the parameter *'angle_direction'* to *'positive'* the angle is specified between the main axis of the object and the horizontal axis of the coordinate system in the mathematically positive direction (counterclockwise). Setting the parameter *'angle_direction'* to *'negative'* the angle is specified between the main axis of the object and the horizontal axis of the coordinate system in the mathematically negative direction (clockwise). The results of the angles are returned in radians.
List of values: *'positive'*, *'negative'*
Default: *'positive'*

It is possible to query the results of several metrology objects (see the parameter `Index`) and several instances (see the parameter `Instance`) of the metrology objects simultaneously. The results are returned in the following order in `Parameter`: 1st instance of 1st metrology object, 2nd instance of 1st metrology object, etc., 1st instance of 2nd metrology object, 2nd instance of 2nd metrology object, etc.

Parameters

▷ **`MetrologyHandle`** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **`Index`** (input_control) ..... integer(-array) ⇝ *integer* / string
Index of the metrology object.
Default: 0
Suggested values: `Index` ∈ {'all', 0, 1, 2}

▷ **`Instance`** (input_control) ..... integer(-array) ⇝ *string* / integer
Instance of the metrology object.
Default: 'all'
Suggested values: `Instance` ∈ {'all', 0, 1, 2}

▷ **`GenParamName`** (input_control) ..... attribute.name-array ⇝ *string*
Name of the generic parameter.
Default: 'result_type'
List of values: `GenParamName` ∈ {'result_type', 'angle_direction', 'used_edges'}

▷ **`GenParamValue`** (input_control) ..... attribute.value-array ⇝ *string* / real
Value of the generic parameter.
Default: 'all_param'
Suggested values: `GenParamValue` ∈ {'all_param', 'score', 'true', 'false', 'row', 'column', 'amplitude', 'radius', 'phi', 'radius1', 'radius2', 'length1', 'length2', 'row_begin', 'column_begin', 'row_end',

'column_end', 'nrow', 'ncolumn', 'distance', 'x', 'y', 'x_begin', 'y_begin', 'x_end', 'y_end', 'nx', 'ny', 'positive', 'negative'}

▷ **Parameter** (output_control) . . . . . real(-array) ⇝ *real* / integer / string
Result values.

Result

If the parameters are valid, the operator `get_metrology_object_result` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

get_metrology_object_result_contour (
: Contour : MetrologyHandle, Index, Instance, Resolution :)

Query the result contour of a metrology object.

`get_metrology_object_result_contour` returns for the chosen metrology objects and object instances, the result contours of a measurement performed by `apply_metrology_model` in image coordinates.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle `MetrologyHandle`. The parameter `Index` specifies for which metrology objects the result contours are queried. For `Index` set to *'all'*, the result contours of all metrology objects are returned. If for a metrology object several results (instances) were computed, then the parameter `Instance` specifies, for which instances the result contours are returned in `Contour`. The result contours for all instances are obtained by setting `Instance` to *'all'*.

The resolution of the resulting contour `Contour` is controlled via `Resolution` containing the Euclidean distance between neighboring contour points in pixel. If the input value falls below the minimal possible value (1.192e-7), then the resolution is set internally to the smallest valid value.

Parameters

▷ **Contour** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Result contour for the given metrology object.

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *integer* / string
Index of the metrology object.
Default: 0
Suggested values: `Index` ∈ {'all', 0, 1, 2}

▷ **Instance** (input_control) . . . . . integer(-array) ⇝ *string* / integer
Instance of the metrology object.
Default: 'all'
Suggested values: `Instance` ∈ {'all', 0, 1, 2}

▷ **Resolution** (input_control) . . . . . real ⇝ *real*
Distance between neighboring contour points.
Default: 1.5
Restriction: Resolution >= 1.192e-7

Result

If the parameters are valid, the operator `get_metrology_object_result_contour` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

2D Metrology

read_metrology_model (: : FileName : MetrologyHandle)

Read a metrology model from a file.

`read_metrology_model` reads a metrology model, which has been written to file with `write_metrology_model`, from the file `FileName`. The default HALCON file extension for a metrology model is 'mtr'. The values contained in the read metrology model are stored in a metrology model with the handle `MetrologyHandle`. Access to the parameters of the metrology model is possible, e.g., with the operator `get_metrology_object_param` or `get_metrology_object_fuzzy_param`.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
File extension: `.mtr`

▷ **MetrologyHandle** (output_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

Result

If the parameters are valid, the operator `read_metrology_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

`write_metrology_model`

Module

2D Metrology

reset_metrology_object_fuzzy_param (: : MetrologyHandle, Index :)

Reset all fuzzy parameters and fuzzy functions of a metrology model.

reset_metrology_object_fuzzy_param discards all fuzzy parameters and fuzzy functions of the metrology objects that can be set by the operator set_metrology_object_fuzzy_param and restores the default values.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle. The parameter Index determines the metrology objects to reset. With Index set to *'all'*, all metrology objects are reset.

Parameters

▷ **MetrologyHandle** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) ..... integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index ∈ {'all', 0, 1, 2}

Result

If the parameters are valid, the operator reset_metrology_object_fuzzy_param returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

serialize_metrology_model (: : MetrologyHandle : SerializedItemHandle)

Serialize a metrology model.

serialize_metrology_model serializes the data of a metrology model (see fwrite_serialized_item for an introduction of the basic principle of serialization).

The same data that is written in a file by write_metrology_model is converted to a serialized item. The metrology model is defined by the handle MetrologyHandle. The serialized metrology model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_metrology_model.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_metrology_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

2D Metrology

set_metrology_model_image_size (: : MetrologyHandle, Width, Height :)

Set the size of the image of metrology objects.

set_metrology_model_image_size is used to set or change the size of the image in which the edge detection that is related to a metrology model will be performed.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle. The image width must be specified by the parameter Width. The image height must specified by the parameter Height.

Attention

Note that the operator set_metrology_model_image_size should be called before adding metrology objects to the metrology model using the operators add_metrology_object_generic, add_metrology_object_circle_measure, add_metrology_object_ellipse_measure, add_metrology_object_line_measure, or add_metrology_object_rectangle2_measure. Otherwise, all measure regions of existing metrology objects will be recomputed automatically upon calling set_metrology_model_image_size or apply_metrology_model.

Parameters

▷ **MetrologyHandle** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the image to be processed.
Default: 640
Suggested values: Width ∈ {128, 192, 256, 512, 640, 768, 1024, 1280, 2048}
Value range: 0 ≤ Width (lin)
Minimum increment: 1
Recommended increment: 16

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the image to be processed.
Default: 480
Suggested values: Height ∈ {128, 192, 256, 512, 640, 768, 1024, 1280, 2048}
Value range: 0 ≤ Height (lin)
Minimum increment: 1
Recommended increment: 16

Result

If the parameters are valid, the operator set_metrology_model_image_size returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

set_metrology_model_param (: : MetrologyHandle, GenParamName, GenParamValue :)

Set parameters that are valid for the entire metrology model.

set_metrology_model_param sets or changes parameters that are valid for the entire metrology model MetrologyHandle.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The following values for GenParamName and GenParamValue are possible:

Calibration

If both internal camera parameters and the 3D pose of the measurement plane are set, apply_metrology_model calculates the results in metric coordinates.

'camera_param': Often the internal camera parameters are the result of calibrating the camera with the operator calibrate_cameras (see Calibration for the sequence of the parameters and the underlying camera model). It is possible to discard the internal camera parameters by setting *'camera_param'* to [].
Default: []

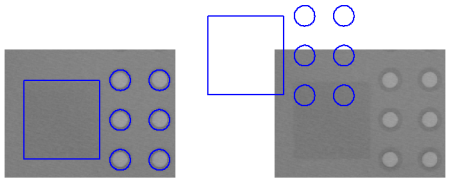
'plane_pose': The 3D pose of the measurement plane in camera coordinates. It is possible to discard the pose by setting *'plane_pose'* to [].
Default: []

Definition of a new reference system

When adding the metrology objects to the metrology model using e.g., add_metrology_object_generic, add_metrology_object_circle_measure etc. the positions and orientations are given with respect to the image coordinate system which has its origin in the upper left corner of the image. In some cases it may be necessary to change the reference system with respect to which the metrology objects are given. This is for instance the case when using a shape model to align the metrology model in a new image. The results from find_generic_shape_model can only be directly used in align_metrology_model if the reference system of the metrology model is the same as the system in which the shape model is given (see align_metrology_model for more details).

'reference_system': The tuple given in GenParamValue should contain [row, column, angle]. By default the reference system is the image coordinate system which has its origin in the top left corner. A new reference system is defined with respect to the image coordinate system by its translation (row,colum) and its rotation angle (angle). All components of the metrology model are converted into the new reference coordinate system. In the following figure, the reference system of the metrology model is set to the center of the image.

```
set_metrology_model_param(MetrologyHandle, 'reference_system',
[Height/2,Width/2,0])
```



(1) (2)

(1) Several metrology objects and their contours are shown in blue. (2) The new reference system for the metrology model is placed in the center of the image. As a consequence, the positions and orientations of the metrology objects are moved into the reverse direction. The resulting contours of the metrology objects are shown in blue.

Default: *[0, 0, 0]*

Scaling the results

The results of the measurement queried by `get_metrology_object_result` can be scaled by setting a scaling factor.

'scale': The parameter *'scale'* must be specified as the ratio of the *desired unit* to the *original unit*. If no camera parameters are given, the default unit is pixel.

If *'camera_param'* and *'plane_pose'* are set, the original unit is determined by the coordinates of the calibration object. Standard HALCON calibration plates are defined in metric coordinates. If it was used for the calibration, the desired unit can be set directly. The relation of units to scaling factors is given in the following table:

Unit	Scaling factor
m	1
dm	10
cm	100
mm	1000
um, microns	10^6

Suggested values: *1.0*, *0.1*, *'m'*, *'cm'*, *'mm'*, *'microns'*, *'um'*

Default: *1.0*

Parameters

▷ **`MetrologyHandle`** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **`GenParamName`** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'camera_param'
List of values: `GenParamName` ∈ {'camera_param', 'plane_pose', 'scale', 'reference_system'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
Value of the generic parameter.
Default: []
Suggested values: `GenParamValue` ∈ {1.0, 0.1, 'm', 'cm', 'mm', 'microns', 'um'}

Result

If the parameters are valid, the operator `set_metrology_model_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

set_metrology_object_param, align_metrology_model, get_metrology_model_param

Module

2D Metrology

set_metrology_object_fuzzy_param (: : MetrologyHandle, Index, GenParamName, GenParamValue :)

Set fuzzy parameters or fuzzy functions for a metrology model.

set_metrology_object_param is used to set or change the fuzzy parameters or fuzzy functions of a metrology object in order to adapt the model to a particular edge selection before applying the operator apply_metrology_model.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle. The parameter Index specifies the metrology objects for which the parameters should be changed or set. The parameters of all metrology objects are set if the parameter Index is set to *'all'*.

The fuzzy parameter or the type of fuzzy function is passed in the parameter GenParamName. The corresponding value or the fuzzy function is passed in the parameter GenParamValue. If at least one fuzzy function is set, internally the operator fuzzy_measure_pos will be used when searching the objects with the operator apply_metrology_model. More information about fuzzy functions can be found with the operator fuzzy_measure_pos. The following generic parameters and parameter values for GenParamName and GenParamValue are possible:

'fuzzy_thresh': The parameter specifies the minimum fuzzy value. The meaning and the use of this parameter is described with the operator fuzzy_measure_pos. There, the parameter corresponds to the parameter FuzzyThresh.

Default: *0.5*

'function_contrast': The parameter specifies a fuzzy function of type contrast. The meaning and the use of this parameter is described with the operator set_fuzzy_measure. There, the parameter corresponds to the parameter SetType with the value *'contrast'* and its value corresponds to the parameter Function.

Default: *'disabled'*

'function_position': The parameter specifies a fuzzy function of type position. The meaning and the use of this parameter is described with the operator set_fuzzy_measure. There, the parameter corresponds to the parameter SetType with the value *'position'* and its value corresponds to the parameter Function.

Default: *'disabled'*

'function_position_center': The parameter specifies a fuzzy function of type position_center. The meaning and the use of this parameter is described with the operator set_fuzzy_measure. There, the parameter corresponds to the parameter SetType with the value *'position'* and its value corresponds to the parameter Function.

Default: *'disabled'*

'function_position_end': The parameter specifies a fuzzy function of type position_end. The meaning and the use of this parameter is described with the operator set_fuzzy_measure. There, the parameter corresponds to the parameter SetType with the value *'position_end'* and its value corresponds to the parameter Function.

Default: *'disabled'*

'function_position_first_edge': The parameter specifies a fuzzy function of type `position_first_edge`. The meaning and the use of this parameter is described with the operator `set_fuzzy_measure`. There, the parameter corresponds to the parameter `SetType` with the value *'position_first_edge'* and its value corresponds to the parameter `Function`.

Default: *'disabled'*

'function_position_last_edge': The parameter specifies a fuzzy function of type `position_last_edge`. The meaning and the use of this parameter is described with the operator `set_fuzzy_measure`. There, the parameter corresponds to the parameter `SetType` with the value *'position_last_edge'* and its value corresponds to the parameter `Function`.

Default: *'disabled'*

A fuzzy function is discarded if the fuzzy function value is set to *'disabled'*. All previously defined fuzzy functions and fuzzy parameters can be discarded completely using `reset_metrology_object_fuzzy_param`. The current configuration of the metrology objects can be accessed with `get_metrology_object_fuzzy_param`. Note that if at least one fuzzy function is specified, the operator `fuzzy_measure_pos` is used for the edge detection.

Parameters

▷ **`MetrologyHandle`** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **`Index`** (input_control) . . . . . integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: `Index` ∈ {'all', 0, 1, 2}

▷ **`GenParamName`** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: 'fuzzy_thresh'
List of values: `GenParamName` ∈ {'function_contrast', 'function_position', 'function_position_center', 'function_position_end', 'function_position_first_edge', 'function_position_last_edge', 'fuzzy_thresh'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value-array ⇝ *real* / integer
Values of the generic parameters.
Default: 0.5
Suggested values: `GenParamValue` ∈ {0.1, 0.3, 0.5, 0.6, 0.7, 0.9, 1, 2, 3, 4, 5, 10, 20}

Result

If the parameters are valid, the operator `set_metrology_object_fuzzy_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

`set_metrology_object_param`

Module

2D Metrology

set_metrology_object_param (: : MetrologyHandle, Index, GenParamName, GenParamValue :)

Set parameters for the metrology objects of a metrology model.

set_metrology_object_param is used to set or change the different parameters of a metrology object.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

The metrology model is defined by the handle MetrologyHandle. The parameter Index specifies the metrology objects for which the parameters are set. The parameters of all metrology objects are set if the parameter Index is set to *'all'*. All parameters can also be set when creating a metrology object with add_metrology_object_generic, add_metrology_object_circle_measure, add_metrology_object_ellipse_measure, add_metrology_object_line_measure, or add_metrology_object_rectangle2_measure. The current configuration of the metrology model can be accessed with get_metrology_object_param. All parameters that can be set with set_metrology_object_param can be reset with reset_metrology_object_param.

In the following all generic parameters with the default values are listed. But note that for a lot of applications the default values are sufficient and no adjustment is necessary. The following values for GenParamName and GenParamValue are possible - ordered by different categories:

Creating measure regions:

'measure_length1': The value of this parameter specifies the half length of the measure regions perpendicular to the metrology object boundary. It is equivalent to the measure tolerance. The unit of this value is pixel.

Suggested values: *10.0*, *20.0*, *30.0*

Default: *20.0*

Restriction: *'measure_length1'* >= *1.0*

'measure_length2': The value of this parameter specifies the half length of the measure regions tangential to the metrology object boundary. The unit of this value is pixel.

Suggested values: *3.0*, *5.0*, *10.0*

Default: *5.0*

Restriction: *'measure_length2'* >= *0.0*

'measure_distance': The value of this parameter specifies the desired distance between the centers of two measure regions. If the value leads to too few measure regions, the parameter has no influence and the number of measure regions will be increased to the minimum required number of measure regions (circle = 3, ellipse = 5, line = 2, rectangle = 2 per side = 8). The unit of this value is pixel.

If this value is set, the parameter *'num_measures'* has no influence.

Suggested values: *5.0*, *15.0*, *20.0*, *30.0*

Default: *10.0*

'num_measures': The value of this parameter specifies the desired number of measure regions.

The minimum number of measure regions depends on the type of the metrology object:

- Line: 2 measure regions
- Circle: 3 measure regions
- Circular arc: 4 measure regions
- Ellipse: 5 measure regions
- Elliptic arc: 6 measure regions
- Rectangle: 8 measure regions (2 regions each side)

If the chosen value is too low, *'num_measures'* is automatically set to the respective minimum value.

If this value is set, the parameter *'measure_distance'* has no influence.

Suggested values: *8*, *10*, *16*, *20*, *30*, *50*, *100*

Edge detection:

'measure_sigma': The parameter specifies the sigma for the Gaussian smoothing. The meaning, the use, and the default value of this parameter are described with the operator measure_pos by the parameter Sigma.

'measure_threshold': The parameter specifies the minimum edge amplitude. The meaning, the use, and the default value of this parameter are described with the operator measure_pos by the parameter Threshold.

'measure_select': The parameter specifies the selection of end points of the edges. The meaning, the use, and the default value of this parameter are described with the operator measure_pos by the parameter Select.

'measure_transition': The parameter specifies the use of dark/light or light/dark edges. The meaning and the use of the values *'all'*, *'positive'*, and *'negative'* for the parameter *'measure_transition'* is described with the operator measure_pos by the parameter Transition. Additionally, *'measure_transition'* can be set to the value *'uniform'*. Then, all positive edges (dark/light edges) and all negative edges (light/dark edges) are detected by the edge detection but when fitting the geometric shapes, the edges with different edge types are used separately, i.e., for each instance of a geometric shape either only the positive edges or the negative edges are used.

The measure direction within the measure regions is from the inside to the outside of the metrology object for objects of the types circle, ellipse, or rectangle. For metrology objects of the type line measure direction within the measure regions is from the left to the right, seen from the first point of the line (see RowBegin and ColumnBegin of the operator add_metrology_object_line_measure).

List of values: *'all'*, *'negative'*, *'positive'*, *'uniform'*

Default: *'all'*

'measure_interpolation': The parameter specifies the type of interpolation to be used. The meaning, the use and the default value of this parameter is described with the operator gen_measure_rectangle2 by the parameter Interpolation.

Fitting the geometric shapes:

'min_score': The parameter determines what score a potential instance must at least have to be regarded as a valid instance of the metrology object. The score is the number of detected edges that are used to compute the results divided by the maximum number of measure regions (see apply_metrology_model). If it can be expected that all edges of the metrology object are present, the parameter *'min_score'* can be set to a value as high as *0.8* or even *0.9*. Note that in images with a high degree of clutter or strong background texture the parameter *'min_score'* should be set to a value not much lower than *0.7* since otherwise false instances of a metrology object could be found.

Suggested values: *0.5*, *0.7*, *0.9*

Default: *0.7*

'num_instances': The parameter specifies the maximum number of successfully fitted instances of each metrology object after which the fitting will stop (see apply_metrology_model). Successfully fitted instances of the metrology objects must have a score of at least the value of *'min_score'*.

Suggested values: *1*, *2*, *3*, *4*

Default: *1*

'distance_threshold': apply_metrology_model uses a randomized search algorithm (RANSAC) to fit the geometric shapes. An edge point is considered to be part of a fitted geometric shape, if the distance of the edge point to the geometric shape does not exceed the value of *'distance_threshold'*.

Suggested values: *0*, *1.0*, *2.0*, *3.5*, *5.0*

Default: *3.5*

'max_num_iterations': The RANSAC algorithm estimates the number of iterations necessary for fitting the requested geometric shape. The estimation is based on the extracted edge data and the complexity of the shape. When setting the value of the parameter *'max_num_iterations'*, an upper limit for the computed number of iterations is defined. The number of iterations is still estimated by the RANSAC algorithm but cannot exceed the value of *'max_num_iterations'*. Setting this parameter can be helpful, if the quality of the fitting is not as important as observing time limits. However, if *'max_num_iterations'* is set too low, the algorithm will return low-quality or no results.

By default, *'max_num_iterations'* is set to -1, indicating that no additional upper limit is set for the number of iterations of the RANSAC algorithm.

Suggested values: *10*, *100*, *1000*

Default: *-1*

'rand_seed': The parameter specifies the seed for the random number generator for the RANSAC algorithm that is used by the selection of the edges the in operator apply_metrology_model. If the value of the parameter *'rand_seed'* is set to a number unequal to the value *0*, the operator yields the same result on every call with the same parameters, because the internally used random number generator is initialized with the value of the parameter *'rand_seed'*.

If the parameter *'rand_seed'* is set to the value *0*, the random number generator is initialized with the current time. In this case, the results are not reproducible.

Suggested values: *0*, *1*, *42*

Default: *42*

'instances_outside_measure_regions': The parameter specifies the validation of the results of measurements. If the value of the parameter *'instances_outside_measure_regions'* is set to the value *'false'*, only resulting instances of an metrology object are valid that are inside the major axis of the measure regions of this metrology object. Instances which are not valid are not stored. If the value of the parameter *'instances_outside_measure_regions'* is set to the value *'true'*, all instances of a metrology object are valid.

List of values: *'true'*, *'false'*

Default: *'false'*

Parameters

▷ **MetrologyHandle** (input_control) . . . . . metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *string* / integer
Index of the metrology objects.
Default: 'all'
Suggested values: Index ∈ {'all', 0, 1, 2}

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: 'num_instances'
List of values: GenParamName ∈ {'distance_threshold', 'instances_outside_measure_regions', 'max_num_iterations', 'measure_distance', 'measure_interpolation', 'measure_length1', 'measure_length2', 'measure_select', 'measure_sigma', 'measure_threshold', 'measure_transition', 'min_score', 'num_instances', 'num_measures', 'rand_seed'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters.
Default: 1
Suggested values: GenParamValue ∈ {1, 2, 3, 4, 5, 10, 20, 'all', 'true', 'false', 'first', 'last', 'positive', 'negative', 'uniform', 'nearest_neighbor', 'bilinear', 'bicubic'}

Result

If the parameters are valid, the operator set_metrology_object_param returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MetrologyHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

2D Metrology

write_metrology_model (: : MetrologyHandle, FileName :)

Write a metrology model to a file.

write_metrology_model writes a metrology model to the file FileName. The metrology model is defined by the handle MetrologyHandle. The metrology model can be read with read_metrology_model. The default HALCON file extension for a metrology model is 'mtr'.

For an explanation of the concept of 2D metrology see the introduction of chapter 2D Metrology.

Attention

Note that only the input values are saved, i.e., no measure regions and no results obtained by the operator apply_metrology_model are saved.

Parameters

▷ **MetrologyHandle** (input_control) ..... metrology_model ⇝ *handle*
Handle of the metrology model.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
File name.
File extension: .mtr

Result

If the parameters are valid, the operator write_metrology_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

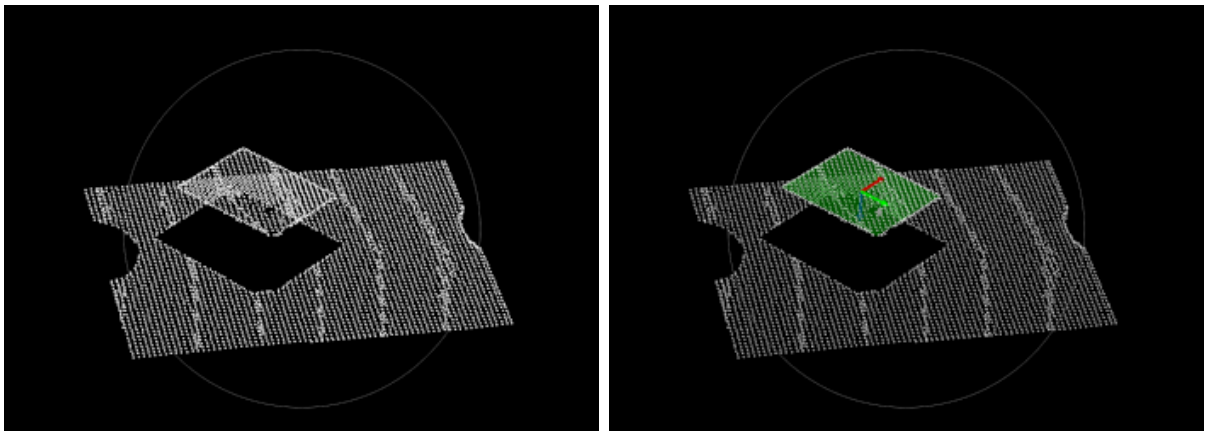
Chapter 3

3D Matching

This chapter gives an overview of the different 3D matching approaches available in HALCON.

3D Box Finder

As it is already contained in its name, the box finder can be used to locate box-shaped objects in 3D data. Thereby, no model of the object is needed as an input for the operator `find_box_3d`, but only the dimensions of the boxes to be found. As a result you can retrieve the pose of a gripping point, which can be especially useful in the case of a bin picking application.



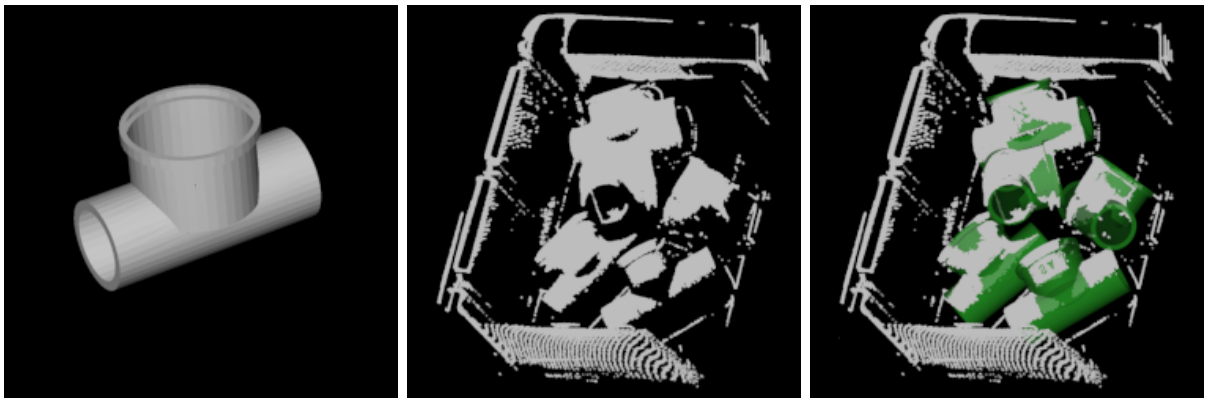
(1) (2)

(1) 3D input data (scene), (2) found instance, including a gripping point.

Surface-Based Matching

The surface-based matching approach is suited to locate more complex objects as well. The shape of these objects is passed to the operator `find_surface_model`, or `find_surface_model_image` respectively, in the form of a surface model. The poses of the found object instances in the scene are then returned.

Note that there are several different approaches when using surface-based matching. For detailed explanations regarding when and how to use these approaches, tips, tricks, and troubleshooting, have a look at the technical note on `Surface-Based Matching`.

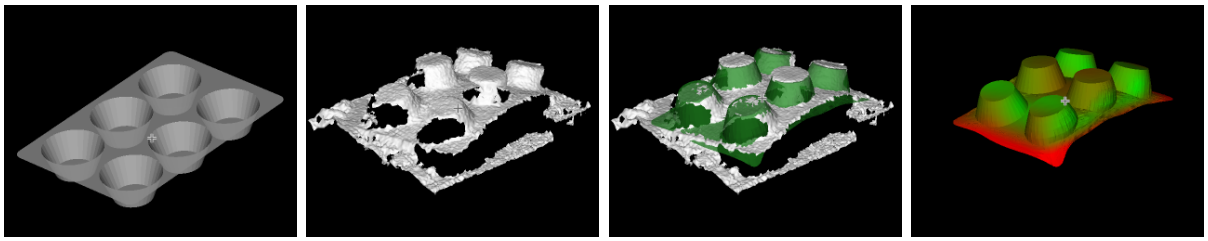


(1) (2) (3)

(1) 3D model to be searched for, (2) 3D input data (scene), (3) matching result.

Deformable Surface-Based Matching

In case an object can occur in the scene in different, deformed states you can use a deformable surface model to locate the object in the scene. If an instance of such an object is found by the operator `find_deformable_surface_model`, the object model can be retrieved featuring the respective deformation and pose.

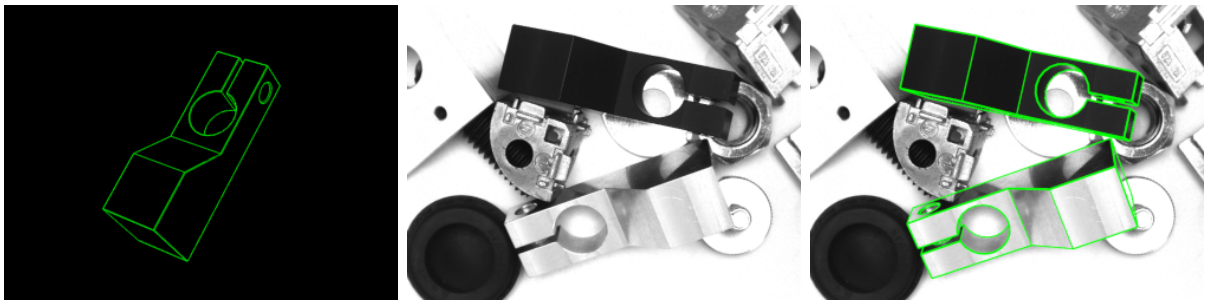


(1) (2) (3) (4)

(1) 3D object model, (2) 3D input data to be searched (scene), (3) model, transformed into the matched pose, (4) deformed object model.

Shape-Based Matching

With shape-based matching, instances of a 3D CAD model are searched in 2D images instead of 3D point clouds. For this, the edges of the wanted object need to be clearly visible in the image and the used camera needs to be calibrated beforehand. As a result, the object pose is computed and returned by the operator `find_shape_model_3d`.

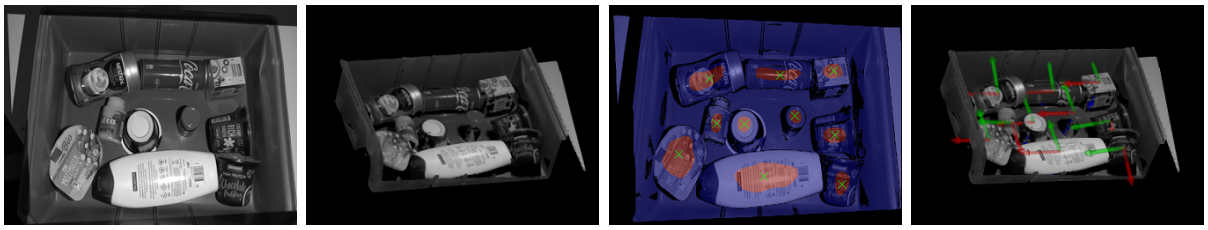


(1) (2) (3)

(1) 3D shape model, (2) input image, (3) found shape model, projected into the image.

3D Gripping Point Detection

3D Gripping Point Detection is a deep-learning-based approach to detect gripping points on arbitrary objects in a 3D scene. For further information please see the chapter 3D Matching / 3D Gripping Point Detection.



(1) (2) (3) (4)

(1) 2D input image (intensity image), (2) 3D scene (generated from XYZ-images), (3) Visualization of estimated gripping points on the 2D input image, (4) Visualization of estimated gripping points as poses in the 3D scene.

Deep 3D Matching

Deep 3D Matching is a deep-learning-based approach to detect objects in a scene and compute their 3D pose. For further information please see the chapter 3D Matching / Deep 3D Matching.

(1) (2) (3)

(1) Input scenes for an object, (2) computed 3D poses of the object in 2D image, (3) computed 3D poses of the object in 3D plot.

3.1 3D Box

```
find_box_3d ( : : ObjectModel3DScene, SideLen1, SideLen2, SideLen3,
    MinScore, GenParam : GrippingPose, Score, ObjectModel3DBox,
    BoxInformation )
```

Find boxes in 3D data.

`find_box_3d` finds boxes in the 3D object model `ObjectModel3DScene` and returns the pose of a gripping point `GrippingPose`, a 3D object model `ObjectModel3DBox` a score value `Score` and a dictionary `BoxInformation`, containing further information about the found boxes, for each found box.

The side lengths of the boxes are passed in `SideLen1`, `SideLen2`, and `SideLen3`. Each length consists of a tuple of two values, indicating the minimum and maximum length of that side. If only a single face of the box is expected to be visible, or no restriction should be applied to the remaining box length, `SideLen3` can be set to *-1*.

The parameter `MinScore` sets the minimum score for boxes to be returned. Boxes with a score smaller than this value will not be returned.

`ObjectModel3DScene` must contain a XYZ-mapping, like it is, e.g., the case, when creating it with `xyz_to_object_model_3d`.

Typical Workflow

A typical workflow for detecting 3D boxes in 3D data looks as follows:

1. Obtain the 3D data either as XYZ-images, or directly as a 3D object model with XYZ-mapping.

2. Remove as much background and clutter that is not part of any box from the scene as possible, in order to increase robustness and speed. Therefore, e.g., use `threshold` and `reduce_domain` on the XYZ-images before calling `xyz_to_object_model_3d`. Further options are described in the section "Troubleshooting" below.
3. If the 3D data exists in the form of XYZ-images, convert them to a 3D object model using `xyz_to_object_model_3d`.
4. Obtain the approximate box edge lengths that should be found. Note that changing those lengths later on might make it necessary to also change other parameters, such as `MinScore`.
5. Call `find_box_3d`, passing the 3D object model with the scene and the approximate box edge lengths.
6. Use the procedure `visualize_object_model_3d` to visualize the results, if necessary.

Understanding the Results

The boxes are returned in several ways.

First, the pose of a gripping point is returned in `GrippingPose`. The used side of the box and the z-axis of the gripping pose are set according to the XYZ-mapping. If only a single side of the box is visible, the center of the gripping pose is in the center of that side, and its z-axis is oriented away from the viewing point of the XYZ-mapping. If multiple sides of the box are visible, the gripping pose lies in the center of the side that is most parallel to the viewing point of the XYZ-mapping. The z-axis is again oriented away from the viewing point of the XYZ-mapping. The x-axis of the gripping pose is set to the box axis that is roughly the most aligned with the column direction of the XYZ-mapping. The y-axis is computed based on the x- and z-axis.

The box is also returned in triangulated form in `ObjectModel3DBox`. This allows a quick visualization of the results.

For each found box, a score between *0* and *1* is returned in `Score`. The score indicates how well the box and its edges are visible, and how well the found box matches the specified dimensions.

Finally, additional information about the results is returned in the dictionary `BoxInformation`. `get_dict_param` and `get_dict_tuple` can be used to obtain further information about the results. Also, the HDevelop handle inspect window can be used to inspect the returned dictionary.

The dictionary `BoxInformation` contains the following keys:

`results`: This key references a dictionary containing the found boxes. They are sorted according to their score in descending order with ascending integer keys starting at `0`.

Each box result is a dictionary with the following keys:

`box_pose`: This is the box's pose in the coordinate system of the scene. This pose is used for visualizing the found box.

`box_length_x`, `box_length_y`, `box_length_z`: The side lengths of the found box corresponding to `box_pose`. `box_length_x` and `box_length_y` will always contain a positive number. If only a single side of the box is visible, `box_length_z` will be set to *0*.

`gripping_pose`: The same pose as returned in `GrippingPose`.

`gripping_length_x`, `gripping_length_y`, `gripping_length_z`: The side lengths of the found box corresponding to `GrippingPose`. `gripping_length_x` and `gripping_length_y` will always contain a positive number. If only a single side of the box is visible, `gripping_length_z` will be set to *0*.

`score`: The same score as returned in `Score`.

`one_side_only`: Boolean indicating whether only one side of the box is visible (*'true'*) or not (*'false'*).

`gen_param`: This is a dictionary with the parameters passed to `find_box_3d`. `SideLen1`, `SideLen2`, and `SideLen3` are pooled in a tuple with key `lengths`. The key `min_score` references `MinScore`. The other keys are denoted analogously to the generic parameters of the dictionary `GenParam`.

`sampled_edges`: This is the 3D object model with sampled edges. It contains the viewing direction of the edge points as normal vectors.

`sampled_edges_direction`: This is the 3D object model with sampled edges (same as for key `sampled_edges`. It contains the edge directions of the edge points as normal vectors.

`sampled_scene`: This is the sampled scene in which the boxes are looked for. It can be used for visualization or debugging the sampling distance.

sampled_reference_points: This is a 3D object model with all points from the 3D scene that were used as reference points in the matching process. For each reference point, the optimum pose of the box is computed under the assumption that the reference point lies on the surface of the box.

Generic Parameters

Additional parameters can be passed as key/tuple pairs in the dictionary GenParam in order to improve the matching process. The following parameter names serve as keys to their corresponding tuples (see create_dict and set_dict_tuple).

3d_edges: Allows to manually set the 3D scene edges. The parameter must be a 3D object model handle. The edges are usually a result of the operator edges_object_model_3d but can further be filtered in order to remove outliers. If this parameter is not given, find_box_3d will internally extract the 3D edges similar to the operator edges_object_model_3d.

3d_edge_min_amplitude: Sets the minimum amplitude of a discontinuity in order for it to be classified as an edge. Note that if edges were passed manually with the generic parameter 3d_edges, this parameter is ignored. Otherwise, it behaves similar to the parameter MinAmplitude of the operator edges_object_model_3d.

Restriction: 3d_edge_min_amplitude >= *0*

Default: 10% of the smallest box diagonal.

max_gap: If no edges are passed with 3d_edges, the operator will extract 3D edges internally. The parameter can be used to control the edge extraction.

max_gap has the same meaning as in edges_object_model_3d.

remove_outer_edges: Removes the outermost edges when set to *'true'*. This is for example helpful for bin picking applications in order to remove the bin.

List of values: *'false'*, *'true'*

Default: *'false'*

max_num_boxes: Limits the number of returned boxes. By default, find_box_3d will return all detected boxes with a score larger than MinScore. This parameter can be used to limit the number of boxes respectively.

Default: *0* (return all boxes)

box_type: Sets the type of boxes to search for. For *'full_box_visible'* only boxes with more than one side visible are returned. If *'single_side_visible'* is set, boxes with only one visible side are searched for. If further box sides are visible nonetheless, they are ignored. For *'all'* both types are returned.

List of values: *'all'*, *'single_side_visible'*, *'full_box_visible'*

Default: *'all'*

Troubleshooting

***Visualizing extracted edges and sampled scene*:** To debug the box detector, some of the internally used data can be visualized by obtaining it from the returned dictionary BoxInformation, using get_dict_tuple.

The sampled 3D scene can be extracted with the key sampled_scene. Finding smaller boxes requires a denser sampling and subsequently slows down the box detection.

The sampled 3D edges can be extracted with the key sampled_edges and sampled_edges_directions. Both 3D object models contain the same points, however, sampled_edges contains the viewing direction of the edge points as normal vectors, while sampled_edges_directions contains the edge directions of the edge points as normal vectors. Note that the edge directions should be perpendicular to the edges, pointing outwards of the boxes.

***Improve performance*:** If find_box_3d is taking too long, the following steps might help to increase its performance.

- **Remove more background and clutter**: A significant improvement in runtime and detection accuracy can usually be achieved by removing as much of the background and clutter from the 3D scene as possible.
  The most common approaches for removing unwanted data are:
  - Thresholding the X-, Y- and Z-coordinates, either by using threshold and reduce_domain on the XYZ-images before calling xyz_to_object_model_3d, or by using select_points_object_model_3d directly on the 3D object model that contains the scene.

  - Some sensors return an intensity image along with the 3D data. Filters on the intensity image can be used to remove parts of the image that contain background.
  - Use background subtraction. If the scene is static, for example, if the sensor is mounted in a fixed position over a conveyor belt, the XYZ-images of the background can be acquired once without any boxes in it. Afterwards, `sub_image` and `threshold` can be used on the Z-images to select parts of the 3D data that are not part of the background.
- **Increase minimum score**: An increased minimum score `MinScore` might lead to more boxes being removed earlier in the detection pipeline.
- **Increase the smallest possible box**: The smaller the smallest possible box side is, the slower `find_box_3d` runs. For example, if all boxes are usually seen from a single side, it might make sense to set `SideLen3` to *-1*. Additionally, `box_type` can be set to limit the type of boxes that are searched.
- **Manually computing and filtering edges**: The edges of the scene can be extracted manually, using `edges_object_model_3d`, and passed to `find_box_3d` using the generic parameter `3d_edges` (see above). Thus, the manual extraction can be used as a further way of filtering the edges.

Parameters

▷ **`ObjectModel3DScene`** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of 3D object model where to search the box.

▷ **`SideLen1`** (input_control) . . . . . real-array ⇝ *real*
Length of the first box side.

▷ **`SideLen2`** (input_control) . . . . . real-array ⇝ *real*
Length of the second box side.

▷ **`SideLen3`** (input_control) . . . . . real-array ⇝ *real*
Length of the third box side.
Default: -1

▷ **`MinScore`** (input_control) . . . . . real ⇝ *real* / integer
Minimum score of the returned boxes.
Default: 0.6
Restriction: 0 <= MinScore <= 1

▷ **`GenParam`** (input_control) . . . . . dict ⇝ *handle*
Dictionary for generic parameters.
Default: []

▷ **`GrippingPose`** (output_control) . . . . . pose(-array) ⇝ *real* / integer
Gripping poses of the detected boxes.

▷ **`Score`** (output_control) . . . . . real-array ⇝ *real*
Scores of the detected boxes.

▷ **`ObjectModel3DBox`** (output_control) . . . . . object_model_3d-array ⇝ *handle*
Detected boxes as triangulated 3D object models.

▷ **`BoxInformation`** (output_control) . . . . . dict ⇝ *handle*
Additional debug information as dictionary.

Result

If all parameters are valid and no error occurs, `find_box_3d` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

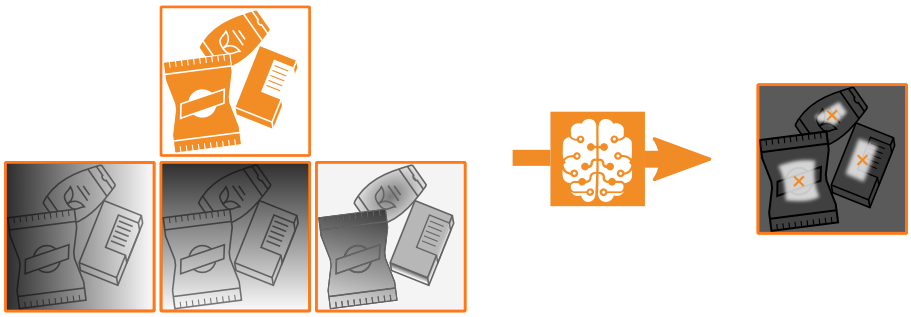
3.2 3D Gripping Point Detection

This chapter explains how to use 3D Gripping Point Detection.

3D Gripping Point Detection is used to find suitable gripping points on the surface of arbitrary objects in a 3D scene. The results can be used to target the gripping points with a robot arm and pick up the objects using vacuum grippers with suction cups.



A possible example for a 3D Gripping Point Detection application: A 3D scene (e.g., an RGB image and XYZ-images) is analyzed and possible gripping points are suggested.

HALCON provides a pretrained model which is ready for inference without an additional training step. To finetune the model for a specific task, it is possible to retrain it on a custom application domain. 3D Gripping Point Detection also works on objects that were not seen in training. Thus, there is no need to provide a 3D model of the objects that are to be targeted. 3D Gripping Point Detection can also cope with scenes containing various different objects at once, scenes with partly occluded objects, and with scenes containing cluttered 3D data.

The general inference workflow as well as the retraining are described in the following sections.

General Inference Workflow

This paragraph describes how to determine a suitable gripping point on arbitrary object surfaces using a 3D Gripping Point Detection model. An application scenario can be seen in the HDevelop example `3d_gripping_point_detection_workflow.hdev`.

1. Read the pretrained 3D Gripping Point Detection model by using
   - `read_dl_model`.
2. Set the model parameter regarding, e.g., the used devices or image dimensions using
   - `set_dl_model_param`.
3. Generate a data dictionary `DLSample` for each 3D scene. This can be done using the procedure
   - `gen_dl_samples_3d_gripping_point_detection`,

   which can cope with different kinds of 3D data. For further information on the data requirements see the section “Data” below.
4. Preprocessing of the data before the inference. For this, you can use the procedure
   - `preprocess_dl_samples`.

   The required preprocessing parameters can be generated from the model with

- create_dl_preprocess_param_from_model

or set manually using

- create_dl_preprocess_param.

Note that the preprocessing of the data has significant impact on the inference. See the section "3D scenes" below for further details.

5. Apply the model using the operator
   - apply_dl_model.
6. Perform a post-processing step on the resulting DLResult to retrieve gripping points for your scene using the procedure
   - gen_dl_3d_gripping_points_and_poses.
7. Visualize the 2D and 3D results using the procedure
   - dev_display_dl_data or
   - dev_display_dl_3d_data, respectively.

Training and Evaluation of the Model

This paragraph describes how the 3D Gripping Point Detection model can be retrained and evaluated using custom data. An application scenario can be seen in the HDevelop example 3d_gripping_point_detection_training_workflow.hdev.

Preprocess the data This part is about how to preprocess your data.

1. The information content of your dataset needs to be converted. This is done by the procedure
   - read_dl_dataset_3d_gripping_point_detection.

   It creates a dictionary DLDataset which serves as a database and stores all necessary information about your data. For more information about the data and the way it is transferred, see the section "Data" below and the chapter Deep Learning / Model.
2. Split the dataset represented by the dictionary DLDataset. This can be done using the procedure
   - split_dl_dataset.
3. The network imposes several requirements on the images. These requirements (for example the image size and gray value range) can be retrieved with
   - get_dl_model_param.

   For this you need to read the model first by using
   - read_dl_model.
4. Now you can preprocess your dataset. For this, you can use the procedure
   - preprocess_dl_dataset.

   To use this procedure, specify the preprocessing parameters as, e.g., the image size. Store all the parameter with their values in a dictionary DLPreprocessParam, for which you can use the procedure
   - create_dl_preprocess_param_from_model.

   We recommend to save this dictionary DLPreprocessParam in order to have access to the preprocessing parameter values later during the inference phase.

Training of the model This part explains the finetuning of the 3D Gripping Point Detection model by retraining it.

1. Set the training parameters and store them in the dictionary TrainParam. This can be done using the procedure

- `create_dl_train_param`.

2. Train the model. This can be done using the procedure
   - `train_dl_model`.

   The procedure expects:
   - the model handle `DLModelHandle`,
   - the dictionary `DLDataset` containing the data information,
   - the dictionary `TrainParam` containing the training parameters.

Evaluation of the retrained model In this part, we evaluate the 3D Gripping Point Detection model.

1. Set the model parameters which may influence the evaluation.
2. The evaluation can be done conveniently using the procedure
   - `evaluate_dl_model`.

   This procedure expects a dictionary `GenParam` with the evaluation parameters.
3. The dictionary `EvaluationResult` holds the evaluation measures. To get a clue on how the retrained model performed against the pretrained model you can compare their evaluation values. To understand the different evaluation measures, see section "Evaluation Measures for 3D Gripping Point Detection Results".

Data

This section gives information on the data that needs to be provided for the model inference or training and evaluation of a 3D Gripping Point Detection model.

As a basic concept, the model handles data by dictionaries, meaning it receives the input data from a dictionary `DLSample` and returns a dictionary `DLResult`. More information on the data handling can be found in the chapter Deep Learning / Model.

3D scenes 3D Gripping Point Detection processes 3D scenes, which consist of regular 2D images and depth information.

In order to adapt these 3D data to the network input requirements, a preprocessing step is necessary for the inference. See the section "Specific Preprocessing Parameters" below for information on certain preprocessing parameters. It is recommended to use a high resolution 3D sensor, in order to ensure the necessary data quality. The following data are needed:

2D image

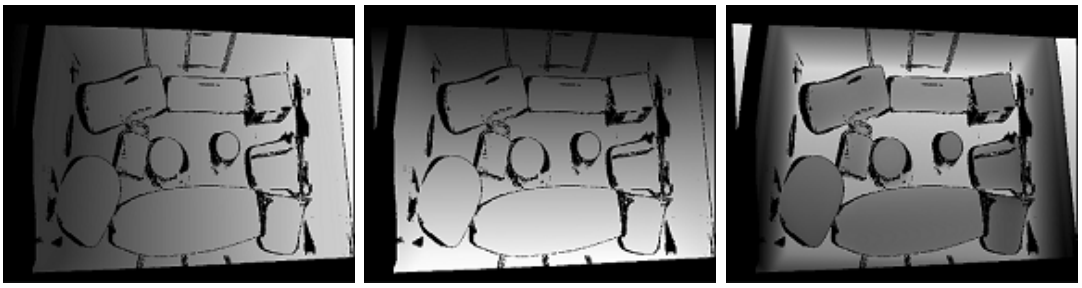
- RGB image, or
- intensity (gray value) image

Intensity image.

Depth information

- X-image (values need to increase from left to right)
- Y-image (values need to increase from top to bottom)

- Z-image (values need to increase from points close to the sensor to far points; this is for example the case if the data is given in the camera coordinate system)

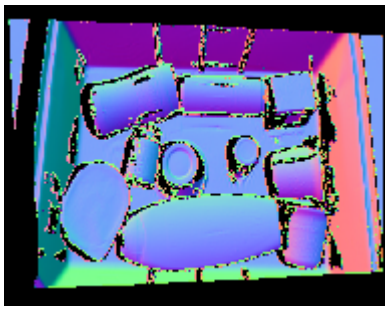


(1) (2) (3)

(1) X-image, (2) Y-image, (3) Z-image.

Normals (optional)

- 2D mappings (3-channel image)



Normals image.

Providing normal images improves the runtime, as this avoids the need for their computation.

In order to restrict the search area, the domain of the RGB/intensity image can be reduced. For details, see the section "Specific Preprocessing Parameters" below. Note that the domain of the XYZ-images and the (optional) normals images need to be identical. Furthermore, for all input data, only valid pixels may be part of the used domain.

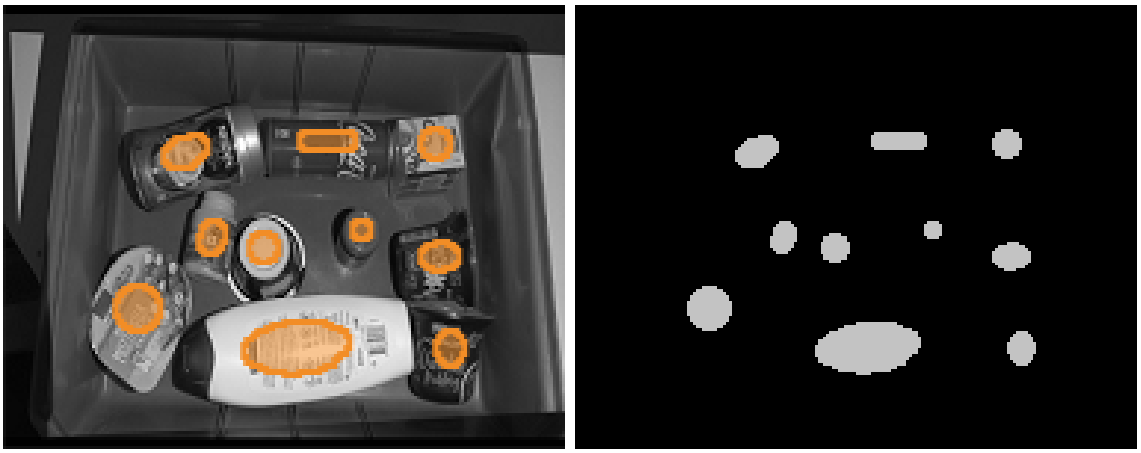
Data for Training and Evaluation The training data is used to train and evaluate a network specifically for your application.

The dataset needed for this consists of 3D scenes and corresponding information on possible gripping surfaces given as segmentation images. They have to be provided in a way the model can process them. Concerning the 3D scene requirements, find more information in the section "3D scenes" above.

How the data has to be formatted in HALCON for a DL model is explained in the chapter Deep Learning / Model. In short, a dictionary `DLDataset` serves as a database for the information needed by the training and evaluation procedures.

The data for `DLDataset` can be read using `read_dl_dataset_3d_gripping_point_detection`. See the reference of `read_dl_dataset_3d_gripping_point_detection` for information on the required contents of a 3D Gripping Point Detection `DLDataset`.

Along with 3D scenes, segmentation images need to be provided, which function as the ground truth. The segmentation images contain two gray values that denote every pixel in the scene to be either a valid gripping point or not. You can label your data using the MVTec Deep Learning Tool, available from the MVTec website.



(1) (2)

(1) Labeling of an intensity image. (2) Segmentation image, denoting gripping points (gray).

Make sure that the whole labeled area provides robust gripping points for the robot. Consider the following aspects when labeling your data:

- Gripping points need to be on a surface that can be accessed by the robot arm without being obstructed.
- Gripping points need to be on a surface that the robot arm can grip with its suction cup. Therefore, consider the object's material, shape, and surface tilt with regard to the ground plane.
- Take the size of the robots suction cup into account.
- Take the strength of the suction cup into account.
- Tend to label gripping points near the object's center of mass (especially for potentially heavier items).
- Gripping points should not be at an object's border.
- Gripping points should not be at the border of visible object regions.

Model output As inference output, the model will return a dictionary `DLResult` for every sample. This dictionary includes the following entries:

- `'gripping_map'`: Binary image, indicating for each pixel of the scene whether the model predicted a gripping point (pixel value = *1.0*) or not (*0.0*).
- `'gripping_confidence'`: Image, containing raw, uncalibrated confidence values for every point in the scene.

Evaluation Measures for 3D Gripping Point Detection Results

For 3D Gripping Point Detection, the following evaluation measures are supported in HALCON:

`mean_pro` Mean overlap of all ground truth regions labeled as gripping class with the predictions (Per-Region Overlap). See the paper referenced below for a detailed description of this evaluation measure.

`mean_precision` Mean pixel-level precision of the predictions for the gripping class. The precision is the proportion of true positives to all positives (true (TP) and false (FP) ones).

$$\text{precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

`mean_iou` Intersection over union (IoU) between the ground truth pixels and the predicted pixels of the gripping class. See Deep Learning / Semantic Segmentation and Edge Extraction for a detailed description of this evaluation measure.

gripping_point_precision Proportion of true positives to all positives (true and false ones).

For this measure, a true positive is a correctly predicted gripping point, meaning the predicted point is located within a ground truth region. However, only one gripping point per region is considered a true positive, additional predictions in the same region are considered false positives.

gripping_point_recall The recall is the proportion of the number of correctly predicted gripping points to the number of all ground truth regions of the gripping class.

$$\text{recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

gripping_point_f_score To represent precision and recall with a single number, we provide the F-score, the harmonic mean of precision and recall.

$$\text{F-score} = 2 * \frac{\text{precision} * \text{recall}}{\text{precision} + \text{recall}}$$

Postprocessing

The model results `DLResult` can be postprocessed with `gen_dl_3d_gripping_points_and_poses` in order to generate gripping points. Furthermore, this procedure can be parameterized in order to reject small gripping regions using `min_area_size`, or serve as a template to define custom selection criteria.

The procedure adds the following entry to the dictionary `DLResult`:

- `'gripping_points'`: Tuple of dictionaries containing information on suitable gripping points in a scene:
  - `'region'`: Connected region of potential gripping points. The determined gripping point lies inside this region.
  - `'row'`: Row coordinate of the gripping point in the preprocessed RGB/intensity image.
  - `'column'`: Column coordinate of the gripping point in the preprocessed RGB/intensity image.
  - `'pose'`: 3D pose of the gripping point (relative to the coordinate system of the XYZ-images, i.e., of the camera) which can be used by the robot.

Specific Preprocessing Parameters

In the preprocessing step, along with the data, preprocessing parameters need to be passed to `preprocess_dl_samples`. Two pairs of those preprocessing parameters have particularly significant impact:

- `'image_width'`, `'image_height'`: Determine the image dimensions of the images to be inferred.

  With larger image dimensions and thus a better resolution, smaller gripping surfaces can be detected. However, the runtime and memory consumption of the application increases.

- `'min_z'`, `'max_z'`: Determine the allowed distance from the camera for 3D points based on the Z-image.

  These parameters can therefore help to reduce erroneous outliers and therefore increase the application robustness.

A restriction of the search area can be done by reducing the domain of the input images (using `reduce_domain`). The way `preprocess_dl_samples` handles the domain is set using the preprocessing parameter `'domain_handling'`. The parameter `'domain_handling'` should be used in a way that only essential information is passed on to the network for inference. The following images show how an input image with reduced domain is passed on after the preprocessing step depending on the set `'domain_handling'`.

(1) (2) (3) (4)

(1) Input image with reduced domain (red), (2) image for `'full_domain'`, (3) image for `'keep_domain'`, (4) image for `'crop_domain'`.

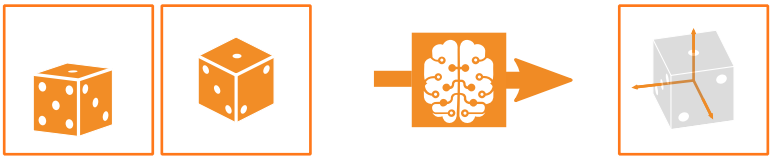
3.3 Deep 3D Matching

This chapter explains how to use Deep 3D Matching.

Deep 3D Matching is used to accurately detect objects in a scene and compute their 3D pose. This approach is particularly effective for complex scenarios where traditional 3D matching techniques (like shape-based 3D matching) may struggle due to variations in object appearance, occlusions, or noisy data. Compared to surface-based matching, Deep 3D Matching works with a calibrated multi-view setup and does not require data from a 3D sensor.



A possible example for a Deep 3D Matching application: Images from different angles are used to detect an object. As a result the 3D pose of the object is computed.

The Deep 3D Matching model consists of two components, which are dedicated to two distinct tasks, the detection, which localizes objects, and the estimation of object poses. For a Deep 3D Matching application, both components need to be trained on the 3D CAD model of the object to be found in the application scenes.

Note: For now only inference is possible in HALCON, the custom training of a model will be available in a future version of HALCON. If you want to use the feature for your applications, please contact your HALCON sales partner for further information.

Once trained, the deep learning model can be used to infer the pose of the object in new application scenes. During the inference process, images from different angles are used as input.

General Inference Workflow

This paragraph describes how to determine a 3D pose using the Deep 3D Matching method. An application scenario can be seen in the HDevelop example `deep_3d_matching_workflow.hdev`.

1. Read the trained Deep 3D Matching model by using
   - `read_deep_matching_3d`.
2. Optimize the deep learning network for the use with -interfaces
   (a) Extract the detection network from the deep 3d matching model using

- get_deep_matching_3d_param.

(b) Optimize the parameter for inference with

- optimize_dl_model_for_inference.

(c) Set the optimized detection network using

- set_deep_matching_3d_param.

(d) Repeat these steps for the 3D pose estimation network.

(e) Save the optimized model using

- write_deep_matching_3d.

Note that the optimization of the model has significant impact on the runtime, if it is done with every inference run. So writing the optimized model saves time in the inference.

3. Set the camera parameters using

- set_deep_matching_3d_param.

4. Apply the model using the operator

- apply_deep_matching_3d.

5. Visualize the resulting 3D poses.

Training and Evaluation of the Model

For now only inference is possible in HALCON, training of a model will be available in a future version. If you want to use the feature for your applications, please contact your HALCON sales partner for further information.

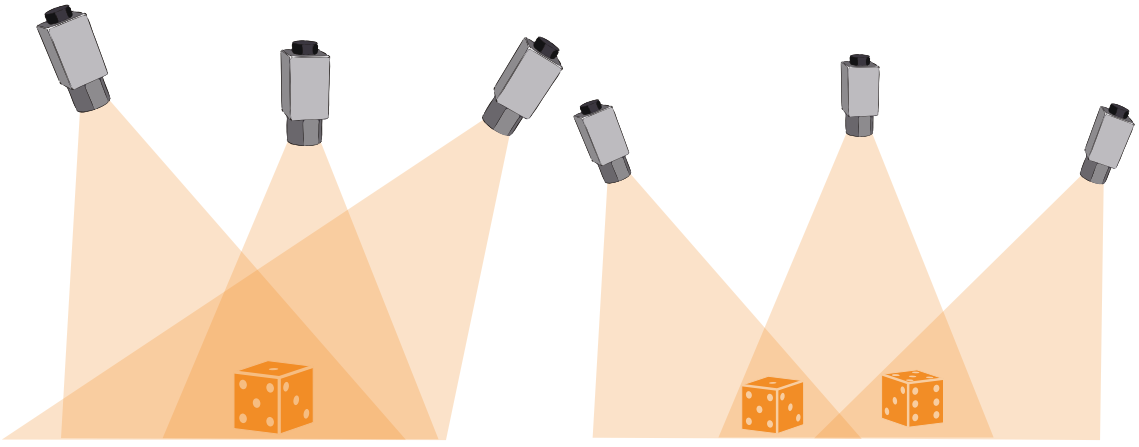
Data

This section gives information on the camera setup and data that needs to be provided for the model inference or training and evaluation of a Deep 3D Matching model.

As a basic concept, the model handles data by dictionaries, meaning it receives the input data from a dictionary `DLSample` and returns a dictionary `DeepMatchingResults`. More information on the data handling can be found in the chapter Deep Learning / Model.

Multi-View Camera Setup In order to use Deep 3D Matching with high accuracy you need a calibrated stereo or multi-view camera setup. In comparison to stereo reconstruction, Deep 3D Matching can deal with more strongly varying camera constellations and distances. Also there is no need to use 3D sensors in the setup. For information how to calibrate the used setup, please refer to the chapter Calibration / Multi-View.

The objects to be detected must be captured from two or more different perspectives in order to calculate the 3D poses.



(1) (2)

Example setups for Deep 3D Matching: Scenes are recorded by several cameras, the objects to be detected do not have to be seen by every single camera (but by at least two cameras).

Data for Training and Evaluation The training data is used to train and evaluate a Deep 3D Matching model specifically for your application.

The required training data is generated using CAD models. Synthetic images of the object are created from various angles, lighting conditions, and backgrounds. Note that there are no real images required, the required data is generated based of the CAD model.

The data needed for this is a CAD model and corresponding information on material, surface finish and color. Information about possible axial and radial symmetries can significantly improve the generated training data.

```
apply_deep_matching_3d (
    Images : : Deep3DMatchingModel : DeepMatchingResults )
```

Find the pose of objects using Deep 3D Matching.

The operator `apply_deep_matching_3d` finds instances of the object defined in `Deep3DMatchingModel` in the images `Images` and returns the detected instances and their 3D poses in `DeepMatchingResults`.

Input Images

`Images` must be an image array with exactly as many images as there are cameras set in the Deep 3D Matching model (see `set_deep_matching_3d_param`). The image resolutions must match the resolution of the corresponding camera parameters. The images must be either of type *'byte'* or *'float'*, and they must have 1 or 3 channels.

Deep Learning Models

`apply_deep_matching_3d` uses deep learning technology for detecting the object instances. For an efficient execution, it is strongly recommended to use appropriate hardware accelerators and to optimize the deep learning models. See `get_deep_matching_3d_param` on how to obtain the deep learning models in order to set the device on which they are executed and `optimize_dl_model_for_inference` for optimizing the models for a particular hardware.

Detection Steps

1. **Object Detection** The object detection deep learning model is used to find instances of the target object in all images.
2. **3D pose estimation** The pose estimation deep learning model is used to estimate the 3D pose of all instances found in the previous step. Poses of the same object found in different images are combined into a single instance.
3. **Pose Refinement** The poses found in the previous step are further refined using edges visible in the image. Additionally, their score is computed.
4. **Filter Results** The detected instances are filtered using the minimum score (*'min_score'*), the minimum number of cameras in which instances must be visible (*'min_num_views'*), as well es the maximum number of instances to return (*'num_matches'*).

Result Format

The results are returned in `DeepMatchingResults` as a dictionary. The dictionary key *'results'* contains all detected results. Each result has the following keys:

'score':
The score of the result instance.

'pose':
The pose of the result instance in world coordinate systems.

'cameras':
A tuple of integers containing the camera indices in which the instance was detected in.

Parameters

▷ **Images** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / real
Input images.

▷ **Deep3DMatchingModel** (input_control) . . . . . deep_matching_3d ⇝ *handle*
Deep 3D matching model.

▷ **DeepMatchingResults** (output_control) . . . . . dict-array ⇝ *handle*
Results.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

get_deep_matching_3d_param (: : Deep3DMatchingModel, GenParamName : GenParamValue)

Read a parameter from a Deep 3D Matching model.

The operator get_deep_matching_3d_param returns the parameter values of GenParamName for the Deep 3D Matching model Deep3DMatchingModel in GenParamValue.

The following table gives an overview, which parameters can be set using set_deep_matching_3d_param and which can be retrieved using get_deep_matching_3d_param.

GenParamName	set	get
'camera_parameter N'	x	x
'camera_pose N'	x	x
'delete_cameras'	x	
'dl_model_detection'	x	x
'dl_model_pose_estimation'	x	x
'min_num_views'	x	x
'min_score'	x	x
'num_matches'	x	x
'orig_3d_model'		x

In the following the parameters are described:

'camera_parameter N', *'camera_pose N'*, *'delete_cameras'*:
These parameters control the camera setup used for matching, i.e., the camera poses and the camera parameters. *'delete_cameras'* can be set with an empty tuple as value to delete all cameras from a Deep 3D Matching model.

The keys for accessing the parameters of the N'th camera are *'camera_parameter N'* and *'camera_pose N'*, where N is the zero-based index of the camera. For example, to access the parameters of the first camera, use *'camera_parameter 0'* and *'camera_pose 0'*. Note that cameras must be added in order.

Further note that the camera parameters should not contain any distortion. It is recommended to remove any distortion from the camera parameters and images beforehand, using, for example, change_radial_distortion_cam_par in combination with change_radial_distortion_image or gen_radial_distortion_map and map_image.

The camera pose is the pose of the camera in an arbitrary world coordinate system. The poses of detected objects are returned in that world coordinate system. The angles must be passed in radians.

'dl_model_detection', *'dl_model_pose_estimation'*:
The deep learning models used for Deep 3D Matching. Both models are already pre-trained for the target object. They can be obtained and written back in order to, optimize it using `optimize_dl_model_for_inference` or change the device on which they are executed.

'min_num_views':
This parameter determines the minimum number of cameras in which an instance must be visible in order to be returned by `apply_deep_matching_3d`. The parameter can be either an integer larger than zero, or the string *'auto'*. If *'auto'*, instances must be visible in a single camera if only a single camera is used, and in at least two cameras otherwise.

Suggested values: *'auto'*, *2*, *3*

Default: *'auto'*

Value range: ≥ 0.

'min_score':
This parameter determines the minimum score of detected instances. In other words, `apply_deep_matching_3d` ignores all detected instances with a score smaller than this value. The score computed by the Deep 3D Matching model lies between *0* and *1*, where *0* indicates a bad match and *1* is a very good match.

Value range: $[0, \ldots, 1]$

Default: *0.2*

'num_matches':
This parameter determines the maximum number of matches to return by `apply_deep_matching_3d`. If the operator finds more instances than set in *'num_matches'*, only the *'num_matches'* instances with the highest scores are returned. This parameter can be set to zero, in which case all instances above *'min_score'* are returned.

Value range: ≥ 0.

Default: *0*

'orig_3d_model':
This parameter returns the original 3D CAD model used for creating the Deep 3D Matching model. It can be used to, visualize detection results.

Attention

Deep 3D Matching requires images to not have too much of a distortion. It is recommended to remove any distortion from the camera parameters and images beforehand, using, for example, `change_radial_distortion_cam_par` in combination with `change_radial_distortion_image` or `gen_radial_distortion_map` and `map_image`.

Parameters

▷ **`Deep3DMatchingModel`** (input_control) . . . . . deep_matching_3d ⇝ *handle*
Deep 3D Matching model.

▷ **`GenParamName`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of parameter.
Default: 'min_score'
Suggested values: `GenParamName` ∈ {'min_score', 'num_matches', 'orig_3d_model', 'min_num_views', 'dl_model_detection', 'dl_model_pose_estimation', 'camera_parameter', 'camera_pose'}

▷ **`GenParamValue`** (output_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer / handle
Obtained value of parameter.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

read_deep_matching_3d (: : FileName : Deep3DMatchingModel)

Read a Deep 3D Matching model from a file.

The operator read_deep_matching_3d reads a Deep 3D Matching model. Such models have to be in the HALCON format. As a result, the handle Deep3DMatchingModel is returned.

The model is loaded from the file FileName. The default HALCON file extension for Deep 3D Matching models is '.dm3'.

Please note that the values of runtime specific parameters are not written to file, see write_deep_matching_3d. As a consequence when reading a model these parameters are initialized with their default value, see get_deep_matching_3d_param.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Filename
File extension: .dm3

▷ **Deep3DMatchingModel** (output_control) ..... deep_matching_3d ⇝ *handle*
Handle of the Deep 3D Matching model.

Result

If the parameters are valid, the operator read_deep_matching_3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_deep_matching_3d_param, get_deep_matching_3d_param, apply_deep_matching_3d

Module

3D Metrology

set_deep_matching_3d_param (: : Deep3DMatchingModel, GenParamName, GenParamValue :)

Set a parameter of a Deep 3D Matching model.

The operator set_deep_matching_3d_param sets the selected parameters GenParamName in the Deep 3D Matching model Deep3DMatchingModel to the values passed in GenParamValue.

The possible parameters are listed and described in get_deep_matching_3d_param.

Parameters

▷ **Deep3DMatchingModel** (input_control) ..... deep_matching_3d ⇝ *handle*
Deep 3D Matching model.

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Name of parameter.
Default: 'min_score'
Suggested values: GenParamName ∈ {'min_score', 'num_matches', 'min_num_views', 'dl_model_detection', 'dl_model_pose_estimation', 'camera_parameter', 'camera_pose', 'delete_cameras'}

▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *string* / real / integer / handle
Value of parameter.
Default: 0.2

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

write_deep_matching_3d (: : Deep3DMatchingModel, FileName :)

Write a Deep 3D Matching model in a file.

write_deep_matching_3d writes the Deep 3D Matching model Deep3DMatchingModel to the file given by FileName. Please note that the runtime specific parameters *'device'* and *'batch_size'* of the deep learning models are not written.

The default HALCON file extension for Deep 3D Matching models is '.dm3'.

The Deep 3D Matching model can be read with read_deep_matching_3d.

Parameters

▷ **Deep3DMatchingModel** (input_control) ..... deep_matching_3d ⇝ *handle*
Handle of the Deep 3D Matching model.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Filename
File extension: .dm3

Result

If the parameters are valid, the operator write_deep_matching_3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3.4 Deformable Surface-Based

add_deformable_surface_model_reference_point (
: : DeformableSurfaceModel, ReferencePointX, ReferencePointY,
ReferencePointZ : ReferencePointIndex)

Add a reference point to a deformable surface model.

The operator add_deformable_surface_model_reference_point adds one or more reference points to the deformable surface model passed in DeformableSurfaceModel. The 3D coordinates of the reference points is passed in the parameters ReferencePointX, ReferencePointY and ReferencePointZ. The index of the new reference points is returned in ReferencePointIndex.

Reference points are defined in model coordinates, i.e., in the coordinate frame of the model parameter of `create_deformable_surface_model`. The operators `find_deformable_surface_model` and `refine_deformable_surface_model` return the position of all added reference points as found in the scene.

Parameters

▷ **`DeformableSurfaceModel`** (input_control) . . . . . deformable_surface_model ⇝ *handle*
Handle of the deformable surface model.

▷ **`ReferencePointX`** (input_control) . . . . . real(-array) ⇝ *real* / integer
x-coordinates of a reference point.

▷ **`ReferencePointY`** (input_control) . . . . . real(-array) ⇝ *real* / integer
x-coordinates of a reference point.

▷ **`ReferencePointZ`** (input_control) . . . . . real(-array) ⇝ *real* / integer
x-coordinates of a reference point.

▷ **`ReferencePointIndex`** (output_control) . . . . . integer(-array) ⇝ *integer*
Index of the new reference point.

Result

`add_deformable_surface_model_reference_point` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- DeformableSurfaceModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

3D Metrology

`add_deformable_surface_model_sample` `( : : DeformableSurfaceModel, ObjectModel3D : )`

Add a sample deformation to a deformable surface model

The operator `add_deformable_surface_model_sample` adds the example deformation passed in `ObjectModel3D` to the deformable surface model `DeformableSurfaceModel`. The point cloud given in `ObjectModel3D` must have exactly as many points as the sampled deformation model, and is usually the result of the operator `find_deformable_surface_model` or `refine_deformable_surface_model`. The deformable surface model must have been created beforehand using, for example, `create_deformable_surface_model`. The operator re-trains the deformable surface model including the passed deformation. This allows `find_deformable_surface_model` to find deformations that are similar to the one given in `ObjectModel3D`.

Parameters

▷ **DeformableSurfaceModel** (input_control) . . . . . deformable_surface_model ⇝ *handle*
Handle of the deformable surface model.

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the deformed 3D object model.

Result

`add_deformable_surface_model_sample` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DeformableSurfaceModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

3D Metrology

clear_deformable_surface_matching_result (: : DeformableSurfaceMatchingResult :)

Free the memory of a deformable surface matching result.

The operator `clear_deformable_surface_matching_result` frees the memory of a deformable surface matching result that was created with `find_deformable_surface_model` or `refine_deformable_surface_model`. After calling `clear_deformable_surface_matching_result`, the result can no longer be used. The handle `DeformableSurfaceMatchingResult` becomes invalid.

Parameters

▷ **DeformableSurfaceMatchingResult** (input_control) . . . . . deformable_surface_matching_result(-array) ⇝ *handle*

Handle of the deformable surface matching result.

Result

If the handle of the result is valid, the operator `clear_deformable_surface_matching_result` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DeformableSurfaceMatchingResult

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

`create_deformable_surface_model` (: : `ObjectModel3D`, `RelSamplingDistance`, `GenParamName`, `GenParamValue` : `DeformableSurfaceModel`)

Create the data structure needed to perform deformable surface-based matching.

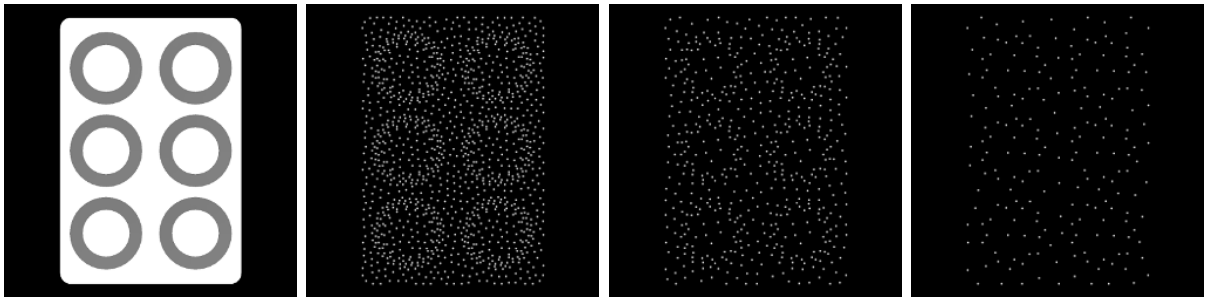
The operator create_deformable_surface_model creates a model for deformable surface-based matching for the 3D object stored in the 3D object model ObjectModel3D. The 3D object model can, for example, have been read previously from a file by using read_object_model_3d or it can have been created by using xyz_to_object_model_3d. The created surface model is returned in DeformableSurfaceModel.

The creation of the deformable surface model requires that the 3D object model contains points and normals. The following combinations are possible:

- points and point normals, e.g., from a call to surface_normals_object_model_3d
- points and a triangular or polygon mesh, e.g., from a CAD file
- points and a 2D-Mapping, e.g., from an XYZ image triple converted with xyz_to_object_model_3d

Note that the direction and orientation (inward or outward) of the normals of the model are important for matching.

The deformable surface model is created by sampling the 3D object model with a certain distance. The sampling distance must be specified in the parameter RelSamplingDistance and is parametrized relative to the diameter of the axis-parallel bounding box of the 3D object model. For example, if RelSamplingDistance is set to 0.05 and the diameter of ObjectModel3D is 10 cm, the points sampled from the object's surface will be approximately 5 mm apart. The sampled points can be obtained with the operator get_deformable_surface_model_param using the value *'sampled_model'*. Note that outlier points in the object model should be avoided, as they would corrupt the diameter. Reducing RelSamplingDistance leads to more points, and in turn to a more stable but slower matching. Increasing RelSamplingDistance leads to less points, and in turn to a less stable but faster matching.



(1) (2) (3) (4)

(1) Original 3D model. (2) 3D model sampled with RelSamplingDistance = *0.02*. (3) RelSamplingDistance = *0.03*. (4) RelSamplingDistance = *0.05*.

By default, deformable surface models created with create_deformable_surface_model can handle a moderate amount of deformation. The operator add_deformable_surface_model_sample can be used to add additional training samples, thus expanding the range of possible deformations. The amount of deformation that can be found can also be controlled with the generic parameters *'scale_min'*, *'scale_max'* and *'bending_max'* (see below).

The generic parameter pair GenParamName and GenParamValue is used to set additional parameters for the model generation. GenParamName contains the tuple of parameter names that shall be set and GenParamValue contains the corresponding values. The following values are possible for GenParamName:

'model_invert_normals': Invert the orientation of the surface normals of the model. The normal orientation needs to be known for the model generation. If both the model and the scene are acquired with the same setup, the normals will already point in the same direction. If the model was loaded from a CAD file, the normals might point into the opposite direction. If you experience the effect that the model is found on the 'outside' of the scene surface and the model was created from a CAD file, try to set this parameter to *'true'*. Also, make sure that the normals in the CAD file all point either outward or inward, i.e., are oriented consistently.

List of values: *'false'*, *'true'*

Default: *'false'*

'scale_min' **and** *'scale_max'*: The minimum and maximum allowed scaling of the model. Note that if you set one of the two parameters, the other one must be set too.

Suggested values: *0.8*, *1*, *1.2*

Default: No scaling

Restriction: *0* < *'scale_min'* < *'scale_max'*

'bending_max': Controls the maximum automatic deformation of the model. The model is deformed automatically by bending it with an angle up to the value of *'bending_max'*. This allows for deformations to be found that are within this bending range. The angle is passed in degrees.

Suggested values: *5*, *10*, *30*

Default: *20*

Restriction: *0 <= 'bending_max' < 90*

'stiffness': Control the stiffness of the model when performing the refinement. Larger values of this parameter lead to a more stiff model that can be less deformed. Smaller values lead to a less stiff model that allows more deformation.

Suggested values: *0.2*, *0.5*, *0.8*

Default: *0.5*

Restriction: *0 < 'stiffness' <= 1*

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model.

▷ **RelSamplingDistance** (input_control) . . . . . real ⇝ *real*
Sampling distance relative to the object's diameter
Default: 0.05
Suggested values: RelSamplingDistance ∈ {0.1, 0.05, 0.03, 0.02, 0.01}
Restriction: 0 < RelSamplingDistance < 1

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters.
Default: []
Suggested values: GenParamName ∈ {'model_invert_normals', 'scale_min', 'scale_max', 'bending_max', 'stiffness'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false', 1, 0.9, 1.1, 5, 10, 20, 30, 0.05, 0.1, 0.2}

▷ **DeformableSurfaceModel** (output_control) . . . . . deformable_surface_model ⇝ *handle*
Handle of the deformable surface model.

Result

create_deformable_surface_model returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

read_object_model_3d, xyz_to_object_model_3d, get_object_model_3d_params

Possible Successors

deserialize_deformable_surface_model (: : SerializedItemHandle : DeformableSurfaceModel)

Deserialize a deformable surface model.

deserialize_deformable_surface_model deserializes a deformable surface model, that was serialized by serialize_deformable_surface_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized deformable surface model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created deformable surface model with the handle DeformableSurfaceModel.

Parameters

- ▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
  Handle of the serialized item.
- ▷ **DeformableSurfaceModel** (output_control) ..... deformable_surface_model ⇝ *handle*
  Handle of the deformable surface model.

Result

If the parameters are valid, the operator deserialize_deformable_surface_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

find_deformable_surface_model (: : DeformableSurfaceModel, ObjectModel3D, RelSamplingDistance, MinScore, GenParamName, GenParamValue : Score, DeformableSurfaceMatchingResult)

Find the best match of a deformable surface model in a 3D scene.

The operator find_deformable_surface_model finds the best match of the deformable surface model DeformableSurfaceModel in the 3D scene ObjectModel3D. The deformable surface model must have been created previously with, for example, create_deformable_surface_model.

The matching requires that the 3D object model ObjectModel3D contains points and normals. The scene shall provide one of the following options:

- points and point normals
- points and a 2D-Mapping, e.g., an XYZ image triple converted with xyz_to_object_model_3d

It is important for an accurate pose that the normals of the scene and the model point in the same direction (see *'scene_invert_normals'*). Note that triangles or polygons in the passed scene are ignored. Instead, only the vertices are used for matching. It is thus in general not recommended to use this operator on meshed scenes, such as CAD data. Instead, such a scene must be sampled beforehand using sample_object_model_3d to create points and normals. When using noisy point clouds, e.g., from time-of-flight cameras, the generic parameter *'scene_normal_computation'* should be set to *'mls'* in order to obtain more robust results (see below).

First, points are sampled uniformly from the scene passed in ObjectModel3D. The sampling distance is controlled with the parameter RelSamplingDistance, and is given relative to the diameter of the surface model. Decreasing RelSamplingDistance leads to more sampled points, and in turn to a more stable but slower matching. Increasing RelSamplingDistance reduces the number of sampled scene points, which leads to a less stable but faster matching. For an illustration showing different values for RelSamplingDistance, please refer to the operator create_deformable_surface_model.

The operator get_deformable_surface_matching_result can be used to retrieve the sampled scene points for visual inspection. For a robust matching it is recommended that at least 50-100 scene points are sampled for each object instance.

The method first finds an approximate position of the object. This position is then refined. The generic parameters controlling the deformation are described further down.

If a match was found, the score of the match is returned in Score and a deformable surface matching result handle is returned in DeformableSurfaceMatchingResult. Details of the matching result, such as the deformed model and the position of the reference points, can be queried with the operator get_deformable_surface_matching_result using the result handle.

The score is normalized between *0* and *1* and represents the amount of model surface visible in the scene. A value of *1* represents a perfect match. The parameter MinScore can be used to filter the result. A match is returned only if its score exceeds the value of MinScore.

The parameters GenParamName and GenParamValue are used to set generic parameters. Both get a tuple of equal length, where the tuple passed to GenParamName contains the names of the parameters to set, and the tuple passed to GenParamValue contains the corresponding values. The possible parameter names and values are described below.

'scene_normal_computation': This parameter controls the normal computation of the sampled scene. In the default mode *'fast'*, normals are computed based on a small neighborhood of points. In the mode *'mls'*, normals are computed based on a larger neighborhood and using the more complex but more accurate *'mls'* method. A more detailed description of the *'mls'* method can be found in the description of the operator surface_normals_object_model_3d. The *'mls'* mode is intended for noisy data, such as images from time-of-flight cameras.

List of values: *'fast'*, *'mls'*

Default: *'fast'*

'scene_invert_normals': Invert the orientation of the surface normals of the scene. The orientation of surface normals of the scene have to match with the orientation of the model. If both the model and the scene are acquired with the same setup, the normals will already point in the same direction. If you experience the effect that the model is found on the 'outside' of the scene surface, try to set this parameter to *'true'*. Also, make sure that the normals in the scene all point either outward or inward, i.e., are oriented consistently.

List of values: *'false'*, *'true'*

Default: *'false'*

'pose_ref_num_steps': Number of iterations for the refinement. Increasing the number of iteration leads to a more accurate position at the expense of runtime. However, once convergence is reached, the accuracy can no longer be increased, even if the number of steps is increased.

Suggested values: *1*, *10*, *25*, *50*

Default: *25*

Restriction: *'pose_ref_num_steps' > 0*

'pose_ref_dist_threshold_rel': Set the distance threshold for refinement relative to the diameter of the surface model. Only scene points that are closer to the object than this distance are used for the optimization. Scene points further away are ignored.

Suggested values: *0.05*, *0.1*, *0.25*, *0.3*

Default: *0.25*

Restriction: *0 < 'pose_ref_dist_threshold_rel'*

'pose_ref_dist_threshold_abs': Set the distance threshold for dense pose refinement as absolute value. See *'pose_ref_dist_threshold_rel'* for a detailed description. Only one of the parameters *'pose_ref_dist_threshold_rel'* and *'pose_ref_dist_threshold_abs'* can be set. If both are set, only the value of the last parameter is used.

Restriction: *0 < 'pose_ref_dist_threshold_abs'*

'pose_ref_scoring_dist_rel': Set the distance threshold for scoring relative to the diameter of the surface model. See the following *'pose_ref_scoring_dist_abs'* for a detailed description. Only one of the parameters *'pose_ref_scoring_dist_rel'* and *'pose_ref_scoring_dist_abs'* can be set. If both are set, only the value of the last parameter is used.

Suggested values: *0.1*, *0.05*, *0.03*, *0.005*

Default: *0.03*

Restriction: *0 < 'pose_ref_scoring_dist_rel'*

'pose_ref_scoring_dist_abs': Set the distance threshold for scoring. Only scene points that are closer to the object than this distance are considered to be 'on the model' when computing the score after the refinement. All other scene points are considered not to be on the model. The value should correspond to the amount of noise on the coordinates of the scene points. Only one of the parameters *'pose_ref_scoring_dist_rel'* and *'pose_ref_scoring_dist_abs'* can be set. If both are set, only the value of the last parameter is used.

Restriction: *0 < 'pose_ref_scoring_dist_abs'*

Parameters

▷ **`DeformableSurfaceModel`** (input_control) . . . . . deformable_surface_model ⇝ *handle*
Handle of the deformable surface model.

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model containing the scene.

▷ **`RelSamplingDistance`** (input_control) . . . . . real ⇝ *real*
Scene sampling distance relative to the diameter of the surface model.
Default: 0.05
Suggested values: `RelSamplingDistance` ∈ {0.1, 0.07, 0.05, 0.04, 0.03}
Restriction: 0 < RelSamplingDistance < 1

▷ **`MinScore`** (input_control) . . . . . real ⇝ *real* / integer
Minimum score of the returned match.
Default: 0
Restriction: MinScore >= 0

▷ **`GenParamName`** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: `GenParamName` ∈ {'scene_normal_computation', 'scene_invert_normals', 'pose_ref_num_steps', 'pose_ref_dist_threshold_rel', 'pose_ref_dist_threshold_abs', 'pose_ref_scoring_dist_abs', 'pose_ref_scoring_dist_rel'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: `GenParamValue` ∈ {'fast', 'mls', 0, 1, 10, 25, 50, 0.05, 0.1, 0.25, 0.3, 0.05, 0.03, 0.005}

▷ **`Score`** (output_control) . . . . . real(-array) ⇝ *real*
Score of the found instance of the surface model.

▷ **DeformableSurfaceMatchingResult** (output_control) .....
deformable_surface_matching_result(-array) ⇝ *handle*

Handle of the matching result.

Result

`find_deformable_surface_model` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

get_deformable_surface_matching_result

```
get_deformable_surface_matching_result (
    : : DeformableSurfaceMatchingResult, ResultName,
    ResultIndex : ResultValue )
```

Get details of a result from deformable surface based matching.

The operator `get_deformable_surface_matching_result` returns details about the results of deformable surface based matching or the deformable surface refinement. The results are stored in `DeformableSurfaceMatchingResult`, which must have been created by `find_deformable_surface_model` or `refine_deformable_surface_model`.

The parameter `ResultName` is used to select which result detail shall be returned. For some result details, `ResultIndex` selects the index of the result detail. `ResultIndex` is ignored for certain values of `ResultName`.

The following values are possible for `ResultName`:

'sampled_scene': A 3D object model handle is returned that contains the sampled scene points that were used in the matching or refinement. This is helpful for tuning the sampling distance of the scene (see parameter RelSamplingDistance of operators `find_deformable_surface_model` and `refine_deformable_surface_model`). The parameter `ResultIndex` is ignored.

'rigid_pose': If `DeformableSurfaceMatchingResult` was created by `find_deformable_surface_model`, a rigid pose is returned that approximates the deformable matching result. The parameter `ResultIndex` is ignored. This parameter is not available if `DeformableSurfaceMatchingResult` was created by `refine_deformable_surface_model`.

'reference_point_x':

'reference_point_y':

'reference_point_z': Returns the x-, y- or z-coordinates of a transformed reference point. The reference point must have been added to the deformable surface model using the operator `add_deformable_surface_model_reference_point`. The indices of the reference points to be returned are passed in `ResultIndex`. If *'all'* is passed in `ResultIndex`, the position of all reference points is returned.

'deformed_model': Returns a deformed variant of the 3D object model that was originally passed to `create_deformable_surface_model`. The 3D object model is deformed with the reconstructed deformation. Triangles, polygons and extended attributes contained in the original 3D object model are maintained. The parameter `ResultIndex` is ignored.

'deformed_sampled_model': Returns a deformed variant of the 3D object model that was sampled by `create_deformable_surface_model`. The returned 3D object model has the same number of points as the original, undeformed sampled model, and the points are in the same order. Details about the sampling are described in `create_deformable_surface_model`. The original, undeformed sampled model can be obtained with `get_deformable_surface_model_param`. The parameter `ResultIndex` is ignored.

Parameters

▷ **`DeformableSurfaceMatchingResult`** (input_control) ..... deformable_surface_matching_result ⇝ *handle*

Handle of the deformable surface matching result.

▷ **`ResultName`** (input_control) ..... string(-array) ⇝ *string*
Name of the result property.
Default: 'sampled_scene'
List of values: `ResultName` ∈ {'sampled_scene', 'rigid_pose', 'reference_point_x', 'reference_point_y', 'reference_point_z', 'deformed_model', 'deformed_sampled_model'}

▷ **`ResultIndex`** (input_control) ..... integer(-array) ⇝ *integer* / string
Index of the result property.
Default: 0
Suggested values: `ResultIndex` ∈ {0, 1, 2, 3, 'all'}
Restriction: ResultIndex >= 0

▷ **`ResultValue`** (output_control) ..... integer(-array) ⇝ *integer* / string / real / handle
Value of the result property.

Result

If the handle of the result is valid, the operator `get_deformable_surface_matching_result` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

get_deformable_surface_model_param (: : DeformableSurfaceModel, GenParamName : GenParamValue)

Return the parameters and properties of a deformable surface model.

The operator get_deformable_surface_model_param returns parameters and properties of the surface model DeformableSurfaceModel. The surface model must have been created with, for example, create_deformable_surface_model.

The following values are possible for GenParamName:

'diameter': Diameter of the model point cloud. The diameter is the length of the diagonal of the axis-parallel bounding box.

'sampled_model': The 3D points sampled from the model for matching. This returns a 3D object model that contains all points sampled from the model surface for matching.

'training_models': This returns all 3D object models that were used for the training of the deformable surface model. This includes the 3D object model passed to and sampled by create_deformable_surface_model, and the 3D object models added with add_deformable_surface_model_sample.

'reference_points_x':

'reference_points_y':

'reference_points_z': Returns the x-, y- or z-coordinates of all reference points added with the operator add_deformable_surface_model_reference_point.

Parameters

▷ **DeformableSurfaceModel** (input_control) . . . . . deformable_surface_model ⇝ *handle*
Handle of the deformable surface model.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the parameter.
Default: 'sampled_model'
List of values: GenParamName ∈ {'diameter', 'sampled_model', 'sampled_pose_refinement', 'training_models', 'reference_points_x', 'reference_points_y', 'reference_points_z', 'original_model'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *real* / string / integer
Value of the parameter.

Result

get_deformable_surface_model_param returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

3D Metrology

read_deformable_surface_model (: : FileName : DeformableSurfaceModel)

Read a deformable surface model from a file.

The operator read_deformable_surface_model reads the deformable surface model, which has been written with write_deformable_surface_model, from the file FileName. The handle of the deformable surface model is returned in DeformableSurfaceModel. If no absolute path is given in FileName, the file is searched in the current directory of the HALCON process. The default HALCON file extension for the deformable surface model file is 'dsfm'. If no file named FileName exists, the default file extension is appended to FileName.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the file to read.
File extension: .dsfm

▷ **DeformableSurfaceModel** (output_control) ..... deformable_surface_model ⇝ *handle*
Handle of the read deformable surface model.

Result

read_deformable_surface_model returns 2 (H_MSG_TRUE) if all parameters are correct and the file can be read. If the file is not a deformable surface model file, the error 9506 is raised. If the file has a version that can not be read by this version of HALCON, the error 9507 is raised. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

refine_deformable_surface_model (: : DeformableSurfaceModel, ObjectModel3D, RelSamplingDistance, InitialDeformationObjectModel3D, GenParamName, GenParamValue : Score, DeformableSurfaceMatchingResult)

Refine the position and deformation of a deformable surface model in a 3D scene.

The operator refine_deformable_surface_model refines the initial position and deformation given in InitialDeformationObjectModel3D of the surface model DeformableSurfaceModel in the 3D scene ObjectModel3D. The deformable surface model DeformableSurfaceModel must have been created previously with, for example, create_deformable_surface_model.

refine_deformable_surface_model is useful if the position and deformation of an object in a scene is approximately known and only needs to be refined. Additional information about the output parameters can be found in find_deformable_surface_model.

InitialDeformationObjectModel3D must contain as many points as the sampled deformation model obtained by get_deformable_surface_model_param and in the same order.

The score of the refined result is returned in Score and a deformable surface matching result handle is returned in DeformableSurfaceMatchingResult. Details of the result, such as the deformed model and the position of the reference points, can be queried with the operator get_deformable_surface_matching_result using the result handle.

The score is normalized between *0* and *1* and represents the amount of model surface visible in the scene. A value of *1* represents a perfect match.

The parameters GenParamName and GenParamValue are used to set generic parameters. Details about the generic parameters are described in the documentation of find_deformable_surface_model.

Parameters

▷ **DeformableSurfaceModel** (input_control) . . . . . deformable_surface_model ⇝ *handle*
Handle of the deformable surface model.

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model containing the scene.

▷ **RelSamplingDistance** (input_control) . . . . . real ⇝ *real*
Relative sampling distance of the scene.
Default: 0.05
Suggested values: RelSamplingDistance ∈ {0.1, 0.07, 0.05, 0.04, 0.03}
Restriction: 0 < RelSamplingDistance < 1

▷ **InitialDeformationObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Initial deformation of the 3D object model

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'scene_normal_computation', 'pose_ref_num_steps', 'pose_ref_dist_threshold_rel', 'pose_ref_dist_threshold_abs', 'pose_ref_scoring_dist_abs', 'pose_ref_scoring_dist_rel'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {'fast', 'mls', 0, 1, 10, 25, 50, 0.05, 0.1, 0.25, 0.3, 0.05, 0.03, 0.005}

▷ **Score** (output_control) . . . . . real(-array) ⇝ *real*
Score of the refined model.

▷ **DeformableSurfaceMatchingResult** (output_control) . . . . . deformable_surface_matching_result(-array) ⇝ *handle*
Handle of the matching result.

Result

refine_deformable_surface_model returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

serialize_deformable_surface_model (: : DeformableSurfaceModel : SerializedItemHandle)

Serialize a deformable surface_model.

serialize_deformable_surface_model serializes the data of a deformable surface model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_deformable_surface_model is converted to a serialized item. The deformable surface model is defined by the handle DeformableSurfaceModel. The serialized deformable surface model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_deformable_surface_model.

Parameters

▷ **DeformableSurfaceModel** (input_control) ..... deformable_surface_model ⇝ *handle*
Handle of the deformable surface model.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_deformable_surface_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_deformable_surface_model (: : DeformableSurfaceModel, FileName :)

Write a deformable surface model to a file.

The operator write_deformable_surface_model writes a deformable surface model to the file FileName. The file can be read again with read_deformable_surface_model. The default HALCON file extension for the deformable surface model file is 'dsfm'.

Parameters

▷ **DeformableSurfaceModel** (input_control) . . . . . deformable_surface_model ⇝ *handle*
Handle of the deformable surface model to write.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name to write to.
File extension: .dsfm

Result

write_deformable_surface_model returns 2 (H_MSG_TRUE) if all parameters are correct and the HALCON process has write permission to the file. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3.5 Shape-Based

clear_shape_model_3d (: : ShapeModel3DID :)

Free the memory of a 3D shape model.

The operator clear_shape_model_3d frees the memory of a 3D shape model that was created by create_shape_model_3d. After calling clear_shape_model_3d, the model can no longer be used. The handle ShapeModel3DID becomes invalid.

Parameters

▷ **ShapeModel3DID** (input_control) . . . . . shape_model_3d(-array) ⇝ *handle*
Handle of the 3D shape model.

Result

If the handle of the model is valid, the operator clear_shape_model_3d returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ShapeModel3DID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

3D Metrology

create_cam_pose_look_at_point (: : CamPosX, CamPosY, CamPosZ, LookAtX, LookAtY, LookAtZ, RefPlaneNormal, CamRoll : CamPose)

Create a 3D camera pose from camera center and viewing direction.

The operator create_cam_pose_look_at_point creates a 3D camera pose with respect to a world coordinate system based on two points and the camera roll angle.

The first of the two points defines the position of the optical center of the camera in the world coordinate system, i.e., the origin of the camera coordinate system. It is given by its three coordinates CamPosX, CamPosY, and CamPosZ. The second of the two points defines the viewing direction of the camera. It represents the point in the world coordinate system at which the camera is to look. It is also specified by its three coordinates LookAtX, LookAtY, and LookAtZ. Consequently, the second point lies on the z axis of the camera coordinate system.

Finally, the remaining degree of freedom to be specified is a rotation of the camera around its z axis, i.e., the roll angle of the camera. To determine this rotation, the normal of a reference plane can be specified in RefPlaneNormal, which defines the reference orientation of the camera. Finally, the camera roll angle can be specified in CamRoll, which describes a rotation of the camera around its z axis with respect to its reference orientation.

The reference plane can be seen as a plane in the world coordinate system that is parallel to the x axis of the camera (in its reference orientation, i.e., with a roll angle of 0). In an alternative interpretation, the normal vector of the reference plane projected onto the image plane points upwards, i.e., it is mapped to the negative y axis of the camera coordinate system. The parameter RefPlaneNormal may take one of the following values:

'x': The reference plane is the yz plane of the world coordinate system. The projected x axis of the world coordinate system points *upwards* in the image plane.

'-x': The reference plane is the yz plane of the world coordinate system. The projected x axis of the world coordinate system points *downwards* in the image plane.

'y': The reference plane is the xz plane of the world coordinate system. The projected y axis of the world coordinate system points *upwards* in the image plane.

'-y': The reference plane is the xz plane of the world coordinate system. The projected y axis of the world coordinate system points *downwards* in the image plane.

'z': The reference plane is the xy plane of the world coordinate system. The projected z axis of the world coordinate system points *upwards* in the image plane.

'-z': The reference plane is the xy plane of the world coordinate system. The projected z axis of the world coordinate system points *downwards* in the image plane.

Alternatively to the above values, an arbitrary normal vector can be specified in RefPlaneNormal, which is not restricted to the coordinate axes. For this, a tuple of three values representing the three components of the normal vector must be passed.

Note that the position of the optical center and the point at which the camera looks must differ from each other. Furthermore, the normal vector of the reference plane and the z axis of the camera must not be parallel. Otherwise, the camera pose is not well-defined.

create_cam_pose_look_at_point is particularly useful if a 3D object model or a 3D shape model should be visualized from a certain camera position. In this case, the pose that is created by create_cam_pose_look_at_point can be passed to project_object_model_3d or project_shape_model_3d, respectively.

It is also possible to pass tuples of different length for different input parameters. In this case, internally the maximum number of parameter values over all input control parameters is computed. This number is taken as

the number of output camera poses. Then, all input parameters can contain a single value or the same number of values as output camera poses. In the first case, the single value is used for the computation of all camera poses, while in the second case the respective value of the element in the parameter is used for the computation of the corresponding camera pose.

Parameters

- ▷ **CamPosX** (input_control) . . . . . real(-array) ⇝ *real*
  X coordinate of the optical center of the camera.
- ▷ **CamPosY** (input_control) . . . . . real(-array) ⇝ *real*
  Y coordinate of the optical center of the camera.
- ▷ **CamPosZ** (input_control) . . . . . real(-array) ⇝ *real*
  Z coordinate of the optical center of the camera.
- ▷ **LookAtX** (input_control) . . . . . real(-array) ⇝ *real*
  X coordinate of the 3D point to which the camera is directed.
- ▷ **LookAtY** (input_control) . . . . . real(-array) ⇝ *real*
  Y coordinate of the 3D point to which the camera is directed.
- ▷ **LookAtZ** (input_control) . . . . . real(-array) ⇝ *real*
  Z coordinate of the 3D point to which the camera is directed.
- ▷ **RefPlaneNormal** (input_control) . . . . . string-array ⇝ *string* / real
  Normal vector of the reference plane (points up).
  Default: '-y'
  List of values: RefPlaneNormal ∈ {'x', 'y', 'z', '-x', '-y', '-z'}
- ▷ **CamRoll** (input_control) . . . . . angle.rad(-array) ⇝ *real*
  Camera roll angle.
  Default: 0
- ▷ **CamPose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
  3D camera pose.

Result

If the parameters are valid, the operator create_cam_pose_look_at_point returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters are chosen such that the pose is not well defined, the error 8940 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

create_shape_model_3d (: : ObjectModel3D, CamParam, RefRotX, RefRotY, RefRotZ, OrderOfRotation, LongitudeMin, LongitudeMax, LatitudeMin, LatitudeMax, CamRollMin, CamRollMax, DistMin, DistMax, MinContrast, GenParamName, GenParamValue : ShapeModel3DID)

Prepare a 3D object model for matching.

The operator create_shape_model_3d prepares a 3D object model, which is passed in ObjectModel3D, as a 3D shape model used for matching. The 3D object model must previously been read from a file by using read_object_model_3d.

The 3D shape model is generated by computing different views of the 3D object model within a user-specified pose range. The views are automatically generated by placing virtual cameras around the 3D object model and projecting the 3D object model into the image plane of each virtual camera position. For each such obtained view a 2D shape representation is computed. Thus, for the generation of the 3D shape model, no images of the object are used but only the 3D object model, which is passed in `ObjectModel3D`. The shape representations of all views are stored in the 3D shape model, which is returned in `ShapeModel3DID`. During the matching process with `find_shape_model_3d`, the shape representations are used to find out the best-matching view, from which the pose is subsequently refined and returned.

In order to create the model views correctly, the camera parameters of the camera that will be used for the matching must be passed in `CamParam`. The camera parameters are necessary, for example, to determine the scale of the projections by using the actual focal length of the camera. Furthermore, they are used to treat radial distortions of the lens correctly. Consequently, it is essential to calibrate the camera by using `calibrate_cameras` before creating the 3D shape model. On the one hand, this is necessary to obtain accurate poses from `find_shape_model_3d`. On the other hand, this makes the 3D matching applicable even when using lenses with significant radial distortions.

The pose range within which the model views are generated can be specified by the parameters `RefRotX`, `RefRotY`, `RefRotZ`, `OrderOfRotation`, `LongitudeMin`, `LongitudeMax`, `LatitudeMin`, `LatitudeMax`, `CamRollMin`, `CamRollMax`, `DistMin`, and `DistMax`. Note that the model will only be recognized during the matching if it appears within the specified pose range. The parameters are described in the following:

Before computing the views, the origin of the coordinate system of the 3D object model is moved to the reference point of the 3D object model, which is the center of the smallest enclosing axis-parallel cuboid and can be queried by using `get_object_model_3d_params`. The virtual cameras, which are used to create the views, are arranged around the 3D object model in such a way that they all look at the origin of the coordinate system, i.e., the z axes of the cameras pass through the origin. The pose range can then be specified by restricting the views to a certain quadrilateral on the sphere around the origin. This naturally leads to the use of the spherical coordinates longitude, latitude, and radius. The definition of the spherical coordinate system is chosen such that the equatorial plane corresponds to the xz plane of the Cartesian coordinate system with the y axis pointing to the south pole (negative latitude) and the negative z axis pointing in the direction of the zero meridian (see `convert_point_3d_spher_to_cart` or `convert_point_3d_cart_to_spher` for further details about the conversion between Cartesian and spherical coordinates). The advantage of this definition is that a camera with the pose [0,0,z,0,0,0,0] has its optical center at longitude=0, latitude=0, and radius=z. In this case, the radius represents the distance of the optical center of the camera to the reference point of the 3D object model.

The longitude range, for which views are to be generated, can be specified by `LongitudeMin` and `LongitudeMax`, both given in radians. Accordingly, the latitude range can be specified by `LatitudeMin` and `LatitudeMax`, also given in radians. `LongitudeMin` and `LongitudeMax` are adjusted to maintain a range of 360° (2π). If an adjustment is possible, `LongitudeMin` and the range are preserved. The minimum and maximum distance between the camera center and the model reference point is specified by `DistMin` and `DistMax`. Thereby, the model origin is in the center of the smallest enclosing cuboid and does not necessarily coincide with the origin of the CAD coordinate system. Note that the unit of the distance must be meters (assuming that the parameter `Scale` has been correctly set when reading the CAD file with `read_object_model_3d`). Finally, the minimum and the maximum camera roll angle can be specified in `CamRollMin` and `CamRollMax`. This interval specifies the allowable camera rotation around its z axis with respect to the 3D object model. If the image plane is parallel to the plane on which the objects reside and if it is known that the object may rotate in this plane only in a restricted range, then it is reasonable to specify this range in `CamRollMin` and `CamRollMax`. In all other cases the interpretation of the camera roll angle is difficult, and hence, it is recommended to set this interval to $[-\pi, +\pi]$. Note that the larger the specified pose range is chosen the more memory the model will consume (except from the range of the camera roll angle) and the slower the matching will be.

The orientation of the coordinate system of the 3D object model is defined by the coordinates within the CAD file that was read by using `read_object_model_3d`. Therefore, it is reasonable to previously rotate the 3D object model into a reference orientation such that the view that corresponds to longitude=0 and latitude=0 is approximately at the center of the pose range. This can be achieved by passing appropriate values for the reference orientation in `RefRotX`, `RefRotY`, `RefRotZ`, and `OrderOfRotation`. The rotation is performed around the axes of the 3D object model, which origin was set to the reference point. The longitude and latitude range can then be interpreted as a variation of the 3D object model pose around the reference orientation. There are two possible ways to specify the reference orientation. The first possibility is to specify three rotation angles in `RefRotX`, `RefRotY`, and `RefRotZ` and the order in which the three rotations are to be applied in `OrderOfRotation`, which can either be *'gba'* or *'abg'*. The second possibility is to specify the three components of the Rodriguez

rotation vector in RefRotX, RefRotY, and RefRotZ. In this case, OrderOfRotation must be set to *'rodriguez'* (see create_pose for detailed information about the order of the rotations and the definition of the Rodriguez vector).

Thus, two transformations are applied to the 3D object model before computing the model views within the pose range. The first transformation is the translation of the origin of the coordinate systems to the reference point. The second transformation is the rotation of the 3D object model to the desired reference orientation around the axes of the reference coordinate system. By combining both transformations one obtains the reference pose of the 3D shape model. The reference pose of the 3D shape model thus describes the pose of the reference coordinate system with respect to the coordinate system of the 3D object model defined by the CAD file. Let $t = (x, y, z)'$ be the coordinates of the reference point of the 3D object model and R be the rotation matrix containing the reference orientation. Then, a point p_m given in the 3D object model coordinate system can be transformed to a point p_r in the reference coordinate system of the 3D shape model by applying the following formula:

$$p_r = R \cdot (p_m - t)$$

This transformation can be expressed by a homogeneous 3D transformation matrix or alternatively in terms of a 3D pose. The latter can be queried by passing *'reference_pose'* for the parameter GenParamName of the operator get_shape_model_3d_params. The above formula can be best imagined as a pose of pose type 8, 10, or 12, depending on the value that was chosen for OrderOfRotation (see create_pose for detailed information about the different pose types). Note, however, that get_shape_model_3d_params always returns the pose using the pose type 0. Finally, poses that are given in one of the two coordinate systems can be transformed to the other coordinate system by using trans_pose_shape_model_3d.

Furthermore, it should be noted that the reference coordinate system is introduced only to specify the pose range in a convenient way. The pose resulting from the 3D matching that is performed with find_shape_model_3d always refers to the original 3D object model coordinate system used in the CAD file.

With MinContrast, it can be determined which edge contrast the model must at least have in the recognition performed by find_shape_model_3d. In other words, this parameter separates the model from the noise in the image. Therefore, a good choice is the range of gray value changes caused by the noise in the image. If, for example, the gray values fluctuate within a range of 10 gray levels, MinContrast should be set to 10. If multichannel images are used for the search images, the noise in one channel must be multiplied by the square root of the number of channels to determine MinContrast. If, for example, the gray values fluctuate within a range of 10 gray levels in a single channel and the image is a three-channel image, MinContrast should be set to 17. If the model should be recognized in very low contrast images, MinContrast must be set to a correspondingly small value. If the model should be recognized even if it is severely occluded, MinContrast should be slightly larger than the range of gray value fluctuations created by noise in order to ensure that the pose of the model is extracted robustly and accurately by find_shape_model_3d.

The parameters described above are application-dependent and must be always specified when creating a 3D shape model. In addition, there are some generic parameters that can optionally be used to influence the model creation. For most applications these parameters need not to be specified but can be left at their default values. If desired, these parameters and their corresponding values can be specified by using GenParamName and GenParamValue, respectively. The following values for GenParamName are possible:

'num_levels': For efficiency reasons the model views are generated on multiple pyramid levels. On higher levels fewer views are generated than on lower levels. With the parameter *'num_levels'* the number of pyramid levels on which model views are generated can be specified. It should be chosen as large as possible because by this the time necessary to find the model is significantly reduced. On the other hand, the number of levels must be chosen such that the shape representations of the views on the highest pyramid level are still recognizable and contain a sufficient number of points (at least four). If not enough model points are generated for a certain view, the view is deleted from the model and replaced by a view on a lower pyramid level. If for all views on a pyramid level not enough model points are generated, the number of levels is reduced internally until for at least one view enough model points are found on the highest pyramid level. If this procedure would lead to a model with no pyramid levels, i.e., if the number of model points is too small for all views already on the lowest pyramid level, create_shape_model_3d returns an error message. If *'num_levels'* is set to *'auto'* (default value), create_shape_model_3d determines the number of pyramid levels automatically. In this case all model views on all pyramid levels are automatically checked whether their shape representations are still recognizable. If the shape representation of a certain view is found to be not recognizable, the view is deleted from the model and replaced by a view on a lower pyramid level. Note that if *'num_levels'* is set to *'auto'*, the number of pyramid levels can be different for different views. In rare cases, it might happen that create_shape_model_3d determines a value for the number of pyramid levels that

is too large or too small. If the number of pyramid levels is chosen too large, the model may not be recognized in the image or it may be necessary to select very low parameters for `MinScore` or `Greediness` in `find_shape_model_3d` in order to find the model. If the number of pyramid levels is chosen too small, the time required to find the model in `find_shape_model_3d` may increase. In these cases, the views on the pyramid levels should be checked by using the output of `get_shape_model_3d_contours`.

Suggested values: *'auto'*, *3*, *4*, *5*, *6*

Default: *'auto'*

'fast_pose_refinement': The parameter specifies whether the pose refinement during the search with `find_shape_model_3d` is sped up. If *'fast_pose_refinement'* is set to *'false'*, for complex models with a large number of faces the pose refinement step might amount to a significant part of the overall computation time. If *'fast_pose_refinement'* is set to *'true'*, some of the calculations that are necessary during the pose refinement are already performed during the model generation and stored in the model. Consequently, the pose refinement during the search will be faster. Please note, however, that in this case the memory consumption of the model may increase significantly (typically by less than 30 percent). Further note that the resulting poses that are returned by `find_shape_model_3d` might slightly differ depending on the value of *'fast_pose_refinement'*, because internally the pose refinement is approximated if the parameter is set to *'true'*.

List of values: *'true'*, *'false'*

Default: *'true'*

'lowest_model_level': In some cases the model generation process might be very time consuming and the memory consumption of the model might be very high. The reason for this is that in these cases the number of views, which must be computed and stored in the model, is very high. The larger the pose range is chosen and the larger the objects appear in the image (measured in pixels) the more views are necessary. Consequently, especially the use of large images (e.g., images exceeding a size of 640×480) can result in very large models. Because the number of views is highest on lower pyramid levels, the parameter *'lowest_model_level'* can be used to exclude the lower pyramid levels from the generation of views. The value that is passed for *'lowest_model_level'* determines the lowest pyramid level down to which views are generated and stored in the 3d shape model. If, for example, a value of *2* is passed for large models, the time to generate the model as well as the size of the resulting model is reduced to approximately one third of the original values. If *'lowest_model_level'* is not passed, views are generated for all pyramid levels, which corresponds to the behavior when passing a value of *1* for *'lowest_model_level'*. If for *'lowest_model_level'* a value larger than *1* is passed, in `find_shape_model_3d` the tracking of matches through the pyramid will be stopped at this level. However, if in `find_shape_model_3d` a least-squares adjustment is chosen for pose refinement, the matches are refined on the lowest pyramid level using the least-squares adjustment. Note that for different values for *'lowest_model_level'* different matches might be found during the search. Furthermore, the score of the matches depends on the chosen method for pose refinement. Also note that the higher *'lowest_model_level'* is chosen the higher the portion of the refinement step with respect to the overall run-time of `find_shape_model_3d` will be. As a consequence for higher values of *'lowest_model_level'* the influence of the generic parameter *'fast_pose_refinement'* (see above) on the runtime will increase. A large value for *'lowest_model_level'* on the one hand may lead to long computation times of `find_shape_model_3d` if *'fast_pose_refinement'* is switches off (*'false'*). On the other hand it may lead to a decreased accuracy if *'fast_pose_refinement'* is switches on (*'true'*) because in this mode the pose refinement is only approximated. Therefore, the value for *'lowest_model_level'* should be chosen as small as possible. Furthermore, *'lowest_model_level'* should be chosen small enough such that the edges of the 3D object model are still observable on this level.

Suggested values: *1*, *2*, *3*

Default: *1*

'optimization': For models with particularly large model views, it may be useful to reduce the number of model points by setting *'optimization'* to a value different from *'none'*. If *'optimization'* = *'none'*, all model points are stored. In all other cases, the number of points is reduced according to the value of *'optimization'*. If the number of points is reduced, it may be necessary in `find_shape_model_3d` to set the parameter `Greediness` to a smaller value, e.g., 0.7 or 0.8. For models with small model views, the reduction of the number of model points does not result in a speed-up of the search because in this case usually significantly more potential instances of the model must be examined. If *'optimization'* is set to *'auto'*, `create_shape_model_3d` automatically determines the reduction of the number of model points for each model view.

List of values: *'auto'*, *'none'*, *'point_reduction_low'*, *'point_reduction_medium'*, *'point_reduction_high'*

Default: *'auto'*

'metric': This parameter determines the conditions under which the model is recognized in the image. If *'metric'* = *'ignore_part_polarity'*, the contrast polarity is allowed to change only between different parts of the model, whereas the polarity of model points that are within the same model part must not change. Please note that the term *'ignore_part_polarity'* is capable of being misunderstood. It means that polarity changes between neighboring model parts do not influence the score, and hence are ignored. Appropriate model parts are automatically determined. The size of the parts can be controlled by the generic parameter *'part_size'*, which is described below. Note that this metric only works for one-channel images. Consequently, if the model is created by using this metric and searched in a multi-channel image by using `find_shape_model_3d` an error will be returned. If *'metric'* = *'ignore_local_polarity'*, the model is found even if the contrast polarity changes for each individual model point. This metric works for one-channel images as well as for multi-channel images. The metric *'ignore_part_polarity'* should be used if the images contain strongly textured backgrounds or clutter objects, which might result in wrong matches. Note that in general the scores of the matches that are returned by `find_shape_model_3d` are lower for *'ignore_part_polarity'* than for *'ignore_local_polarity'*. This should be kept in mind when choosing the right value for the parameter `MinScore` of `find_shape_model_3d`.

List of values: *'ignore_local_polarity'*, *'ignore_part_polarity'*

Default: *'ignore_local_polarity'*

'part_size': This parameter determines the size of the model parts that is used when *'metric'* is set to *'ignore_part_polarity'* (see above). The size must be specified in pixels and should be approximately twice as large as the size of the background texture in the image. For example, if an object should be found in front of a chessboard with black and white squares of size 5×5 pixels, *'part_size'* should be set to *10*. Note that higher values of *'part_size'* might also decrease the scores of correct instances especially when searching for objects with shiny or reflective surfaces. Therefore, the risk of missing correct instances might increase if *'part_size'* is set to a higher value. If *'metric'* is set to *'ignore_local_polarity'*, the value of *'part_size'* is ignored.

Suggested values: *2*, *3*, *4*, *6*, *8*, *10*

Default: *4*

'min_face_angle': 3D edges are only included in the shape representations of the views if the angle between the two 3D faces that are incident with the 3D object model edge is at least *'min_face_angle'*. If *'min_face_angle'* is set to *0.0*, all edges are included. If *'min_face_angle'* is set to π (equivalent to 180 degrees), only the silhouette of the 3D object model is included. This parameter can be used to suppress edges within curved surfaces, e.g., the surface of a cylinder or cone. Curved surfaces are approximated by multiple planar faces. The edges between such neighboring planar faces should not be included in the shape representation because they also do not appear in real images of the model. Thus, *'min_face_angle'* should be set sufficiently high to suppress these edges. The effect of different values for *'min_face_angle'* can be inspected by using `project_object_model_3d` before calling `create_shape_model_3d`. Note that if edges that are not visible in the search image are included in the shape representation, the performance (robustness and speed) of the matching may decrease considerably.

Suggested values: *'rad(10)'*, *'rad(20)'*, *'rad(30)'*, *'rad(45)'*

Default: *'rad(30)'*

'min_size': This value determines a threshold for the selection of significant model components based on the size of the components, i.e., connected components that have fewer points than the specified minimum size are suppressed. This threshold for the minimum size is divided by two for each successive pyramid level.

Suggested values: *'auto'*, *0*, *3*, *5*, *10*, *20*

Default: *'auto'*

'model_tolerance': The parameter specifies the tolerance of the projected 3D object model edges in the image, given in pixels. The higher the value is chosen, the fewer views need to be generated. Consequently, a higher value results in models that are less memory consuming and faster to find with `find_shape_model_3d`. On the other hand, if the value is chosen too high, the robustness of the matching will decrease. Therefore, this parameter should only be modified with care. For most applications, a good compromise between speed and robustness is obtained when setting *'model_tolerance'* to *1*.

Suggested values: *0*, *1*, *2*

Default: *1*

'union_adjacent_contours': This parameter specifies if adjacent projected contours should be joined by the operator `project_shape_model_3d` or not. Activating this option is equivalent to calling `union_adjacent_contours_xld` afterwards, but significantly faster.

List of values: *'true'*, *'false'*
Default: *'false'*

If the system variable (see `set_system`) *'opengl_hidden_surface_removal_enable'* is set to *'true'* (which is default if it is available) the graphics card is used to accelerate the computation of the visible faces in the model views. Depending on the graphics card this is significantly faster than the analytic visibility computation. If *'fast_pose_refinement'* is set to *'true'*, the precomputations necessary for the pose refinement step in `find_shape_model_3d` are also performed on the graphics card. Be aware that the results of the OpenGL projection are slightly different compared to the analytic projection.

Parameters

- ▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d ⇝ *handle*
  Handle of the 3D object model.
- ▷ **`CamParam`** (input_control) . . . . . campar ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **`RefRotX`** (input_control) . . . . . angle.rad ⇝ *real*
  Reference orientation: Rotation around x-axis or x component of the Rodriguez vector (in radians or without unit).
  Default: 0
  Suggested values: `RefRotX` ∈ {-1.57, -0.78, -0.17, 0., 0.17, 0.78, 1.57}
- ▷ **`RefRotY`** (input_control) . . . . . angle.rad ⇝ *real*
  Reference orientation: Rotation around y-axis or y component of the Rodriguez vector (in radians or without unit).
  Default: 0
  Suggested values: `RefRotY` ∈ {-1.57, -0.78, -0.17, 0., 0.17, 0.78, 1.57}
- ▷ **`RefRotZ`** (input_control) . . . . . angle.rad ⇝ *real*
  Reference orientation: Rotation around z-axis or z component of the Rodriguez vector (in radians or without unit).
  Default: 0
  Suggested values: `RefRotZ` ∈ {-1.57, -0.78, -0.17, 0., 0.17, 0.78, 1.57}
- ▷ **`OrderOfRotation`** (input_control) . . . . . string ⇝ *string*
  Meaning of the rotation values of the reference orientation.
  Default: 'gba'
  List of values: `OrderOfRotation` ∈ {'gba', 'abg', 'rodriguez'}
- ▷ **`LongitudeMin`** (input_control) . . . . . angle.rad ⇝ *real*
  Minimum longitude of the model views.
  Default: -0.35
  Suggested values: `LongitudeMin` ∈ {-0.78, -0.35, -0.17}
- ▷ **`LongitudeMax`** (input_control) . . . . . angle.rad ⇝ *real*
  Maximum longitude of the model views.
  Default: 0.35
  Suggested values: `LongitudeMax` ∈ {0.17, 0.35, 0.78}
  Restriction: LongitudeMax >= LongitudeMin
- ▷ **`LatitudeMin`** (input_control) . . . . . angle.rad ⇝ *real*
  Minimum latitude of the model views.
  Default: -0.35
  Suggested values: `LatitudeMin` ∈ {-0.78, -0.35, -0.17}
  Restriction: - pi / 2 <= LatitudeMin && LatitudeMin <= pi / 2
- ▷ **`LatitudeMax`** (input_control) . . . . . angle.rad ⇝ *real*
  Maximum latitude of the model views.
  Default: 0.35
  Suggested values: `LatitudeMax` ∈ {0.17, 0.35, 0.78}
  Restriction: - pi / 2 <= LatitudeMax && LatitudeMax <= pi / 2 && LatitudeMax >= LatitudeMin
- ▷ **`CamRollMin`** (input_control) . . . . . angle.rad ⇝ *real*
  Minimum camera roll angle of the model views.
  Default: -3.1416
  Suggested values: `CamRollMin` ∈ {-3.14, -1.57, -0.39, 0.0, 0.39, 1.57, 3.14}

▷ **CamRollMax** (input_control) . . . . . angle.rad ⇝ *real*
Maximum camera roll angle of the model views.
Default: 3.1416
Suggested values: CamRollMax ∈ {-3.14, -1.57, -0.39, 0.0, 0.39, 1.57, 3.14}
Restriction: CamRollMax >= CamRollMin

▷ **DistMin** (input_control) . . . . . number ⇝ *real*
Minimum camera-object-distance of the model views.
Default: 0.3
Suggested values: DistMin ∈ {0.05, 0.1, 0.2, 0.5}
Restriction: DistMin > 0

▷ **DistMax** (input_control) . . . . . number ⇝ *real*
Maximum camera-object-distance of the model views.
Default: 0.4
Suggested values: DistMax ∈ {0.1, 0.2, 0.5, 1.0}
Restriction: DistMax >= DistMin

▷ **MinContrast** (input_control) . . . . . number ⇝ *integer*
Minimum contrast of the objects in the search images.
Default: 10
Suggested values: MinContrast ∈ {1, 2, 3, 5, 7, 10, 20, 30, 1000, 2000, 5000}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of (optional) parameters for controlling the behavior of the operator.
Default: []
List of values: GenParamName ∈ {'num_levels', 'fast_pose_refinement', 'lowest_model_level', 'optimization', 'metric', 'part_size', 'min_face_angle', 'min_size', 'model_tolerance', 'union_adjacent_contours'}

▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *integer* / real / string
Values of the optional generic parameters.
Default: []
Suggested values: GenParamValue ∈ {0, 1, 2, 3, 4, 6, 8, 10, 'auto', 'none', 'point_reduction_low', 'point_reduction_medium', 'point_reduction_high', 0.1, 0.2, 0.3, 'ignore_local_polarity', 'ignore_part_polarity', 'true', 'false'}

▷ **ShapeModel3DID** (output_control) . . . . . shape_model_3d ⇝ *handle*
Handle of the 3D shape model.

Result

If the parameters are valid, the operator create_shape_model_3d returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. If the parameters are chosen such that all model views contain too few points, the error 8510 is raised. In the case that the projected model is bigger than twice the image size in at least one model view, the error 8910 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

deserialize_shape_model_3d (: : SerializedItemHandle : ShapeModel3DID)

Deserialize a serialized 3D shape model.

deserialize_shape_model_3d deserializes a 3D shape model, that was serialized by serialize_shape_model_3d (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized 3D shape model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created 3D shape model with the handle ShapeModel3DID.

Parameters

- ▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
  Handle of the serialized item.
- ▷ **ShapeModel3DID** (output_control) ..... shape_model_3d ⇝ *handle*
  Handle of the 3D shape model.

Result

If the parameters are valid, the operator deserialize_shape_model_3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

find_shape_model_3d (Image : : ShapeModel3DID, MinScore, Greediness, NumLevels, GenParamName, GenParamValue : Pose, CovPose, Score)

Find the best matches of a 3D shape model in an image.

The operator find_shape_model_3d finds the best matches of the 3D shape model ShapeModel3DID in the input Image. The 3D shape model must have been created previously by calling create_shape_model_3d or read_shape_model_3d.

The 3D pose of the found instances of the model is returned in Pose. The pose is in the form ${}^{ccs}\mathbf{P}_{mcs}$, where *ccs* denotes the camera coordinate system and *mcs* the model coordinate system (which is a 3D world coordinate system), see Transformations / Poses and "Solution Guide III-C - 3D Vision". Hence, it describes the pose of the 3D object model in camera coordinates. It should be noted that the resulting Pose does not refer to reference coordinate system that is introduced in create_shape_model_3d but to the original 3D object model coordinate system used in the CAD file. If a pose refinement was applied (see below), additionally the accuracy of the six pose parameters are returned in CovPose. By default, CovPose contains the 6 standard

deviations of the pose parameters for each match. In contrast, if the generic parameter *'cov_pose_mode'* (see below) was set to *'covariances'*, CovPose contains the 36 values of the complete 6×6 covariance matrix of the 6 pose parameters. Note that this reflects only an inner accuracy from which the real accuracy of the pose may differ. Finally, the score of each found instance is returned in Score. The score is a number between 0 and 1, which is an approximate measure of how much of the model is visible in the image. If, for example, half of the model is occluded, the score cannot exceed 0.5.

Input parameters in detail

Image and its domain: The domain of the image Image determines the search space for the reference point of the 3D object model. There is no need to correct any distortions in Image as the calibration data has already been provided during the model creation.

MinScore: The parameter MinScore determines what score a potential match must at least have to be regarded as an instance of the model in the image. The larger MinScore is chosen, the faster the search is. If the model can be expected never to be occluded in the images, MinScore may be set as high as 0.8 or even 0.9. Note that in images with a high degree of clutter or strong background texture, MinScore should be set to a value not much lower than *0.7* since otherwise false matches could be found.

Greediness: The parameter Greediness determines how "greedily" the search should be carried out. If Greediness $= 0$, a safe search heuristic is used, which always finds the model if it is visible in the image. However, the search will be relatively time consuming in this case. If Greediness $= 1$, an unsafe search heuristic is used, which may cause the model not to be found in rare cases, even though it is visible in the image. For Greediness $= 1$, the maximum search speed is achieved. In almost all cases, the 3D shape model will always be found for Greediness $= 0.9$.

NumLevels: The number of pyramid levels used during the search is determined with NumLevels. If necessary, the number of levels is clipped to the range given when the 3D shape model was created with create_shape_model_3d. If NumLevels is set to *0*, the number of pyramid levels specified in create_shape_model_3d is used. Optionally, NumLevels can contain a second value that determines the lowest pyramid level to which the found matches are tracked. Hence, a value of *[4,2]* for NumLevels means that the matching starts at the fourth pyramid level and tracks the matches to the second lowest pyramid level (the lowest pyramid level is denoted by a value of 1). This mechanism can be used to decrease the runtime of the matching. If the lowest pyramid level to use is chosen too large, it may happen that the desired accuracy cannot be achieved, or that wrong instances of the model are found because the model is not specific enough on the higher pyramid levels to facilitate a reliable selection of the correct instance of the model. In this case, the lowest pyramid level to use must be set to a smaller value.

GenParamName and GenParamValue: In addition to the parameters described above, there are some generic parameters that can optionally be used to influence the matching. For most applications these parameters need not to be specified but can be left at their default values. If desired, these parameters and their corresponding values can be specified by using GenParamName and GenParamValue, respectively. The following values for GenParamName are possible:

- If the pose range in which the model is to be searched is smaller than the pose range that was specified during the model creation with create_shape_model_3d, the pose range can be restricted appropriately with the following parameters. If the values lie outside the pose range of the model, the values are automatically clipped to the pose range of the model.

  'longitude_min': Sets the minimum longitude of the pose range.
  Suggested values: *'rad(-45)'*, *'rad(-30)'*, *'rad(-15)'*
  Default: *'rad(-180)'*

  'longitude_max': Sets the maximum longitude of the pose range.
  Suggested values: *'rad(15)'*, *'rad(30)'*, *'rad(45)'*
  Default: *'rad(180)'*

  'latitude_min': Sets the minimum latitude of the pose range.
  Suggested values: *'rad(-45)'*, *'rad(-30)'*, *'rad(-15)'*
  Default: *'rad(-90)'*

  'latitude_max': Sets the maximum latitude of the pose range.
  Suggested values: *'rad(15)'*, *'rad(30)'*, *'rad(45)'*
  Default: *'rad(90)'*

  'cam_roll_min': Sets the minimum camera roll angle of the pose range.
  Suggested values: *'rad(-45)'*, *'rad(-30)'*, *'rad(-15)'*
  Default: *'rad(-180)'*

'cam_roll_max': Sets the maximum camera roll angle of the pose range.
Suggested values: *'rad(15)'*, *'rad(30)'*, *'rad(45)'*
Default: *'rad(180)'*

'dist_min': Sets the minimum camera-object-distance of the pose range.
Suggested values: *0.05*, *0.1*, *0.5*, *1.0*
Default: *0*

'dist_max': Sets the maximum camera-object-distance of the pose range.
Suggested values: *0.05*, *0.1*, *0.5*, *1.0*
Default: (∞)

- Further generic parameters that do not concern the pose range can be specified:

'num_matches': With this parameter the maximum number of instances to be found can be determined. If more than the specified number of instances with a score greater than `MinScore` are found in the image, only the best *'num_matches'* instances are returned. If fewer than *'num_matches'* are found, only that number is returned, i.e., the parameter `MinScore` takes precedence over *'num_matches'*. If *'num_matches'* is set to *0*, all matches that satisfy the score criterion are returned. Note that the more matches should be found the slower the matching will be.
Suggested values: *0*, *1*, *2*, *3*
Default: *1*

'max_overlap': It may happen that multiple instances with similar positions but with different orientations are found in the image. The parameter *'max_overlap'* determines by what fraction (i.e., a number between 0 and 1) two instances may at most overlap in order to consider them as different instances, and hence to be returned separately. If two instances overlap each other by more than the specified value only the best instance is returned. The calculation of the overlap is based on the smallest enclosing rectangle of arbitrary orientation (see `smallest_rectangle2`) of the found instances. If in `create_shape_model_3d` for *'lowest_model_level'* a value larger than *1* was passed, the overlap calculation is based on the projection of the smallest enclosing axis-parallel cuboid of the 3D object model. Because in this case the overlap might be overestimated, in some cases it could be necessary to increase the value for *'max_overlap'*. If $'max\_overlap' = 0$, the found instances may not overlap at all, while for $'max\_overlap' = 1$ all instances are returned.
Suggested values: *0.0*, *0.2*, *0.4*, *0.6*, *0.8*, *1.0*
Default: *0.5*

'pose_refinement': This parameter determines whether the poses of the instances should be refined after the matching. If *'pose_refinement'* is set to *'none'* the model's pose is only determined with a limited accuracy. In this case, the accuracy depends on several sampling steps that are used inside the matching process and, therefore cannot be predicted very well. Therefore, *'pose_refinement'* should only be set to *'none'* when the computation time is of primary concern and an approximate pose is sufficient. In all other cases the pose should be determined through a least-squares adjustment, i.e., by minimizing the distances of the model points to their corresponding image points. In order to achieve a high accuracy, this refinement is directly performed in 3D. Therefore, the refinement requires additional computation time. If the system variable (see `set_system`) *'opengl_hidden_surface_removal_enable'* is set to *'true'* (which is default if it is available) and the model `ShapeModel3DID` was created with *'fast_pose_refinement'* set to *'false'*, the projection of the model in the pose refinement step is accelerated using the graphics card. Depending on the graphics card this is significantly faster than the non accelerated algorithm. Be aware that the results of the OpenGL projection are slightly different compared to the analytic projection. The different modes for least-squares adjustment (*'least_squares'*, *'least_squares_high'*, and *'least_squares_very_high'*) can be used to determine the accuracy with which the minimum distance is searched for. The higher the accuracy is chosen, the longer the pose refinement will take, however. For most applications *'least_squares_high'* should be chosen because this results in the best trade-off between runtime and accuracy. Note that the pose refinement can be sped up by passing *'fast_pose_refinement'* for the parameter `GenParamName` of the operator `create_shape_model_3d`.
List of values: *'none'*, *'least_squares'*, *'least_squares_high'*, *'least_squares_very_high'*
Default: *'least_squares_high'*

'recompute_score': This parameter determines whether the score of the matches is recomputed after the pose refinement. If *'recompute_score'* is set to *'false'*, the score is returned that was computed before the pose refinement. In some cases, however, the pose refinement changes the object pose by more than one pixel in the image. Consequently, the original score does not appropriately describe the refined match any longer. This could result in wrong matches obtaining high scores or perfect

matches obtaining low scores. To obtain a more meaningful score that reflects the pose changes due to the pose refinement, the score can be recomputed after the pose refinement by setting *'recompute_score'* to *'true'*. Note that this might change the order of the matches as well as the selection of matches that is returned. Also note that the recomputation of the score values needs additional computation time. This increase of the run-time can be reduced by setting the generic parameter *'fast_pose_refinement'* of the operator `create_shape_model_3d` to *'true'*.
List of values: *'false'*, *'true'*
Default: *'false'*

'outlier_suppression': This parameter only takes effect if *'pose_refinement'* is set to a value other than *'none'*, and hence, a least-squares adjustment is performed. Then, in some cases it might be useful to apply a robust outlier suppression during the least-squares adjustment. This might be necessary, for example, if a high degree of clutter is present in the image, which prevents the least-squares adjustment from finding the optimum pose. In this case, *'outlier_suppression'* should be set to either *'medium'* (eliminates a medium proportion of outliers) or *'high'* (eliminates a high proportion of outliers). However, in most applications, no robust outlier suppression is necessary, and hence, *'outlier_suppression'* can be set to *'none'*. It should be noted that activating the outlier suppression comes along with a significantly increasing computation time.
List of values: *'none'*, *'medium'*, *'high'*
Default: *'none'*

'cov_pose_mode': This parameter only takes effect if *'pose_refinement'* is set to a value other than *'none'*, and hence, a least-squares adjustment is performed. *'cov_pose_mode'* determines the mode in which the accuracies that are computed during the least-squares adjustment are returned in `CovPose`. If *'cov_pose_mode'* is set to *'standard_deviations'*, the 6 standard deviations of the 6 pose parameters are returned for each match. In contrast, if *'cov_pose_mode'* is set to *'covariances'*, `CovPose` contains the 36 values of the complete 6×6 covariance matrix of the 6 pose parameters.
List of values: *'standard_deviations'*, *'covariances'*
Default: *'standard_deviations'*

'border_model': The model is searched within those points of the domain of the image in which the model lies completely within the image. This means that the model will not be found if it extends beyond the borders of the image, even if it would achieve a score greater than `MinScore`. Note that, if for a certain pyramid level the model touches the image border, it might not be found even if it lies completely within the original image. As a rule of thumb, the model might not be found if its distance to an image border falls below $2^{NumLevels-1}$. This behavior can be changed by setting *'border_model'* to *'true'*, which will cause models that extend beyond the image border to be found if they achieve a score greater than `MinScore`. Here, points lying outside the image are regarded as being occluded, i.e., they lower the score. It should be noted that the runtime of the search will increase in this mode. Note further, that in rare cases, which occur typically only for artificial images, the model might not be found also if for certain pyramid levels the model touches the border of the reduced domain. Then, it may help to enlarge the reduced domain by $2^{NumLevels-1}$ using, e.g., `dilation_circle`.
List of values: *'false'*, *'true'*
Default: *'false'*

Parameters

▷ **`Image`** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2
Input image in which the model should be found.

▷ **`ShapeModel3DID`** (input_control) . . . . . shape_model_3d ⇝ *handle*
Handle of the 3D shape model.

▷ **`MinScore`** (input_control) . . . . . real ⇝ *real*
Minimum score of the instances of the model to be found.
Default: 0.7
Suggested values: `MinScore` ∈ {0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: $0 \leq$ `MinScore` ≤ 1
Minimum increment: 0.01
Recommended increment: 0.05

▷ **Greediness** (input_control) . . . . . real ⇝ *real*
"Greediness" of the search heuristic (0: safe but slow; 1: fast but matches may be missed).
Default: 0.9
Suggested values: Greediness ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Value range: 0 ≤ Greediness ≤ 1
Minimum increment: 0.01
Recommended increment: 0.05

▷ **NumLevels** (input_control) . . . . . integer-array ⇝ *integer*
Number of pyramid levels used in the matching (and lowest pyramid level to use if |NumLevels| = 2).
Default: 0
List of values: NumLevels ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of (optional) parameters for controlling the behavior of the operator.
Default: []
List of values: GenParamName ∈ {'longitude_min', 'longitude_max', 'latitude_min', 'latitude_max', 'cam_roll_min', 'cam_roll_max', 'dist_min', 'dist_max', 'num_matches', 'max_overlap', 'pose_refinement', 'cov_pose_mode', 'outlier_suppression', 'border_model', 'recompute_score'}

▷ **GenParamValue** (input_control) . . . . . attribute.name-array ⇝ *integer* / real / string
Values of the optional generic parameters.
Default: []
Suggested values: GenParamValue ∈ {-0.78, -0.35, -0.17, 0.0, 0.17, 0.35, 0.78, 0.1, 0.2, 0.5, 'none', 'false', 'true', 'least_squares', 'least_squares_high', 'least_squares_very_high', 'standard_deviations', 'covariances', 'medium', 'high'}

▷ **Pose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
3D pose of the 3D shape model.

▷ **CovPose** (output_control) . . . . . real-array ⇝ *real*
6 standard deviations or 36 covariances of the pose parameters.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
Score of the found instances of the 3D shape model.

Example

```
read_object_model_3d (DXFModelFileName, 'm', [], [], ObjectModel3D, \
                      DxfStatus)
CamParam := ['area_scan_division',0.01221,2791,7.3958e-6,7.4e-6,\
             308.21,245.92,640,480]
create_shape_model_3d (ObjectModel3D, CamParam, 0, 0, 0, 'gba', \
                       -rad(20), rad(20), -rad(20), rad(20), 0, \
                       rad(360), 0.15, 0.2, 10, [], [], ShapeModel3DID)
grab_image_async (Image, AcqHandle, -1)
find_shape_model_3d (Image, ShapeModel3DID, 0.6, 0.9, 0, [], [], \
                     Pose, CovPose, Score)
project_shape_model_3d (ModelContours, ShapeModel3DID, CamParam, \
                        Pose, 'true', rad(30))
```

Result

If the parameter values are correct, the operator find_shape_model_3d returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised. If the model was created with find_shape_model_3d by setting *'metric'* to *'ignore_part_polarity'* and a multi-channel input image is passed in Image, the error 3359 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

get_shape_model_3d_contours (: ModelContours : ShapeModel3DID, Level, View : ViewPose)

Return the contour representation of a 3D shape model view.

The operator get_shape_model_3d_contours returns a representation of a single model view of the 3D shape model ShapeModel3DID as XLD contours in ModelContours. The parameters Level and View determine for which model view the contour representation should be returned, where Level denotes the pyramid level and View denotes the model view on this pyramid level.

The permitted range of values for Level and View can previously be determined by using the operator get_shape_model_3d_params and passing *'num_views_per_level'* for GenParamName.

The contours can be used to visualize and rate the 3D shape model that was created with create_shape_model_3d. With this it is possible, for example, to decide whether the number of pyramid levels in the model is appropriate or not. If the contours on the highest pyramid do not show enough details to be representative for the model view, the number of pyramid levels that are used during the search with find_shape_model_3d should be adjusted downwards. In contrast, if the contours show too many details even on the highest pyramid level, a higher number of pyramid levels should be chosen already during the creation of the 3D shape model by using create_shape_model_3d.

Additionally, the pose of the selected view is returned in ViewPose. It can be used, for example, to project the 3D shape model according to the view pose by using project_shape_model_3d. The rating of the model contours that was described above can then be performed by comparing the ModelContours to the projected model. Note that the position of the contours of the projection and the position of the model contours may slightly differ because of radial distortions.

Parameters

- ▷ **ModelContours** (output_object) ..... xld_cont-array ⇝ *object*
  Contour representation of the model view.
- ▷ **ShapeModel3DID** (input_control) ..... shape_model_3d ⇝ *handle*
  Handle of the 3D shape model.
- ▷ **Level** (input_control) ..... integer ⇝ *integer*
  Pyramid level for which the contour representation should be returned.
  Default: 1
  Suggested values: Level ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
  Restriction: Level >= 1
- ▷ **View** (input_control) ..... integer ⇝ *integer*
  View for which the contour representation should be returned.
  Default: 1
  Suggested values: View ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
  Restriction: View >= 1
- ▷ **ViewPose** (output_control) ..... pose ⇝ *real* / integer
  3D pose of the 3D shape model at the current view.

Result

If the parameters are valid, the operator get_shape_model_3d_contours returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

get_shape_model_3d_params (: : ShapeModel3DID, GenParamName : GenParamValue)

Return the parameters of a 3D shape model.

The operator `get_shape_model_3d_params` allows to query parameters of the 3D shape model. The names of the desired parameters are passed in the generic parameter `GenParamName`, the corresponding values are returned in `GenParamValue`.

The following parameters can be queried:

'cam_param': Internal parameters of the camera that is used for the matching.

'ref_rot_x': Reference orientation: Rotation around x-axis or x component of the Rodriguez vector (in radians or without unit).

'ref_rot_y': Reference orientation: Rotation around y-axis or y component of the Rodriguez vector (in radians or without unit).

'ref_rot_z': Reference orientation: Rotation around z-axis or z component of the Rodriguez vector (in radians or without unit).

'order_of_rotation': Meaning of the rotation values of the reference orientation.

'longitude_min': Minimum longitude of the model views.

'longitude_max': Maximum longitude of the model views.

'latitude_min': Minimum latitude of the model views.

'latitude_max': Maximum latitude of the model views.

'cam_roll_min': Minimum camera roll angle of the model views.

'cam_roll_max': Maximum camera roll angle of the model views.

'dist_min': Minimum camera-object-distance of the model views.

'dist_max': Maximum camera-object-distance of the model views.

'min_contrast': Minimum contrast of the objects in the search images.

'num_levels': User-specified number of pyramid levels.

'num_levels_max': Maximum number of used pyramid levels over all model views.

'optimization': Kind of optimization by reducing the number of model points.

'metric': Match metric.

'part_size': Size of the model parts that is used when *'metric'* is set to *'ignore_part_polarity'*.

'min_face_angle': Minimum 3D face angle for which 3D object model edges are included in the 3D shape model.

'min_size': Minimum size of the projected 3D object model edge (in number of pixels) to include the projected edge in the 3D shape model.

'model_tolerance': Maximum acceptable tolerance of the projected 3D object model edges (in pixels).

'num_views_per_level': Number of model views per pyramid level. For each pyramid level the number of views that are stored in the 3D shape model are returned. Thus, the number of returned elements corresponds to the number of used pyramid levels, which can be queried with *'num_levels_max'*. Note that for pyramid levels below *'lowest_model_level'* (see documentation of `create_shape_model_3d`), the value *0* is returned.

'reference_pose': Reference position and orientation of the 3d shape model. The returned pose is in the form ${}^{rcs}\mathbf{P}_{mcs}$, where *rcs* denotes the reference coordinates system and *mcs* the model coordinate system (which is a 3D world coordinate system), see Transformations / Poses and "Solution Guide III-C - 3D Vision". Hence, it describes the pose of the coordinate system that is used in the underlying 3D object model relative to the internally used reference coordinate system of the 3D shape model. With this pose, points given in the object coordinate system can be transformed into the reference coordinate system.

'reference_point': 3D coordinates of the reference point of the underlying 3D object model.

'bounding_box1': Smallest enclosing axis-parallel cuboid of the underlying 3D object model in the following order: [min_x, min_y, min_z, max_x, max_y, max_z].

'fast_pose_refinement': Describes whether the pose refinement during the search is performed in a sped up mode (*'true'*) or in the conventional mode (*'false'*).

'lowest_model_level': Lowest pyramid level down to which views are stored in the model.

'union_adjacent_contours': Describes whether in project_shape_model_3d adjacent contours should be joined or not.

A detailed description of the parameters can be looked up with the operator create_shape_model_3d.

It is possible to query the values of several parameters with a single operator call by passing a tuple containing the names of all desired parameters to GenParamName. As a result a tuple of the same length with the corresponding values is returned in GenParamValue. Note that this is solely possible for parameters that return only a single value.

Parameters

▷ **ShapeModel3DID** (input_control) . . . . . shape_model_3d ⇝ *handle*
Handle of the 3D shape model.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that are to be queried for the 3D shape model.
Default: 'num_levels_max'
List of values: GenParamName ∈ {'cam_param', 'ref_rot_x', 'ref_rot_y', 'ref_rot_z', 'order_of_rotation', 'longitude_min', 'longitude_max', 'latitude_min', 'latitude_max', 'cam_roll_min', 'cam_roll_max', 'dist_min', 'dist_max', 'min_contrast', 'num_levels', 'num_levels_max', 'optimization', 'metric', 'part_size', 'min_face_angle', 'min_size', 'model_tolerance', 'num_views_per_level', 'reference_pose', 'reference_point', 'bounding_box1', 'fast_pose_refinement', 'lowest_model_level', 'union_adjacent_contours'}

▷ **GenParamValue** (output_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Values of the generic parameters.

Result

If the parameters are valid, the operator get_shape_model_3d_params returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

project_shape_model_3d (: ModelContours : ShapeModel3DID, CamParam, Pose, HiddenSurfaceRemoval, MinFaceAngle :)

Project the edges of a 3D shape model into image coordinates.

The operator project_shape_model_3d projects the edges of the 3D object model that was used to create the 3D shape model ShapeModel3DID into the image coordinate system and returns the projected edges in ModelContours. The coordinates of the 3D object model are given in the 3D world coordinate system (*mcs*). First, they are transformed into the camera coordinate system (*ccs*) using the external camera parameters given in Pose. Then, these coordinates are projected into the image coordinate system based on the internal camera parameters CamParam.

The internal camera parameters CamParam describe the projection characteristics of the camera (see Calibration). The Pose is in the form ${}^{ccs}\mathbf{P}_{mcs}$, see Transformations / Poses and "Solution Guide III-C - 3D Vision". Hence, it describes the position and orientation of the model coordinate system defined by the 3D object model relative to the camera coordinate system.

The parameter HiddenSurfaceRemoval can be used to switch on or to switch off the removal of hidden surfaces. If HiddenSurfaceRemoval is set to *'true'*, only those projected edges are returned that are not hidden by faces of the 3D object model. If HiddenSurfaceRemoval is set to *'false'*, all projected edges are returned. This is faster than a projection with HiddenSurfaceRemoval set to *'true'*.

If the system variable (see set_system) *'opengl_hidden_surface_removal_enable'* is set to *'true'* (which is default if it is available) and HiddenSurfaceRemoval is set to *'true'*, the projection of the model is accelerated using the graphics card. Depending on the graphics card this is significantly faster than the non accelerated algorithm. Be aware that the results of the OpenGL projection are slightly different compared to the analytic projection. Notable, only the contours visible through CamParam are projected in this mode.

3D edges are only projected if the angle between the two 3D faces that are incident with the 3D edge is at least MinFaceAngle. If MinFaceAngle is set to *0.0*, all edges are projected. If MinFaceAngle is set to π (equivalent to 180 degrees), only the silhouette of the 3D object model is returned. This parameter can be used to suppress edges within curved surfaces, e.g., the surface of a cylinder.

If for the model creation with create_shape_model_3d the parameter *'union_adjacent_contours'* was activated, adjacent contours are joined.

project_shape_model_3d and project_object_model_3d return the same result if the 3D object model that was used to create the 3D shape model is passed to project_object_model_3d.

project_shape_model_3d is especially useful in order to visualize the matches that are returned by find_shape_model_3d in the case that the underlying 3D object model is no longer available.

Parameters

- ▷ **ModelContours** (output_object) ..... xld_cont-array ⇝ *object*
  Contour representation of the model view.
- ▷ **ShapeModel3DID** (input_control) ..... shape_model_3d ⇝ *handle*
  Handle of the 3D shape model.
- ▷ **CamParam** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **Pose** (input_control) ..... pose ⇝ *real* / integer
  3D pose of the 3D shape model in the world coordinate system.
- ▷ **HiddenSurfaceRemoval** (input_control) ..... string ⇝ *string*
  Remove hidden surfaces?
  Default: 'true'
  List of values: HiddenSurfaceRemoval ∈ {'true', 'false'}
- ▷ **MinFaceAngle** (input_control) ..... angle.rad ⇝ *real* / integer
  Smallest face angle for which the edge is displayed
  Default: 0.523599
  Suggested values: MinFaceAngle ∈ {0.17, 0.26, 0.35, 0.52}

Result

If the parameters are valid, the operator project_shape_model_3d returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

read_shape_model_3d (: : FileName : ShapeModel3DID)

Read a 3D shape model from a file.

The operator read_shape_model_3d reads a 3D shape model, which has been written with write_shape_model_3d, from the file FileName. The default HALCON file extension for the 3D shape model is 'sm3'.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
File name.
File extension: .sm3

▷ **ShapeModel3DID** (output_control) ..... shape_model_3d ⇝ *handle*
Handle of the 3D shape model.

Result

If the file name is valid, the operator read_shape_model_3d returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

serialize_shape_model_3d (
: : ShapeModel3DID : SerializedItemHandle)

Serialize a 3D shape model.

serialize_shape_model_3d serializes the data of a 3D shape model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_shape_model_3d is converted to a serialized item. The 3D shape model is defined by the handle ShapeModel3DID. The serialized 3D shape model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_shape_model_3d.

Parameters

▷ **ShapeModel3DID** (input_control) ..... shape_model_3d ⇝ *handle*
Handle of the 3D shape model.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_shape_model_3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

trans_pose_shape_model_3d (: : ShapeModel3DID, PoseIn, Transformation : PoseOut)

Transform a pose that refers to the coordinate system of a 3D object model to a pose that refers to the reference coordinate system of a 3D shape model and vice versa.

The operator trans_pose_shape_model_3d transforms the pose PoseIn into the pose PoseOut by using the transformation direction specified in Transformation. In the majority of cases, the operator will be used to transform a camera pose that is given relative to the source coordinate system to a camera pose that refers to the target coordinate system.

The pose can be transformed between two coordinate systems. The first coordinate system is the reference coordinate system of the 3D shape model (*ref*) that is passed in ShapeModel3DID. The origin of the reference coordinate system lies at the reference point of the underlying 3D object model. The orientation of the reference coordinate system is determined by the reference orientation that was specified when creating the 3D shape model with create_shape_model_3d.

The second coordinate system is the world coordinate system, i.e., the coordinate system of the 3D object model (*mcs*) that underlies the 3D shape model. This coordinate system is implicitly determined by the coordinates that are stored in the CAD file that was read by using read_object_model_3d.

If Transformation is set to *'ref_to_model'*, it is assumed that PoseIn refers to the reference coordinate system of the 3D shape model. Thus, PoseIn is ${}^{cs}\mathbf{P}_{rcs}$, where *cs* denotes the coordinate system the input pose transforms into (e.g., the camera coordinate system). For further information we refer to Transformations / Poses and "Solution Guide III-C - 3D Vision". The resulting output pose PoseOut in this case refers to the coordinate system of the 3D object model, thus ${}^{cs}\mathbf{P}_{mcs}$.

If Transformation is set to *'model_to_ref'*, it is assumed that PoseIn refers to the coordinate system of the 3D object model, ${}^{cs}\mathbf{P}_{mcs}$. The resulting output pose PoseOut in this case refers to the reference coordinate system of the 3D shape model, thus ${}^{cs}\mathbf{P}_{rcs}$.

The relative pose of the two coordinate systems can be queried by passing *'reference_pose'* for GenParamName in the operator get_shape_model_3d_params.

Parameters

▷ **ShapeModel3DID** (input_control) . . . . . shape_model_3d ⇝ *handle*
Handle of the 3D shape model.

▷ **PoseIn** (input_control) . . . . . pose ⇝ *real* / integer
Pose to be transformed in the source system.

▷ **Transformation** (input_control) . . . . . string ⇝ *string*
Direction of the transformation.
Default: 'ref_to_model'
List of values: `Transformation` ∈ {'ref_to_model', 'model_to_ref'}

▷ **PoseOut** (output_control) . . . . . pose ⇝ *real* / integer
Transformed 3D pose in the target system.

Result

If the parameters are valid, the operator `trans_pose_shape_model_3d` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_shape_model_3d (: : ShapeModel3DID, FileName :)

Write a 3D shape model to a file.

The operator `write_shape_model_3d` writes a 3D shape model to the file `FileName`. The model can be read again with `read_shape_model_3d`. The default HALCON file extension for the 3D shape model is 'sm3'.

Parameters

▷ **ShapeModel3DID** (input_control) . . . . . shape_model_3d ⇝ *handle*
Handle of the 3D shape model.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name.
File extension: `.sm3`

Result

If the file name is valid (write permission), the operator `write_shape_model_3d` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3.6 Surface-Based

clear_surface_matching_result (: : SurfaceMatchingResultID :)

Free the memory of a surface matching result.

The operator clear_surface_matching_result frees the memory of a surface matching result that was created by find_surface_model or refine_surface_model_pose. After calling clear_surface_matching_result, the result can no longer be used. The handle SurfaceMatchingResultID becomes invalid.

Parameters

▷ **SurfaceMatchingResultID** (input_control) . . . . . surface_matching_result(-array) ⇝ *handle*
Handle of the surface matching result.

Result

If the handle of the result is valid, the operator clear_surface_matching_result returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SurfaceMatchingResultID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

read_surface_model, create_surface_model

Module

3D Metrology

create_surface_model (: : ObjectModel3D, RelSamplingDistance, GenParamName, GenParamValue : SurfaceModelID)

Create the data structure needed to perform surface-based matching.

The operator create_surface_model creates a model for surface-based matching for the 3D object model ObjectModel3D. The 3D object model can, for example, have been read previously from a file by using read_object_model_3d, or been created by using xyz_to_object_model_3d. The created surface model is returned in SurfaceModelID.

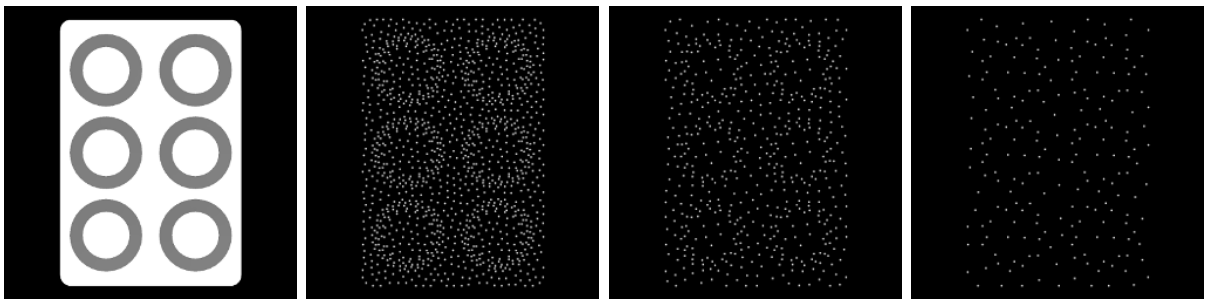
Additional parameters of the surface model can be set with set_surface_model_param after the model was created.

The creation of the surface model requires that the 3D object model contains points and normals. The following combinations are possible:

- points and point normals;
- points and a triangular or polygon mesh, e.g., from a CAD file;
- points and a 2D-Mapping, e.g., an XYZ image triple converted with xyz_to_object_model_3d.

Note that the direction and orientation (inward or outward) of the normals of the model are important for matching. For edge-supported surface-based matching the normals need to point inwards and further the model must contain a triangular or polygon mesh (see below).

The surface model is created by sampling the 3D object model with a certain distance. The sampling distance must be specified in the parameter RelSamplingDistance and is parametrized relative to the diameter of the axis-parallel bounding box of the 3D object model. For example, if RelSamplingDistance is set to *0.05* and the diameter of ObjectModel3D is *10 cm*, the points sampled from the object's surface will be approximately *5 mm* apart. The sampled points are used for the approximate matching in the operator find_surface_model (see below). The sampled points can be obtained with the operator get_surface_model_param using the value *'sampled_model'*. Note that outlier points in the object model should be avoided, as they would corrupt the diameter. Reducing RelSamplingDistance leads to more points, and in turn to a more stable but slower matching. Increasing RelSamplingDistance leads to less points, and in turn to a less stable but faster matching.



(1) (2) (3) (4)

(1) Original 3D model. (2) 3D model sampled with RelSamplingDistance = *0.02*. (3) RelSamplingDistance = *0.03*. (4) RelSamplingDistance = *0.05*.

The sampled points are used for finding the object model in a scene by using the operator find_surface_model. For this, all possible pairs of points from the point set are examined, and the distance and relative surface orientation of each pair is computed. Both values are discretized and stored for matching. The generic parameters *'feat_step_size_rel'* and *'feat_angle_resolution'* can be used to set the discretization of the distance and the orientation angles, respectively (see below).

The 3D object model is sampled a second time for the pose refinement. The second sampling is done with a smaller sampling distance, leading to more points. The generic parameter *'pose_ref_rel_sampling_distance'* sets the sampling distance relative to the object's diameter. Decreasing the value results in a more accurate pose refinement but a larger model and a slower model generation and matching. Increasing the value leads to a less accurate pose refinement but a smaller model and faster model generation and matching (see below).

Surface-based matching can additionally use 3D edges to improve the alignment. This is particularly helpful for objects that are planar or contain larger planar sides, such that they are found in incorrect rotations or in a background plane. In order to allow find_surface_model to also align edges, the surface model must be trained by setting the generic parameter *'train_3d_edges'* to *'true'*. In this case, the model must contain a triangular or polygon mesh where the order of the points results in normals that point inwards. Also, the training for edge-supported surface-based matching requires OpenGL 2.1, GLSL 1.2, and the OpenGL extensions GL_EXT_framebuffer_object and GL_EXT_framebuffer_blit. Note that the training can take significantly longer than without edge-support.

Additionally, the model can be prepared to support view-based score computation. This is particularly helpful for models where only a small part of the 3D object model is visible, which results in low scores if the ratio to the total number of points is used. Accordingly, the view-based score is computed using the ratio of the matched points to the maximum number of potentially visible model points from a certain viewpoint. In order to allow find_surface_model to compute a view-based score, the surface model must be trained by setting the generic parameter *'train_view_based'* to *'true'*. Similar to *'train_3d_edges'*, the model must contain a triangular or polygon mesh where the order of the points results in normals that point inwards.

Note that using noisy data for the creation of your 3D object model results in the computation of deficient surface normals. Especially when the model is prepared for the use with 3D edges or the support of view-based score, this can lead to unreliable scores. In order to reduce noisy 3D data you can, e.g., use smooth_object_model_3d or simplify_object_model_3d.

The generic parameter pair GenParamName and GenParamValue are used to set additional parameters for the model generation. GenParamName contains the tuple of parameter names that shall be set and GenParamValue contains the corresponding values. The following values are possible for GenParamName:

'model_invert_normals': Invert the orientation of the surface normals of the model. The normal orientation needs to be known for the model generation. If both the model and the scene are acquired with the same setup, the normals will already point in the same direction. If the model was loaded from a CAD file, the normals might point into the opposite direction. If you experience the effect that the model is found on the 'outside' of the scene surface and the model was created from a CAD file, try to set this parameter to *'true'*. Also, make sure that the normals in the CAD file all point either outward or inward, i.e., are oriented consistently. The normal direction is irrelevant for the pose refinement of the surface model. Therefore, if the object model is only used with the operator refine_surface_model_pose, the value of *'model_invert_normals'* has no effect on the result.

List of values: *'false'*, *'true'*

Default: *'false'*

'pose_ref_rel_sampling_distance': Set the sampling distance for the pose refinement relative to the object's diameter. Decreasing this value leads to a more accurate pose refinement but a larger model and slower model generation and refinement. Increasing the value leads to a less accurate pose refinement but a smaller model and faster model generation and matching.

Suggested values: *0.05*, *0.02*, *0.01*, *0.005*

Default: *0.01*

Restriction: *0 < 'pose_ref_rel_sampling_distance' < 1*

'feat_step_size_rel': Set the discretization distance of the point pair distance relative to the object's diameter. This value defaults to the value of RelSamplingDistance. It is not recommended to change this value. For very noisy scenes, the value can be increased to improve the robustness of the matching against noisy points.

Suggested values: *0.1*, *0.05*, *0.03*

Default: Value of RelSamplingDistance

Restriction: *0 < 'feat_step_size_rel' < 1*

'feat_angle_resolution': Set the discretization of the point pair orientation as the number of subdivisions of the angle. It is recommended to not change this value. Increasing the value increases the precision of the matching but decreases the robustness against incorrect normal directions. Decreasing the value decreases the precision of the matching but increases the robustness against incorrect normal directions. For very noisy scenes where the normal directions can not be computed accurately, the value can be set to *25* or *20*.

Suggested values: *20*, *25*, *30*

Default: *30*

Restriction: *'feat_angle_resolution'* > *1*

'train_3d_edges': Enable the training for edge-supported surface-based matching and refinement. In this case the model must contain a mesh, i.e. triangles or polygons. Also, it is important that the computed normal vectors point inwards. This parameter requires OpenGL.

List of values: *'false'*, *'true'*

Default: *'false'*

'train_view_based': Enable the training for view-based score computation for surface-based matching and refinement. In this case the model must contain a mesh, i.e. triangles or polygons. Also, it is important that the computed normal vectors point inwards. This parameter requires OpenGL.

List of values: *'false'*, *'true'*

Default: *'false'*

'train_self_similar_poses': Prepares the surface model for optimizations regarding self-similar, almost symmetric poses. For this, poses are found under which the model is very similar to itself, i.e., poses that can be distinguished only by very small properties of the model (such as boreholes) and that can be confused by `find_surface_model`. When calling `find_surface_model`, it will automatically be determined which of those self-similar poses are correct.

List of values: *'false'*, *'true'*

Default: *'false'*

Parameters

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model.

▷ **`RelSamplingDistance`** (input_control) . . . . . real ⇝ *real*
Sampling distance relative to the object's diameter
Default: 0.03
Suggested values: `RelSamplingDistance` ∈ {0.1, 0.05, 0.03, 0.02, 0.01}
Restriction: 0 < RelSamplingDistance < 1

▷ **`GenParamName`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters.
Default: []
Suggested values: `GenParamName` ∈ {'model_invert_normals', 'pose_ref_rel_sampling_distance', 'feat_step_size_rel', 'feat_angle_resolution', 'train_3d_edges', 'train_view_based', 'train_self_similar_poses'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: `GenParamValue` ∈ {0, 1, 'true', 'false', 0.005, 0.01, 0.02, 0.05, 0.1}

▷ **`SurfaceModelID`** (output_control) . . . . . surface_model ⇝ *handle*
Handle of the surface model.

Result

`create_surface_model` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

read_object_model_3d, xyz_to_object_model_3d, get_object_model_3d_params, surface_normals_object_model_3d

Possible Successors

find_surface_model, refine_surface_model_pose, get_surface_model_param, write_surface_model, clear_surface_model, set_surface_model_param

Alternatives

read_surface_model

deserialize_surface_model (: : SerializedItemHandle : SurfaceModelID)

Deserialize a surface model.

deserialize_surface_model deserializes a surface model, that was serialized by serialize_surface_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized surface model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created surface model with the handle SurfaceModelID.

Parameters

- ▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
  Handle of the serialized item.
- ▷ **SurfaceModelID** (output_control) ..... surface_model ⇝ *handle*
  Handle of the surface model.

Result

If the parameters are valid, the operator deserialize_surface_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

```
find_surface_model ( : : SurfaceModelID, ObjectModel3D,
    RelSamplingDistance, KeyPointFraction, MinScore,
    ReturnResultHandle, GenParamName, GenParamValue : Pose, Score,
    SurfaceMatchingResultID )
```

Find the best matches of a surface model in a 3D scene.

The operator `find_surface_model` finds the best matches of the surface model `SurfaceModelID` in the 3D scene `ObjectModel3D` and returns their pose in `Pose`.

The matching is divided in three steps:

1. `Approximate matching`
2. `Sparse pose refinement`
3. `Dense pose refinement`

These steps are described in more detail in the technical note `Surface-Based Matching`. The generic parameters used to control these steps are described in the respective sections below. The further paragraphs describe the parameters and mention further points to note.

The matching process and the parameters can be visualized and inspected using the HDevelop procedure `debug_find_surface_model`.

Points to Note

Matching the surface model uses points and normals of the 3D scene `ObjectModel3D`. The scene shall provide one of the following options:

- points and point normals.
- points and a 2D-Mapping, e.g., an XYZ image triple converted with `xyz_to_object_model_3d`. In this case the normals are calculated using the 2D-Mapping.
- points only. The normals are estimated based on the 3D neighborhood. Note, this option is not recommended, since it generally leads to a longer processing time and additionally the computed normals are usually less accurate, leading to less accurate results.

It is important for an accurate `Pose` that the normals of the scene and the model point in the same direction (see *'scene_invert_normals'*).

If the model was trained for edge-supported surface-based matching and the edge-supported matching has not been turned off via *'use_3d_edges'*, only the second combination is possible, i.e., the scene must contain a 2D mapping.

If the model was trained for edge-supported surface-based matching and the scene contains a mapping, normals contained in the input point cloud are not used (see *'scene_normal_computation'* below).

Further, for models which were trained for edge-supported surface-based matching it is necessary that the normal vectors point inwards.

Note that triangles or polygons in the passed scene are ignored. Instead, only the vertices are used for matching. It is thus in general not recommended to use this operator on meshed scenes, such as CAD data. Instead, such a scene must be sampled beforehand using `sample_object_model_3d` to create points and normals (e.g., using the method *'fast_compute_normals'*).

When using noisy point clouds, e.g., from time-of-flight cameras, the generic parameter *'scene_normal_computation'* could be set to *'mls'* in order to obtain more robust results (see below).

Parameter Description

`SurfaceModelID` is the handle of the surface model. The model must have been created previously with `create_surface_model` or read in with `read_surface_model`, respectively. Certain surface model parameters influencing the matching can be set using `set_surface_model_param`, such as *'pose_restriction_max_angle_diff'* restricting the allowed range of rotations.

`ObjectModel3D` is the handle of the 3D object model containing the scene in which the matches are searched. Note that in most cases, it is assumed the scene was observed from a camera looking along the z-axis. This is important to align the scene normals if they are re-computed (see *'scene_normal_computation'* below). In contrast, when the model was trained for edge-supported surface-based matching and the scene contains a mapping, normals are automatically aligned consistently.

The parameter RelSamplingDistance controls the sampling distance during the step Approximate matching and the Score calculation during the step Sparse pose refinement. Its value is given relative to the diameter of the surface model. Decreasing RelSamplingDistance leads to more sampled points, and in turn to a more stable but slower matching. Increasing RelSamplingDistance reduces the number of sampled scene points, which leads to a less stable but faster matching. For an illustration showing different values for RelSamplingDistance, please refer to the operator create_surface_model. The sampled scene points can be retrieved for a visual inspection using the operator get_surface_matching_result. For a robust matching it is recommended that at least 50-100 scene points are sampled for each object instance.

The parameter KeyPointFraction controls how many points out of the sampled scene points are selected as key points. For example, if the value is set to *0.1*, 10% of the sampled scene points are used as key points. For stable results it is important that each instance of the object is covered by several key points. Increasing KeyPointFraction means that more key points are selected from the scene, resulting in a slower but more stable matching. Decreasing KeyPointFraction has the inverse effect and results in a faster but less stable matching. The operator get_surface_matching_result can be used to retrieve the selected key points for visual inspection.

The parameter MinScore can be used to filter the results. Only matches with a score exceeding the value of MinScore are returned. If MinScore is set to zero, all matches are returned.

For edged-supported surface-based matching (see create_surface_model) four different sub-scores are determined (see their explanation below). For surface-based matching models where view-based score computation is trained (see create_surface_model), an additional fifth sub-score is determined. As a consequence, you can filter the results based on each of them by passing a tuple with up to five threshold values to MinScore. These threshold values are sorted in the order of the scores (see below) and missing entries are regarded as *0*, meaning no filtering based on this sub-score. To find suitable values for the thresholds, the corresponding sub-scores of found object instances can be obtained using get_surface_matching_result. Depending on the settings, not all sub-scores might be available. The thresholds for unavailable sub-scores are ignored. The five sub-scores, whose threshold values have to be passed in exactly this order in MinScore, are:

1. The overall score as returned in Score and through *'score'* by get_surface_matching_result,
2. the surface fraction of the score, i.e., how much of the object's surface was detected in the scene, returned through *'score_surface'* by get_surface_matching_result,
3. the 3D edge fraction of the score, i.e., how well the 3D edges of the object silhouette are aligned with the 3D edges detected in the scene returned through *'score_3d_edges'* by get_surface_matching_result,
4. the 2D edge fraction of the score, i.e., how well the object silhouette projected into the images aligns with edges detected in the images (available only for the operators find_surface_model_image and refine_surface_model_pose_image), returned through *'score_2d_edges'* by get_surface_matching_result, and
5. the view-based score, i.e., how many model points were detected in the scene, in relation to how many of the object points are potentially visible from the determined viewpoint, returned through *'score_view_based'* by get_surface_matching_result.

The parameter ReturnResultHandle determines if a surface matching result handle is returned or not. If the parameter is set to *'true'*, the handle is returned in the parameter SurfaceMatchingResultID. Additional details of the matching process can be queried with the operator get_surface_matching_result using that handle.

The parameters GenParamName and GenParamValue are used to set generic parameters. Both get a tuple of equal length, where the tuple passed to GenParamName contains the names of the parameters to set, and the tuple passed to GenParamValue contains the corresponding values. The possible parameter names and values are described in the paragraph The three steps of the matching.

The output parameter Pose gives the 3D poses of the found object instances. For every found instance of the surface model its pose is given in the scene coordinate system, thus the pose is in the form ${}^{scs}\mathbf{P}_{mcs}$, where *scs* denote the coordinate system of the scene (which often is identical with the coordinate system of the sensor, the camera coordinate system) and *mcs* the model coordinate system (which is a 3D world coordinate system), see Transformations / Poses and "Solution Guide III-C - 3D Vision". Thereby, the pose refers to the original coordinate system of the 3D object model that was passed to create_surface_model.

The output parameter Score returns a score for each match. Its value and interpretation differs for the cases distinguished below.

- **With pose refinement**
  For a matching with pose refinement, the score depends on whether edge-support was activated:
  - Without edge-support, compute the surface fraction, i.e. the approximate fraction of the object's surface that is visible in the scene. This is done by counting the number of model points that have a corresponding scene point and dividing this number either by:
    * the total number of points on the model, if the surface-based model is not prepared for view-based score computation
      or by:
    * the maximum number of potentially visible model points based on the current viewpoint, if the surface-based model is prepared for view-based score computation.

    $0 \leq Score \leq 1$
  - With edge-support, compute the geometric mean of the surface fraction and the edge fraction. The surface fraction is affected by whether the surface-based model is prepared for view-based score computation or not, as explained above. The edge fraction is the number of points from the sampled model edges that are aligned with edges of the scene, divided by the maximum number of potentially visible points of edges on the model. Note that if the edges are extracted from multiple viewpoints, this might lead to score greater than 1.
    $0 \leq Score \leq 1$ (if the scene was acquired from one single viewpoint)
    $0 \leq Score \leq N$ (if the scene was merged from scenes that were acquired from N different viewpoints)

  Note that for the computation of the score after the sparse pose refinement, the sampled scene points are used. For the computation of the score after the dense pose refinement, all scene points are used. Therefore, after the dense pose refinement, the score values does not depend on the sampling distance of the scene.
- **Without pose refinement**
  If only the first step, `Approximate Matching`, out of the three steps described in `The three steps of the matching` takes place, the possible score value and interpretation only differs whether there is edge-support or not:
  - Without edge-support:
    The score is the approximate number of points from the subsampled scene that lie on the found object.
    $Score \geq 0$
  - With edge-support:
    The score is the approximate number of points from the subsampled scene that lie on the found object multiplied with the number of points from the sampled scene edges that are aligned with edges of the model.
    $Score \geq 0$

The output parameter `SurfaceMatchingResultID` returns a handle for the surface matching result. Using this handle, additional details of the matching process can be queried with the operator `get_surface_matching_result`. Note, that in order to return the handle, `ReturnResultHandle` has to be set to *'true'*.

The Three Steps of the Matching

The matching is divided into three steps:

1. Approximate matching The approximate poses of the instances of the surface model in the scene are searched.
The following generic parameters control the approximate matching and can be set with `GenParamName` and `GenParamValue`:

'num_matches': Sets the maximum number of matches that are returned.
Suggested values: *1*, *2*, *5*
Default: *1*
Restriction: *'num_matches' > 0*

'max_overlap_dist_rel': For efficiency reasons, the maximum overlap can not be defined in 3D. Instead, only the minimum distance between the centers of the axis-aligned bounding boxes of two matches can be specified with *'max_overlap_dist_rel'*. The value is set relative to the diameter of the object. Once an object with a high `Score` is found, all other matches are suppressed if the centers of their bounding boxes lie too close to the center of the first object. If the resulting matches must not overlap, the value for *'max_overlap_dist_rel'* should be set to *1.0*.

Note that only one of the parameters *'max_overlap_dist_rel'* and *'max_overlap_dist_abs'* should be set. If both are set, only the value of the last modified parameter is used.
Suggested values: *0.1*, *0.5*, *1*
Default: *0.5*
Restriction: *'max_overlap_dist_rel'* >= *0*

'max_overlap_dist_abs': This parameter has the same effect as the parameter *'max_overlap_dist_rel'*. Note that in contrast to *'max_overlap_dist_rel'*, the value for *'max_overlap_dist_abs'* is set as an absolute value. See *'max_overlap_dist_rel'* above, for a description of the effect of this parameter.
Note that only one of the parameters *'max_overlap_dist_rel'* and *'max_overlap_dist_abs'* should be set. If both are set, only the value of the last modified parameter is used.
Suggested values: *1*, *2*, *3*
Restriction: *'max_overlap_dist_abs'* >= *0*

'scene_normal_computation': This parameter controls the normal computation of the sampled scene.
In the default mode *'fast'*, in most cases normals from the 3D scene are used (if it already contains normals) or computed based on a small neighborhood of points (if not). The computed normals n are then oriented such that $n_z \geq 0$ in case no original normals exist. This orientation of $n_z \geq 0$ implies the assumption that the scene was observed from a camera looking along the z-axis.
In the default mode *'fast'*, in case the model was trained for edge-supported surface-based matching and the scene contains a mapping, input normals are not used and normals are always computed from the mapping contained in the 3D scene. Further, the computed normals are oriented inwards consistently with respect to the mapping.
In the mode *'mls'*, normals are recomputed based on a larger neighborhood and using the more complex but often more accurate *'mls'* method. A more detailed description of the *'mls'* method can be found in the description of the operator `surface_normals_object_model_3d`. The *'mls'* mode is intended for noisy data, such as images from time-of-flight cameras. The recomputed normals are oriented as the normals in mode *'fast'*.
List of values: *'fast'*, *'mls'*
Default: *'fast'*

'scene_invert_normals': Invert the orientation of the surface normals of the scene. The orientation of surface normals of the scene have to match with the orientation of the model. If both the model and the scene are acquired with the same setup, the normals will already point in the same direction. If you experience the effect that the model is found on the 'outside' of the scene surface, try to set this parameter to *'true'*. Also, make sure that the normals in the scene all point either outward or inward, i.e., are oriented consistently. For edge-supported surface-based matching, the normal vectors have to point inwards, but typically are automatically generated flipped inwards consistently with respect to the mapping. The orientation of the normals can be inspected using the procedure `debug_find_surface_model`.
List of values: *'false'*, *'true'*
Default: *'false'*

'3d_edges': Allows to manually set the 3D scene edges for edge-supported surface-based matching, i.e. if the surface model was created with *'train_3d_edges'* enabled. The parameter must be a 3D object model handle. The edges are usually a result of the operator `edges_object_model_3d` but can further be filtered in order to remove outliers. If this parameter is not given, `find_surface_model` will internally extract the edges similar to the operator `edges_object_model_3d`.

'3d_edge_min_amplitude_rel': Sets the threshold when extracting 3D edges for edge-supported surface-based matching, i.e. if the surface model was created with *'train_3d_edges'* enabled. The threshold is set relative to the diameter of the object. Note that if edges were passed manually with the generic parameter *'3d_edges'*, this parameter is ignored. Otherwise, it behaves identically to the parameter `MinAmplitude` of operator `edges_object_model_3d`.
Suggested values: *0.05*, *0.1*, *0.5*
Default: *0.05*
Restriction: *'3d_edge_min_amplitude_rel'* >= *0*

'3d_edge_min_amplitude_abs': Similar to *'3d_edge_min_amplitude_rel'*, however, the value is given as absolute distance and not relative to the object diameter.
Restriction: *'3d_edge_min_amplitude_abs'* >= *0*

'viewpoint': This parameter specifies the viewpoint from which the 3D data is seen. It is used for surface models that are prepared for view-based score computation (i.e. with *'train_view_based'* enabled) to get the maximum number of potentially visible points of the model based on the current viewpoint. For this, `GenParamValue` must contain a string consisting of the three coordinates (x, y, and z) of the view-

point, separated by spaces. The viewpoint is defined in the same coordinate frame as ObjectModel3D and should roughly correspond to the position the scene was acquired from. A visualization of the viewpoint can be created using the procedure debug_find_surface_model in order to inspect its position.
Default: *'0 0 0'*

'max_gap': Gaps in the 3D data are closed, as far as they do not exceed the maximum gap size *'max_gap'* [pixels] and the surface model was created with *'train_3d_edges'* enabled. Larger gaps will contain edges at their boundary, while gaps smaller than this value will not. This suppresses edges around smaller patches that were not reconstructed by the sensor as well as edges at the more distant part of a discontinuity. For sensors with very large resolutions, the value should be increased to avoid spurious edges. Note that if edges were passed manually with the generic parameter *'3d_edges'*, this parameter is ignored. Otherwise, it behaves identically to the parameter GenParamName of the operator edges_object_model_3d when *'max_gap'* is set.
The influence of *'max_gap'* can be inspected using the procedure debug_find_surface_model.
Default: *30*

'use_3d_edges': Turns the edge-supported matching on or off. This can be used to perform matching without 3D edges, even though the model was created for edge-supported matching. If the model was not created for edge-supported surface-based matching, an error is returned.
List of values: *'true'*, *'false'*
Default: *'true'*

2. Sparse pose refinement In this second step, the approximate poses found in the previous step are further refined. This increases the accuracy of the poses and the significance of the score value.

The following generic parameters control the sparse pose refinement and can be set with GenParamName and GenParamValue:

'sparse_pose_refinement': Enables or disables the sparse pose refinement.
List of values: *'true'*, *'false'*
Default: *'true'*

'pose_ref_use_scene_normals': Enables or disables the usage of scene normals for the pose refinement. If this parameter is enabled, and if the scene contains point normals, then those normals are used to increase the accuracy of the pose refinement. For this, the influence of scene points whose normal points in a different direction than the model normal is decreased. Note that the scene must contain point normals. Otherwise, this parameter is ignored.
List of values: *'true'*, *'false'*
Default: *'false'*

'use_view_based': Turns the view-based score computation for surface-based matching on or off. This can be used to perform matching without using the view-based score, even though the model was prepared for view-based score computation. The influence of *'use_view_based'* on the score is explained in the documentation of Score above.
If the model was not prepared for view-based score computation, an error is returned.
List of values: *'true'*, *'false'*
Default: *'false'*, if *'train_view_based'* was disabled when creating the model, otherwise *'true'*.

3. Dense pose refinement Accurately refines the poses found in the previous steps.

The following generic parameters influence the accuracy and speed of the dense pose refinement and can be set with GenParamName and GenParamValue:

'dense_pose_refinement': Enables or disables the dense pose refinement.
List of values: *'true'*, *'false'*
Default: *'true'*

'pose_ref_num_steps': Number of iterations for the dense pose refinement. Increasing the number of iteration leads to a more accurate pose at the expense of runtime. However, once convergence is reached, the accuracy can no longer be increased, even if the number of steps is increased. Note that this parameter is ignored if the dense pose refinement is disabled.
Suggested values: *1*, *3*, *5*, *20*
Default: *5*
Restriction: *'pose_ref_num_steps'* > *0*

'pose_ref_sub_sampling': Set the rate of scene points to be used for the dense pose refinement. For example, if this value is set to *5*, every 5th point from the scene is used for pose refinement. This parameter allows an easy trade-off between speed and accuracy of the pose refinement: Increasing the value leads to less

points being used and in turn to a faster but less accurate pose refinement. Decreasing the value has the inverse effect. Note that this parameter is ignored if the dense pose refinement is disabled.
Suggested values: *1*, *2*, *5*, *10*
Default: *2*
Restriction: *'pose_ref_sub_sampling' > 0*

'pose_ref_dist_threshold_rel': Set the distance threshold for dense pose refinement relative to the diameter of the surface model. Only scene points that are closer to the object than this distance are used for the optimization. Scene points further away are ignored.
Note that only one of the parameters *'pose_ref_dist_threshold_rel'* and *'pose_ref_dist_threshold_abs'* should be set. If both are set, only the value of the last modified parameter is used. Note that this parameter is ignored if the dense pose refinement is disabled.
Suggested values: *0.03*, *0.05*, *0.1*, *0.2*
Default: *0.1*
Restriction: *'pose_ref_dist_threshold_rel' > 0*

'pose_ref_dist_threshold_abs': Set the distance threshold for dense pose refinement as an absolute value. See *'pose_ref_dist_threshold_rel'* for a detailed description.
Note that only one of the parameters *'pose_ref_dist_threshold_rel'* and *'pose_ref_dist_threshold_abs'* should be set. If both are set, only the value of the modified last parameter is used.
Restriction: *'pose_ref_dist_threshold_abs' > 0*

'pose_ref_scoring_dist_rel': Set the distance threshold for scoring relative to the diameter of the surface model. See the following *'pose_ref_scoring_dist_abs'* for a detailed description.
Note that only one of the parameters *'pose_ref_scoring_dist_rel'* and *'pose_ref_scoring_dist_abs'* should be set. If both are set, only the value of the last modified parameter is used. Note that this parameter is ignored if the dense pose refinement is disabled.
Suggested values: *0.2*, *0.01*, *0.005*, *0.0001*
Default: *0.005*
Restriction: *'pose_ref_scoring_dist_rel' > 0*

'pose_ref_scoring_dist_abs': Set the distance threshold for scoring. Only scene points that are closer to the object than this distance are considered to be 'on the model' when computing the score after the pose refinement. All other scene points are considered not to be on the model. The value should correspond to the amount of noise on the coordinates of the scene points. Note that this parameter is ignored if the dense pose refinement is disabled.
Note that only one of the parameters *'pose_ref_scoring_dist_rel'* and *'pose_ref_scoring_dist_abs'* should be set. If both are set, only the value of the last modified parameter is used.

'pose_ref_use_scene_normals': Enables or disables the usage of scene normals for the pose refinement. This parameter is explained in more details in the section `Sparse pose refinement` above.
List of values: *'true'*, *'false'*
Default: *'false'*

'pose_ref_dist_threshold_edges_rel': Set the distance threshold of edges for dense pose refinement relative to the diameter of the surface model. Only scene edges that are closer to the object edges than this distance are used for the optimization. Scene edges further away are ignored.
Note that only one of the parameters *'pose_ref_dist_threshold_edges_rel'* and *'pose_ref_dist_threshold_edges_abs'* should be set. If both are set, only the value of the last modified parameter is used. Note that this parameter is ignored if the dense pose refinement is disabled or if no edge-supported surface-based matching is used.
Suggested values: *0.03*, *0.05*, *0.1*, *0.2*
Default: *0.1*
Restriction: *'pose_ref_dist_threshold_edges_rel' > 0*

'pose_ref_dist_threshold_edges_abs': Set the distance threshold of edges for dense pose refinement as an absolute value. See *'pose_ref_dist_threshold_edges_rel'* for a detailed description.
Note that only one of the parameters *'pose_ref_dist_threshold_edges_rel'* and *'pose_ref_dist_threshold_edges_abs'* should be set. If both are set, only the value of the last modified parameter is used. Note that this parameter is ignored if the dense pose refinement is disabled or if no edge-supported surface-based matching is used.
Restriction: *'pose_ref_dist_threshold_edges_abs' > 0*

'pose_ref_scoring_dist_edges_rel': Set the distance threshold of edges for scoring relative to the diameter of the surface model. See the following *'pose_ref_scoring_dist_edges_abs'* for a detailed description.
Note that only one of the parameters *'pose_ref_scoring_dist_edges_rel'* and

'pose_ref_scoring_dist_edges_abs' should be set. If both are set, only the value of the last modified parameter is used. Note that this parameter is ignored if the dense pose refinement is disabled or if no edge-supported surface-based matching is used.
Suggested values: *0.2*, *0.01*, *0.005*, *0.0001*
Default: *0.005*
Restriction: *'pose_ref_scoring_dist_edges_rel'* > *0*

'pose_ref_scoring_dist_edges_abs': Set the distance threshold of edges for scoring as an absolute value. Only scene edges that are closer to the object edges than this distance are considered to be 'on the model' when computing the score after the pose refinement. All other scene edges are considered not to be on the model. The value should correspond to the expected inaccuracy of the extracted scene edges and the inaccuracy of the refined pose.
Note that only one of the parameters *'pose_ref_scoring_dist_edges_rel'* and *'pose_ref_scoring_dist_edges_abs'* should be set. If both are set, only the value of the last modified parameter is used. Note that this parameter is ignored if the dense pose refinement is disabled or if no edge-supported surface-based matching is used.
Restriction: *'pose_ref_scoring_dist_edges_abs'* > *0*

'use_view_based': Turns the view-based score computation for surface-based matching on or off. For further details, see the respective description in the section about the sparse pose refinement above.
If the model was not prepared for view-based score computation, an error is returned.
List of values: *'true'*, *'false'*
Default: *'false'*, if *'train_view_based'* was disabled when creating the model, otherwise *'true'*.

'use_self_similar_poses': Turns the optimization regarding self-similar, almost symmetric poses on or off.
If the model was not created with activated parameter *'train_self_similar_poses'*, an error is returned when setting *'use_self_similar_poses'* to *'true'*.
List of values: *'true'*, *'false'*
Default: *'false'*, if *'train_self_similar_poses'* was disabled when creating the model, otherwise *'true'*.

Parameters

▷ **SurfaceModelID** (input_control) . . . . . surface_model ⇝ *handle*
Handle of the surface model.

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model containing the scene.

▷ **RelSamplingDistance** (input_control) . . . . . real ⇝ *real*
Scene sampling distance relative to the diameter of the surface model.
Default: 0.05
Suggested values: RelSamplingDistance ∈ {0.1, 0.07, 0.05, 0.04, 0.03}
Restriction: 0 < RelSamplingDistance < 1

▷ **KeyPointFraction** (input_control) . . . . . real ⇝ *real*
Fraction of sampled scene points used as key points.
Default: 0.2
Suggested values: KeyPointFraction ∈ {0.3, 0.2, 0.1, 0.05}
Restriction: 0 < KeyPointFraction <= 1

▷ **MinScore** (input_control) . . . . . real(-array) ⇝ *real* / integer
Minimum score of the returned poses.
Default: 0
Restriction: MinScore >= 0

▷ **ReturnResultHandle** (input_control) . . . . . string ⇝ *string*
Enable returning a result handle in SurfaceMatchingResultID.
Default: 'false'
Suggested values: ReturnResultHandle ∈ {'true', 'false'}

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'num_matches', 'max_overlap_dist_rel', 'max_overlap_dist_abs', 'sparse_pose_refinement', 'dense_pose_refinement', 'pose_ref_num_steps', 'pose_ref_sub_sampling', 'pose_ref_dist_threshold_rel', 'pose_ref_dist_threshold_abs', 'pose_ref_scoring_dist_rel', 'pose_ref_scoring_dist_abs', 'pose_ref_use_scene_normals', 'scene_normal_computation', 'scene_invert_normals', '3d_edge_min_amplitude_rel', '3d_edge_min_amplitude_abs', 'viewpoint',

'max_gap', '3d_edges', 'pose_ref_dist_threshold_edges_rel', 'pose_ref_dist_threshold_edges_abs', 'pose_ref_scoring_dist_edges_rel', 'pose_ref_scoring_dist_edges_abs', 'use_3d_edges', 'use_view_based', 'use_self_similar_poses'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {0, 1, 'true', 'false', 0.005, 0.01, 0.03, 0.05, 0.1, 'num_scene_points', 'model_point_fraction', 'num_model_points', 'fast', 'mls'}

▷ **Pose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
3D pose of the surface model in the scene.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
Score of the found instances of the surface model.

▷ **SurfaceMatchingResultID** (output_control) . . . . . surface_matching_result(-array) ⇝ *handle*
Handle of the matching result, if enabled in ReturnResultHandle.

Result

find_surface_model returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

read_object_model_3d, xyz_to_object_model_3d, get_object_model_3d_params, read_surface_model, create_surface_model, get_surface_model_param, edges_object_model_3d

Possible Successors

refine_surface_model_pose, get_surface_matching_result, clear_surface_matching_result, clear_object_model_3d

Alternatives

refine_surface_model_pose, find_surface_model_image

Module

3D Metrology

find_surface_model_image (Image : : SurfaceModelID, ObjectModel3D, RelSamplingDistance, KeyPointFraction, MinScore, ReturnResultHandle, GenParamName, GenParamValue : Pose, Score, SurfaceMatchingResultID)

Find the best matches of a surface model in a 3D scene and images.

The operator find_surface_model_image finds the best matches of the surface model SurfaceModelID in the scene that is comprised of the 3D surface in ObjectModel3D and the images of the scene in Image. Note that the number of images passed in Image must correspond to the number of cameras set with set_surface_model_param. Note also that the surface model must have been created by create_surface_model with the parameter *'train_3d_edges'* enabled.

The images are used only in the sparse and dense refinement step. For this, the refinement simultaneously optimizes the alignment of the model with the 3D scene as well as the alignment of the reprojected edges of the model silhouette with edges in the passed images. The domain of the images is ignored.

In addition to the parameters documented in `find_surface_model`, `find_surface_model_image` also supports the following generic parameters:

'min_contrast': Sets the minimum contrast of the object in the search images. Edges with a contrast below this threshold are ignored in the refinement.

Suggested values: *5*, *10*, *20*

Default: *10*

Restriction: *'min_contrast'* >= *0*

'max_deformation': Sets the search range in pixels for corresponding edges in the image. This parameter can be used if the shape of the object is slightly deformed compared to the original 3D model used in `create_surface_model`. Note that increasing this parameter can have a significant impact on the runtime of the refinement.

Suggested values: *0*, *1*, *5*

Default: *1*

Restriction: *'max_deformation'* >= *0*

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2
Images of the scene.

▷ **SurfaceModelID** (input_control) ..... surface_model ⇝ *handle*
Handle of the surface model.

▷ **ObjectModel3D** (input_control) ..... object_model_3d ⇝ *handle*
Handle of the 3D object model containing the scene.

▷ **RelSamplingDistance** (input_control) ..... real ⇝ *real*
Scene sampling distance relative to the diameter of the surface model.
Default: 0.05
Suggested values: `RelSamplingDistance` ∈ {0.1, 0.07, 0.05, 0.04, 0.03}
Restriction: 0 < RelSamplingDistance < 1

▷ **KeyPointFraction** (input_control) ..... real ⇝ *real*
Fraction of sampled scene points used as key points.
Default: 0.2
Suggested values: `KeyPointFraction` ∈ {0.3, 0.2, 0.1, 0.05}
Restriction: 0 < KeyPointFraction <= 1

▷ **MinScore** (input_control) ..... real(-array) ⇝ *real* / integer
Minimum score of the returned poses.
Default: 0
Restriction: MinScore >= 0

▷ **ReturnResultHandle** (input_control) ..... string ⇝ *string*
Enable returning a result handle in `SurfaceMatchingResultID`.
Default: 'false'
Suggested values: `ReturnResultHandle` ∈ {'true', 'false'}

▷ **GenParamName** (input_control) ..... attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: `GenParamName` ∈ {'num_matches', 'max_overlap_dist_rel', 'max_overlap_dist_abs', 'sparse_pose_refinement', 'dense_pose_refinement', 'pose_ref_num_steps', 'pose_ref_sub_sampling', 'pose_ref_dist_threshold_rel', 'pose_ref_dist_threshold_abs', 'pose_ref_scoring_dist_rel', 'pose_ref_scoring_dist_abs', 'pose_ref_use_scene_normals', 'scene_normal_computation', 'scene_invert_normals', '3d_edge_min_amplitude_rel', '3d_edge_min_amplitude_abs', 'viewpoint', 'max_gap', '3d_edges', 'max_deformation', 'min_contrast', 'use_3d_edges', 'use_view_based', 'use_self_similar_poses'}

▷ **GenParamValue** (input_control) ..... attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: `GenParamValue` ∈ {0, 1, 'true', 'false', 0.005, 0.01, 0.03, 0.05, 0.1, 'num_scene_points', 'model_point_fraction', 'num_model_points', 'fast', 'mls'}

▷ **Pose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
3D pose of the surface model in the scene.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
Score of the found instances of the surface model.

▷ **SurfaceMatchingResultID** (output_control) . . . . . surface_matching_result(-array) ⇝ *handle*
Handle of the matching result, if enabled in ReturnResultHandle.

Result

find_surface_model_image returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

get_surface_matching_result (: : SurfaceMatchingResultID, ResultName, ResultIndex : ResultValue)

Get details of a result from surface based matching.

The operator get_surface_matching_result returns details about the results of surface based matching or the surface pose refinement. The results are stored in SurfaceMatchingResultID, which must have been created by find_surface_model or refine_surface_model_pose.

The parameter ResultName is used to select which result detail shall be returned. If details about one of the results shall be retrieved, ResultIndex selects the result index, where *0* selects the first result. ResultIndex is ignored for certain values of ResultName.

The following values are possible for ResultName if SurfaceMatchingResultID was created by find_surface_model or find_surface_model_image:

'sampled_scene': A 3D object model handle is returned that contains the sampled scene points that were used in the approximate matching step. This is helpful for tuning the sampling distance for the matching (see parameter RelSamplingDistance of operator find_surface_model). The parameter ResultIndex is ignored.

'key_points': A 3D object model handle is returned that contains all points from the 3D scene that were used as key points in the matching process. This is helpful for tuning the sampling distance and key point rate for the matching (see parameter KeyPointFraction of operator find_surface_model). The parameter ResultIndex is ignored. At least 10 key points should be on the object of interest for stable results.

'score_unrefined': The score of the result before the dense pose refinement is returned. If the sparse pose refinement was disabled, this is the score of the approximate matching. Otherwise the score of the sparse pose refinement is returned. See `find_surface_model` for details about the score. In `ResultIndex` the index of the result must be specified. If `SurfaceMatchingResultID` was created by `refine_surface_model_pose`, 0 is returned.

'sampled_3d_edges': If the surface model was trained with *'train_3d_edges'* enabled, a 3D object model handle is returned that contains the sampled 3D edge points that were used in the approximate matching step and in the sparse refinement step. The parameter `ResultIndex` is ignored.

The following values are always possible for `ResultName`, regardless the operator `SurfaceMatchingResultID` was created with:

'pose': Returns the pose of the matching or refinement result. In `ResultIndex` the index of the result must be specified.

'score_refined': Returns the score of the result after the dense pose refinement. See `find_surface_model` for details about this score. In `ResultIndex` the index of the result must be specified. If `SurfaceMatchingResultID` was created by `find_surface_model` and dense pose refinement was disabled, *0* is returned.

'score': Returns the combined score of the result indexed in `ResultIndex`, thus this parameter is equal to `Score` returned in `find_surface_model`.

'score_surface': Returns the surface-based score of the result indexed in `ResultIndex`. If not specifically set otherwise, this score is equal to *'score_refined'*.

'score_3d_edges': Returns the 3D edge score of the result indexed in `ResultIndex`. This score is only applicable for edged-supported surface-based matching.

'score_2d_edges': Returns the 2D edge score of the result indexed in `ResultIndex`. This score is only applicable for edged-supported surface-based matching.

'score_view_based': Returns the view-based score of the result indexed in `ResultIndex`. This score is only applicable if the surface model supports view-based score computation.

'all_scores': Returns for the result indexed in `ResultIndex` the values of the five scores *'score'*, *'score_surface'*, *'score_3d_edges'*, *'score_2d_edges'*, and *'score_view_based'*. Thereby the scores have the same order as the thresholds given through the parameter `MinScore` in the matching and refinement operators.

Parameters

▷ **`SurfaceMatchingResultID`** (input_control) ..... surface_matching_result ⇝ *handle*
Handle of the surface matching result.

▷ **`ResultName`** (input_control) ..... string(-array) ⇝ *string*
Name of the result property.
Default: 'pose'
List of values: `ResultName` ∈ {'sampled_scene', 'key_points', 'pose', 'score_unrefined', 'score_refined', 'sampled_3d_edges', 'score', 'score_surface', 'score_3d_edges', 'score_2d_edges', 'score_view_based', 'all_scores'}

▷ **`ResultIndex`** (input_control) ..... integer ⇝ *integer*
Index of the matching result, starting with 0.
Default: 0
Suggested values: `ResultIndex` ∈ {0, 1, 2, 3}
Restriction: ResultIndex >= 0

▷ **`ResultValue`** (output_control) ..... integer(-array) ⇝ *integer* / string / real / handle
Value of the result property.

Result

If the handle of the result is valid, the operator `get_surface_matching_result` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

get_surface_model_param (: : SurfaceModelID, GenParamName : GenParamValue)

Return the parameters and properties of a surface model.

The operator get_surface_model_param returns parameters and properties of the surface model SurfaceModelID. The surface model must have been created by create_surface_model or read_surface_model. The names of the desired properties are passed in the generic parameter GenParamName, the corresponding values are returned in GenParamValue.

The following values are possible for GenParamName:

'diameter': Diameter of the model point cloud. The diameter is the length of the diagonal of the axis-parallel bounding box (see parameter *'bounding_box1'*).

'center': Center point of the model. The center point is the center of the axis-parallel bounding box (see parameter *'bounding_box1'*).

'bounding_box1': Smallest enclosing axis-parallel cuboid (min_x, min_y, min_z, max_x, max_y, max_z).

'sampled_model': The 3D points sampled from the model for matching. This returns an ObjectModel3D that contains all points sampled from the model surface for matching.

'sampled_pose_refinement': The 3D model points subsampled from the model for the pose refinement. This returns an ObjectModel3D that contains all points sampled from the model surface for pose refinement.

'3d_edges_trained': Returns if the surface model was prepared for edge-supported surface-based matching, i.e., if the parameter *'train_3d_edges'* was enabled in create_surface_model. The returned value is either *'true'* or *'false'*.

'view_based_trained': Returns if the surface model was prepared to support view-based score computation for surface-based matching, i.e., if the parameter *'train_view_based'* was enabled in create_surface_model. The returned value is either *'true'* or *'false'*.

'camera_parameter':

'camera_parameter X': Returns the camera parameters for camera number X, where X is a zero-based index for the cameras. If not given, X defaults zero (first camera). The camera parameters must previously have been set by set_surface_model_param.

'camera_pose':

'camera_pose X': Returns the camera pose for camera number X, where X is a zero-based index for the cameras. If not given, X defaults zero (first camera).

'symmetry_axis_direction':

'symmetry_axis_origin': Returns the symmetry axis or origin, respectively, as set with set_surface_model_param. If no axis is set, an empty tuple is returned.

'symmetry_poses': Returns the symmetry poses as set with set_surface_model_param.

'symmetry_poses_all': Returns all symmetry poses created by set_surface_model_param based on the symmetry poses set with set_surface_model_param.

'pose_restriction_reference_pose': Returns the reference pose as set with `set_surface_model_param`, or an empty tuple if not set.

'pose_restriction_max_angle_diff': Returns the maximum angular difference between the reference pose and found poses, in radians, or an empty tuple if not set.

'pose_restriction_allowed_axis_direction':

'pose_restriction_allowed_axis_origin': Returns the allowed rotation axis and origin, respectively, as set with `set_surface_model_param`. If no axis is set, an empty tuple is returned.

'pose_restriction_filter_final_poses_only': Returns *'true'* if only the final poses are filtered, or *'false'* if the poses are filtered during the matching process (default).

'self_similar_poses_trained': Returns if the surface model was prepared for optimizations regarding self-similar, almost symmetric poses, i.e., if the parameter *'train_self_similar_poses'* was enabled in `create_surface_model`. The returned value is either *'true'* or *'false'*.

'sampled_self_similarity': Returns an ObjectModel3D that contains those 3D points of the model that were sampled for the search of self-similar poses.

'self_similar_poses': Returns the poses under which the object is self-similar, i.e., almost symmetric. If the parameter *'train_self_similar_poses'* was not enabled in `create_surface_model`, an empty tuple is returned.

'self_similar_poses_models': Returns a tuple of ObjectModel3Ds that contains a copy of the original model, transformed into the poses returned by *'self_similar_poses'*. This allows for a visual inspection of the self-similar poses. This parameter is only available if the surface model was created with activated parameter *'train_self_similar_poses'*.

Parameters

▷ **SurfaceModelID** (input_control) . . . . . surface_model ⇝ *handle*
Handle of the surface model.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the parameter.
Default: 'diameter'
List of values: `GenParamName` ∈ {'diameter', 'center', 'bounding_box1', 'sampled_model', 'sampled_pose_refinement', '3d_edges_trained', 'camera_parameter', 'camera_pose', 'symmetry_axis_direction', 'symmetry_axis_origin', 'symmetry_poses', 'symmetry_poses_all', 'pose_restriction_reference_pose', 'pose_restriction_max_angle_diff', 'pose_restriction_allowed_axis_direction', 'pose_restriction_allowed_axis_origin', 'pose_restriction_filter_final_poses_only', 'view_based_trained', 'self_similar_poses_trained', 'sampled_self_similarity', 'self_similar_poses', 'self_similar_poses_models'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *real* / string / integer / handle
Value of the parameter.

Result

`get_surface_model_param` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

read_surface_model (: : FileName : SurfaceModelID)

Read a surface model from a file.

The operator read_surface_model reads the surface model, which has been written with write_surface_model, from the file FileName. The handle of the surface model is returned in SurfaceModelID. If no absolute path is given in FileName, the file is searched in the current directory of the HALCON process. The default HALCON file extension for the surface model (SFM) file is 'sfm'. If no file named FileName exists, the default file extension is appended to FileName.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the SFM file.
File extension: .sfm

▷ **SurfaceModelID** (output_control) ..... surface_model ⇝ *handle*
Handle of the read surface model.

Result

read_surface_model returns 2 (H_MSG_TRUE) if all parameters are correct and the file can be read. If the file is not a surface model file, the error 9506 is raised. If the file has a version that can not be read by this version of HALCON, the error 9507 is raised. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

refine_surface_model_pose (: : SurfaceModelID, ObjectModel3D, InitialPose, MinScore, ReturnResultHandle, GenParamName, GenParamValue : Pose, Score, SurfaceMatchingResultID)

Refine the pose of a surface model in a 3D scene.

The operator refine_surface_model_pose refines the approximate pose InitialPose of the surface model SurfaceModelID in the 3D scene ObjectModel3D. The surface model SurfaceModelID must have been created previously with create_surface_model or read_surface_model. Additionally, set_surface_model_param can be used to set certain parameters that influence the refinement, such as restricting the allowed range of rotations.

refine_surface_model_pose is useful if the pose of an object in a scene is approximately known and only needs to be refined. The refined pose is returned in Pose, along with a score in Score. It is possible to pass multiple poses for refinement. Note that, contrary to find_surface_model, the returned poses are not sorted by their score but are returned in the same order as the input poses.

The maximum possible error in the approximate pose that can still be refined depends on the type of object, the amount of clutter in the scene and the visible parts of the objects. In general, differences in the orientation of up to 15° and differences in the position of up to 10% can be refined.

The accuracy of the pose refinement is limited to around 0.1% of the model's size due to numerical reasons. The accuracy further depends on the noise of the scene points, the number of scene points and the shape of the model.

Details about the pose refinement and the parameters are described in the documentation of `find_surface_model` in the section about the dense pose refinement step. The following generic parameters can be set for `refine_surface_model_pose`, and are also documented in `find_surface_model`: *'pose_ref_num_steps'*, *'pose_ref_sub_sampling'*, *'pose_ref_dist_threshold_rel'*, *'pose_ref_dist_threshold_abs'*, *'pose_ref_scoring_dist_rel'*, *'pose_ref_scoring_dist_abs'*, *'pose_ref_use_scene_normals'*, *'3d_edge_min_amplitude_rel'*, *'3d_edge_min_amplitude_abs'*, *'3d_edges'*, *'use_3d_edges'*, *'use_view_based'*, *'use_self_similar_poses'*, *'pose_ref_dist_threshold_edges_rel'*, *'pose_ref_dist_threshold_edges_abs'*, *'pose_ref_scoring_dist_edges_rel'*, and *'pose_ref_scoring_dist_edges_abs'*.

Parameters

- ▷ **SurfaceModelID** (input_control) . . . . . surface_model ⇝ *handle*
  Handle of the surface model.
- ▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
  Handle of the 3D object model containing the scene.
- ▷ **InitialPose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
  Initial pose of the surface model in the scene.
- ▷ **MinScore** (input_control) . . . . . real(-array) ⇝ *real* / integer
  Minimum score of the returned poses.
  Default: 0
  Restriction: MinScore >= 0
- ▷ **ReturnResultHandle** (input_control) . . . . . string ⇝ *string*
  Enable returning a result handle in `SurfaceMatchingResultID`.
  Default: 'false'
  List of values: `ReturnResultHandle` ∈ {'true', 'false'}
- ▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
  Names of the generic parameters.
  Default: []
  List of values: `GenParamName` ∈ {'pose_ref_num_steps', 'pose_ref_sub_sampling', 'pose_ref_dist_threshold_rel', 'pose_ref_dist_threshold_abs', 'pose_ref_scoring_dist_rel', 'pose_ref_scoring_dist_abs', 'pose_ref_use_scene_normals', '3d_edge_min_amplitude_rel', '3d_edge_min_amplitude_abs', 'viewpoint', '3d_edges', 'use_3d_edges', 'use_view_based', 'use_self_similar_poses'}
- ▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
  Values of the generic parameters.
  Default: []
  Suggested values: `GenParamValue` ∈ {0, 1, 'true', 'false', 0.005, 0.01, 0.03, 0.05, 0.1}
- ▷ **Pose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
  3D pose of the surface model in the scene.
- ▷ **Score** (output_control) . . . . . real-array ⇝ *real*
  Score of the found instances of the model.
- ▷ **SurfaceMatchingResultID** (output_control) . . . . . surface_matching_result(-array) ⇝ *handle*
  Handle of the matching result, if enabled in `ReturnResultHandle`.

Result

`refine_surface_model_pose` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

refine_surface_model_pose_image (Image : : SurfaceModelID, ObjectModel3D, InitialPose, MinScore, ReturnResultHandle, GenParamName, GenParamValue : Pose, Score, SurfaceMatchingResultID)

Refine the pose of a surface model in a 3D scene and in images.

The operator refine_surface_model_pose_image refines the approximate pose InitialPose of the surface model SurfaceModelID in the 3D scene comprised of the 3D surface in ObjectModel3D and the images of the scene in Image. Note that the number of images passed in Image must correspond to the number of cameras set with set_surface_model_param. Note also that the surface model must have been created by create_surface_model with the parameter *'train_3d_edges'* enabled.

The refinement simultaneously optimizes the alignment of the model with the 3D scene as well as the alignment of the reprojected edges with edges in the passed images. The domain of the images is ignored.

In addition to the parameters documented in refine_surface_model_pose, refine_surface_model_pose_image also supports the generic parameters *'min_contrast'* and *'max_deformation'*, documented in find_surface_model_image.

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Images of the scene.

▷ **SurfaceModelID** (input_control) . . . . . surface_model ⇝ *handle*
Handle of the surface model.

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model containing the scene.

▷ **InitialPose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
Initial pose of the surface model in the scene.

▷ **MinScore** (input_control) . . . . . real(-array) ⇝ *real* / integer
Minimum score of the returned poses.
Default: 0
Restriction: MinScore >= 0

▷ **ReturnResultHandle** (input_control) . . . . . string ⇝ *string*
Enable returning a result handle in SurfaceMatchingResultID.
Default: 'false'
List of values: ReturnResultHandle ∈ {'true', 'false'}

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'pose_ref_num_steps', 'pose_ref_sub_sampling', 'pose_ref_dist_threshold_rel', 'pose_ref_dist_threshold_abs', 'pose_ref_scoring_dist_rel',

'pose_ref_scoring_dist_abs', 'pose_ref_use_scene_normals', 'max_deformation', 'min_contrast', '3d_edge_min_amplitude_rel', '3d_edge_min_amplitude_abs', 'viewpoint', '3d_edges', 'use_3d_edges', 'use_view_based', 'use_self_similar_poses'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {0, 1, 'true', 'false', 0.005, 0.01, 0.03, 0.05, 0.1}

▷ **Pose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
3D pose of the surface model in the scene.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
Score of the found instances of the model.

▷ **SurfaceMatchingResultID** (output_control) . . . . . surface_matching_result(-array) ⇝ *handle*
Handle of the matching result, if enabled in ReturnResultHandle.

Result

refine_surface_model_pose_image returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

3D Metrology

serialize_surface_model (
: : SurfaceModelID : SerializedItemHandle)

Serialize a surface_model.

serialize_surface_model serializes the data of a surface model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_surface_model is converted to a serialized item. The surface model is defined by the handle SurfaceModelID. The serialized surface model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_surface_model.

Parameters

▷ **SurfaceModelID** (input_control) . . . . . surface_model ⇝ *handle*
Handle of the surface model.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_surface_model` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

`set_surface_model_param` (: : `SurfaceModelID`, `GenParamName`, `GenParamValue` :)

Set parameters and properties of a surface model.

The operator `set_surface_model_param` sets parameters and properties of the surface model `SurfaceModelID`. The surface model must have been created by `create_surface_model` or `read_surface_model`. The names of the desired properties are passed in the generic parameter `GenParamName`, the corresponding values are passed in `GenParamValue`.

The possible values for `GenParamName` are listed below.

- **Defining cameras for image-based refinement.** The following parameters allow to set and clear camera parameters and poses. Those are used by the operators `find_surface_model_image` and `refine_surface_model_pose_image` to project the surface model into the passed image.

  Note that the camera parameters must be set before the camera pose.

  'camera_parameter':

  'camera_parameter X': Sets the camera parameters for camera number X, where X is a zero-based index for the cameras. If not given, X defaults zero (first camera). The camera parameters are used by the operators `find_surface_model_image` and `refine_surface_model_pose_image`, which use the images corresponding to the camera for the 3D pose refinement. Cameras must be added in increasing order.

  'camera_pose':

  'camera_pose X': Sets the camera pose for camera number X, where X is a zero-based index for the cameras. If not given, X defaults zero (first camera). The pose defaults to the zero-pose *[0,0,0,0,0,0,0]* when adding a new camera with *'camera_parameter'*. This usually means that camera and 3D sensor have the same point of origin.

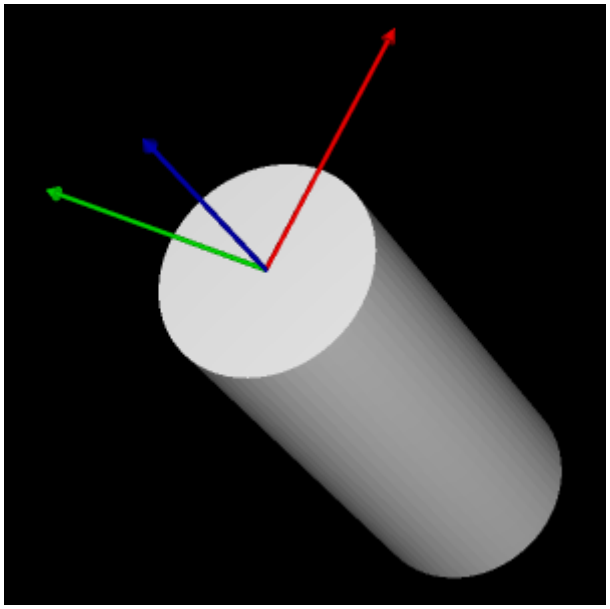
  'clear_cameras': Removes all previously set cameras from the surface model.

- **Defining Object Symmetries.** The following parameters can be used to define symmetries of the 3D object which was used for the creation of the surface model. If the 3D object is symmetric, that information can be used to speed up the surface-based matching. Note that for surface models created with the *'train_3d_edges'* parameter enabled, no symmetries can be set.

  By default, no symmetry is active.

  Note that for performance reasons, when changing the symmetry with any of the parameters below, certain internal data structures of the surface model are re-created, which can take a few seconds.

'symmetry_axis_direction': Set the direction of the symmetry axis of the model. GenParamValue must be a tuple with three numbers, containing the x-, y- and z-value of the axis direction. The model is modified to use this symmetry information for speeding up the matching process.
To remove the symmetry information, pass an empty tuple in GenParamValue. Note that either a symmetry axis or symmetry poses can be set, but not both.

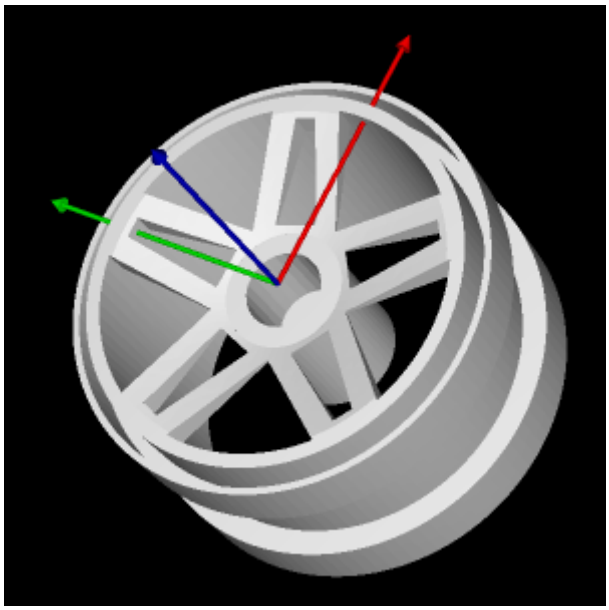


An object (cylinder) with the symmetry axis direction *[0,0,1]*.

In case that *'symmetry_axis_direction'* is used in combination with a restriction of the pose range as described below, the value of *'symmetry_axis_direction'* is also used as if set with the parameter *'pose_restriction_allowed_axis_direction'*.

'symmetry_axis_origin': Set a point on the symmetry axis of the model. GenParamValue must be a tuple with three numbers, which represent a point in model coordinates that lies on the symmetry axis of the model. This parameter is optional and defaults to the center of the model as returned by get_surface_model_param.
In case that *'symmetry_axis_origin'* is used in combination with a restriction of the pose range as described below, the value of *'symmetry_axis_origin'* is also used as if set with the parameter *'pose_restriction_allowed_axis_origin'*.

'symmetry_poses': Set one or more symmetry poses of the model (see create_pose). The model must be identical when transformed with any of those poses. The model is modified to use this symmetry information for speeding up the matching process.
When setting one or more symmetry poses, set_surface_model_param will internally create all poses that can be created by chaining and inverting the passed poses. To obtain all internally created poses, use get_surface_model_param with the argument *'symmetry_poses_all'*. If more than 100 poses are created internally, an error is returned, which indicates that the passed symmetry poses are invalid.
To remove the symmetry poses, pass an empty tuple in GenParamValue. Note that either a symmetry axis or symmetry poses can be set, but not both.



An object with a discontinuous symmetry. The symmetry pose for this object is *[0,0,0, 0,0,360.0/5, 0]*.

- **Restrict the pose range.** The following parameters can be used to restrict the range of rotations in which the surface model is searched for by `find_surface_model`, or the allowed range of rotations for the refinement with `refine_surface_model_pose`.

  By default, no pose range restriction is active.

  Note that for performance reasons, when changing the pose range with any of the parameters below, certain internal data structures of the surface model are re-created, which can take a few seconds.

  'pose_restriction_reference_pose': Set a reference pose of the model. The reference pose can be used along with *'pose_restriction_max_angle_diff'*, to restrict the allowed range of rotations of the model.
  If `GenParamValue` is an empty tuple, any previously set reference pose is cleared and no pose range restriction will be active for the model.
  Otherwise, `GenParamValue` must be a pose (see `create_pose`). Note that the translation part of the pose is ignored. Also note that both *'pose_restriction_reference_pose'* and *'pose_restriction_max_angle_diff'* must be set in order for the pose restriction to be active.

  'pose_restriction_max_angle_diff': Set by how much the rotation of a pose found with `find_surface_model` or refined with `refine_surface_model_pose` may deviate from the rotation set with *'pose_restriction_reference_pose'*, in radians.
  If `GenParamValue` is an empty tuple, any previously set maximum deviation angle is cleared and no pose range restriction will be active for the model.
  Otherwise, `GenParamValue` must be an angle, which indicates by how much the rotations of a detected pose *'P'* and the reference pose *'R'* set with *'pose_restriction_reference_pose'* may differ. The comparison is performed for every model point using the formula $\angle(R\mathbf{v}, P\mathbf{v}) \leq \text{max\_angle\_diff}$, where $\mathbf{v}$ is the 3D point vector.

  'pose_restriction_allowed_axis_direction': Set an axis for which rotations are ignored when evaluating the pose range (see *'pose_restriction_reference_pose'* and *'pose_restriction_max_angle_diff'*). If `GenParamValue` is an empty tuple, any previously set axis is cleared.
  Otherwise, `GenParamValue` must contain a tuple of three numbers which are the direction of the axis in model coordinates.
  If such an axis is set, then a pose is considered to be within the allowed range if the angle between the axis in the reference pose and the compared pose is smaller than the allowed angle, using $\angle(R\,\text{axis}, P\,\text{axis}) \leq \text{max\_angle\_diff}$.

  'pose_restriction_allowed_axis_origin': Set a point on the allowed rotation axis of the model. `GenParamValue` must be a tuple with three numbers, which represent a point in model coordinates that lies on the symmetry axis of the model. This parameter is optional and defaults to the center of the model as returned by `get_surface_model_param`.

  'pose_restriction_filter_final_poses_only': This flag allows to switch between two different modes for the pose range restriction.
  If `GenParamValue` is *'false'* (default), poses outside the defined pose range are removed early in the matching process. Use this setting if the object pose in the scene is always within the de-

fined rotation range, but the object is sometimes found with incorrect rotations. Note that with this setting, find_surface_model might return poses that the algorithm considers to be locally suboptimal, because the locally more optimal poses are outside the allowed pose range. Also note that with this setting, the pose restriction is observed strictly. When passing an input pose to refine_surface_model_pose that is outside the allowed pose range, it will be transformed to be within the allowed pose range.
If GenParamValue is *'true'*, only the final poses are filtered before returning them. This allows removing poses that are valid object poses, but are not needed by the application because, for example, the object cannot be picked up by the robot in a certain orientation. Note that in this setting, less poses than requested might be returned by find_surface_model if one or more of the final poses are outside the allowed pose range.

- **Modifying self-similarities.** The following parameters can be used to adapt the optimization regarding self-similar poses, i.e., poses under which the model is almost symmetric. The parameters can only be set if the parameter *'train_self_similar_poses'* was activated during the call of create_surface_model.
  Note that for performance reasons, when changing the self-similarity search with any of the parameters below, certain internal data structures of the surface model are re-created, which can take a few seconds.

  'self_similar_poses': Set the self-similar poses of the model. Those are poses under which the model is very similar to itself and which can be confused during search.
  find_surface_model will find such poses automatically if the parameter *'use_self_similar_poses'* is activated. The poses can be obtained with get_surface_model_param. If the automatically determined poses are not sufficient to resolve self-similarities, the self-similar poses can be adapted with this parameter. It is usually not recommended to modify this parameter.
  GenParamValue must contain a list of poses. The identity pose will automatically be added to the list of poses, if it is not already contained in it.

Attention

Note that in some cases, if this operator encounters an error condition while modifying the surface model, such as an out-of-memory error, the model might be left in an inconsistent, partly changed state. In such cases, it is recommended to clear the surface model and to no longer use it.

This does not apply to error codes due to invalid parameters, which are checked before performing any model modification.

Also note that setting some of the options requires re-generation of internal data structures and can take as long as the original create_surface_model.

Parameters

▷ **SurfaceModelID** (input_control) . . . . . surface_model ⇝ *handle*
Handle of the surface model.

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Name of the parameter.
Default: 'camera_parameter'
List of values: GenParamName ∈ {'camera_parameter', 'camera_pose', 'clear_cameras', 'symmetry_axis_direction', 'symmetry_axis_origin', 'symmetry_poses', 'pose_restriction_reference_pose', 'pose_restriction_max_angle_diff', 'pose_restriction_allowed_axis_direction', 'pose_restriction_allowed_axis_origin', 'pose_restriction_filter_final_poses_only', 'self_similar_poses'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / string / integer
Value of the parameter.
Suggested values: GenParamValue ∈ {'true', 'false', [], [0,0,0,0,0,0,0], [0,0,1]}

Result

set_surface_model_param returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- SurfaceModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

3D Metrology

write_surface_model (: : SurfaceModelID, FileName :)

Write a surface model to a file.

The operator `write_surface_model` writes a surface model to the file `FileName`. The file can be read again with `read_surface_model`. The default HALCON file extension for the surface model (SFM) file is 'sfm'.

Parameters

▷ **SurfaceModelID** (input_control) . . . . . surface_model ⇝ *handle*
Handle of the surface model.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name.
File extension: `.sfm`

Result

`write_surface_model` returns `2` (`H_MSG_TRUE`) if all parameters are correct and the HALCON process has write permission to the file. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Chapter 4

3D Object Model

4.1 Creation

clear_object_model_3d (: : ObjectModel3D :)

Free the memory of a 3D object model.

The operator clear_object_model_3d frees the memory of a 3D object model that was previously created. After calling clear_object_model_3d, the model can no longer be used. The handle ObjectModel3D becomes invalid.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

Result

If the handle of the model is valid, the operator clear_object_model_3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ObjectModel3D

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

read_object_model_3d, xyz_to_object_model_3d

Module

3D Metrology

copy_object_model_3d (: : ObjectModel3D,
Attributes : CopiedObjectModel3D)

Copy a 3D object model.

A 3D object model consists of a set of attributes. The operator copy_object_model_3d creates a new 3D object model and copies the selected attributes of the input 3D object model to this new output 3D object

model. The input 3D object model is defined by a handle ObjectModel3D. The operator returns the handle CopiedObjectModel3D of the new 3D object model. The operator can be used to save memory space by removing not needed attributes. Access to the attributes of the 3D object model is possible, e.g., with the operator get_object_model_3d_params.

The parameter Attributes determines which attributes should be copied. In addition, attributes can be excluded from copying by using the prefix ~. In order to remove attributes from a 3D object model, the operator remove_object_model_3d_attrib can be used instead.

Note that because a 3D object model itself consists of a set of attributes, even the point coordinates are an attribute of the model. This means, that at least this one attribute must be selected for copy_object_model_3d else the object model to be copied would be empty. So if only a 3D object model representing a point cloud shall be copied without further attributes, Attributes must be set to *'point_coord'*. If an attribute to be copied is not available or no attribute is selected, an exception is raised.

The following values for the parameter Attributes are possible:

'point_coord': This value specifies that the attribute with the 3D point coordinates is copied.

'point_normal': This value specifies that the attribute with the 3D point normals and the attribute with the 3D point coordinates are copied.

'triangles': This value specifies that the attribute with the face triangles and attribute with the 3D point coordinates are copied.

'polygons': This value specifies that the attribute with the face polygons and the attribute with the 3D point coordinates are copied.

'lines': This value specifies that the attribute with the lines and the attribute with the 3D point coordinates are copied.

'xyz_mapping': This value specifies that the attribute with the mapping to image coordinates and the attribute with the 3D point coordinates are copied.

'extended_attribute': This value specifies that all extended attributes are copied. If it is necessary to copy further attributes that are related to the extended attributes, these attributes are copied, too. These further attributes could be, e.g., 3D point coordinates, face triangles, face polygons, or lines.

'primitives_all': This value specifies that the attribute with the parameters of the primitive (including an empty primitive) is copied (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_plane': This value specifies that the attribute with the primitive plane is copied (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_sphere': This value specifies that the attribute with the primitive sphere is copied (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_cylinder': This value specifies that the attribute with the primitive cylinder is copied (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_box': This value specifies that the attribute with the primitive cylinder is copied.

'shape_based_matching_3d_data': This value specifies that the attribute with the prepared shape model for shape-based 3D matching is copied.

'distance_computation_data': This value specifies that the attribute with the distance computation data structure is copied. The distance computation data can be created with prepare_object_model_3d, and can be used with distance_object_model_3d. If this attribute is selected, then the corresponding target data attribute of the distance computation is copied as well. For example, if the distance computation was prepared for triangles, the triangles and the vertices are copied.

'surface_based_matching_data': This value specifies that the data for surface based matching are copied. The attributes with the 3D point coordinates and the attribute with the point normals are copied. If the attribute with point normals is not available, the attribute with the mapping from the 3D point coordinates to the image coordinates is copied. If the attribute with the mapping from the 3D point coordinates to the image coordinates is not available, the attribute with the face triangles is copied. If the attribute with face triangles is not available, too, the attribute with the face polygons is copied. If none of these attributes is available, an exception is raised.

'segmentation_data': This value specifies that the data for a 3D segmentation is copied. The attributes with the 3D point coordinates and the attribute with the face triangles are copied. If the attribute with the face triangles is not available, the attribute with the mapping from the 3D point coordinates to the image coordinates is copied. If none of these attributes is available, an exception is raised.

'score': This value specifies that the attribute with the scores and the attribute with the 3D point coordinates are copied. Scores may be obtained from the operator reconstruct_surface_stereo.

'red': This value specifies that the attribute containing the red color and the attribute with the 3D point coordinates are copied.

'green': This value specifies that the attribute containing the green color and the attribute with the 3D point coordinates are copied.

'blue': This value specifies that the attribute containing the blue color and the attribute with the 3D point coordinates are copied.

'original_point_indices': This value specifies that the attribute with the original point indices and the attribute with the 3D point coordinates are copied. Original point indices may be obtained from the operator triangulate_object_model_3d.

'all': This value specifies that all available attributes are copied. That is, the attributes are the point coordinates, the point normals, the face triangles, the face polygons, the mapping to image coordinates, the shape model for matching, the parameter of a primitive, and the extended attributes.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the input 3D object model.

▷ **Attributes** (input_control) . . . . . string(-array) ⇝ *string* / real / integer
Attributes to be copied.
Default: 'all'
List of values: Attributes ∈ {'point_coord', 'point_normal', 'triangles', 'polygons', 'xyz_mapping', 'extended_attribute', 'shape_based_matching_3d_data', 'primitives_all', 'primitive_plane', 'primitive_sphere', 'primitive_cylinder', 'primitive_box', 'surface_based_matching_data', 'segmentation_data', 'distance_computation_data', 'score', 'red', 'green', 'blue', 'all', 'original_point_indices'}

▷ **CopiedObjectModel3D** (output_control) . . . . . object_model_3d ⇝ *handle*
Handle of the copied 3D object model.

Result

copy_object_model_3d returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

deserialize_object_model_3d (
: : SerializedItemHandle : ObjectModel3D)

Deserialize a serialized 3D object model.

deserialize_object_model_3d deserializes a 3D object model that was serialized by serialize_object_model_3d (see fwrite_serialized_item for an introduction of the basic

principle of serialization). The serialized 3D object model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created 3D object model with the handle ObjectModel3D.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **ObjectModel3D** (output_control) ..... object_model_3d ⇝ *handle*
Handle of the 3D object model.

Result

If the parameters are valid, the operator deserialize_object_model_3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_box_object_model_3d (: : Pose, LengthX, LengthY, LengthZ : ObjectModel3D)

Create a 3D object model that represents a box.

gen_box_object_model_3d creates a box-shaped 3D primitive, i.e., a 3D object model that represents a box. The box is specified by a Pose and the side lengths LengthX, LengthY, and LengthZ along the respective axis of the pose. The handle of the resulting 3D object model is returned by parameter ObjectModel3D.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **Pose** (input_control) ..... pose(-array) ⇝ *real* / integer
The pose that describes the position and orientation of the box. The pose has its origin in the center of the box.

▷ **LengthX** (input_control) ..... number(-array) ⇝ *real*
The length of the box along the x-axis.

▷ **LengthY** (input_control) ..... number(-array) ⇝ *real*
The length of the box along the y-axis.
Number of elements: LengthY == LengthX

▷ **LengthZ** (input_control) ..... number(-array) ⇝ *real*
The length of the box along the z-axis.
Number of elements: LengthZ == LengthX

▷ **ObjectModel3D** (output_control) ..... object_model_3d(-array) ⇝ *handle*
Handle of the resulting 3D object model.

Result

`gen_box_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

gen_cylinder_object_model_3d (: : Pose, Radius, MinExtent, MaxExtent : ObjectModel3D)

Create a 3D object model that represents a cylinder.

`gen_cylinder_object_model_3d` creates a cylinder-shaped 3D primitive, i.e., a 3D object model that represents a cylinder. A cylinder is described by its center and the direction of its axis in `Pose` and by its radius in `Radius`. The pose has the origin on the rotation axis of the cylinder and is oriented such that the z-axis is aligned with the main direction of the cylinder. Additionally, the extensions of the cylinder are given by `MinExtent` and `MaxExtent`. `MinExtent` and `MaxExtent` represent the z-coordinates of the lowest and highest points of the cylinder on the rotation axis. The handle of the 3D object model is returned by the parameter `ObjectModel3D`.

Parameters

▷ **Pose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
The pose that describes the position and orientation of the cylinder.

▷ **Radius** (input_control) . . . . . number(-array) ⇝ *real*
The radius of the cylinder.

▷ **MinExtent** (input_control) . . . . . number(-array) ⇝ *real*
Lowest z-coordinate of the cylinder in the direction of the rotation axis.

▷ **MaxExtent** (input_control) . . . . . number(-array) ⇝ *real*
Highest z-coordinate of the cylinder in the direction of the rotation axis.
Restriction: MinExtent < MaxExtent

▷ **ObjectModel3D** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the resulting 3D object model.

Result

`gen_cylinder_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

Module

3D Metrology

gen_empty_object_model_3d (: : : EmptyObjectModel3D)

Create an empty 3D object model.

gen_empty_object_model_3d creates an empty 3D object model. The handle of the 3D object model is returned by the parameter EmptyObjectModel3D. Attributes can be added using the operators set_object_model_3d_attrib or set_object_model_3d_attrib_mod.

Parameters

▷ **EmptyObjectModel3D** (output_control) ..... object_model_3d ⇝ *handle*
Handle of the new 3D object model.

Result

gen_empty_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_object_model_3d_attrib, set_object_model_3d_attrib_mod

Module

3D Metrology

gen_object_model_3d_from_points (: : X, Y, Z : ObjectModel3D)

Create a 3D object model that represents a point cloud from a set of 3D points.

gen_object_model_3d_from_points creates a 3D object model that represents a point cloud. The points are described by x-, y-, and z-coordinates in the parameters X, Y, and Z.

Parameters

▷ **X** (input_control) ..... point3d.x(-array) ⇝ *real*
The x-coordinates of the points in the 3D point cloud.

▷ **Y** (input_control) ..... point3d.y(-array) ⇝ *real*
The y-coordinates of the points in the 3D point cloud.

▷ **Z** (input_control) . . . . . point3d.z(-array) ⇝ *real*
The z-coordinates of the points in the 3D point cloud.

▷ **ObjectModel3D** (output_control) . . . . . object_model_3d ⇝ *handle*
Handle of the resulting 3D object model.

Result

`gen_object_model_3d_from_points` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

gen_plane_object_model_3d (: : Pose, XExtent, YExtent : ObjectModel3D)

Create a 3D object model that represents a plane.

`gen_plane_object_model_3d` creates a planar 3D primitive, i.e., a 3D object model that represents a plane. The plane is described by its center and rotation. The normal vector of the plane is aligned to the z-axis of the rotated coordinate system. The center and the rotation is set with the parameter `Pose`. Additionally, the plane can be limited by a polygon, that is defined by points with the coordinates `XExtent` and `YExtent`. The handle of the 3D object model is returned by the parameter `ObjectModel3D`.

Parameters

▷ **Pose** (input_control) . . . . . pose ⇝ *real* / integer
The center and the rotation of the plane.
Number of elements: Pose == 7

▷ **XExtent** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
x coordinates specifying the extent of the plane.

▷ **YExtent** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
y coordinates specifying the extent of the plane.
Number of elements: XExtent == YExtent

▷ **ObjectModel3D** (output_control) . . . . . object_model_3d ⇝ *handle*
Handle of the resulting 3D object model.

Result

`gen_plane_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

Module

3D Metrology

gen_sphere_object_model_3d (: : Pose, Radius : ObjectModel3D)

Create a 3D object model that represents a sphere.

gen_sphere_object_model_3d creates a sphere-shaped 3D primitive, i.e., a 3D object model that represents a sphere. A sphere is defined by its center given in Pose and its radius given in Radius. The handle of the 3D object model is returned by the parameter ObjectModel3D.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **Pose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
The pose that describes the position of the sphere.

▷ **Radius** (input_control) . . . . . number(-array) ⇝ *real*
The radius of the sphere.

▷ **ObjectModel3D** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the resulting 3D object model.

Result

gen_sphere_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

gen_sphere_object_model_3d_center (: : X, Y, Z, Radius : ObjectModel3D)

Create a 3D object model that represents a sphere from x,y,z coordinates.

gen_sphere_object_model_3d_center creates a sphere-shaped 3D primitive, i.e., a 3D object model that represents a sphere. A sphere is defined by its center given in X, Y, and Z, and its radius given in Radius. The handle of the 3D object model is returned by the parameter ObjectModel3D.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

- ▷ **X** (input_control) ..... point3d.x(-array) ⇝ *real* / integer
  The x-coordinate of the center point of the sphere.
- ▷ **Y** (input_control) ..... point3d.y(-array) ⇝ *real* / integer
  The y-coordinate of the center point of the sphere.
- ▷ **Z** (input_control) ..... point3d.z(-array) ⇝ *real* / integer
  The z-coordinate of the center point of the sphere.
- ▷ **Radius** (input_control) ..... number(-array) ⇝ *real*
  The radius of the sphere.
- ▷ **ObjectModel3D** (output_control) ..... object_model_3d(-array) ⇝ *handle*
  Handle of the resulting 3D object model.

Result

gen_sphere_object_model_3d_center returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

read_object_model_3d (: : FileName, Scale, GenParamName, GenParamValue : ObjectModel3D, Status)

Read a 3D object model from a file.

The operator read_object_model_3d reads a 3D object model from the file FileName and returns a 3D object model handle in ObjectModel3D.

The operator supports the following file formats:

'om3': HALCON format for 3D object model. Files with this format can be written by `write_object_model_3d`. The default file extension for this format is 'om3'.

'dxf': AUTOCAD format. HALCON supports only the ASCII version of the format. See below for details about reading this file format. The default file extension for this format is 'dxf'.

'off': Object File Format. This is a simple ASCII-based format that can hold 3D points and polygons. The binary OFF format is not supported. The default file extension for this format is 'off'.

'ply': Polygon File Format (also Stanford Triangle Format). This is a simple format that can hold 3D points, point normals, polygons, color information and point-based extended attributes. HALCON supports both the ASCII and the binary version of the format. If the file to be read contains unsupported information, the additional data is ignored and only the supported data is read. If the name of a `property` entry of a 'ply' file coincides with the name of a standard attribute (see `set_object_model_3d_attrib`), the property will preferably be read into the standard attribute. The default file extension for this format is 'ply'.

'obj': OBJ file format, also 'Wavefront OBJ-Format'. This is an ASCII-based format that can hold 3D points, polygons, normals, texture coordinates, materials and other information. HALCON supports points ('v'-lines), point normals ('vn'-lines) and polygonal faces ('f'-lines). Existing point normals are only returned if there are exactly as many point normals as there are points. Other entities are ignored. The default file extension for this format is 'obj'.

'stl',

'stl_binary',

'stl_ascii': STL file format, also 'Stereolithography format', 'SurfaceTesselationLanguage ', 'StandardTriangulationLanguage', and 'StandardTesselationLanguage'. This format stores triangles and triangle normals. However, as triangle normals are not supported by HALCON 3D object models, only triangles are read while the triangle normals are ignored. Normals are recomputed from the triangles if required. HALCON reads both the ASCII and the binary version of this format. If *'stl'* is set, HALCON will auto-detect the type. Setting the type to *'stl_binary'* or *'stl_ascii'* will enforce the corresponding format. The default file extension for this format is 'stl'.

'step': STEP file format, also STP or 'Standard for the Exchange of Product Model Data'. This is a complex format that stores a large variety of geometrical definitions which allows an accurate storage of 3D models. Due to the limited support for the geometrical structures defined by STEP in HALCON 3D object models, triangulation is performed on these geometries, resulting in models comprised of triangle meshes. The default file extensions for this format are 'step' and 'stp'.

'generic_ascii': This format can be used to read different ASCII files containing 3D data in tabular form, e.g. 'ptx', 'pts', 'xyz' or 'pcd'. Currently, only point based attributes are supported, no triangles or polygons. The information for each 3D point is expected to be written in a single line, one point at a time. The file format must be further specified by setting the generic parameter *'ascii_format'*.

When reading a DXF file, the output parameter `Status` contains information about the number of 3D faces that were read and, if necessary, warnings that parts of the DXF file could not be interpreted.

The parameter `Scale` defines the scale of the file. For example, if the parameter is set to *'mm'*, all units in the file are assumed to have the unit *'mm'* and are transformed into the usual HALCON-internal unit *'m'* by multiplication with *0.001*. A value of *'100 mm'* thus becomes *'0.1 m'*. Alternatively, a scaling factor can be passed to `Scale`, which is multiplied with all coordinate values found in the file. The relation of units to scaling factors is given in the following table:

Unit	Scaling factor
m	1
dm	0.1
cm	0.01
mm	0.001
um, microns	10^{-6}
nm	10^{-9}
km	1000
in	0.0254
ft	0.3048
yd	0.9144

Note that the parameter Scale is ignored for files of type *'om3'* and *'step'*. om3-files are always read without any scale changes. For step-files, the unit is directly defined in the files, read along with the stored data and used to scale to the HALCON-internal unit *'m'*. For changing the scale manually after reading a 3D object model, use affine_trans_object_model_3d.

A set of additional optional parameters can be set. The names and values of the parameters are passed in GenParamName and GenParamValue, respectively. Some of the optional parameters can only be set for a certain file type. The following values for GenParamName are possible:

'file_type': Forces a file type. If this parameter is not set, the operator read_object_model_3d tries to auto-detect the file type using the file ending and the file header. If the parameter is set, the given file is interpreted as this file format.

List of values: *'om3'*, *'dxf'*, *'off'*, *'ply'*, *'obj'*, *'stl'*, *'step'*, *'generic_ascii'*.

'convert_to_triangles': Convert all faces to triangles. If this parameter is set to *'true'*, all faces read from the file are converted to triangles.

Valid for formats: 'dxf', 'ply', 'off', 'obj'.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'invert_normals': Invert normals and face orientations. If this parameter is set to *'true'*, the orientation of all normals and faces is inverted.

Valid for formats: 'dxf', 'ply', 'off', 'obj', 'stl', 'step', 'generic_ascii'.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'max_approx_error', *'min_num_points'*: DXF-specific parameters (see below).

Valid for formats: 'dxf'.

'max_surface_deviation': STEP-specific parameter.

Specifies the maximum allowed deviation (in *'m'*) from the model surface during the triangulation. A smaller value will generate a more accurate model but will also increase the reading time and the number of points and triangles in the resulting model. Set the parameter to *'auto'* in order to estimate it automatically depending on the size of the model.

Valid for formats: 'step'.

Suggested values: *'auto'*, *0.0001*, *0.00001*.

Default: *'auto'*.

Restriction: *'max_surface_deviation' > 0*

'split_level': STEP-specific parameter.

STEP files can contain definitions of independent model components. With this parameter, each component can be imported as a HALCON 3D object model. If the parameter is set to *0*, the file is imported as a single model. With *1* the model components are roughly separated from each other, while *2* separates the model components at a more detailed level.

Valid for formats: 'step'.

List of values: *0*, *1*, *2*.

Default: *0*.

'ascii_format': generic_ascii-specific parameter.

Specifies the format of the ASCII file to be read. As value, a dict containing information about the file content must be provided. The dict defines the columns to be read and meta-data like the first line number containing point information. Examples are given at the bottom of the operator reference or in the HDevelop example read_object_model_3d_generic_ascii.hdev. The following parameters can be set as dict keys:

'columns': **(mandatory)** Defines the column attributes in the read file, given as a tuple of strings. All point-related standard and extended attributes as listed in the reference of set_object_model_3d_attrib are supported. At least, *'point_coord_x'*, *'point_coord_y'* and *'point_coord_z'* must be set. When setting normals, all three components *'point_normal_x'*, *'point_normal_y'* and *'point_normal_z'* must be set. Ignoring columns is possible by setting *''* at the according tuple position.

Suggested values: *['point_coord_x', 'point_coord_y', 'point_coord_z']*, *['point_normal_x', 'point_normal_y', 'point_normal_z']*, *'red'*, *'green'*, *'blue'*, *'&my_custom_attrib'*, *''*.

'separator': **(mandatory)** Defines the separator between the columns. Currently, whitespace (blanks or tabs) and semicolon are supported.
List of values: *' '*, *';'*.

'first_point_line': **(optional)** Describes the number of the first line to be read from the file and can e.g. be used to skip header information. The top line in the file corresponds to *'first_point_line' 1*.
Default: *1*.
Restriction: *'first_point_line'* > *0*

'last_point_line': **(optional)** Describes the number of the last line to be read from the file and can e.g. be used to skip unsupported information. The top line in the file corresponds to *'last_point_line' 1*. When *'last_point_line'* is set to *-1*, all lines are read.
Default: *-1*.
Restriction: *'last_point_line'* >= -1

'comment': **(optional)** Describes the start of comments in the read file. Information behind the comment start are ignored when reading the file.
Suggested values: *'#'*, *'*'*, *'/'*, *'comment'*.

Valid for formats: 'generic_ascii'.

'xyz_map_width': Creates for the read 3D object model a mapping that assigns an image coordinate to each read 3D point, as in `xyz_to_object_model_3d`. It is assumed that the read file contains the 3D points row-wise. The passed value is used as width of the image. The height of the image is computed automatically. If this parameter is set, the read 3D object model can be projected by `object_model_3d_to_xyz` using the method *'from_xyz_map'*. Only one of the two parameters *'xyz_map_width'* and *'xyz_map_height'* can be set.

Valid for formats: 'ply', *'off'*, *'obj'*, *'generic_ascii'*.

Default: *-1*.

Restriction: *'xyz_map_width'* > 0

'xyz_map_height': As *'xyz_map_width'*, but assuming that the 3D points are aligned column-wise. The width of the image is computed automatically. Only one of the two parameters *'xyz_map_width'* and *'xyz_map_height'* can be set.

Valid for formats: 'ply', *'off'*, *'obj'*, *'generic_ascii'*.

Default: *-1*.

Restriction: *'xyz_map_height'* > 0

Note that in many cases, it is recommended to use the 2D mapping data, if available, for speed and robustness reasons. This is beneficial especially when using `sample_object_model_3d`, `surface_normals_object_model_3d`, or when preparing a 3D object model for surface-based matching, e.g., smoothing, removing outliers, and reducing the domain.

The operator `read_object_model_3d` supports the following DXF entities:

- POLYLINE
  - Polyface meshes (Polyline flag 64)
  - 3D Polylines (Polyline flag 8,9)
  - 2D Polylines (Polyline flag 0)
- LWPOLYLINE
  - 2D Polylines
- 3DFACE
- LINE
- CIRCLE
- ARC
- SOLID
- BLOCK
- INSERT

The two-dimensional linear DXF entities LINE, CIRCLE and ARC are not interpreted as faces. Only if these elements are extruded, the resulting faces are inserted in the 3D object model. All elements that represent no faces but lines are added as 3D lines to the 3D object model.

The curved surface of extruded DXF entities of the type CIRCLE and ARC is approximated by planar faces. The accuracy of this approximation can be controlled with the two generic parameters *'min_num_points'* and *'max_approx_error'*. The parameter *'min_num_points'* defines the minimum number of sampling points that are used for the approximation of the DXF element CIRCLE or ARC. Note that the parameter *'min_num_points'* always refers to the full circle, even for ARCs, i.e., if *'min_num_points'* is set to *50* and a DXF entity of the type ARC is read that represents a semi-circle, this semi-circle is approximated by at least 25 sampling points. The parameter *'max_approx_error'* defines the maximum deviation of the XLD contour from the ideal circle. The determination of this deviation is carried out in the units used in the DXF file. For the determination of the accuracy of the approximation both criteria are evaluated. Then, the criterion that leads to the more accurate approximation is used.

Internally, the following default values are used for the generic parameters:

- *'min_num_points' = 20*
- *'max_approx_error' = 0.25*

To achieve a more accurate approximation, either the value for *'min_num_points'* must be increased or the value for *'max_approx_error'* must be decreased.

One possible way to create a suitable DXF file is to create a 3D model of the object with the CAD program AutoCAD. Ensure that the surface of the object is modeled, not only its edges. Lines that, e.g., define object edges, will not be used by HALCON, because they do not define the surface of the object. Once the modeling is completed, you can store the model in DWG format. To convert the DWG file into a DXF file that is suitable for HALCON's 3D matching, carry out the following steps:

- Export the 3D CAD model to a 3DS file using the 3dsout command of AutoCAD. This will triangulate the object's surface, i.e., the model will only consist of planes. (Users of AutoCAD 2007 or newer versions can download this command utility from Autodesk's web site.)
- Open a new empty sheet in AutoCAD.
- Import the 3DS file into this empty sheet with the 3dsin command of AutoCAD.
- Save the object into a DXF R12 file.

Users of other CAD programs should ensure that the surface of the 3D model is triangulated before it is exported into the DXF file. If the CAD program is not able to carry out the triangulation, it is often possible to save the 3D model in the proprietary format of the CAD program and to convert it into a suitable DXF file by using a CAD file format converter that is able to perform the triangulation.

Parameters

▷ **`FileName`** (input_control) . . . . . filename.read ⇝ *string*
Filename of the file to be read.
Default: 'mvtec_bunny_normals'
Suggested values: `FileName` ∈ {'mvtec_bunny', 'glass_mug', 'bmc_mini', 'pipe_joint', 'clamp_sloped', 'tile_spacer', 'engine_part_bearing'}
File extension: `.off`, `.ply`, `.dxf`, `.om3`, `.obj`, `.stl`, `.step`, `.stp`

▷ **`Scale`** (input_control) . . . . . number ⇝ *string* / real / integer
Scale of the data in the file.
Default: 'm'
Suggested values: `Scale` ∈ {'m', 'cm', 'mm', 'microns', 'um', 'nm', 'km', 'in', 'ft', 'yd', 1.0, 0.01, 0.001, 1.0e-6, 0.0254, 0.3048, 0.9144}

▷ **`GenParamName`** (input_control) . . . . . string(-array) ⇝ *string*
Names of the generic parameters.
Default: []
List of values: `GenParamName` ∈ {'ascii_format', 'convert_to_triangles', 'invert_normals', 'file_type', 'min_num_points', 'max_approx_error', 'max_surface_deviation', 'split_level', 'xyz_map_width', 'xyz_map_height'}

▷ **GenParamValue** (input_control) ..... string(-array) ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false', 1, 0, 'auto', 'om3', 'off', 'ply', 'dxf', 'obj', 'stl', 'stl_binary', 'stl_ascii', 'step', 'generic_ascii'}

▷ **ObjectModel3D** (output_control) ..... object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **Status** (output_control) ..... string(-array) ⇝ *string*
Status information.

Example

```
* Example how to use file_type generic_ascii and generic parameter ascii_format to read
FileFormat := dict{}
FileFormat.separator := ' '
FileFormat.columns := ['point_coord_x', 'point_coord_y', 'point_coord_z', 'point_normal_
FileFormat.first_point_line := 14
FileFormat.last_point_line := 2273
FileFormat.comment := 'comment'
read_object_model_3d ('glass_mug.ply', 'm', ['file_type', 'ascii_format'], ['generic_asc
```

Result

The operator read_object_model_3d returns the value 2 (H_MSG_TRUE) if the given parameters are correct, the file can be read, and the file is valid. If the file format is unknown or cannot be determined, the error 9512 is raised. If the file is invalid, the error 9510 is raised. If necessary, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

3D Metrology

remove_object_model_3d_attrib (: : ObjectModel3D,
Attributes : ObjectModel3DOut)

Remove attributes of a 3D object model.

remove_object_model_3d_attrib copies the 3d object model ObjectModel3D and removes within this copy the standard and/or extended attributes given in Attributes. The new 3d object model is returned in ObjectModel3DOut. Doing so does not modify the 3d object model ObjectModel3D but a new model is created. This is in contrast to the operator remove_object_model_3d_attrib_mod, which modifies the input model but functions identically otherwise.

If the Attributes do not exist in ObjectModel3D, no exception is raised.

Standard attributes

The following values for the parameter Attributes are possible:

'point_normal': This value specifies that the attribute with the 3D point normals and the attribute with the 3D point coordinates are removed.

'triangles': This value specifies that the attribute with the face triangles is removed.

'polygons': This value specifies that the attribute with the face polygon is removed.

'lines': This value specifies that the attribute with the lines is removed.

'xyz_mapping': This value specifies that the attribute with the mapping to image coordinates is removed.

'extended_attribute': This value specifies that all user-defined extended attributes are removed.

'primitives_all': This value specifies that the attribute with the parameters of the primitive (including an empty primitive) is removed (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_plane': This value specifies that the attribute with the primitive plane is removed (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_sphere': This value specifies that the attribute with the primitive sphere is removed (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_cylinder': This value specifies that the attribute with the primitive cylinder is removed (e.g., obtained from the operator fit_primitives_object_model_3d).

'primitive_box': This value specifies that the attribute with the primitive cylinder is removed.

'shape_based_matching_3d_data': This value specifies that the attribute with the prepared shape model for shape-based 3D matching is removed.

'distance_computation_data': This value specifies that the attribute with the distance computation data structure is removed. The distance computation data can be created with prepare_object_model_3d, and can be used with distance_object_model_3d.

'all': This value specifies that all available attributes are removed except for the point coordinates. That is, the attributes are the point normals, the face triangles, the face polygons, the mapping to image coordinates, the shape model for matching, the parameter of a primitive, and the extended attributes.

Extended attributes

Extended attributes are attributes, that can be derived from standard attributes by special operators (e.g., distance_object_model_3d), or user-defined attributes (set with set_object_model_3d_attrib or set_object_model_3d_attrib_mod). The extended attributes can be removed by setting their names in Attributes.

The following predefined extended attributes can be removed:

'original_point_indices': This value specifies that the attribute with the original point indices is removed. Original point indices may be obtained from the operator triangulate_object_model_3d.

'score': This value specifies that the attribute with the scores is removed. Scores may be obtained from the operator reconstruct_surface_stereo.

'red': This value specifies that the attribute containing the red color is removed.

'green': This value specifies that the attribute containing the green color is removed.

'blue': This value specifies that the attribute containing the blue color is removed.

'edge_dir_x': This value specifies that the vector for the X axis is removed.

'edge_dir_y': This value specifies that the vector for the Y axis is removed.

'edge_dir_z': This value specifies that the vector for the Z axis is removed.

'edge_amplitude': This value specifies that the vector for the amplitude is removed.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the input 3D object model.

▷ **Attributes** (input_control) . . . . . string(-array) ⇝ *string*
Name of the attributes to be removed.
Default: 'extended_attribute'
List of values: Attributes ∈ {'point_normal', 'triangles', 'lines', 'polygons', 'xyz_mapping', 'shape_based_matching_3d_data', 'distance_computation_data', 'primitives_all', 'primitive_plane', 'primitive_sphere', 'primitive_cylinder', 'primitive_box', 'extended_attribute', 'score', 'red', 'green', 'blue', 'original_point_indices', 'all'}

▷ **ObjectModel3DOut** (output_control) . . . . . object_model_3d ⇝ *handle*
Handle of the resulting 3D object model.

Result

If the parameters are valid, the operator remove_object_model_3d_attrib returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

remove_object_model_3d_attrib_mod (: : ObjectModel3D,
Attributes :)

Remove attributes of a 3D object model.

remove_object_model_3d_attrib_mod removes the standard and/or extended attributes given in Attributes of a 3D object model ObjectModel3D. Doing so changes the 3D object model. This is in contrast to the operator remove_object_model_3d_attrib, which creates a new model but functions identically otherwise.

If the Attributes do not exist in ObjectModel3D, no exception is raised.

For a detailed description of Attributes see operator remove_object_model_3d_attrib.

Attention

remove_object_model_3d_attrib_mod removes Attributes unchecked from the 3D object model. Special attention must be paid to retain a consistent 3D object model, as most of the operators expect consistent 3D object models. Furthermore, the mapping of the 3D points to image coordinates should not be removed because it speeds up the computation of many operators.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the input 3D object model.

▷ **Attributes** (input_control) ..... string(-array) ⇝ *string*
Name of the attributes to be removed.
Default: 'extended_attribute'
List of values: `Attributes` ∈ {'point_normal', 'triangles', 'lines', 'polygons', 'xyz_mapping', 'shape_based_matching_3d_data', 'distance_computation_data', 'primitives_all', 'primitive_plane', 'primitive_sphere', 'primitive_cylinder', 'primitive_box', 'extended_attribute', 'score', 'red', 'green', 'blue', 'original_point_indices', 'all'}

Result

If the parameters are valid, the operator `remove_object_model_3d_attrib_mod` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

serialize_object_model_3d (: : ObjectModel3D : SerializedItemHandle)

Serialize a 3D object model.

`serialize_object_model_3d` serializes the data of a 3D object model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file using the file format 'om3' of `write_object_model_3d` is converted to a serialized item. The 3D object model is defined by the handle `ObjectModel3D`. The serialized 3D object model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_object_model_3d`.

Parameters

▷ **ObjectModel3D** (input_control) ..... object_model_3d ⇝ *handle*
Handle of the 3D object model.
▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_object_model_3d` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

set_object_model_3d_attrib (: : ObjectModel3D, AttribName, AttachExtAttribTo, AttribValues : ObjectModel3DOut)

Set attributes of a 3D object model.

set_object_model_3d_attrib sets the standard attributes or the extended attributes given in AttribName of a 3D object model ObjectModel3D to the values in AttribValues and returns a 3D object model with the new attribute values in ObjectModel3DOut. set_object_model_3d_attrib is identical to set_object_model_3d_attrib_mod with the exception that it creates a new 3D object model and leaves the original 3D object model unchanged. It is possible to attach the values of extended attributes to already existing standard attributes of the 3D object model by setting the parameter AttachExtAttribTo. For standard attributes, AttachExtAttribTo is ignored.

If the attributes in AttribName do not exist, they are created if possible. If already existing attributes are set, the length of AttribValues must match the existing attribute values. In this case the existing attribute values are replaced. If extended attributes are attached to already existing standard attributes with AttachExtAttribTo, the length of AttribValues must match the existing attribute values.

Standard attributes

The following standard attributes can be set:

'point_coord_x': The x-coordinates of the 3D points are set with AttribValues. If the attribute does not exist, the x-, y- and z-coordinates must be set with *'point_coord_x'*, *'point_coord_y'*, and *'point_coord_z'* at once. The number of x-, y-, and z-coordinates must be identical.

'point_coord_y': The y-coordinates of the 3D points are set with AttribValues. If the attribute does not exist, the x-, y- and z-coordinates must be set with *'point_coord_x'*, *'point_coord_y'*, and *'point_coord_z'* at once. The number of x-, y-, and z-coordinates must be identical.

'point_coord_z': The z-coordinates of the 3D points are set with AttribValues. If the attribute does not exist, the x-, y- and z-coordinates must be set with *'point_coord_x'*, *'point_coord_y'*, and *'point_coord_z'* at once. The number of x-, y-, and z-coordinates must be identical.

'point_normal_x': The x-components of the 3D point normals of the 3D points are set with AttribValues. If the attribute does not exist, the x-, y- and z-components of 3D point normals must be set with *'point_normal_x'*, *'point_normal_y'*, and *'point_normal_z'* at once. The number of x-, y-, and z-components must be identical to the number of 3D points. Note that the given 3D point normals will not be normalized to a length of 1.

'point_normal_y': The y-components of the 3D point normals of the 3D points are set with AttribValues. If the attribute does not exist, the x-, y- and z-components of 3D point normals must be set with *'point_normal_x'*, *'point_normal_y'*, and *'point_normal_z'* at once. The number of x-, y-, and z-components must be identical to the number of 3D points. Note that the given 3D point normals will not be normalized to a length of 1.

'point_normal_z': The z-components of the 3D point normals of the 3D points are set with AttribValues. If the attribute does not exist, the x-, y- and z-components of 3D point normals must be set with *'point_normal_x'*, *'point_normal_y'*, and *'point_normal_z'* at once. The number of x-, y-, and z-components must be identical to the number of 3D points. Note that the given 3D point normals will not be normalized to a length of 1.

'triangles': The indices of the 3D points that represent triangles are set with AttribValues in the following order: The first three values of AttribValues (input values 0,1,2) represent the first triangle and contain the indices of the corresponding 3D points of the triangle corners. The second three values (input values 3,4,5) represent the second triangle etc. The direction of the triangles results from the order of the point indices.

'polygons': The indices of the 3D points that represent polygons are set with AttribValues in the following order: The first value of AttribValues contains the number n of points of the first polygon. The following values (input values 1,2,..,n) contains the indices of the points of the first polygon. The next value (input value n+1) contains the number m of the points of the second polygon. The following m values (input values n+2,n+3,..,n+1+m) contain the indices of the points of the second polygon etc.

'lines': The indices of the 3D points that represent polylines are set with AttribValues in the following order: The first value of AttribValues contains the number n of points of the first polyline. The following values (input values 1,2,..,n) represent the indices of the points of the first polyline. The next value (input value n+1) contains the number m of points of the second polyline. The following m values (input values n+2,n+3,..,n+1+m) represent the indices of the points of the second polyline etc. All indices correspond to already existing 3D points.

'xyz_mapping': The mapping of 3D points to image coordinates is set with AttribValues in the following order: The first two values of AttribValues (input value 0 and 1) contain the width and height of the respective image. The following n values (input values 2,3,..,n+1, with n being the number of 3D points) represent the row coordinates of the n points given in image coordinates. The next n input values (input values n+2,n+3,..,n*2+1) represent the column coordinates of the n points in image coordinates. Hence, the total number of input values is n*2+2.

Extended attributes

Extended attributes are attributes, that can be derived from standard attributes by special operators (e.g., distance_object_model_3d), or user-defined attributes. Predefined extended attributes can only be set separately, for these attributes AttachExtAttribTo will be ignored. The names of user-defined extended attributes are arbitrary, but must start with the prefix *'&'*, e.g., *'&my_attrib'*. Extended attributes can have an arbitrary number of floating point values.

The following predefined extended attributes can be set:

'original_point_indices': The original points indices of the 3D points are set with AttribValues. The number of the original points indices must be identical to the number of 3D points.

'score': The score of a 3D reconstruction of the 3D points are set with AttribValues. Since the score is evaluated separately for each 3D point, the number of the score-components must be identical to the number of 3D points.

'red': The red channel intensities of the 3D points are set with AttribValues. The number of color values must be identical to the number of 3D points.

'green': The green channel intensities of the 3D points are set with AttribValues. The number of color values must be identical to the number of 3D points.

'blue': The blue channel intensities of the 3D points are set with AttribValues. The number of color values must be identical to the number of 3D points.

'edge_dir_x': The x-component of a vector that is perpendicular to the edge direction and the viewing direction.

'edge_dir_y': The y-component of a vector that is perpendicular to the edge direction and the viewing direction.

'edge_dir_z': The z-component of a vector that is perpendicular to the edge direction and the viewing direction.

'edge_amplitude': Contains the amplitude of edge points.

Extended attributes can be attached to already existing standard attributes of the 3D object model by setting the parameter AttachExtAttribTo. The following values of AttachExtAttribTo are possible:

'object' **or** *[]*: If this value is set, the extended attribute specified in AttribName is associated to the 3D object model as a whole. The number of values specified in AttribValues is not restricted.

'points': If this value is set, the extended attribute specified in AttribName is associated to the 3D points of the object model. The number of values specified in AttribValues must be the same as the number of already existing 3D points.

'triangles': If this value is set, the extended attribute specified in `AttribName` is associated to the triangles of the object model. The number of values specified in `AttribValues` must be the same as the number of already existing triangles.

'polygons': If this value is set, the extended attribute specified in `AttribName` is associated to the polygons of the object model. The number of values specified in `AttribValues` must be the same as the number of already existing polygons.

'lines': If this value is set, the extended attribute specified in `AttribName` is associated to the lines of the object model. The number of values specified in `AttribValues` must be the same as the number of already existing lines.

Attention

If multiple attributes are given in `AttribName`, `AttribValues` is divided into sub-tuples of equal length. Each sub-tuple is then assigned to one attribute. E.g., if `AttribName` and `AttribValues` are set to

`AttribName` := *['&attrib1','&attrib2','&attrib3']*,

`AttribValues` := *[0.0,1.0,2.0,3.0,4.0,5.0]*,

the following values are assigned to the individual attributes:

'&attrib1' = [0.0,1.0], *'&attrib2' = [2.0,3.0]*, *'&attrib3' = [4.0,5.0]*.

Consequently, it is not possible to set multiple attributes of different lengths in one call.

`set_object_model_3d_attrib` stores the input `AttribValues` unmodified in the 3D object model. Therefore, special attention must be paid to the consistency of the input data, as most of the operators expect consistent 3D object models.

Parameters

▷ **`ObjectModel3D`** (input_control) ..... object_model_3d ⇝ *handle*
Handle of the input 3D object model.

▷ **`AttribName`** (input_control) ..... string(-array) ⇝ *string*
Name of the attributes.
List of values: `AttribName` ∈ {'point_coord_x', 'point_coord_y', 'point_coord_z', 'point_normal_x', 'point_normal_y', 'point_normal_z', 'triangles', 'polygons', 'lines', 'xyz_mapping', 'red', 'green', 'blue', 'score', 'original_point_indices'}

▷ **`AttachExtAttribTo`** (input_control) ..... string ⇝ *string*
Defines where extended attributes are attached to.
Default: []
List of values: `AttachExtAttribTo` ∈ {[], 'object', 'points', 'polygons', 'triangles', 'lines'}

▷ **`AttribValues`** (input_control) ..... real(-array) ⇝ *real* / integer
Attribute values.

▷ **`ObjectModel3DOut`** (output_control) ..... object_model_3d ⇝ *handle*
Handle of the resulting 3D object model.

Result

If the parameters are valid, the operator `set_object_model_3d_attrib` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

set_object_model_3d_attrib_mod (: : ObjectModel3D, AttribName, AttachExtAttribTo, AttribValues :)

Set attributes of a 3D object model.

set_object_model_3d_attrib_mod sets the standard attributes or the extended attributes given in AttribName of a 3D object model ObjectModel3D to the values in AttribValues. set_object_model_3d_attrib_mod is identical to set_object_model_3d_attrib, with the exception that it does not create a new 3D object model but modifies the given one. It is possible to attach the values of extended attributes to already existing standard attributes of the 3D object model by setting the parameter AttachExtAttribTo. For standard attributes, AttachExtAttribTo is ignored.

If the attributes in AttribName do not exist, they are created if possible. If already existing attributes are set, the length of AttribValues must match the existing attribute values. In this case the existing attribute values are replaced. If extended attributes are attached to already existing standard attributes with AttachExtAttribTo, the length of AttribValues must match the existing attribute values.

For a detailed description see operator set_object_model_3d_attrib.

Attention

If multiple attributes are given in AttribName, AttribValues is divided into sub-tuples of equal length. Each sub-tuple is then assigned to one attribute. E.g., if AttribName and AttribValues are set to

AttribName := *['&attrib1','&attrib2','&attrib3']*,

AttribValues := *[0.0,1.0,2.0,3.0,4.0,5.0]*,

the following values are assigned to the individual attributes:

'&attrib1' = [0.0,1.0], *'&attrib2' = [2.0,3.0]*, *'&attrib3' = [4.0,5.0]*.

Consequently, it is not possible to set multiple attributes of different lengths in one call.

set_object_model_3d_attrib_mod modifies the content of an already existing 3D object model. The operator stores the input AttribValues unmodified in the 3D object model. Therefore, special attention must be paid to the consistency of the input data, as most of the operators expect consistent 3D object models.

Parameters

- ▷ **ObjectModel3D** (input_control) ..... object_model_3d ⇝ *handle*
  Handle of the 3D object model.
- ▷ **AttribName** (input_control) ..... string(-array) ⇝ *string*
  Name of the attributes.
  List of values: AttribName ∈ {'point_coord_x', 'point_coord_y', 'point_coord_z', 'point_normal_x', 'point_normal_y', 'point_normal_z', 'triangles', 'polygons', 'lines', 'xyz_mapping', 'red', 'green', 'blue', 'score', 'original_point_indices'}
- ▷ **AttachExtAttribTo** (input_control) ..... string ⇝ *string*
  Defines where extended attributes are attached to.
  Default: []
  List of values: AttachExtAttribTo ∈ {[], 'object', 'points', 'polygons', 'triangles', 'lines'}
- ▷ **AttribValues** (input_control) ..... real(-array) ⇝ *real* / integer
  Attribute values.

Result

If the parameters are valid, the operator set_object_model_3d_attrib_mod returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

set_object_model_3d_attrib

See also

copy_object_model_3d, remove_object_model_3d_attrib_mod

Module

3D Metrology

union_object_model_3d (: : ObjectModels3D, Method : UnionObjectModel3D)

Combine several 3D object models to a new 3D object model.

union_object_model_3d combines the data of all input models in ObjectModels3D to a new 3D object model that is returned in UnionObjectModel3D.

Overlapping areas in the 3D object models might cause the potential 2D mapping, polygons, or triangles in the output to be less useful, since they might overlap, too.

The only supported Method is so far *'points_surface'*, which combines all points, surfaces and lines into the output UnionObjectModel3D. Extended Attributes are copied if no holes appear, i.e., if they are present in all input object models where the standard attribute they are attached to exists.

Attention

union_object_model_3d ignores 3D object models of type 3D primitive and 3D shape model.

Parameters

▷ **ObjectModels3D** (input_control) ..... object_model_3d(-array) ⇝ *handle*
Handle of input 3D object models.

▷ **Method** (input_control) ..... string ⇝ *string*
Method used for the union.
Default: 'points_surface'
List of values: Method ∈ {'points_surface'}

▷ **UnionObjectModel3D** (output_control) ..... object_model_3d ⇝ *handle*
Handle of the resulting 3D object model.

Example

```
gen_object_model_3d_from_points ([0,0,0,0],[1,1,0,0], [0,1,1,0],\
                                 ObjectModel3D1)
gen_object_model_3d_from_points ([1,1,1,1],[1,1,0,0], [0,1,1,0],\
                                 ObjectModel3D2)
get_object_model_3d_params (ObjectModel3D1, 'diameter', DiameterOld)
union_object_model_3d ([ObjectModel3D1,ObjectModel3D2], 'points_surface',\
                       UnionObjectModel3D)
get_object_model_3d_params (UnionObjectModel3D, 'diameter', DiameterNew)
```

Result

union_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If there is no attribute common in all input objects, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

write_object_model_3d (: : ObjectModel3D, FileType, FileName, GenParamName, GenParamValue :)

Writes a 3D object model to a file.

The operator write_object_model_3d writes the 3D object model ObjectModel3D to the file FileName. The object model can be read again with read_object_model_3d, or can be imported into an appropriate CAD program. Please note, that primitives may only be stored in the HALCON format *'om3'*. Should it be necessary to store the primitives in another format, the operator sample_object_model_3d has to be called beforehand. However, this results in a transformation of the primitives into 3D points and therefore only corresponds to an approximation of the primitives.

All coordinates are written in meters. If the file is read later using read_object_model_3d, the parameter Scale must be set to *'m'* to avoid scaling the data.

The parameter FileType determines the type of the file. The following types are supported by this operator:

'om3': HALCON format for object model 3D. Files with this format can be read by read_object_model_3d. The default file extension for this format is 'om3'.

'dxf': AUTOCAD format. See read_object_model_3d for details about reading this file format. The default file extension for this format is 'dxf'.

'off': Object File Format. This is an ASCII-based format that can hold 3D points and polygons. The default file extension for this format is 'off'.

'ply',

'ply_binary': Polygon File Format (also Stanford Triangle Format). This is a simple format that can hold 3D points, point normals, polygons, color information and point-based extended attributes. HALCON supports the writing of both the ASCII and the binary version of this format. The default file extension for this format is 'ply'.

'obj': OBJ file format, also Wavefront OBJ-Format. This is an ASCII-based format that can hold 3D points, polygons, normals, and triangles, which are stored as polygons. The default file extension for this format is 'obj'.

'stl',

'stl_binary',

'stl_ascii': STL file format, also 'Stereolithography format', 'SurfaceTesselationLanguage ', 'StandardTriangulationLanguage', and 'StandardTesselationLanguage'. This format stores triangles and triangle normals. However, as triangle normals are not supported by HALCON 3D object models and point normals (which are, for example, calculated by surface_normals_object_model_3d) are not supported by the STL format, no normals are written to file. If the 3D object model contains polygons, they are converted to triangles before before writing them to disc. If the file type is set to *'stl'* or *'stl_binary'*, the binary version of STL is written while *'stl_ascii'* selects the ASCII version. The default file extension for this format is 'stl'.

A set of additional optional parameters can be set. The names and values of the parameters are passed in GenParamName and GenParamValue, respectively. Some of the optional parameters can only be set for a certain file type. The following values for GenParamName are possible:

'invert_normals': Invert normals and face orientation before saving the 3D object model. If this value is set to *'true'*, for the formats *'off'*, *'ply'*, *'obj'*, and *'stl'* the orientation of faces (triangles and polygons) is inverted . For formats that support point normals (*'ply'*,*'obj'*), all normals are inverted before writing them to disc. Note that for the types *'om3'* and *'dxf'* the parameter has no effect.
Valid for formats: 'off', 'ply', 'obj', 'stl'. **List of values:** *'true'*, *'false'*.
Default: *'false'*.

Parameters

▷ **ObjectModel3D** (input_control) ..... object_model_3d ⇝ *handle*
Handle of the 3D object model.

▷ **FileType** (input_control) ..... string ⇝ *string*
Type of the file that is written.
Default: 'om3'
List of values: FileType ∈ {'off', 'ply', 'ply_binary', 'dxf', 'om3', 'obj', 'stl', 'stl_binary', 'stl_ascii'}

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Name of the file that is written.
File extension: .off, .ply, .dxf, .om3, .obj, .stl

▷ **GenParamName** (input_control) ..... string(-array) ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'invert_normals'}

▷ **GenParamValue** (input_control) ..... string(-array) ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

Result

The operator write_object_model_3d returns the value 2 (H_MSG_TRUE) if the given parameters are correct and the file can be written. If necessary, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

4.2 Features

area_object_model_3d (: : ObjectModel3D : Area)

Calculate the area of all faces of a 3D object model.

area_object_model_3d calculates the area of all faces in a 3D object model. The 3D object model requires faces or triangles. The resulting area is returned in Area.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **Area** (output_control) . . . . . number(-array) ⇝ *real*
Calculated area.
Number of elements: Area == ObjectModel3D

Example

```
gen_box_object_model_3d ([0,0,0,0,0,0,0],3,2,1, ObjectModel3D)
convex_hull_object_model_3d (ObjectModel3D, ObjectModel3DConvexHull)
area_object_model_3d (ObjectModel3DConvexHull, Area)
```

Result

`area_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

3D Metrology

distance_object_model_3d (: : ObjectModel3DFrom, ObjectModel3DTo, Pose, MaxDistance, GenParamName, GenParamValue :)

Compute the distances of the points of one 3D object model to another 3D object model.

The operator `distance_object_model_3d` computes the distances of the points in the 3D object model `ObjectModel3DFrom` to the points, triangles, polygons, or primitive in the 3D object model `ObjectModel3DTo`. The distances are stored as an extended attribute named *'&distance'* in the 3D object model `ObjectModel3DFrom`. This attribute can subsequently be queried with `get_object_model_3d_params` or be processed with `select_points_object_model_3d` or other operators that use extended attributes.

The target data (points, triangles, polygons, or primitive) is selected based on the attributes contained in `ObjectModel3DTo`. It is selected based on the presence of the data in the following precedence: Primitive, triangles, polygons, and points. As alternative to this automatic target data selection, the target data type can also be set with the generic parameter *'distance_to'* (see below). Generic, non-triangular polygons are internally triangulated by the operator before the distance to the resulting triangles is calculated. Thus, calling the operator with triangulated objects is faster than calling it with objects having different polygon faces.

`MaxDistance` can be used to limit the range of the distance values to be computed. If `MaxDistance` is set to *0*, all distances are computed. If `MaxDistance` is set to another value, points whose distance would exceed `MaxDistance` are not processed and set to `MaxDistance`. Thus, setting `MaxDistance` to a value different than *0* can significantly speed up the execution of this operator.

If `Pose` is a non-empty tuple, it must contain a pose which is applied to the points in `ObjectModel3DFrom` before computing the distances. The pose can be inverted using the generic parameter *'invert_pose'* (see below).

Depending on the target data type (points, triangles, or primitive), several methods for computing the distances are available. Some of these methods compute a data structure on the elements of ObjectModel3DTo to speed up the distance computation. Those data structures can be precomputed using the operator prepare_object_model_3d. This allows multiple calls to distance_object_model_3d to re-use the data structure, thus saving the time to re-compute it for each call. For objects with non-triangular polygon faces, the operator prepare_object_model_3d can additionally perform the triangulation and save it to the object to further speed-up the distance_object_model_3d operator. This triangulation is only performed when the generic parameter *'distance_to'* is set to *'triangles'*. Note that this triangulation, contrary to that of the operator triangulate_object_model_3d, does not clear out the polygons attribute.

When computing the distance to points or to triangles, the operator can optionally return the index of the closest point or triangle for each point in ObjectModel3DFrom by setting the generic parameter *'store_closest_index'* to *'true'* (see below). The index is stored as extended attribute named *'&closest_index'* in the 3D object model ObjectModel3DFrom. Note that the closest index can not be computed when using the *'voxel'* method. If a point's distance to its closest element exceeds the maximum distance set in MaxDistance, the closest index is set to -1.

Optionally, signed distances to points, triangles or to a primitive can be calculated. Therefore, the generic parameter *'signed_distances'* has to be set to *'true'*. Note that signed distances can not be computed when using the *'voxel'* method in combination with point to point distances.

In the following, the different target types and methods are explained, and their advantages and disadvantages are described. Note that the operator automatically selects a default method depending on the target data type. This method can be overridden using the generic parameter *'method'*.

Distance to points: The following methods are available to compute the distances from points to points:

- **Linear search:** For each point in ObjectModel3DFrom, the distances to all points in ObjectModel3DTo are computed, and the smallest distance is used. This method requires no precomputed data structure, and is the fastest for a small number of points in ObjectModel3DTo.
- **KD-Tree:** The points in ObjectModel3DTo are organized in a KD-Tree, which speeds up the search for the closest point. The construction of the tree is very efficient. The search time is approximately logarithmic to the number of points in ObjectModel3DTo. However, the search time is not constant, and can vary significantly depending on the position of the query points in ObjectModel3DFrom.
- **Voxel:** The points in ObjectModel3DTo are organized in a voxel structure. This voxel structure allows searching in almost constant time, i.e., independent from the position of the query points in ObjectModel3DFrom and the number of points in ObjectModel3DTo.
  Note that the preparation of this data structure takes several seconds or minutes. However, it is possible to perform a precomputation using prepare_object_model_3d on ObjectModel3DTo with Purpose set to *'distance_computation'*.

Distance to triangles: For computing the distances to triangles, the following methods are supported:

- **Linear search:** For each point in ObjectModel3DFrom, the distances to all triangles in ObjectModel3DTo are computed, and the smallest distance is used. This method requires no precomputed data structure, and is the fastest for a small number of triangles in ObjectModel3DTo.
- **KD-Tree:** The triangles in ObjectModel3DTo are organized in a KD-Tree, which speeds up the search for the closest triangle. The construction of the tree is efficient. The search time is approximately logarithmic to the number of triangles in ObjectModel3DTo. However, the search time is not constant, and can vary significantly depending on the position of the query points in ObjectModel3DFrom.
- **Voxel:** The triangles in ObjectModel3DTo are organized in a voxel structure. This voxel structure allows searching in almost constant time, i.e., independent from the position of the query points in ObjectModel3DFrom and the number of triangles in ObjectModel3DTo.
  Note that the preparation of this data structure takes several seconds or minutes. However, it is possible to perform a precomputation using prepare_object_model_3d on ObjectModel3DTo with Purpose set to *'distance_computation'*. For creating the voxel data structure, the triangles are sampled. The corresponding sampling distance can be set with the generic parameters *'sampling_dist_rel'* and *'sampling_dist_abs'*.
  By default, a relative sampling distance of *0.03* is used. See below for a more detailed description of the sampling distance. Note that this data structure is only approximate. It is possible that some of the distances are off by around 10% of the sampling distance. In these cases, the returned distances will always be larger than the actual distances.

Distance to primitive: Since ObjectModel3DTo can contain only one primitive, the distances from the query points to this primitive are computed linearly. The creation or usage of a data structure is not possible.

Note that computing the distance to primitive planes fitted with segment_object_model_3d or fit_primitives_object_model_3d can be slow, since those planes contain a complex convex hull of the points that were used to fit the plane. If only the distance to the plane is required, and the boundary should be ignored, it is recommended to obtain the plane pose using get_object_model_3d_params with parameter *'primitive_parameter_pose'* and create a new plane using gen_plane_object_model_3d.

The following table lists the different target data types, methods, and their properties. The search time is the approximate time per point in ObjectModel3DFrom. N is the number of target elements in ObjectModel3DTo.

Target Data	Method	Creation Time	Approximate Search Time	Properties
points	linear	0	$O(N)$	· No precomputation · Fastest for small N · Default for $N < 100$
points	kd-tree	$O(N \log(N))$	$O(\log(N))$	· Fast structure creation · Non-constant search time · Default for $N \geq 100$
points	voxel	$O(N \log(N))$	$O(\log(\log(N)))$	· Slow structure creation · Very fast search · Default for precomputation with prepare_object_model_3d
triangles	linear	0	$O(N)$	· No precomputation · Fastest for small N · Default
triangles	kd-tree	$O(N \log(N))$	$O(\log(N))$	· Fast structure creation · Non-constant search time
triangles	voxel	$O(N \log(N))$	$O(\log(\log(N)))$	· Slow structure creation · Requires sampling distance · Very fast search · Small errors possible · Default for precomputation with prepare_object_model_3d
primitive	linear	0	$O(1)$	

Additionally to the parameters described above, the following parameters can be set to influence the distance computation. If desired, these parameters and their corresponding values can be specified by using GenParamName and GenParamValue, respectively. All of the following parameters are optional.

'distance_to' This parameter can be used to explicitly set the target data to which the distances are computed.

'auto' (Default) Automatically set the target data. The following list of attributes is queried, and the first appearing attribute from the list is used as target data: Primitive, Triangle, Point.

'primitive' Compute the distance to the primitive contained in `ObjectModel3DTo`.

'triangles' Compute the distance to the triangles contained in `ObjectModel3DTo`.

'points' Compute the distance to the points contained in `ObjectModel3DTo`.

'method' This parameter can be used to explicitly set the method to be used for the distance computation. Note that not all methods are available for all target data types. For the list of possible pairs of target data type and method, see above.

'auto' (Default) Use the default method for the used target data type.

'linear' Use a linear search for computing the distances.

'kd-tree' Use a KD-Tree for computing the distances.

'voxel' Use a voxel structure for computing the distances.

'invert_pose' This parameter can be used to invert the pose given in `Pose`.

'false' (Default) The pose is not inverted.

'true' The pose is inverted.

'output_attribute' This parameter can be used to set the name of the attribute in which the distances are stored. By default, the distances are stored in an extended attribute named *'&distance'* in `ObjectModel3DFrom`. However, if the same 3D object model is used for different calls of this operator, the result of the previous call would be overwritten. This can be avoided by changing the name of the extended attribute. Valid extended attribute names start with a *'&'*.

'sampling_dist_rel', *'sampling_dist_abs'* These parameters are used when computing the distances to triangles using the voxel method. For this, the triangles need to be sampled. The sampling distance can be set either in absolute terms, using *'sampling_dist_abs'*, or relative to the diameter of the axis aligned bounding box, using *'sampling_dist_rel'*. By default, *'sampling_dist_rel'* is set to 0.03. Only one of the two parameters can be set. The diameter of the axis aligned bounding box can be queried using `get_object_model_3d_params`. Note that the creation of the voxel data structure is very time consuming, and is usually performed offline using `prepare_object_model_3d` (see above).

'store_closest_index' This parameter can be used to return the index of the closest point or triangle in the extended attribute '&closest_index'.

'false' (Default) The index is not returned.

'true' The index is returned.

'signed_distances' This parameter can be used to calculate signed distances of the points in the 3D object model `ObjectModel3DFrom` to the points, triangles or primitive in the 3D object model `ObjectModel3DTo`.

'false' (Default) Unsigned distances are returned.

'true' Signed distances are returned.

Dependent on the available target data (points, triangles or primitive) the following particularities have to be considered:

Distance to points: The computation of signed distances is only supported for the methods *'kd-tree'* and *'linear'*. However, signed distances can only be calculated if point normals are available for the points in the 3D object model or attached via the operator `set_object_model_3d_attrib_mod`.

Distance to triangles: Signed distances can be calculated for all methods listed above. The operator returns a negative distance, if the dot product with the normal vector of the triangle is less than zero. Otherwise, the distance is positive.

Distance to primitive: When calculating signed distances to a cylindrical, spherical or box-shaped primitive, the points of the 3D object model `ObjectModel3DFrom` inside the primitive obtain a negative distance, whereas all others have a positive distance. When calculating signed distances to planes, all points beneath the plane obtain a negative distance, whereas all others have a positive one.

Parameters

▷ **ObjectModel3DFrom** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the source 3D object model.

▷ **ObjectModel3DTo** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the target 3D object model.

▷ **Pose** (input_control) . . . . . pose ⇝ *real* / integer
Pose of the source 3D object model in the target 3D object model.
Default: []

▷ **MaxDistance** (input_control) . . . . . number ⇝ *real* / integer
Maximum distance of interest.
Default: 0

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic input parameters.
Default: []
List of values: GenParamName ∈ {'distance_to', 'method', 'invert_pose', 'output_attribute', 'sampling_dist_rel', 'sampling_dist_abs', 'signed_distances', 'store_closest_index'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Values of the generic input parameters.
Default: []
List of values: GenParamValue ∈ {'auto', 'triangles', 'points', 'polygons', 'primitive', 'kd-tree', 'voxel', 'linear', 'true', 'false'}

Result

distance_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

get_object_model_3d_params (: : ObjectModel3D, GenParamName : GenParamValue)

Return attributes of 3D object models.

A 3D object model consists of a set of attributes and meta data. The operator get_object_model_3d_params allows to access attributes and meta data of the given 3D object models. The name of the requested attribute or meta data is passed in the generic parameter GenParamName, the corresponding value is returned in GenParamValue. If a requested attribute or meta data is not available, an exception is raised. get_object_model_3d_params supports to access several 3D object models and several attributes at once. Note that the attributes or meta data can have different lengths. Some of the standard attributes have a defined length as noted in the attribute description below. The length of other attributes depends on the actual 3D object model, and can be queried by setting the parameter GenParamName to, e.g.,

'num_points', *'num_triangles'*, *'num_polygons'*, or *'num_lines'*. Thus, to get the length of the standard attribute *'point_coord_x'*, set GenParamName to *'num_points'*.

Standard attributes

The following standard attributes and meta data can be accessed:

'point_coord_x': The x-coordinates of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator xyz_to_object_model_3d or read_object_model_3d.

'point_coord_y': The y-coordinates of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator xyz_to_object_model_3d or read_object_model_3d.

'point_coord_z': The z-coordinates of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator xyz_to_object_model_3d or read_object_model_3d.

'point_normal_x': The x-components of 3D point normals of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator smooth_object_model_3d.

'point_normal_y': The y-components of 3D point normals of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator smooth_object_model_3d.

'point_normal_z': The z-components of 3D point normals of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator smooth_object_model_3d.

'mapping_row': The row-components of the 2D mapping of the set of 3D points. (length can be queried by *'num_points'*, height of the original image can be queried by *'mapping_size'*). This attribute is obtained typically from the operator xyz_to_object_model_3d.

'mapping_col': The column-components of the 2D mapping of the set of 3D points. (length can be queried by *'num_points'*, width of the original image can be queried by *'mapping_size'*). This attribute is obtained typically from the operator xyz_to_object_model_3d.

'mapping_size': The size of the original image. A tuple with the two entries width and height is returned.

'triangles': The indices of the 3D points that represent triangles in the following order: The first three values (return values 0,1,2) represent the first triangle. The next three values (return values 3,4,5) represent the second triangle etc. All indices correspond to the coordinates of the 3D points. Access to the coordinates of the 3D points is possible, e.g., with the generic parameter GenParamName set to the values *'point_coord_x'*, *'point_coord_y'*, and *'point_coord_z'*, respectively. The length of this attribute corresponds to three times the number of triangles, which can be queried using *'num_triangles'*. This attribute is obtained typically from the operator triangulate_object_model_3d or read_object_model_3d.

'polygons': The indices of the 3D points that represent polygons in the following order: The first return value contains the number n of the points of the first polygon. The following values (return values 1,2,..,n) represent the indices of the points of the first polygon. The next value (return value n+1) contains the number m of the points of the second polygon. The following m return values (return values n+2,n+3,..,n+1+m) represent the indices of the points of the second polygon etc. All indices correspond to the coordinates of the 3D points. Access to the coordinates of the 3D points is possible, e.g., with the generic parameter GenParamName set to the values *'point_coord_x'*, *'point_coord_y'*, and *'point_coord_z'*, respectively. The number of polygons per 3D object model can be queried using *'num_polygons'*. This attribute is obtained typically from the operator read_object_model_3d.

'lines': The indices of the 3D points that represent polylines in the following order: The first return value contains the number n of points of the first polyline. The following values (return values 1,2,..,n) represent the indices of the points of the first polyline. The next value (return value n+1) contains the number m of points of the second polyline. The following m values (return values n+2,n+3,..,n+1+m) represent the indices of the points of the second polyline etc. All indices correspond to the coordinates of the 3D points. Access to the coordinates of the 3D points is possible, e.g., with the generic parameter GenParamName set to the values *'point_coord_x'*, *'point_coord_y'*, and *'point_coord_z'*, respectively. The number of lines per 3D object model can be queried using *'num_lines'*. This attribute is obtained typically from the operator intersect_plane_object_model_3d.

'diameter_axis_aligned_bounding_box': The diameter of the set of 3D points, defined as the length of the diagonal of the smallest enclosing axis-parallel cuboid (see parameter *'bounding_box1'*). This attribute has length 1.

'center': 3D coordinates of the center of the set of 3D points. These coordinates are the center of the smallest enclosing axis-parallel cuboid (see parameter *'bounding_box1'*). This attribute has length 3. If there are no 3D coordinates in the 3D object model the following rules are valid:

If the 3D object model is a primitive of type cylinder (see gen_cylinder_object_model_3d) and there are extensions, the center point between the extensions are returned. If there are no extensions the translation parameters of the pose are returned.

If the 3D object model is a primitive of type plane (see gen_plane_object_model_3d) and there are extensions, the center of gravity of the plane is computed from the extensions. If there are no extensions the translation parameters of the pose are returned.

If the 3D object model is a primitive of type sphere or box (see gen_sphere_object_model_3d or gen_box_object_model_3d), the center point of the object model is returned.

'primitive_type': The primitive type (e.g., obtained from the operator fit_primitives_object_model_3d). The return value of a sphere is *'sphere'*. The return value of a cylinder is *'cylinder'*. The return value of a plane is *'plane'*. The return value of a box is *'box'*. This attribute has length 1.

'primitive_parameter': The parameters of the primitive (e.g., obtained from the operator fit_primitives_object_model_3d). The length of this attribute depends on *'primitive_type'* and is between 4 and 10 for each 3D object model.

If the 3D object model is a primitive of type cylinder (see gen_cylinder_object_model_3d), the return values are the (x-, y-, z-)coordinates of the center [x_center, y_center, z_center], the normed (x-, y-, z-)directions of the main axis of the cylinder [x_axis, y_axis, z_axis], and the radius [radius] of the cylinder. The order is [x_center, y_center, z_center, x_axis, y_axis, z_axis, radius].

If the 3D object model is a primitive of type sphere (see gen_sphere_object_model_3d), the return values are the (x-, y-, z-)coordinates of the center [x_center, y_center, z_center] and the radius [radius] of the sphere. The order is [x_center, y_center, z_center, radius].

If the 3D object model is a primitive of type plane (see gen_plane_object_model_3d), the 4 parameters of the hessian normal form are returned, i.e., the unit normal (x-, y-, z-) vector [x, y, z] and the orthogonal distance (d) of the plane from the origin of the coordinate system. The order is [x, y, z, d]. The sign of the distance (d) determines the side of the plane on which the origin is located.

If the 3D object model is a primitive of type box (gen_box_object_model_3d), the return values are the 3D pose (translation, rotation, type of the rotation) and the half edge lengths (length1, length2, length3) of the box. length1 is the length of the box along the x axis of the pose. length2 is the length of the box along the y axis of the pose. length3 is the length of the box along the z axis of the pose. The order is [trans_x, trans_y, trans_z, rot_x, rot_y, rot_z, rot_type, length1, length2, length3]. For details about 3D poses and the corresponding transformation matrices see the operator create_pose.

'primitive_parameter_pose': The parameters of the primitive with format of a 3D pose (e.g., obtained from the operator fit_primitives_object_model_3d). For all types of primitives the return values are the 3D pose (translation, rotation, type of the rotation). For details about 3D poses and the corresponding transformation matrices see the operator create_pose. The length of this attribute depends on *'primitive_type'* and is between 7 and 10 for each 3D object model.

If the 3D object model is a primitive of type cylinder (see gen_cylinder_object_model_3d), additionally, the radius [radius] of the cylinder is returned. The order is [trans_x, trans_y, trans_z, rot_x, rot_y, rot_z, rot_type, radius].

If the 3D object model is a primitive of type sphere (see gen_sphere_object_model_3d), additionally, the radius [radius] of the sphere is returned. The order is [trans_x, trans_y, trans_z, rot_x, rot_y, rot_z, rot_type, radius].

If the 3D object model is a primitive of type plane (see gen_plane_object_model_3d), the order is [trans_x, trans_y, trans_z, rot_x, rot_y, rot_z, rot_type].

If the 3D object model is a primitive of type box (see gen_box_object_model_3d), additionally the half edge lengths (length1, length2, length3) of the box are returned. length1 is the length of the box along the x axis of the pose. length2 is the length of the box along the y axis of the pose. length3 is the length of the box along the z axis of the pose. The order is [trans_x, trans_y, trans_z, rot_x, rot_y, rot_z, rot_type, length1, length2, length3].

'primitive_pose': The parameters of the primitive with format of a 3D pose (e.g., obtained from the operator fit_primitives_object_model_3d). For all types of primitives the return values are the 3D pose

(translation, rotation, type of the rotation). For details about 3D poses and the corresponding transformation matrices see the operator create_pose. The length of this attribute is 7 for each 3D object model. The order is [trans_x, trans_y, trans_z, rot_x, rot_y, rot_z, rot_type].

'primitive_parameter_extension': The extents of the primitive of type cylinder and plane (e.g., obtained from the operator fit_primitives_object_model_3d). The length of this attribute depends on *'primitive_type'* and can be queried using *'num_primitive_parameter_extension'*.

If the 3D object model is a primitive of type cylinder (see gen_cylinder_object_model_3d), the return values are the extents (MinExtent, MaxExtent) of the cylinder. They are returned in the order [MinExtent, MaxExtent]. MinExtent represents the length of the cylinder in negative direction of the rotation axis. MaxExtent represents the length of the cylinder in positive direction of the rotation axis.

If the 3D object model is a primitive of type plane (created using fit_primitives_object_model_3d), the return value is a tuple of co-planar points regarding the fitted plane. The order is [x coordinate of point 1, x coordinate of point 2, x coordinate of point 3, ..., y coordinate of point 1, y coordinate of point 2, y coordinate of point 3, ...]. The coordinate values describe the support points of a convex hull. This is computed based on the projections of those points on the fitted plane which contribute to the fitting. If the plane was created using gen_plane_object_model_3d, all points that were used to create the plane (XExtent, YExtent) are returned.

'primitive_rms': The quadratic residual error of the primitive (e.g., obtained from the operator fit_primitives_object_model_3d). This attribute has length 1.

'reference_point': 3D coordinates of the reference point of the prepared 3D shape model for shape-based 3D matching. The reference point is the center of the smallest enclosing axis-parallel cuboid (see parameter *'bounding_box1'*). This attribute has length 3.

'bounding_box1': Smallest enclosing axis-parallel cuboid (min_x, min_y, min_z, max_x, max_y, max_z). This attribute has length 6.

'num_points': The number of points. This attribute has length 1.

'num_triangles': The number of triangles. This attribute has length 1.

'num_polygons': The number of polygons. This attribute has length 1.

'num_lines': The number of polylines. This attribute has length 1.

'num_primitive_parameter_extension': The number of extended data of primitives. This attribute has length 1.

'has_points': The existence of 3D points. This attribute has length 1.

'has_point_normals': The existence of 3D point normals. This attribute has length 1.

'has_triangles': The existence of triangles. This attribute has length 1.

'has_polygons': The existence of polygons. This attribute has length 1.

'has_lines': The existence of lines. This attribute has length 1.

'has_xyz_mapping': The existence of a mapping of the 3D points to image coordinates. This attribute has length 1.

'has_shape_based_matching_3d_data': The existence of a shape model for shape-based 3D matching. This attribute has length 1.

'has_distance_computation_data': The existence of a precomputed data structure for 3D distance computation. This attribute has length 1. The data structure can be created with prepare_object_model_3d using the purpose *'distance_computation'*. It is used by the operator distance_object_model_3d.

'has_surface_based_matching_data': The existence of data for the surface-based matching. This attribute has length 1.

'has_segmentation_data': The existence of data for a 3D segmentation. This attribute has length 1.

'has_primitive_data': The existence of a primitive. This attribute has length 1.

'has_primitive_rms': The existence of a quadratic residual error of a primitive. This attribute has length 1.

'neighbor_distance':

'neighbor_distance N': For every point the distance of the N-th nearest point. N must be a positive integer and is by default 25. For every point, all other points are sorted according to their distance and the distance of the N-th point is returned.

'num_neighbors X': For every point the number of neighbors within a distance of at most X.

'num_neighbors_fast X': For every point the approximate number of neighbors within a distance of at most X. The distances are approximated using voxels, leading to a faster processing compared to *'num_neighbors'*.

Extended attributes

Extended attributes are attributes, that can be derived from standard attributes by special operators (e.g., `distance_object_model_3d`), or user-defined attributes. User-defined attributes can be created by the operator `set_object_model_3d_attrib`. The following extended attributes and meta data can be accessed:

'extended_attribute_names': The names of all extended attributes. For each extended attribute name a value is returned.

'extended_attribute_types': The type of all extended attributes. For each extended attribute type a value is returned, thereby the values are sorted as the output for the extended attribute names.

'has_extended_attribute': The existence of at least one extended attribute. For each 3D object model a value is returned.

'num_extended_attribute': The number of extended attributes. For each 3D object model a value is returned.

'&attribute_name': The values stored under a user-defined extended attribute. Note that this name must start with *'&'*, e.g., *'&my_attrib'*. The data of the requested extended attributes are returned in `GenParamValue`. The order in which the data is returned is the same as the order of the attribute names specified in `GenParamName`.

'original_point_indices': Indices of the 3D points in a different 3D object model (length can be queried by *'num_points'*). This attribute is obtained typically from the operator `triangulate_object_model_3d`.

'score': The score of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator `reconstruct_surface_stereo`.

'red': The red channel of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator `reconstruct_surface_stereo`.

'green': The green channel of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator `reconstruct_surface_stereo`.

'blue': The blue channel of the set of the 3D points (length can be queried by *'num_points'*). This attribute is obtained typically from the operator `reconstruct_surface_stereo`.

'edge_dir_x': The x-component of a vector that is perpendicular to the edge direction and the viewing direction. This attribute is obtained typically from the operator `edges_object_model_3d`

'edge_dir_y': The y-component of a vector that is perpendicular to the edge direction and the viewing direction. This attribute is obtained typically from the operator `edges_object_model_3d`

'edge_dir_z': The z-component of a vector that is perpendicular to the edge direction and the viewing direction. This attribute is obtained typically from the operator `edges_object_model_3d`

'edge_amplitude': Contains the amplitude of edge points. This attribute is obtained typically from the operator `edges_object_model_3d`

Parameters

▷ **`ObjectModel3D`** (input_control) ..... object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **`GenParamName`** (input_control) ..... attribute.name-array ⇝ *string*
Names of the generic attributes that are queried for the 3D object model.
Default: 'num_points'
List of values: `GenParamName` ∈ {'point_coord_x', 'point_coord_y', 'point_coord_z', 'point_normal_x', 'point_normal_y', 'point_normal_z', 'mapping_row', 'mapping_col', 'mapping_size', 'triangles', 'polygons', 'lines', 'diameter_axis_aligned_bounding_box', 'center', 'primitive_type', 'primitive_rms', 'primitive_parameter', 'primitive_parameter_pose', 'primitive_pose', 'primitive_parameter_extension', 'reference_point', 'bounding_box1', 'num_points', 'num_triangles', 'num_polygons', 'num_lines', 'num_primitive_parameter_extension', 'has_points', 'has_point_normals', 'has_triangles', 'has_polygons', 'has_lines', 'has_xyz_mapping', 'has_shape_based_matching_3d_data', 'has_surface_based_matching_data', 'has_segmentation_data', 'has_primitive_data', 'has_primitive_rms', 'extended_attribute_names', 'extended_attribute_types', 'has_extended_attribute', 'num_extended_attribute', 'has_distance_computation_data', 'red', 'green', 'blue', 'score', 'neighbor_distance', 'num_neighbors', 'num_neighbors_fast', 'original_point_indices', 'edge_amplitude', 'edge_dir_x', 'edge_dir_y', 'edge_dir_z'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Values of the generic parameters.

Result

The operator `get_object_model_3d_params` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

max_diameter_object_model_3d (: : ObjectModel3D : Diameter)

Calculate the maximal diameter of a 3D object model.

`max_diameter_object_model_3d` calculates the maximal diameter of the 3D object model by calculating the convex hull of the object and searching for the pair of points on the convex hull with the largest distance.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **Diameter** (output_control) . . . . . number(-array) ⇝ *real*
Calculated diameter.
Number of elements: Diameter == ObjectModel3D

Example

```
gen_object_model_3d_from_points (rand(200), rand(200),\
                                 rand(200), ObjectModel3D)
max_diameter_object_model_3d (ObjectModel3D, Diameter)
```

Result

`max_diameter_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

moments_object_model_3d (: : ObjectModel3D, MomentsToCalculate : Moments)

Calculates the mean or the central moment of second order for a 3D object model.

moments_object_model_3d calculates the mean or the central moment of second order for a 3D object model. To calculate the mean of the points of the 3D object model, select *'mean_points'* in MomentsToCalculate. If instead the central moment of second order should be calculated, select *'central_moment_2_points'*. The results are the variances of the x, y, z, x-y, x-z, and y-z axes. To compute the three principal axes of the 3D object model select *'principal_axes'* in MomentsToCalculate. The result is a pose with the mean of the points as center. The coordinate system that corresponds to the pose has the x-axis along the first principal axis, the y-axis along the second principal axis and the z-axis along the third principal axis.

Parameters

▷ **ObjectModel3D** (input_control) ..... object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **MomentsToCalculate** (input_control) ..... number(-array) ⇝ *string*
Moment to calculate.
Default: 'mean_points'
List of values: MomentsToCalculate ∈ {'mean_points', 'central_moment_2_points', 'principal_axes'}

▷ **Moments** (output_control) ..... number(-array) ⇝ *real*
Calculated moment.
Number of elements: Moments == ObjectModel3D

Example

```
gen_object_model_3d_from_points (rand(200), rand(200),\
                                 rand(200), ObjectModel3D)
moments_object_model_3d (ObjectModel3D, ['mean_points',\
                         'central_moment_2_points','principal_axes'], \
                         Moments)
```

Result

moments_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

3D Metrology

select_object_model_3d (: : ObjectModel3D, Feature, Operation, MinValue, MaxValue : ObjectModel3DSelected)

Select 3D object models from an array of 3D object models according to global features.

select_object_model_3d selects 3D object models from an array of 3D object models for which the values of specified global features lie within a specified range. The list of possible features that may be specified in Feature are:

'mean_points_x': The mean x-coordinate of the points in the 3D object model.

'mean_points_y': The mean y-coordinate of the points in the 3D object model.

'mean_points_z': The mean z-coordinate of the points in the 3D object model.

'diameter_axis_aligned_bounding_box': The diameter of the set of 3D points, defined as the length of the diagonal of the smallest enclosing axis-parallel cuboid.

'diameter_bounding_box': The diameter of the set of 3D points, defined as the length of the diagonal of the smallest enclosing oriented cuboid. This feature has a high calculation complexity.

'diameter_object': The diameter of the set of 3D points, defined as the length of the distance between two points.

'volume': The volume of the triangulation of the 3D object model over the x-y plane in the coordinate origin. This corresponds to the default parametrization of volume_object_model_3d_relative_to_plane with the plane [0,0,0,0,0,0,0]. The plane con not be changed here.

'volume_axis_aligned_bounding_box': The volume of the smallest enclosing axis-parallel cuboid.

'area': The area of the triangulation of the 3D object model.

'central_moment_2_x': The x-value of the second central moment of the 3D object model.

'central_moment_2_y': The y-value of the second central moment of the 3D object model.

'central_moment_2_z': The z-value of the second central moment of the 3D object model.

'central_moment_2_xy': The xy-value of the second central moment of the 3D object model.

'central_moment_2_xz': The xz-value of the second central moment of the 3D object model.

'central_moment_2_yz': The yz-value of the second central moment of the 3D object model.

'num_points': The number of points.

'num_triangles': The number of triangles.

'num_faces': The number of faces.

'num_lines': The number of polylines.

'has_points': The existence of 3D points.

'has_point_normals': The existence of 3D point normals.

'has_triangles': The existence of triangles.

'has_faces': The existence of faces or polygons.

'has_lines': The existence of lines.

'has_xyz_mapping': The existence of a mapping of the 3D points to image coordinates.

'has_shape_based_matching_3d_data': The existence of a shape model for shape-based 3D matching.

'has_surface_based_matching_data': The existence of data for the surface-based 3D matching.

'has_segmentation_data': The existence of data for a 3D segmentation.

'has_primitive_data': The existence of a 3D primitive.

For all features listed in Feature a minimal and maximal threshold must be specified in MinValue and MaxValue. This range is then used to select all given 3D object models that fulfill the given conditions. These are copied to ObjectModel3DSelected. For logical parameters (e.g., *'has_points'*, *'has_point_normals'*, ...), MinValue and MaxValue can both be set to *'true'* to select all 3D object models that have the respective attribute or to *'false'* to select all that do not have it. MinValue and MaxValue can be set to *'min'* and *'max'* accordingly to ignore the respective threshold.

The parameter Operation defines the logical operation that is used to combine different features in Feature. It can be either a logical *'or'* or *'and'*.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handles of the available 3D object models to select.

▷ **Feature** (input_control) . . . . . string(-array) ⇝ *string*
List of features a test is performed on.
Default: 'has_triangles'
List of values: Feature ∈ {'mean_points_x', 'mean_points_y', 'mean_points_z', 'volume', 'volume_axis_aligned_bounding_box', 'central_moment_2_x', 'central_moment_2_y', 'central_moment_2_z', 'central_moment_2_xy', 'central_moment_2_xz', 'central_moment_2_yz', 'diameter_axis_aligned_bounding_box', 'diameter_bounding_box', 'diameter_object', 'area', 'has_points', 'has_triangles', 'has_faces', 'has_lines', 'has_xyz_mapping', 'has_point_normals', 'has_shape_based_matching_3d_data', 'has_surface_based_matching_data', 'has_segmentation_data', 'has_primitive_data', 'num_points', 'num_triangles', 'num_faces', 'num_lines'}

▷ **Operation** (input_control) . . . . . string ⇝ *string*
Logical operation to combine the features given in Feature.
Default: 'and'
List of values: Operation ∈ {'and', 'or'}

▷ **MinValue** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Minimum value for the given feature.
Default: 1
Suggested values: MinValue ∈ {0, 1, 100, 0.1, 'true', 'false', 'min'}

▷ **MaxValue** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Maximum value for the given feature.
Default: 1
Suggested values: MaxValue ∈ {0, 1, 10, 100, 0.1, 'true', 'false', 'max'}

▷ **ObjectModel3DSelected** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
A subset of ObjectModel3D fulfilling the given conditions.

Example

```
gen_object_model_3d_from_points (rand(20)-1.0, rand(20)-1.0,\
                                 rand(20)-1.0, ObjectModel3D1)
gen_object_model_3d_from_points (rand(20), rand(20),\
                                 rand(20), ObjectModel3D2)
select_object_model_3d ([ObjectModel3D1, ObjectModel3D2],\
                        'mean_points_x', 'and', 0, 1, ObjectModel3DSelected)
```

Result

select_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

smallest_bounding_box_object_model_3d (: : ObjectModel3D, Type : Pose, Length1, Length2, Length3)

Calculate the smallest bounding box around the points of a 3D object model.

smallest_bounding_box_object_model_3d calculates the smallest bounding box around the points of a 3D object model. The resulting bounding box is described using its coordinate system (Pose), which is oriented such that the longest side of the box is aligned with the x-axis, the second longest side is aligned with the y-axis and the smallest side is aligned with the z-axis. The lengths of the sides are returned in Length1, Length2, and Length3, in descending order. The box can be either axis-aligned or oriented, which can be chosen by the Type. The algorithm for *'oriented'* is computationally significantly more costly than the algorithm for *'axis_aligned'*, and returns only an approximation of the oriented bounding box. Note that the algorithm for the oriented bounding box is randomized and can return a different box for each call.

In order to retrieve the corners of the *'axis_aligned'* box, the operator get_object_model_3d_params can be used with the parameter *'bounding_box1'*.

Parameters

- ▷ **ObjectModel3D** (input_control) ..... object_model_3d(-array) ⇝ *handle*
  Handle of the 3D object model.
- ▷ **Type** (input_control) ..... string ⇝ *string*
  The method that is used to estimate the smallest box.
  Default: 'oriented'
  List of values: Type ∈ {'oriented', 'axis_aligned'}
- ▷ **Pose** (output_control) ..... pose(-array) ⇝ *real* / integer
  The pose that describes the position and orientation of the box that is generated. The pose has its origin in the center of the box and is oriented such that the x-axis is aligned with the longest side of the box.
- ▷ **Length1** (output_control) ..... number(-array) ⇝ *real*
  The length of the longest side of the box.
  Number of elements: Length1 == ObjectModel3D
- ▷ **Length2** (output_control) ..... number(-array) ⇝ *real*
  The length of the second longest side of the box.
  Number of elements: Length2 == ObjectModel3D
- ▷ **Length3** (output_control) ..... number(-array) ⇝ *real*
  The length of the third longest side of the box.
  Number of elements: Length3 == ObjectModel3D

Example

```
gen_object_model_3d_from_points (rand(20), rand(20), rand(20), \
                                 ObjectModel3D)
smallest_bounding_box_object_model_3d (ObjectModel3D, 'oriented', \
                                       Pose, Length1, Length2, Length3)
gen_box_object_model_3d (Pose, Length1, Length2, Length3, ObjectModel3D1)
dev_get_window (WindowHandle)
visualize_object_model_3d (WindowHandle, [ObjectModel3D,ObjectModel3D1], \
                           [], [], ['alpha_1'], [0.5], [], [], [], PoseOut)
```

Result

`smallest_bounding_box_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

`smallest_sphere_object_model_3d` `( : : ObjectModel3D : CenterPoint, Radius )`

Calculate the smallest sphere around the points of a 3D object model.

`smallest_sphere_object_model_3d` calculates the smallest sphere around the points of the 3D object model given by `ObjectModel3D`. The resulting center will be stored as x-, y-, and z-coordinates in `CenterPoint` as 3 values representing X, Y, and Z. The Radius is given in `Radius`.

Parameters

▷ **`ObjectModel3D`** (input_control) ..... object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **`CenterPoint`** (output_control) ..... number-array ⇝ *real*
x-, y-, and z-coordinates describing the center point of the sphere.
Number of elements: CenterPoint == 3 * ObjectModel3D

▷ **`Radius`** (output_control) ..... number(-array) ⇝ *real*
The estimated radius of the sphere.
Number of elements: Radius == ObjectModel3D

Example

```
gen_object_model_3d_from_points (rand(20), rand(20), rand(20),\
                                 ObjectModel3D)

smallest_bounding_box_object_model_3d

Module

3D Metrology

volume_object_model_3d_relative_to_plane (: : ObjectModel3D, Plane, Mode, UseFaceOrientation : Volume)

Calculate the volume of a 3D object model.

volume_object_model_3d_relative_to_plane calculates the volume under the faces of a 3D object model relative to a plane. The plane is defined by the x-y plane of the pose given in Plane.

For ObjectModel3D, a triangulation or a list of polygons must be available. With default settings, if the mesh is watertight and ordered, the operator calculates the actual volume of the 3D object model. To also cover cases where the mesh is not closed or the faces are not ordered consistently, the calculation of the volume can be influenced with the parameters Mode and UseFaceOrientation.

How the volume is calculated:

First, the operator calculates the volume of the prisms that are constructed by projecting each face onto the plane.

The individual volumes of the prisms can be positive or negative depending on the orientation of the face (away or towards the plane) or the location of the face (above or below the plane). This can be controlled with the parameter UseFaceOrientation.

After that, the volumes of the prisms are added up depending on the parameter Mode.

The volume returned in Volume is the absolute value of the calculated sum.

How to set the parameters:

Mode can be set to the following options:

'signed' (default) The volumes above and below the plane are added.

'unsigned' The volume below the plane is subtracted from the volume above the plane.

'positive' Only faces above the plane are taken into account.

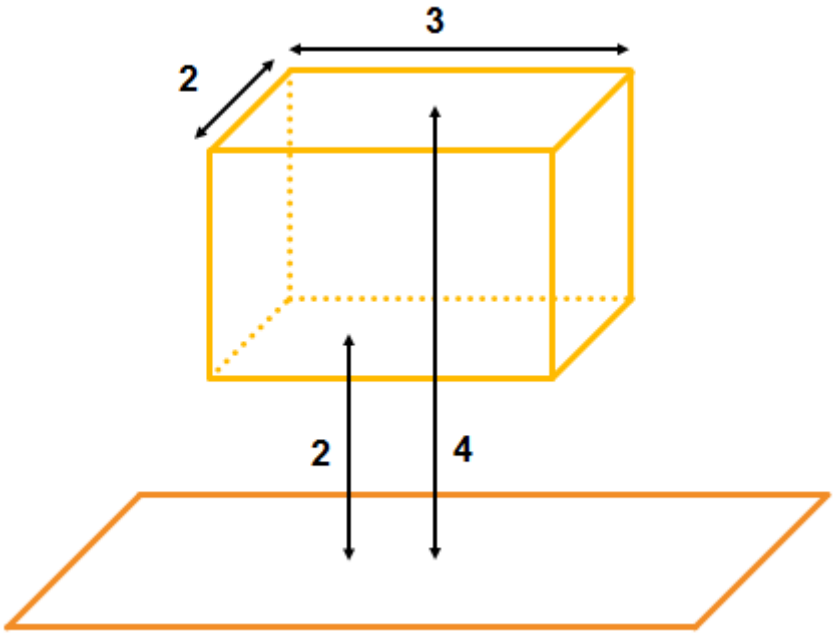
'negative' Only faces below the plane are taken into account.

UseFaceOrientation can be set to the following options:

'true' (default) Use the orientation of the faces relative to the plane. A face points away from the plane if the corner points are ordered clockwise when viewed from the plane. The volume under a face is considered **positive** if the orientation of the face is **away from the plane**. In contrast, it is considered **negative** if the orientation of the face is **towards the plane**.

'false' The volume under a face is considered **positive** if the face is located **above** the plane. In contrast, it is considered **negative** if the face is located **below** the plane.

For example, with the default combination (Mode: *'signed'*, UseFaceOrientation: *'true'*), you can approximate the real volume of a closed object. In this case, the Plane is still required, but does not change the resulting volume.



Example: (A) `Mode`: *'signed'*, `UseFaceOrientation`: *'true'*: $V = (2 * 3 * 4) + (-2 * 3 * 2) = 24 - 12 = 12$ (B) `Mode`: *'signed'*, `UseFaceOrientation`: *'false'*: $V = (2 * 3 * 4) + (2 * 3 * 2) = 24 + 12 = 36$ (C) `Mode`: *'negative'*: $V = 0$

Attention

The calculation of the volume might be numerically unstable in case of a large distance between the plane and the object (approx. distance > 10000 times the object diameter).

Parameters

- ▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
  Handle of the 3D object model.
- ▷ **`Plane`** (input_control) . . . . . pose(-array) ⇝ *real* / integer
  Pose of the plane.
  Default: [0,0,0,0,0,0,0]
- ▷ **`Mode`** (input_control) . . . . . string(-array) ⇝ *string*
  Method to combine volumes laying above and below the reference plane.
  Default: 'signed'
  List of values: `Mode` ∈ {'positive', 'negative', 'unsigned', 'signed'}
- ▷ **`UseFaceOrientation`** (input_control) . . . . . string(-array) ⇝ *string*
  Decides whether the orientation of a face should affect the resulting sign of the underlying volume.
  Default: 'true'
  List of values: `UseFaceOrientation` ∈ {'true', 'false'}
- ▷ **`Volume`** (output_control) . . . . . number(-array) ⇝ *real*
  Absolute value of the calculated volume.
  Number of elements: Volume == ObjectModel3D

Example

```
gen_box_object_model_3d ([0,0,0,0,0,0,0],3,2,1, ObjectModel3D)
convex_hull_object_model_3d (ObjectModel3D, ObjectModel3DConvexHull)
volume_object_model_3d_relative_to_plane (ObjectModel3DConvexHull,\
                                          [0,0,0,0,0,0,0], 'signed',\
                                          'true', Volume)
```

Result

`volume_object_model_3d_relative_to_plane` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

4.3 Segmentation

fit_primitives_object_model_3d (: : ObjectModel3D, GenParamName, GenParamValue : ObjectModel3DOut)

Fit 3D primitives into a set of 3D points.

The operator fit_primitives_object_model_3d fits a 3D primitive, i.e., a simple 3D shape, into a set of 3D points given by a 3D object model with the handle ObjectModel3D. The shapes that are available as 3D primitives comprise a cylinder, a sphere, and a plane. As the operator does not perform a segmentation of the set of 3D points that is contained in the input 3D object model, you have to make sure that the contained 3D points already correspond to a 3D primitive. A segmentation can be performed, e.g., with the operator segment_object_model_3d.

fit_primitives_object_model_3d returns the handle ObjectModel3DOut for the output 3D object model, which contains information that concern, e.g., the type and parameters of the fitted 3D primitive. This information can be queried from the 3D object model with get_object_model_3d_params. Note that the extent of primitives of the type plane and cylinder can be queried with get_object_model_3d_params, as well.

The parameters of a cylinder are the (x-, y-, z-)coordinates of the center, the normed (x-, y-, z-)directions of the main axis of the cylinder, and the radius of the cylinder. The center does not necessarily lie in the center of gravity of the cylinder (see the explanation of the parameters MinExtent and MaxExtent of the operator gen_cylinder_object_model_3d). The sign of the main axis is determined such that the main axis points towards the half space in which the origin is located. For a sphere the parameters are the (x-, y-, z-)coordinates of the center and the radius of the sphere. A plane is given by the 4 parameters of the hessian normal form, i.e., the unit normal (x-, y-, z-) vector and the orthogonal distance of the plane from the origin of the coordinate system. The sign of the hessian normal form is determined such that the normal vector points towards the side of the plane on which the origin is located and the distance is not positive.

If no primitive can be fitted to the set of 3D points, the returned object model will not contain a primitive. However, depending on the parameter values for *'output_point_coord'* and *'output_xyz_mapping'* (see below), the returned object model is either empty, or contains the 3D points, or contains the 3D points and the mapping from the 3D points to image coordinates of the input object model ObjectModel3D.

To control the fitting, you can adjust some generic parameters within GenParamName and GenParamValue. But note that for a lot of applications the default values are sufficient and no adjustment is necessary. The following values for GenParamName and GenParamValue are possible:

'primitive_type': The parameter specifies which type of 3D primitive should be fitted into the set of 3D points. You can specify a specific primitive type by setting *'primitive_type'* to *'cylinder'*, *'sphere'*, or *'plane'*. Then, only the selected type of 3D primitive is fitted into the set of 3D points. You can also specify a set of specific 3D primitives that should be fitted by setting *'primitive_type'* to a tuple consisting of different primitive types. If all types of 3D primitives should be fitted, you can set *'primitive_type'* to *'all'*. Note that if more than one

primitive type is selected, only the best fitting 3D primitive, i.e., the 3D primitive with the smallest quadratic residual error, is returned.

List of values: *'cylinder'*, *'sphere'*, *'plane'*, *'all'*

Default: *'cylinder'*

'fitting_algorithm': The parameter specifies the used algorithm for the fitting of the 3D primitive. When fitting a plane, the results are identical for the different algorithms. If *'fitting_algorithm'* is set to *'least_squares'*, the approach minimizes the quadratic distance between the 3D points and the resulting primitive. If *'fitting_algorithm'* is set to *'least_squares_huber'*, the approach is similar to *'least_squares'*, but the points are weighted to decrease the impact of outliers based on the approach of Huber (see below). If *'fitting_algorithm'* is set to *'least_squares_tukey'*, the approach is also similar to *'least_squares'*, but the points are weighted and outliers are ignored based on the approach of Tukey (see below).

For *'least_squares_huber'* and *'least_squares_tukey'* a robust error statistics is used to estimate the standard deviation of the distances from the object points without outliers from the fitting primitive. The Tukey algorithm removes outliers, whereas the Huber algorithm only damps them, or more precisely, weights them linearly. In practice, the approach of Tukey is recommended.

List of values: *'least_squares'*, *'least_squares_huber'*, *'least_squares_tukey'*

Default: *'least_squares'*

'min_radius': The parameter specifies the minimum radius of a cylinder or a sphere. If a cylinder or a sphere with a smaller radius is fitted, the resulting 3D object model is empty. The parameter is ignored when fitting a plane. The unit is meter.

Suggested values: *0.01*, *0.02*, *0.1*

Default: *0.01*

'max_radius': The parameter specifies the maximum radius of a cylinder or a sphere. If a cylinder or a sphere with a larger radius is fitted, the resulting 3D object model is empty. The parameter is ignored when fitting a plane. The unit is meter.

Suggested values: *0.02*, *0.04*, *0.2*

Default: *0.2*

'output_point_coord': The parameter determines if the 3D points used for the fitting are copied to the output 3D object model. If *'copy_point_coord'* is set to *'true'*, the 3D points are copied. If *'copy_point_coord'* is set to *'false'*, no 3D points are copied.

List of values: *'true'*, *'false'*

Default: *'true'*

'output_xyz_mapping': The parameter determines if a mapping from the 3D points to image coordinates is copied to the output 3D object model. This information is needed, e.g., when using the operator `object_model_3d_to_xyz` after the fitting (e.g., for a visualization). If *'output_xyz_mapping'* is set to *'true'*, the image coordinate mapping is copied. Note that the parameter is only valid, if the image coordinate mapping is available in the input 3D object model. Make sure that, if you derive the input 3D object model by copying it with the operator `copy_object_model_3d` from a 3D object model that contains such a mapping, the mapping is copied, too. Furthermore, the parameter is only valid, if the 3D points are copied to the output 3D object model, which is set with the parameter *'output_point_coord'*.

List of values: *'true'*, *'false'*

Default: *'false'*

The minimum number of 3D points that are necessary to fit a plane is three. The minimum number of 3D points that is necessary to fit a sphere is four. The minimum number of 3D points that is necessary to fit a cylinder is five.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the input 3D object model.

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Number of elements: GenParamName == GenParamValue
List of values: `GenParamName` ∈ {'primitive_type', 'fitting_algorithm', 'min_radius', 'max_radius', 'output_point_coord', 'output_xyz_mapping'}

▷ **GenParamValue** (input_control) . . . . . attribute.name-array ⇝ *string* / real / integer
Values of the generic parameters.
Number of elements: GenParamValue == GenParamName
Suggested values: GenParamValue ∈ {'cylinder', 'sphere', 'plane', 'all', 'least_squares', 'least_squares_huber', 'least_squares_tukey', 0.01, 0.05, 0.1, 0.2, 'true', 'false'}

▷ **Object3DOut** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the output 3D object model.

Result

fit_primitives_object_model_3d returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

segment_object_model_3d

Module

3D Metrology

reduce_object_model_3d_by_view (Region : : ObjectModel3D, CamParam, Pose : ObjectModel3DReduced)

Remove points from a 3D object model by projecting it to a virtual view and removing all points outside of a given region.

reduce_object_model_3d_by_view projects the points of ObjectModel3D into the image plane given by Pose and CamParam and reduces the 3D object model to the points lying inside the region given in Region. In particular, the points are first transformed with the pose and then projected using the camera parameters. Only those points that are located inside the specified region are copied to the new 3D object model.

Faces of a mesh are only contained in the output 3D object model if all corner points are within the region.

As alternative to camera parameters and a pose, an XYZ-mapping contained in ObjectModel3D can be used for the reduction. For this, CamParam must be set to *'xyz_mapping'* or an empty tuple and an empty tuple must be passed to Pose. In this case, the original image coordinates of the 3D points are used to check if a point is inside Region.

Attention

Cameras with hypercentric lenses are not supported.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Region in the image plane.

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **CamParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.
Suggested values: CamParam ∈ {'xyz_mapping', []}

▷ **Pose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
3D pose of the world coordinate system in camera coordinates.
Number of elements: Pose == 7

▷ **ObjectModel3DReduced** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the reduced 3D object model.

Example

```
gen_object_model_3d_from_points (200*(rand(100)-0.5), \
                                 200*(rand(100)-0.5), \
                                 200*(rand(100)-0.5), ObjectModel3D)
gen_circle (Circle, 240, 320, 60)
CamParam := ['area_scan_telecentric_division',1,0,1,1,320,240,640,480]
Pose := [0,0,1,0,0,0,0]
reduce_object_model_3d_by_view (Circle, ObjectModel3D, CamParam, \
                                Pose, ObjectModel3DReduced)
dev_get_window (WindowHandle)
visualize_object_model_3d (WindowHandle, [ObjectModel3D, \
                           ObjectModel3DReduced], CamParam, Pose, \
                           ['color_0', 'point_size_1'], ['blue',6], \
                           [], [], [], PoseOut)
```

Result

`reduce_object_model_3d_by_view` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

`select_points_object_model_3d`

Module

3D Metrology

segment_object_model_3d (: : ObjectModel3D, GenParamName, GenParamValue : ObjectModel3DOut)

Segment a set of 3D points into sub-sets with similar characteristics.

The operator `segment_object_model_3d` segments a set of 3D points given by a 3D object model with the handle `ObjectModel3D` into several sub-sets of neighbored 3D points with similar characteristics like the same normal orientation or curvature. By default, the operator then tries to fit a 3D primitive, i.e., a simple 3D shape like a plane, a sphere, or a cylinder, into each of these sub-sets. As result, the operator returns a tuple of handles for the 3D object models that represent the individual sub-sets of 3D points (`ObjectModel3DOut`). Within these 3D object models information is stored that concern, e.g., the success of the fitting and the type and parameters of the fitted 3D primitive. This information can be queried from the individual 3D object model with `get_object_model_3d_params`.

Before calling `segment_object_model_3d`, the input 3D object model should be prepared for the segmentation using the operator `prepare_object_model_3d` with the parameter `Purpose` set to *'segmentation'*. If the input 3D object model is not prepared this way, the operator `prepare_object_model_3d` is called internally within `segment_object_model_3d` to extend the 3D object model with attributes that were not explicitly but only implicitly contained in the 3D object model.

To control the segmentation and the fitting, you can adjust some generic parameters within GenParamName and GenParamValue. But note that for a lot of applications the default values are sufficient and no adjustment is necessary. The following values for GenParamName and GenParamValue are possible:

'max_orientation_diff': The parameter specifies the maximum angle between the point normals of two neighbored 3D points (in radians) that is allowed so that the two points belong to the same sub-set of 3D points. For a cylinder or sphere, the parameter value depends on the dimension of the object and on the distance of the neighbored 3D points. I.e., if the cylinder or sphere has a very small radius or if the 3D points are not very dense, the value must be chosen higher. For a plane the value is independent from the dimension of the object and can be set to a small value.
Suggested values: *0.10*, *0.15*, *0.20*
Default: *0.15*

'max_curvature_diff': The parameter specifies the maximum difference between the curvatures of the surface at the positions of two neighbored 3D points that is allowed so that the two points belong to the same sub-set of 3D points. The value depends on the noise of the 3D points. I.e., if the noise level of the 3D points is very high, the value must be set to a higher value. Generally, the number of resulting 3D object models decreases for a higher value, because more 3D points are merged to a sub-set of 3D points.
Suggested values: *0.03*, *0.04*, *0.05*
Default: *0.05*

'min_area': The parameter specifies the minimum number of 3D points needed for a sub-set of connected 3D points to be returned by the segmentation. Thus, for a sub-set with fewer points the points are deleted and no output handle is created.
Suggested values: *1*, *10*, *100*
Default: *100*

'fitting': The parameter specifies whether after the segmentation 3D primitives are fitted into the sub-sets of 3D points. If *'fitting'* is set to *'true'*, which is the default, the fitting is calculated and the 3D object models with the resulting handles contain the parameters of the corresponding 3D primitives. The output parameters of a cylinder, a sphere, or a plane are described with the operator fit_primitives_object_model_3d. If *'fitting'* is set to *'false'*, only a segmentation is performed and the output 3D object models contain the segmented sub-sets of 3D points. A later fitting can be performed with the operator fit_primitives_object_model_3d.
List of values: *'false'*, *'true'*
Default: *'true'*

'output_xyz_mapping': The parameter determines if a mapping from the segmented 3D points to image coordinates is copied to the output 3D object model. This information is needed, e.g., when using the operator object_model_3d_to_xyz after the segmentation (e.g., for a visualization). If *'output_xyz_mapping'* is set to *'true'*, the image coordinate mapping is copied. Note that the parameter is only valid, if the image coordinate mapping is available in the input 3D object model. Make sure that, if you derive the input 3D object model by copying it with the operator copy_object_model_3d from a 3D object model that contains such a mapping, the mapping is copied, too. Furthermore, the parameter is only valid, if the 3D points are copied to the output 3D object model, which is set with the parameter *'output_point_coord'*. If *'output_xyz_mapping'* is set to *'false'*, the image coordinate mapping is not copied.
List of values: *'true'*, *'false'*
Default: *'false'*

'primitive_type', *'fitting_algorithm'*, *'min_radius'*, *'max_radius'*, *'output_point_coord'*: These parameters are used, if *'fitting'* is set to *'true'*, which is the default. The meaning and the use of these parameters is described with the operator fit_primitives_object_model_3d.

'surface_check': The parameter determines whether the surface of a triangulated input object model is checked regarding its conformity to the expected requirements. If the input 3D object model contains triangles that are topologically invalid an error message is raised. If the triangulation was created (triangulate_object_model_3d) or edited (e.g., by simplify_object_model_3d) by a HALCON operator, a surface check should not be necessary. The check can be disabled in order to enhance the runtime by setting *'surface_check'* to *'false'*.
List of values: *'true'*, *'false'*
Default: *'true'*

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the input 3D object model.

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters.
Number of elements: GenParamName == GenParamValue
List of values: GenParamName ∈ {'max_orientation_diff', 'max_curvature_diff', 'min_area', 'primitive_type', 'fitting_algorithm', 'min_radius', 'max_radius', 'output_point_coord', 'output_xyz_mapping', 'surface_check'}

▷ **GenParamValue** (input_control) . . . . . attribute.name-array ⇝ *string* / real / integer
Values of the generic parameters.
Number of elements: GenParamValue == GenParamName
Suggested values: GenParamValue ∈ {0.15, 0.05, 100, 'true', 'false', 'cylinder', 'sphere', 'plane', 'all', 'least_squares', 'least_squares_huber', 'least_squares_tukey'}

▷ **ObjectModel3DOut** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the output 3D object model.

Result

segment_object_model_3d returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

select_points_object_model_3d (: : ObjectModel3D, Attrib, MinValue, MaxValue : ObjectModel3DThresholded)

Apply a threshold to an attribute of 3D object models.

select_points_object_model_3d selects points of the 3D object model ObjectModel3D according to the attributes and thresholds passed in Attrib, MinValue, and MaxValue respectively. The selected points are returned in the 3D object model ObjectModel3DThresholded. All attributes that are connected with the points (e.g., polygons or triangles) are adapted in such a way that there is no reference to the removed points left.

Attrib can either contain a tuple of numbers that has the same length as ObjectModel3D has points, or a list of attribute names on which the thresholds are applied.

If Attrib contains a tuple of numbers, exactly one number must be passed in both MinValue and MaxValue. All points for which the corresponding entry in Attrib is between the two thresholds are added to the output 3D object model ObjectModel3DThresholded.

Otherwise, Attrib can contain a list of attribute names that refer to properties of the 3D object model ObjectModel3D. All points, for which the value stored in the attribute Attrib is inside the interval specified in MinValue and MaxValue are stored in the output 3D object model. MinValue and MaxValue must contain exactly as many values as Attrib. If Attrib contains multiple values, only those points are stored in the output 3D object model that fulfill all the criteria.

Depending on the properties of `ObjectModel3D`, the following values are possible for `Attrib`:
The following attributes are available:

'point_coord_x': The x-coordinates of the set of 3D points.

'point_coord_y': The y-coordinates of the set of 3D points.

'point_coord_z': The z-coordinates of the set of 3D points.

'point_normal_x': The x-components of the 3D point normals of the set of 3D points.

'point_normal_y': The y-components of the 3D point normals of the set of 3D points.

'point_normal_z': The z-components of the 3D point normals of the set of 3D points.

'mapping_row': The row-components of the 2D mapping of the set of 3D points.

'mapping_col': The column-components of the 2D mapping of the set of 3D points.

'neighbor_distance':

'neighbor_distance N': The distance of the N-th nearest point. N must be a positive integer and is by default 25. For every point, all other points are sorted according to their distance and the distance of the N-th point is used.

'num_neighbors X': The number of neighbors within a distance of at most X. It can be used to remove sparsely populated parts of the 3D object model, such as outliers or points that are created by smoothing between 3D surfaces.

'num_neighbors_fast X': The approximate number of neighbors within a distance of at most X. The distances are approximated using voxels, leading to a faster processing compared to *'num_neighbors'*.

Extended attribute: Enter the name of an extended attribute of the type *'vertices'* and the selection will be applied based on the values of the extended attribute.

Parameters

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object models.

▷ **`Attrib`** (input_control) . . . . . string(-array) ⇝ *string*
Attributes the threshold is applied to.
Default: 'point_coord_z'
List of values: `Attrib` ∈ {'point_coord_x', 'point_coord_y', 'point_coord_z', 'point_normal_x', 'point_normal_y', 'point_normal_z', 'mapping_row', 'mapping_col', 'neighbor_distance', 'num_neighbors', 'num_neighbors_fast'}

▷ **`MinValue`** (input_control) . . . . . number(-array) ⇝ *real* / integer
Minimum value for the attributes specified by `Attrib`.
Default: 0.5

▷ **`MaxValue`** (input_control) . . . . . number(-array) ⇝ *real* / integer
Maximum value for the attributes specified by `Attrib`.
Default: 1.0

▷ **`ObjectModel3DThresholded`** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the reduced 3D object models.

Example

```
gen_object_model_3d_from_points (rand(100), rand(100),\
                                 rand(100), ObjectModel3D)
select_points_object_model_3d (ObjectModel3D, 'point_coord_z',\
                               0.5, 1, ObjectModel3DThresholded)
get_object_model_3d_params (ObjectModel3DThresholded, 'num_points',\
                            NumPoints)
```

Result

`select_points_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised. If the required points are missing in the object model, i.e., an empty object model is passed, the error 9515 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

4.4 Transformations

affine_trans_object_model_3d (: : ObjectModel3D, HomMat3D : ObjectModel3DAffineTrans)

Apply an arbitrary affine 3D transformation to 3D object models.

affine_trans_object_model_3d applies arbitrary affine 3D transformations, i.e., scaling, rotation, and translation, to 3D object models and returns the handles of the transformed 3D object models. The affine transformations are described by the homogeneous transformation matrices given in HomMat3D.

The transformation matrices can be created using the operators hom_mat3d_identity, hom_mat3d_scale, hom_mat3d_rotate, hom_mat3d_translate, etc., or it can be the result of pose_to_hom_mat3d (see affine_trans_point_3d).

In general, the operator affine_trans_object_model_3d is not necessary in the context of shape based 3D matching. Instead, if a rotation of the 3D object model into a reference orientation should be performed, appropriate values for the parameters RefRotX, RefRotY, RefRotZ, and OrderOfRotation should be passed to the operator create_shape_model_3d.

affine_trans_object_model_3d transforms one or more 3D object models with the same transformation matrix if only one transformation matrix is passed in HomMat3D (N:1). If a single 3D object model is passed in ObjectModel3D, it is transformed with all passed transformation matrices (1:N). If the number of transformation matrices corresponds to the number of 3D object models, every 3D object model is transformed individually with the respective transformation matrix (N:N). In those cases, N can be zero, i.e., no matrix or no 3D object model can be passed to the operator. In this case, an empty tuple is returned in ObjectModel3DAffineTrans. This can be used to, for example, transform the results of other operators without checking first if at least one matrix was returned.

Attention

affine_trans_object_model_3d transforms the attributes of type 3D points, 3D point normals, and the prepared shape model for shape-based 3D matching. Primitives and precomputed data structures for 3D distance computation are not copied. All other attributes are copied without modification. To transform 3D primitives, the operator rigid_trans_object_model_3d must be used.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handles of the 3D object models.

▷ **HomMat3D** (input_control) . . . . . hom_mat3d(-array) ⇝ *real*
Transformation matrices.

▷ **ObjectModel3DAffineTrans** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handles of the transformed 3D object models.

Result

affine_trans_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

connection_object_model_3d (: : ObjectModel3D, Feature, Value : ObjectModel3DConnected)

Determine the connected components of the 3D object model.

connection_object_model_3d determines the connected components of the input 3D object model given in ObjectModel3D. The decision if two parts of the 3D object model are connected can be based on different attributes and respective distance functions. The attribute and distance function can be selected in Feature:

'distance_3d': The euclidean distance between the point coordinates of the set of the 3D points are tested. For any distance below Value the points are considered as connected.

'angle': The angles between the normals of the points in the 3D object model are compared. Similar normals are considered as connected if their angular distance is below Value. Value is specified in radians and should be between 0 and pi.

Prerequisite: The 3D object model must contain normals, which can be computed with surface_normals_object_model_3d.

'distance_mapping': The mapping measures the distance between the pixel coordinates of points in the 3D object model that are stored in the 2D mapping. Use a value larger than 1.5 for Value to get a connection in an 8-neighborhood in the image.

Prerequisite: The 3D object model must contain a 2D mapping, which is available if the 3D object model has been created with xyz_to_object_model_3d.

'mesh': Returns parts of the 3D object model that are connected with triangles or polygons. Value is ignored.

Prerequisite: The 3D object model must provide a triangulation, which can be obtained with triangulate_object_model_3d. Alternatively, if the 3D object model already contains a 2D mapping, prepare_object_model_3d can be used with Purpose set to *'segmentation'* to quickly triangulate the 3D object model.

'lines': Returns parts of the object model that are connected by lines. Value is ignored.

Prerequisite: The 3D object model must contain polylines, which can be computed with intersect_plane_object_model_3d.

Alternatively, the required attributes can be set manually with set_object_model_3d_attrib or set_object_model_3d_attrib_mod. Note that the 3D object model might already contain the required attribute, especially if the 3D object model has been read with read_object_model_3d or if it has been deserialized with deserialize_object_model_3d. To check whether the required attribute is available, use get_object_model_3d_params.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **Feature** (input_control) . . . . . string(-array) ⇝ *string*
Attribute used to calculate the connected components.
Default: 'distance_3d'
List of values: Feature ∈ {'distance_3d', 'angle', 'distance_mapping', 'mesh', 'lines'}

▷ **Value** (input_control) . . . . . number(-array) ⇝ *real* / integer
Maximum value for the distance between two connected components.
Default: 1.0
Suggested values: Value ∈ {1.0, 1.1, 1.5, 10.0, 100.0}

▷ **ObjectModel3DConnected** (output_control) . . . . . object_model_3d-array ⇝ *handle*
Handle of the 3D object models that represent the connected components.

Example

```
gen_object_model_3d_from_points (rand(100), rand(100),\
                                 rand(100), ObjectModel3D)
connection_object_model_3d (ObjectModel3D, 'distance_3d', 0.2,\
                            ObjectModel3DConnected)
dev_get_window (WindowHandle)
visualize_object_model_3d (WindowHandle, [ObjectModel3DConnected], [], [],\
                           ['colored'], [12], [], [], [], PoseOut)
```

Result

connection_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

convex_hull_object_model_3d (: : ObjectModel3D : ObjectModel3DConvexHull)

Calculate the convex hull of a 3D object model.

convex_hull_object_model_3d calculates the convex hull of the 3D object model given in ObjectModel3D. The operator returns the convex hull as a 3D object model with the handle ObjectModel3DConvexHull.

If one of the dimensions of the input points has no deviation at all, the result will consist of lines and not triangles.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **ObjectModel3DConvexHull** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model that describes the convex hull.
Number of elements: ObjectModel3DConvexHull == ObjectModel3D

Example

```
gen_object_model_3d_from_points (rand(20)-0.5, rand(20)-0.5,\
                                 rand(20)-0.5, ObjectModel3D)
```

```
convex_hull_object_model_3d (ObjectModel3D, ObjectModel3DConvexHull)
dev_get_window (WindowHandle)
visualize_object_model_3d (WindowHandle, [ObjectModel3DConvexHull], \
                           [], [], [], [], [], [], [], PoseOut)
```

Result

`convex_hull_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

`edges_object_model_3d` (: : `ObjectModel3D`, `MinAmplitude`, `GenParamName`, `GenParamValue` : `ObjectModel3DEdges`)

Find edges in a 3D object model.

`edges_object_model_3d` finds 3D edges in the 3D object model `ObjectModel3D` and returns them in the 3D object model `ObjectModel3DEdges`.

The operator supports edge extraction only from 3D object models that contain a XYZ mapping, such as models that were created with `xyz_to_object_model_3d` or that were obtained with a sensor that delivers the mapping. `MinAmplitude` defines the minimum amplitude of a discontinuity in order to be classified as an edge. It is given in the same unit as used in `ObjectModel3D`.

The extracted edges are a subset of the points of the input object model. In addition to the coordinates of the edges, the point normal vectors in `ObjectModel3DEdges` contain the viewing direction of each 3D edge point from the viewpoint towards the edge point. Also, the attributes *'edge_dir_x'*, *'edge_dir_y'* and *'edge_dir_z'* contain a vector that is perpendicular to the edge direction and to the viewing direction. The attributes are set such that the 3D object model can be used for edge-supported surface-based matching in `find_surface_model`.

Generic parameters can optionally be used to influence the edge extraction. If desired, these parameters and their corresponding values can be specified with `GenParamName` and `GenParamValue`. The following values for `GenParamName` are possible:

'max_gap': This parameter specifies the maximum gap size in pixels in the XYZ-images that are closed. Gaps larger than this value will contain edges at their boundary, while gaps smaller than this value will not. This suppresses edges around smaller patches that were not reconstructed by the sensor as well as edges at the more distant part of a discontinuity. For sensors with very large resolutions, the value should be increased to avoid spurious edges.

Default: *30*.

'estimate_viewpose': This parameter can be used to turn off the automatic viewpose estimation and set a manual viewpoint.

Default: *'true'*.

'viewpoint': This parameter only has an effect when *'estimate_viewpose'* is set to *'false'*. It specifies the viewpoint from which the 3D data is seen. It is used to determine the viewing directions and edge directions. It defaults to the origin *'0 0 0'* of the 3D data. If the projection center is at a different location, for example, if the 3D

object model was transformed with rigid_trans_object_model_3d or if the 3D sensor performed a similar transformation, the original viewpoint must be set. For this, GenParamValue must contain a string consisting of the three coordinates (x, y and z) of the viewpoint, separated by spaces. The viewpoint is defined in the same coordinate frame as ObjectModel3D. Note that for use of this parameter, the values in the X-, Y-, and Z- images obtained from object_model_3d_to_xyz must have increasing values from left to right, top to bottom, and for object parts further away from the camera, respectively.
Default: *'0 0 0'*.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model whose edges should be computed.

▷ **MinAmplitude** (input_control) . . . . . number ⇝ *real* / integer
Edge threshold.

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'max_gap', 'estimate_viewpose', 'viewpoint'}

▷ **GenParamValue** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Values of the generic parameters.
Default: []
Suggested values: GenParamValue ∈ {'0 0 0', 10, 30, 100, 'true', 'false'}

▷ **ObjectModel3DEdges** (output_control) . . . . . object_model_3d ⇝ *handle*
3D object model containing the edges.

Result

edges_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

fuse_object_model_3d (: : ObjectModel3D, BoundingBox, Resolution, SurfaceTolerance, MinThickness, Smoothing, NormalDirection, GenParamName, GenParamValue : ObjectModel3DFusion)

Fuse 3D object models into a surface.

fuse_object_model_3d fuses multiple point clouds representing an object surface into a watertight surface ObjectModel3DFusion. The operator can be used to simplify the postprocessing step of point clouds that are already registered in the same coordinate system. In particular, unification, suppression of outliers, trade-off between smoothing and preservation of edges, equidistant sub-sampling, hole filling, and meshing of the output surface can often be handled nicely and in high quality. On the other hand, these advantages come at the price of a high runtime.

If you want to fuse 3D point clouds acquired by stereo reconstruction, you should use reconstruct_surface_stereo instead of fuse_object_model_3d.

Workflow

1. Acquire point clouds and transform them into a common coordinate system, for example using register_object_model_3d_pair and register_object_model_3d_global.
2. If not already available, compute triangles or point normals for the point clouds using triangulate_object_model_3d or surface_normals_object_model_3d. A triangulation is more suitable if you have surfaces with many outliers or holes that should be closed. Otherwise, for clean surfaces, you can work with normals.
3. Inspect the normals of the input models using visualize_object_model_3d with GenParamName *'disp_normals'* or dev_inspect_ctrl. The point or triangle normals have to be oriented consistently towards the inside or outside of the object. Set NormalDirection accordingly to *'inwards'* or *'outwards'*.
4. Specify the volume of interest in BoundingBox. To obtain a first guess for BoundingBox, use get_object_model_3d_params with GenParamName set to *'bounding_box1'*.
5. Specify an initial set of parameters: a rough Resolution (e.g., 1/100 of the diameter of the BoundingBox), SurfaceTolerance at least a bit larger (e.g., 5*Resolution), MinThickness as the minimum thickness of the object (if the input point clouds represent the object only from one side, set it very high, so that the object is cut off at the BoundingBox), Smoothing set to *1.0*.
6. Apply fuse_object_model_3d and readjust the parameters to improve the results with respect to quality and runtime, see below. Use a Resolution just fine enough to make out the details of your object while tuning the other parameters, in order to avoid long runtimes. Also consider using the additional parameters in GenParamName.

Parameter Description

See the HDevelop example fuse_object_model_3d_workflow for an explanation how to fine-tune the parameters for your application.

The input point clouds ObjectModel3D have to lie in a common coordinate system and add up to the initial surface. Furthermore, they must contain triangles or point normals. If both attributes are present, normals are used as a default due to speed advantages. If triangles should be used, use copy_object_model_3d to obtain only point and triangle information. Surfaces with many outliers or holes to be closed should be used with a triangulation, clean surfaces with normals. The point or triangle normals have to be oriented consistently towards the inside or outside of the object.

NormalDirection is used to specify whether the point or triangle normals point *'inwards'* or *'outwards'*. If only one value is specified, it is applied to all input models. Otherwise, the number of values has to equal the number of input models.

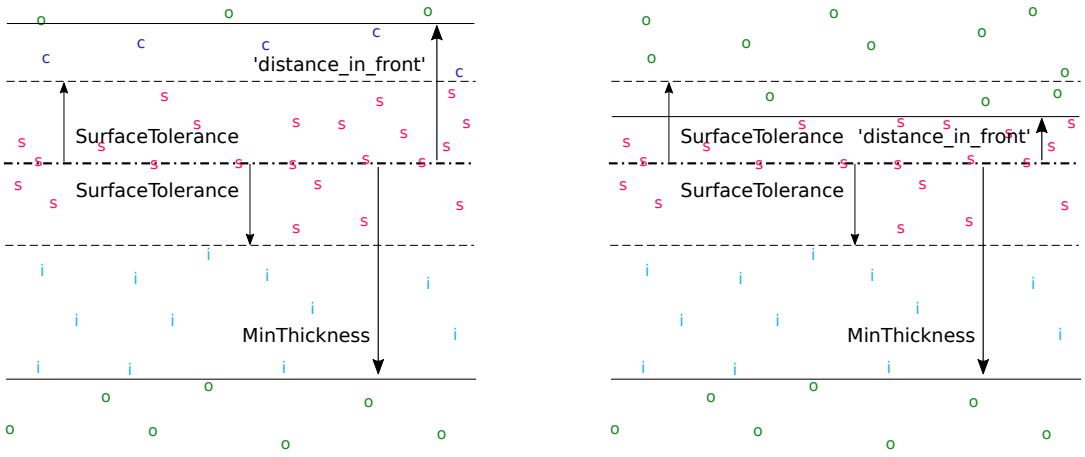
BoundingBox specifies the volume of interest to be taken into account for input and output. Note that points outside the bounding box are discarded. Triangles of the input point cloud with a point outside the BoundingBox are discarded, not clipped. The BoundingBox is specified as a tuple [x1,y1,z1,x2,y2,z2] assigning two opposite corner points P1=[x1,y1,z1] and P2=[x2,y2,z2] of the rectangular cuboid (with edges parallel to the coordinate axes). For a valid bounding box, P1 must be the point on the front lower left corner and P2 on the back upper right corner of the bounding box, i.e., x1<x2, y1<y2 and z1<z2. Note that the operator will try to produce a closed surface. If the input point clouds represent the object from only one point of view, one wants the bounding box usually to cut off the unknown part, wherefore MinThickness should be set e.g., to a value larger than or equal to the length of the diagonal of the bounding box (which can be obtained by using get_object_model_3d_params with the parameter *'diameter_axis_aligned_bounding_box'*). An object cut off by a surface of the bounding box has no points at this specific surface, thus has a hole. Note also that you may have to rotate the input point clouds in order make the bounding box cut off the unknown part in the right place, since the edges of the bounding box are always parallel to the coordinate axes. This can be achieved e.g., using affine_trans_object_model_3d or rigid_trans_object_model_3d.

Resolution specifies the distance of neighboring grid points in each coordinate direction in the discretization of the BoundingBox. Resolution is set in the same unit as used in ObjectModel3D. Too small values will unnecessarily increase the runtime, so it is recommended to begin with a coarse resolution. Too large values will lead to a reconstruction with high loss of details. Smoothing may need to be adapted when Resolution is changed. Resolution should always be a bit smaller than SurfaceTolerance in order to avoid discretization artifacts.

SurfaceTolerance specifies how much noise in the input point cloud should be combined to the surface from its inside and outside. Sole exemption when SurfaceTolerance is larger than *'distance_in_front'*, in that case *'distance_in_front'* determines the surface thickness to the front of the object. SurfaceTolerance is set in the same unit as used in ObjectModel3D. Points in the interior of the object as specified by NormalDirection

(and also GenParamName='angle_threshold') are considered surely inside the object if their distance to the initial surface exceeds SurfaceTolerance but is smaller than MinThickness. SurfaceTolerance always has to be smaller than MinThickness. SurfaceTolerance should always be a bit larger than Resolution in order to avoid discretization artifacts.

MinThickness specifies the thickness of the object in normal direction of the initial surfaces. MinThickness is set in the same unit as used in ObjectModel3D. Points which are specified by NormalDirection (and also GenParamName='angle_threshold') to be in the interior of the object are only considered as being inside if their distance to the initial surface does not exceed MinThickness. Note that this can lead to a hollow part of the object. MinThickness always has to be larger than SurfaceTolerance. For point clouds representing the object from different sides, MinThickness is best set as the thickness of the objects narrowest part. Note that the operator will try to produce a closed surface. If the input point clouds represent the object only from one side, this parameter should be set very large, so that the object is cut off at the bounding box. The backside of the objects is not observed and thus its reconstruction will probably be incorrect. If you observe several distinct objects from only one side, you may want to reduce the parameter MinThickness to restrict the depth of reconstructed objects and thus keep them from being smudged into one surface. Too small values can result in holes or double walls in the fused point cloud. Too large values can result in a distorted point cloud or blow up the surface towards the outside of the object (if the surface is blown up beyond the bounding box, no points will be returned).



(1) (2)

Schematic view of the parameters SurfaceTolerance, MinThickness and the value *'distance_in_front'* with the aid of an example surface (_.): o are points taken as outside, s are points of the surface, i are points surely inside the object, c are points also considered for the evaluation of the surface. (1): *'distance_in_front'* smaller than SurfaceTolerance (2): *'distance_in_front'* larger than SurfaceTolerance.

Smoothing determines how important a small total variation of the distance function is compared to data fidelity. Thus, Smoothing regulates the 'jumpiness' of the resulting surface. Note that the actual value of Smoothing for a given data to result in an appropriate and visually pleasing surface has to be found by trial and error. Too small values lead to integrating many outliers into the surface even if the surface then exhibits many jumps. Too large values lead to lost fidelity towards the input point clouds (how the algorithm views distances to the input point clouds depends heavily on SurfaceTolerance and MinThickness). Smoothing may need to be adapted when Resolution is changed.

By setting GenParamName to the following values, the additional parameters can be set with GenParamValue:

'distance_in_front' Points in the exterior of the object as specified by NormalDirection (and also GenParamName='angle_threshold') are only considered as part of the object if their distance to the initial surface does not exceed *'distance_in_front'*. This is the outside analogous to MinThickness of the interior, except that *'distance_in_front'* does not have to be larger than SurfaceTolerance. In case *'distance_in_front'* is smaller than SurfaceTolerance it determines the surface thickness to the front. This parameter is useful if holes in the surface should be closed along a jump in the surface (for example along the viewing direction of the sensor). In this case, *'distance_in_front'* can be set to a small value in order to avoid a wrong initialization of the distance field. *'distance_in_front'* is set in the same unit as used in ObjectModel3D. *'distance_in_front'* should always be a bit larger than Resolution in order to avoid discretization artifacts. Per default, *'distance_in_front'* is set to a value larger than the bounding box diameter, therewith all points outside of the object in the bounding box are considered.

Suggested values: *0.001*, *0.1*, *1*, *10*.

Default: Larger than the bounding box diameter.

Restriction: *'distance_in_front'* > 0

'angle_threshold' specifies the angle of a cone around a surface normal. *'angle_threshold'* is set in [rad]. When determining the distance information for data fidelity, only points are considered lying in such a cone starting at their closest surface point. For example, if distances to triangles are considered, *'angle_threshold'* can be set to *0.0*, so that only the volume directly above the triangle is considered (thus a right prism). If point normals are used and thus distances to normals are considered, *'angle_threshold'* has to be set to a higher value. When outliers disrupt the result, decreasing *'angle_threshold'* may help. If holes in the surface should be closed along a jump in the surface (for example along the viewing direction of the sensor), enlarging *'angle_threshold'* may help.

Suggested values: *'rad(0.0)'*, *'rad(10.0)'*, *'rad(30.0)'*.

Default: *'rad(10.0)'*.

Restriction: *'angle_threshold'* >= 0

'point_meshing' determines whether the output points should be triangulated with the algorithm 'marching tetrahedra', which can be activated by setting *'point_meshing'* to *'isosurface'*. Note that there are more points in `ObjectModel3DFusion` if meshing of the isosurface is enabled even if the used `Resolution` is the same.

List of values: *'none'*, *'isosurface'*.

Default: *'isosurface'*.

Fusion algorithm

The algorithm will produce a watertight, closed surface (which is maybe cut off at the `BoundingBox`). The goal is to obtain a preferably smooth surface while keeping form fidelity. To this end, the bounding box is sampled and each sample point is assigned an initial distance to a so-called isosurface (consisting of points with distance 0). The final distance values (and thus the isosurface) are obtained by minimizing an error function based on fidelity to the initial point clouds on the one hand and total variation ('jumpiness') of the distance function on the other hand. This leads to a fusion of the input point clouds (see paper in References below).

The calculation of the isosurface can be influenced with the parameters of the operator. The distance between sample points in the bounding box (in each coordinate direction) can be set with the parameter `Resolution`.

Fidelity to the initial point clouds is grasped as the signed distances of sample points, lying on the grid, in the bounding box to their nearest neighbors (points or triangles) on the input point clouds. Whether a sample point in the bounding box is considered to lie outside or inside the object (the sign of the distance) is determined by the normal of its nearest neighbor on the initial surface and the set `NormalDirection`. To determine if a sample point is surely inside or outside the object with respect to an input point cloud, the distance to its nearest neighbor on the initial surface is determined. A point on the inside is considered surely inside if the distance exceeds `SurfaceTolerance` but not `MinThickness`, while a point on the outside counts as exteriorly if the distance exceeds *'distance_in_front'*.

Fidelity to the initial point clouds is only considered for those sample points lying within `MinThickness` inside or within `GenParamName` *'distance_in_front'* outside the initial surface.

Furthermore, fidelity is not maintained for a given sample point lying outside a cone around `GenParamName` *'angle_threshold'*. Thus it is not maintained if the line from the sample point to its nearest neighbor on the initial surface differs from the surface normal of the nearest neighbor by an angle more than `GenParamName` *'angle_threshold'*. Note that the distances to nearest neighboring triangles will often yield more satisfying results while distances to nearest points can be calculated much faster.

The subsequent optimization of the distance values is the same as the one used in `reconstruct_surface_stereo` with `Method`=*'surface_fusion'*.

The parameter `Smoothing` regulates the 'jumpiness' of the distance function by weighing the two terms in the error function: Fidelity to the initial point clouds on the one hand, total variation of the distance function on the other hand. Note that the actual value of `Smoothing` for a given data set to be visually pleasing has to be found by trial and error.

Each 3D point of the object model returned in `ObjectModel3DFusion` is extracted from the isosurface where the distance function equals zero. Its normal vector is calculated from the gradient of the distance function. The so-obtained point cloud can also be meshed using the algorithm 'marching tetrahedra' by setting the `GenParamName` *'point_meshing'* to the `GenParamValue` *'isosurface'*.

Troubleshooting

Please follow the workflow above. If the results are not satisfactory, please consult the following hints and ideas:

Quality of the input point clouds The input point clouds should represent the entire object surface. If point normals are used, the points should be dense on the entire surface, not only along edges of the object. In particular, for CAD-data typically triangulation has to be used.

Used attribute Using triangles instead of point normals will typically yield results of higher quality. If both attributes are present, point normals are used per default. If triangles should be used, use `copy_object_model_3d` to obtain only point and triangle information.

Outliers If outliers of the input models disturb the output surface even for high values of `Smoothing`, try to decrease `GenParamName` *'angle_threshold'*. If wanted, outliers of the input models can also be removed, for example using `connection_object_model_3d`. With reduced influence also modifying `GenParamName` *'distance_in_front'* may help to reduce certain outliers.

Closing of holes If holes in the surface are not closed even for high values of `Smoothing` (for example a jump in the surface along the viewing direction of the sensor), try to decrease `GenParamName` *'distance_in_front'*. Enlarging `GenParamName` *'angle_threshold'* may help the algorithm to close the gap. Note that `triangulate_object_model_3d` can close gaps when triangulating sensor data which contains a 2D mapping.

Empty output If the output contains no point, try to decrease `Smoothing`. If there is no output even for very low values of `Smoothing`, you may want to check if `MinThickness` is set too large and if the set `NormalDirection` is correct.

Runtime

In order to improve the runtime, consider the following hints:

Extent of the bounding box The bounding box should be tight around the volume of interest. Else, the runtime will increase drastically but without any benefit.

Resolution Enlarging the parameter `Resolution` will speed up the execution considerably.

Used attribute Using point normals instead of triangles will speed up the execution. If both, normals and triangles, are present in the input models, normals are used per default.

Density of input point clouds The input point clouds can be thinned out using `sample_object_model_3d` (if normals are used) or `simplify_object_model_3d` with `GenParamName` *'avoid_triangle_flips'* set to *'true'* (if triangles are used).

Distances to surface Make sure that `MinThickness` and `GenParamName` *'distance_in_front'* are not set unnecessarily large, since this can slow down the preparation and distance computation.

Parameters

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handles of the 3D object models.

▷ **`BoundingBox`** (input_control) . . . . . number-array ⇝ *real* / integer
The two opposite bound box corners.

▷ **`Resolution`** (input_control) . . . . . number ⇝ *real* / integer
Used resolution within the bounding box.
Default: 1.0
Suggested values: `Resolution` ∈ {1.0, 1.1, 1.5, 10.0, 100.0}

▷ **`SurfaceTolerance`** (input_control) . . . . . number ⇝ *real* / integer
Distance of expected noise to surface.
Default: 1.0
Suggested values: `SurfaceTolerance` ∈ {1.0, 1.1, 1.5, 10.0, 100.0}

▷ **`MinThickness`** (input_control) . . . . . number ⇝ *real* / integer
Minimum thickness of the object in direction of the surface normal.
Default: 1.0
Suggested values: `MinThickness` ∈ {1.0, 1.1, 1.5, 10.0, 100.0}

▷ **`Smoothing`** (input_control) . . . . . number ⇝ *real* / integer
Weight factor for data fidelity.
Default: 1.0
Suggested values: `Smoothing` ∈ {1.0, 1.1, 1.5, 10.0, 100.0}

▷ **NormalDirection** (input_control) ..... string(-array) ⇝ *string*
Direction of normals of the input models.
Default: 'inwards'
List of values: NormalDirection ∈ {'inwards', 'outwards'}

▷ **GenParamName** (input_control) ..... attribute.name-array ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'point_meshing', 'angle_threshold', 'distance_in_front'}

▷ **GenParamValue** (input_control) ..... attribute.value-array ⇝ *string* / real / integer
Value of the generic parameter.
Default: []
Suggested values: GenParamValue ∈ {'isosurface', 'none', 0.0, 0.1, 0.175, 0.524}

▷ **ObjectModel3DFusion** (output_control) ..... object_model_3d ⇝ *handle*
Handle of the fused 3D object model.

Result

fuse_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

3D Metrology

intersect_plane_object_model_3d (: : ObjectModel3D, Plane : ObjectModel3DIntersection)

Intersect a 3D object model with a plane.

intersect_plane_object_model_3d intersects a 3D object model with a plane that is defined by the x-y plane of the pose that is specified with the parameter Plane. The z-axis of the pose corresponds to the normal of the plane.

The result is a set of 3D points connected by lines that is returned as 3D object model in ObjectModel3DIntersection. Every triangle that intersects with the plane creates two intersection points and a line between the two points. The resulting set of lines is coplanar.

The lines can be displayed with disp_object_model_3d and queried with get_object_model_3d_params using the parameter *'lines'*.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* (*7* for `Plane`) or *N* (*N*7* for `Plane`). Parameters with tuple length *1* (*7* for `Plane`) will be repeated internally such that the number of computed output models is always *N*.

Parameters

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **`Plane`** (input_control) . . . . . pose(-array) ⇝ *real* / integer
Pose of the plane.
Default: [0,0,0,0,0,0,0]

▷ **`ObjectModel3DIntersection`** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model that describes the intersection as a set of lines.

Example

```
gen_object_model_3d_from_points (rand(20)-0.5, rand(20)-0.5,\
                                 rand(20)-0.5, ObjectModel3D)
convex_hull_object_model_3d (ObjectModel3D, ObjectModel3DConvexHull)
intersect_plane_object_model_3d (ObjectModel3DConvexHull, [0,0,0,0,0,0,0], \
                                 ObjectModel3DIntersection)
dev_get_window (WindowHandle)
visualize_object_model_3d (WindowHandle, [ObjectModel3DIntersection, \
                           ObjectModel3DConvexHull], [], [], \
                           ['alpha_1'], [0.5], [], [], [], PoseOut)
```

Result

`intersect_plane_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

3D Metrology

`object_model_3d_to_xyz` (: X, Y, Z : ObjectModel3D, Type, CamParam, Pose :)

Transform 3D points from a 3D object model to images.

The operator `object_model_3d_to_xyz` transforms the 3D points of the 3D object model `ObjectModel3D` into the three images `X`, `Y`, and `Z`.

Three transformation modes are possible. The parameter `Type` is used to select one of them. Note that multiple 3D object models can be passed in `ObjectModel3D` only for the mode *'cartesian_faces'*. All other modes expect a single 3D object model.

'cartesian': First, each point is transformed into the camera coordinate system using the given `Pose`. Then, these coordinates are projected into the image coordinate system based on the internal camera parameters `CamParam`.

The internal camera parameters `CamParam` describe the projection characteristics of the camera (see Calibration). The `Pose` is in the form ${}^{ccs}\mathbf{P}_{mcs}$, where *ccs* denotes camera coordinate system and *mcs* the model coordinate system (which is a 3D world coordinate system), see Transformations / Poses and "`Solution Guide III-C - 3D Vision`". Hence, it describes the position and orientation of the model coordinate system relative to the camera coordinate system.

The X-, Y-, and Z-coordinates of the transformed point are written into the corresponding image at the position of the projection. If multiple points are projected to the same image coordinates, the point with the smallest Z-value is written (hidden-point removal). The dimensions of the returned images are defined by the camera parameters.

The returned images show the object as it would look like when seeing it with the specified camera under the specified pose.

'cartesian_faces': In order to use this transformation, the input 3D object models need to contain faces (triangles or polygons), otherwise, the 3D object model without faces is disregarded. Note that if the 3D object models have polygon faces, those are converted internally to triangles. This conversion can be done beforehand to speed up this operator. For this, `read_object_model_3d` can be called with the `GenParamName` *'convert_to_triangles'* set to *'true'*, to convert all faces to triangles. Alternatively, `triangulate_object_model_3d` can be called prior to this operator.

First, each face of the 3D object models `ObjectModel3D` is transformed into the camera coordinate system using the given `Pose`. Then, these coordinates are projected into the image coordinate system based on the internal camera parameters `CamParam`, while keeping the 3D information (X-, Y-, and Z-coordinates) for each of those pixels. For a more detailed explanation of `CamParam` and `Pose` please refer to the section *'cartesian'*. If multiple faces are projected to the same image coordinates, the value with the smallest Z-value is written (hidden-point removal). The dimensions of the returned images are defined by the camera parameters.

The returned images show the objects as they would look like when seeing them with the specified camera under the specified pose.

In case that OpenGL 2.1, GLSL 1.2, and the OpenGL extensions GL_EXT_framebuffer_object and GL_EXT_framebuffer_blit are available, speed increases.

This `Type` can be used to create 3D object models containing 2D mapping data, by creating a 3D object model from the returned images using `xyz_to_object_model_3d`. Note that in many cases, it is recommended to use the 2D mapping data, if available, for speed and robustness reasons. This is beneficial for example when using `sample_object_model_3d`, `surface_normals_object_model_3d`, or when preparing a 3D object model for surface-based matching, e.g., smoothing, removing outliers, and reducing the domain.

'cartesian_faces_no_opengl': This transformation mode works in the same way as the method *'cartesian_faces'* but does not use OpenGL. In general, *'cartesian_faces'* automatically determines if OpenGL is available. Thus, it is usually not required to use *'cartesian_faces_no_opengl'* explicitly. It can make sense, however, to use it in cases where the automatic mode selection does not work due to, for example, driver issues with OpenGL.

'from_xyz_map': This transformation mode works only if the 3D object model was created with the operator `xyz_to_object_model_3d`. It writes each 3D point to the image coordinate where it originally came from, using the mapping attribute that is stored within the 3D object model.

The parameters `CamParam` and `Pose` are ignored. The dimensions of the returned images are equal to the dimensions of the original images that were used with `xyz_to_object_model_3d` to create the 3D object model and can be queried from `get_object_model_3d_params` with *'mapping_size'*.

This transformation mode is faster than *'cartesian'*. It is suitable, e.g., to visualize the results of a segmentation done with `segment_object_model_3d`.

Attention

Cameras with hypercentric lenses are not supported. For displaying large faces with a non-zero distortion in `CamParam`, note that the distortion is only applied to the points of the model. In the projection, these points are subsequently connected by straight lines. For a good approximation of the distorted lines, please use a triangulation with sufficiently small triangles.

Parameters

▷ **X** (output_object) . . . . . singlechannelimage ⇝ *object :* real
Image with the X-Coordinates of the 3D points.

▷ **Y** (output_object) . . . . . singlechannelimage ⇝ *object :* real
Image with the Y-Coordinates of the 3D points.

▷ **Z** (output_object) . . . . . singlechannelimage ⇝ *object :* real
Image with the Z-Coordinates of the 3D points.

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **Type** (input_control) . . . . . string ⇝ *string*
Type of the conversion.
Default: 'cartesian'
List of values: `Type` ∈ {'cartesian', 'cartesian_faces', 'from_xyz_map', 'cartesian_faces_no_opengl'}

▷ **CamParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Camera parameters.

▷ **Pose** (input_control) . . . . . pose ⇝ *real* / integer
Pose of the 3D object model.
Number of elements: Pose == 0 || Pose == 7 || Pose == 12

Result

The operator `object_model_3d_to_xyz` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

3D Metrology

prepare_object_model_3d (: : ObjectModel3D, Purpose, OverwriteData, GenParamName, GenParamValue :)

Prepare a 3D object model for a certain operation.

The operator `prepare_object_model_3d` prepares the 3D object model `ObjectModel3D` for a following operation given in `Purpose`. It computes values required for the operation and stores them in `ObjectModel3D`, thus speeding up the following operation. It is not necessary to call `prepare_object_model_3d`. However, if the 3D object model is to be used multiple times for the same operation, it can be faster to do so.

The following values are possible for `Purpose`:

'shape_based_matching_3d': The 3D object model is prepared to be used in `create_shape_model_3d`. For this, there are no generic parameters to set.

'segmentation': The 3D object model is prepared to be used in `segment_object_model_3d`. For the preparation the 3D object model must have an attribute with the face triangles and an attribute with the 3D point coordinates.

If the 3D object model has no attribute with the face triangles, a simple triangulation is performed (even if `OverwriteData` is set to *'false'*). For this, the 3D object model must have an attribute with the 3D point

coordinates and an attribute with the mapping from the point coordinates to image coordinates. Only points originating from neighboring pixels are triangulated. Additionally, holes in the image region can be filled with a Delaunay triangulation (see *'max_area_holes'* below). Only holes which are completely surrounded by the image region are closed.

'distance_computation': The 3D object model is prepared to be used in `distance_object_model_3d`.

'gen_xyz_mapping': The XYZ-mapping information of a 3D object model containing an ordered point cloud is computed, i.e. image coordinates are assigned for each 3D point. For this, either the generic parameter *'xyz_map_width'* or *'xyz_map_height'* must be set, to indicate whether the point cloud is ordered row-wise or column-wise and define the image dimensions (see *'xyz_map_width'* and *'xyz_map_height'* below).

Note that in many cases, it is recommended to use the 2D mapping data, if available, for speed and robustness reasons. This is beneficial especially when using `sample_object_model_3d`, `surface_normals_object_model_3d`, or when preparing a 3D object model for surface-based matching, e.g., smoothing, removing outliers, and reducing the domain.

The parameter `OverwriteData` defines if the existing data of an already prepared 3D object model shall be removed. If `OverwriteData` is set to *'true'*, the prepared data, defined with the parameter `Purpose`, is overwritten. If `OverwriteData` is set to *'false'*, the prepared data is not overwritten. If there is no prepared data `OverwriteData` is ignored and data is saved in a 3D object model. The parameter `OverwriteData` can be used for choosing another set of generic parameters `GenParamName` and `GenParamValue`. The parameter `OverwriteData` has no influence if the parameter `Purpose` is set to *'shape_based_matching_3d'*, because for that, there are no generic parameters to set.

The generic parameters can optionally be used to influence the preparation. If desired, these parameters and their corresponding values can be specified by using `GenParamName` and `GenParamValue`, respectively. The following values for `GenParamName` are possible:

'max_area_holes': This parameter is only valid if `Purpose` is set to *'segmentation'*. The parameter specifies which area holes of the point coordinates are closed during a simple Delaunay triangulation. Only holes which are completely surrounded by the image region are closed. If *'max_area_holes'* is set to *0*, no holes are triangulated. If the parameter *'max_area_holes'* is set greater or equal than *1* pixel, the holes with an area less or equal than *'max_area_holes'* are closed by a meshing.

Suggested values: *1*, *10*, *100*.

Default: *10*.

'distance_to': This parameter is only valid if `Purpose` is set to *'distance_computation'*. The parameter specifies the type of data to which the distance shall be computed to. It is described in more detail in the documentation of `distance_object_model_3d`.

List of values: *'auto'*, *'triangles'*, *'points'*, *'primitive'*.

Default: *'auto'*.

'method': This parameter is only valid if `Purpose` is set to *'distance_computation'*. The parameter specifies the method to be used for the distance computation. It is described in more detail in the documentation of `distance_object_model_3d`.

List of values: *'auto'*, *'kd-tree'*, *'voxel'*, *'linear'*.

Default: *'auto'*.

'max_distance': This parameter is only valid if `Purpose` is set to *'distance_computation'*. The parameter specifies the maximum distance of interest for the distance computation. If it is set to *0*, no maximum distance is used. It is described in more detail in the documentation of `distance_object_model_3d`.

Suggested values: *0*, *0.1*, *1*, *10*.

Default: *0*.

'sampling_dist_rel': This parameter is only valid if `Purpose` is set to *'distance_computation'*. The parameter specifies the relative sampling distance when computing the distance to triangles with the method *'voxel'*. It is described in more detail in the documentation of `distance_object_model_3d`.

Suggested values: *0.03*, *0.01*.

Default: *0.03*.

'sampling_dist_abs': This parameter is only valid if `Purpose` is set to *'distance_computation'*. The parameter specifies the absolute sampling distance when computing the distance to triangles with the method *'voxel'*. It is described in more detail in the documentation of `distance_object_model_3d`.

Suggested values: *1*, *5*, *10*.

Default: None.

'xyz_map_width': This parameter is only valid if `Purpose` is set to *'gen_xyz_mapping'*. The parameter indicates that the point cloud is ordered row-wise and the passed value is used as the width of the image. The height of the image is calculated automatically. Only one of the two parameters *'xyz_map_width'* and *'xyz_map_height'* can be set.

Default: None.

'xyz_map_height': This parameter is only valid if `Purpose` is set to *'gen_xyz_mapping'*. The parameter indicates that the point cloud is ordered column-wise and the passed value is used as the height of the image. The width of the image is calculated automatically. Only one of the two parameters *'xyz_map_width'* and *'xyz_map_height'* can be set.

Default: None.

Parameters

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model.

▷ **`Purpose`** (input_control) . . . . . string ⇝ *string*
Purpose of the 3D object model.
Default: 'shape_based_matching_3d'
Suggested values: `Purpose` ∈ {'shape_based_matching_3d', 'segmentation', 'distance_computation', 'gen_xyz_mapping'}

▷ **`OverwriteData`** (input_control) . . . . . string ⇝ *string*
Specify if already existing data should be overwritten.
Default: 'true'
List of values: `OverwriteData` ∈ {'true', 'false'}

▷ **`GenParamName`** (input_control) . . . . . attribute.name-array ⇝ *string* / real / integer
Names of the generic parameters.
Default: []
List of values: `GenParamName` ∈ {'max_area_holes', 'distance_to', 'method', 'max_distance', 'sampling_dist_rel', 'sampling_dist_abs', 'xyz_map_width', 'xyz_map_height'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters.
Default: []
Suggested values: `GenParamValue` ∈ {0, 1, 100, 'auto', 'triangles', 'points', 'primitive', 'kd-tree', 'voxel', 'linear', 0.01, 0.03}

Example

```
read_object_model_3d ('object_model_3d', 'm', [], [], ObjectModel3D, Status)
prepare_object_model_3d (ObjectModel3D, 'gen_xyz_mapping', 'true',\
                         'xyz_map_width', Width)
object_model_3d_to_xyz (X, Y, Z, ObjectModel3D, 'from_xyz_map', [], [])
```

Result

The operator `prepare_object_model_3d` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

3D Metrology

project_object_model_3d (: ModelContours : ObjectModel3D, CamParam, Pose, GenParamName, GenParamValue :)

Project a 3D object model into image coordinates.

The operator project_object_model_3d projects a 3D object model into the image coordinate system and returns the projected contours in ModelContours. This operator is particularly useful for the visualization of 3D object models. Note that primitives are not projected but silently ignored. The coordinates of the 3D object model are given in the model coordinate system (*mcs*), a 3D world coordinate system. First, they are transformed into the camera coordinate system (*ccs*) using the given Pose. Then, these coordinates are projected into the image coordinate system based on the internal camera parameters CamParam. Thereby the pose is needed in the form ${}^{ccs}\mathbf{P}_{mcs}$, see Transformations / Poses and "Solution Guide III-C - 3D Vision". Thus, the Pose describes the position and orientation of the world coordinate system with respect to the camera coordinate system. The internal camera parameters CamParam describe the projection characteristics of the camera (see Calibration).

There are some generic parameters that can optionally be used to influence the projection. If desired, these parameters and their corresponding values can be specified by using GenParamName and GenParamValue, respectively. The following values for GenParamName are possible:

'data': This parameter specifies which geometric data of the 3D object model should be projected. If *'data'* is set to *'faces'*, the faces of the 3D object model are projected. The faces are represented by their border lines in ModelContours. If *'data'* is set to *'lines'*, the 3D lines of the 3D object model are projected. If *'data'* is set to *'points'*, the points of the 3D object model are projected. The projected points can be represented in ModelContours in different ways. The point representation can be selected by using the generic parameter *'point_shape'* (see below). Finally, if *'data'* is set to *'auto'*, HALCON automatically chooses the most descriptive geometry data that is available in the 3D object model for visualization.

List of values: *'auto'*, *'faces'*, *'lines'*, *'points'*.

Default: *'auto'*.

'point_shape': This parameter specifies how points are represented in the output contour ModelContours. Consequently, this parameter only has an effect if the points of the 3D object model are selected for projection (see above). If *'point_shape'* is set to *'circle'*, points are represented by circles, whereas if *'point_shape'* is set to *'cross'*, points are represented by crosses. In both cases the size of the points (i.e., the size of the circles or the size of the crosses) can be specified by the generic parameter *'point_size'* (see below). The orientation of the crosses can be specified by the generic parameter *'point_orientation'* (see below).

List of values: *'circle'*, *'cross'*.

Default: *'circle'*.

'point_size': This parameter specifies the size of the point representation in the output contour ModelContours, i.e., the size of the circles or the size of the crosses depending on the selected *'point_shape'*. Consequently, this parameter only has an effect if the points of the 3D object model are selected for projection (see above). The size must be given in pixel units. If *'point_size'* is set to *0*, each point is represented by a contour that contains a single contour point.

Suggested values: *0*, *2*, *4*.

Default: *4*.

'point_orientation': This parameter specifies the orientation of the crosses in radians. Consequently, this parameter only has an effect if the points of the 3D object model are selected for projection and *'point_shape'* is set to *'cross'* (see above).

Suggested values: *0*, *0.39*, *0.79*.

Default: *0.79*.

'union_adjacent_contours': This parameter specifies if adjacent projected contours should be joined or not. Activating this option is equivalent to calling union_adjacent_contours_xld after this operator, but significantly faster.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'hidden_surface_removal': This parameter can be used to switch on or off the removal of hidden surfaces. If *'hidden_surface_removal'* is set to *'true'*, only those projected edges are returned that are not hidden by faces of the 3D object model. If *'hidden_surface_removal'* is set to *'false'*, all projected edges are returned. This is faster than a projection with *'hidden_surface_removal'* set to *'true'*.

If the system variable (see `set_system`) *'opengl_hidden_surface_removal_enable'* is set to *'true'* (which is the default if it is available) and *'hidden_surface_removal'* is set to *'true'*, the projection of the model is accelerated using the graphics card. Depending on the graphics card this is significantly faster than the non accelerated algorithm. Be aware that the results of the OpenGL projection are slightly different compared to the analytic projection. Notable, only the contours visible through `CamParam` are projected in this mode.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'min_face_angle': 3D edges are only projected if the angle between the two 3D faces that are incident with the 3D edge is at least *'min_face_angle'*. If *'min_face_angle'* is set to *0.0*, all edges are projected. If *'min_face_angle'* is set to π (equivalent to 180 degrees), only the silhouette of the 3D object model is returned. This parameter can be used to suppress edges within curved surfaces, e.g., the surface of a cylinder or cone.

Suggested values: *0.17*, *0.26*, *0.35*, *0.52*.

Default: *0.52*.

Attention

Cameras with hypercentric lenses are not supported. For displaying large faces with a non-zero distortion in `CamParam`, note that the distortion is only applied to the points of the model. In the projection, these points are subsequently connected by straight lines. For a good approximation of the distorted lines, please use a triangulation with sufficiently small triangles.

Parameters

▷ **`ModelContours`** (output_object) ..... xld_cont(-array) ⇝ *object*
Projected model contours.

▷ **`ObjectModel3D`** (input_control) ..... object_model_3d ⇝ *handle*
Handle of the 3D object model.

▷ **`CamParam`** (input_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **`Pose`** (input_control) ..... pose ⇝ *real* / integer
3D pose of the world coordinate system in camera coordinates.
Number of elements: Pose == 7

▷ **`GenParamName`** (input_control) ..... string(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: `GenParamName` ∈ {'true', 'false', 'hidden_surface_removal', 'min_face_angle', 'data', 'point_shape', 'point_size', 'point_orientation', 'union_adjacent_contours'}

▷ **`GenParamValue`** (input_control) ..... string(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
Suggested values: `GenParamValue` ∈ {0.17, 0.26, 0.35, 0.52, 'true', 'false', 'auto', 'points', 'faces', 'lines', 'circle', 'cross', 1, 2, 3, 4, 0.785398}

Result

`project_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised. If the geometric data that was selected for the projection is not available in the 3D object model, the error 9514 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

projective_trans_object_model_3d (: : ObjectModel3D, HomMat3D : ObjectModel3DProjectiveTrans)

Apply an arbitrary projective 3D transformation to 3D object models.

projective_trans_object_model_3d applies an arbitrary projective 3D transformation to the points of 3D object models and returns the handles of the transformed 3D object models. The projective transformation is described by the homogeneous transformation matrix given in HomMat3D (see projective_trans_point_3d).

The transformation matrix can be created, e.g., using the operator vector_to_hom_mat3d.

Attention

projective_trans_object_model_3d transforms the attributes of type 3D points. Attributes of type shape model for shape-based 3D matching, of type 3D primitive, and of type normals are not transformed. Therefore, these attributes do not exist in the transformed 3D object model. All other attributes are copied without modification. To transform 3D primitives, the operator rigid_trans_object_model_3d must be used.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handles of the 3D object models.

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Homogeneous projective transformation matrix.

▷ **ObjectModel3DProjectiveTrans** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handles of the transformed 3D object models.

Result

If the parameters are valid, the operator projective_trans_object_model_3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

3D Metrology

register_object_model_3d_global (: : ObjectModels3D, HomMats3D, From, To, GenParamName, GenParamValue : HomMats3DOut, Scores)

Improve the relative transformations between 3D object models based on their overlaps.

register_object_model_3d_global improves the relative transformations between 3D object models, which is called global registration. In particular, under the assumption that all input 3D objects models in ObjectModels3D have a known approximated spatial relation, all possible pairwise overlapping areas are calculated and optimized for a better alignment. The resulting offset is then synchronously minimized for all pairs. The entire process is then repeated iteratively from the newly resulting starting poses. The result in HomMats3DOut describes a transformation that can be applied with affine_trans_object_model_3d to the input 3D object models to transform all in a common reference frame. Scores contains for every 3D object model the number of found neighbors with a sufficient overlap. If no overlap is found for at least one object, an exception is raised.

Three types for the interpretation of the starting poses in HomMats3D are available, which is controlled by the parameters From and To:

First, if From is set to *'global'*, the parameter HomMats3D must contain a rigid transformation with 12 entries for each 3D object model in ObjectModels3D that describes its position in relation to a common global reference frame. In this case, To must be empty. This case is suitable, e.g., if transformations are applied by a turning table or a robot to either the camera or the object. In this case, all neighborhoods that are possible are considered for the global optimization.

Second, if From is set to *'previous'*, the parameter HomMats3D must contain a rigid transformation for each subsequent pair of 3D object models in ObjectModels3D (one less than for the first case). An example for this situation might be a matching applied consecutively to the previous frame (e.g., with register_object_model_3d_pair). To must be empty again. In this case, all neighborhoods that are possible are considered for the global optimization.

Third, you can describe any transformation in HomMats3D by setting From and To to the indices of the 3D object models for which the corresponding transformation is valid. That is, a given transformation describes the transformation that is needed to move the 3D object model with the index that is specified in From into the coordinate system of the 3D object model with the corresponding index that is specified in To. In this case, HomMats3D should contain all possible neighborhood relations between the objects, since no other than these neighborhoods are considered for the optimization. Please consider, that for all 3D object models at least one path of transformations to each other 3D object model must be contained in the such specified transformations.

If ObjectModels3D contains 3D-primitives, they will internally be transformed into point clouds and will be considered as such.

The accuracy of the returned poses is limited to around 0.1% of the size of the point clouds due to numerical reasons. The accuracy further depends on the noise of the data points, the number of data points and the shape of the point clouds.

The process of the global registration can be controlled further by the following generic parameters in GenParamName and GenParamValue:

'default_parameters': Allows to choose between two default parameter sets, i.e., it allows to switch between a *'fast'* and an *'accurate'* set of parameters.
List of values: *'fast'*, *'accurate'*.
Default: *'accurate'*.

'rel_sampling_distance': The relative sampling rate of the 3D object models. This value is relative to the object's diameter and refers to the minimal distance between two sampled points. A higher value leads to faster results, whereas a lower value leads to more accurate results.
Suggested values: *0.03*, *0.05*, *0.07*.
Default: *0.05* (*'default_parameters'* = *'accurate'*), *0.07* (*'default_parameters'* = *'fast'*).
Restriction: 0 < *'rel_sampling_distance'* < 1

'pose_ref_sub_sampling': Number of points that are skipped for the pose refinement. The value specifies the number of points that are skipped per selected point. Increasing this value allows faster convergence at the cost of less accurate results. The internally used method for the refinement is asymmetric and this parameter only affects the second model of each tested pair.
Suggested values: *1*, *2*, *20*.
Default: *2* (*'default_parameters'* = *'accurate'*), *10* (*'default_parameters'* = *'fast'*).
Restriction: *'pose_ref_sub_sampling'* > 0

'max_num_iterations': Number of iterations applied to adjust the initial alignment. The better the initial alignment is, the less iterations are necessary.

Suggested values: *1*, *3*, *10*.

Default: *3*.

Parameters

▷ **ObjectModels3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handles of several 3D object models.

▷ **HomMats3D** (input_control) . . . . . hom_mat3d-array ⇝ *real* / integer
Approximate relative transformations between the 3D object models.

▷ **From** (input_control) . . . . . number(-array) ⇝ *string* / integer
Type of interpretation for the transformations.
Default: 'global'
List of values: From ∈ {'global', 'previous', 0, 1, 2, 3, 4}

▷ **To** (input_control) . . . . . number(-array) ⇝ *integer*
Target indices of the transformations if From specifies the source indices, otherwise the parameter must be empty.
Default: []
List of values: To ∈ {0, 1, 2, 3, 4}

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of the generic parameters that can be adjusted for the global 3D object model registration.
Default: []
List of values: GenParamName ∈ {'default_parameters', 'rel_sampling_distance', 'pose_ref_sub_sampling', 'max_num_iterations'}

▷ **GenParamValue** (input_control) . . . . . number-array ⇝ *real* / integer / string
Values of the generic parameters that can be adjusted for the global 3D object model registration.
Default: []
Suggested values: GenParamValue ∈ {0.03, 0.05, 0.07, 0.1, 0.25, 0.5, 1, 2, 5, 10, 20, 'fast', 'accurate'}

▷ **HomMats3DOut** (output_control) . . . . . hom_mat3d-array ⇝ *real* / integer
Resulting Transformations.

▷ **Scores** (output_control) . . . . . number-array ⇝ *real*
Number of overlapping neighbors for each 3D object model.

Result

register_object_model_3d_global returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

register_object_model_3d_pair (: : ObjectModel3D1, ObjectModel3D2, Method, GenParamName, GenParamValue : Pose, Score)

Search for a transformation between two 3D object models.

register_object_model_3d_pair searches for a transformation between two 3D object models having an optimal alignment. This process is called registration. The transformation that is returned in Pose can be used to transform ObjectModel3D1 to the reference frame of the second object ObjectModel3D2. Score returns the ratio of the overlapping parts to the not overlapping parts of the two 3D object models. If the two objects are not overlapping, no pose is returned. The parameter Method decides if the initial relative position is calculated by *'matching'* or if only the pose refinement is performed in relation to the then assumed common global reference frame, which can be selected directly with *'icp'*.

The accuracy of the returned pose is limited to around 0.1% of the size of the point clouds due to numerical reasons. The accuracy further depends on the noise of the data points, the number of data points and the shape of the point clouds.

The matching process and the following refinement can be controlled using the following name-value pairs in GenParamName and GenParamValue:

'default_parameters': To allow an easy control over the parameters, three different sets of parameters are available. Selecting the *'fast'* parameter set allows a shorter calculation time. *'accurate'* will give more accurate results. *'robust'* additionally improves the quality of the resulting Score at the cost of calculation time.

List of values: *'fast'*, *'accurate'*, *'robust'*.

Default: *'accurate'*.

'rel_sampling_distance': This parameter controls the relative sampling rate of the 3D object models that is used to represent the surfaces for the computation. This value is relative to the diameter of the respective object and defines the minimal distance between two sampled points. A higher value will lead to faster and a lower value to more accurate results. This parameter can also be set for each object independently by using *'rel_sampling_distance_obj1'* and *'rel_sampling_distance_obj2'*.

Suggested values: *0.03*, *0.05*, *0.07*.

Default: *0.05*.

'key_point_fraction': This parameter controls the ratio of sampled points that are considered as key points for the matching process. The number is relative to the sampled points of the model. Reducing this ratio speeds up the process, whereas increasing leads to more robust results. This parameter can be also set for each object independently by using *'key_point_fraction_obj1'* and *'key_point_fraction_obj2'*.

Suggested values: *0.2*, *0.3*, *0.4*.

Default: *0.3*.

'pose_ref_num_steps': The number of iterative steps used for the pose refinement.

Suggested values: *5*, *7*, *10*.

Default: *5*.

'pose_ref_sub_sampling': Number of points that are skipped for the pose refinement. The value specifies the number of points that are skipped per selected point. Increasing this value allows faster convergence at the cost of less accurate results. This parameter is only relevant for the smaller of the two objects.

Suggested values: *1*, *2*, *20*.

Default: *2*.

'pose_ref_dist_threshold_rel': Maximum distance that two faces might have to be considered as potentially overlapping. This value is relative to the diameter of the larger object.

Suggested values: *0.05*, *0.1*, *0.15*.

Default: *0.1*.

'pose_ref_dist_threshold_abs': Maximum distance that two faces might have to be considered as potentially overlapping, as absolute value.

'model_invert_normals': Invert the normals of the smaller object, if its normals are inverted relative to the other object.

List of values: *'true'*, *'false'*.

Default: *'false'*.

Parameters

▷ **ObjectModel3D1** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the first 3D object model.

▷ **ObjectModel3D2** (input_control) . . . . . object_model_3d ⇝ *handle*
Handle of the second 3D object model.

▷ **Method** (input_control) . . . . . string ⇝ *string*
Method for the registration.
Default: 'matching'
List of values: `Method` ∈ {'matching', 'icp'}

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Names of the generic parameters.
Default: []
List of values: `GenParamName` ∈ {'default_parameters', 'rel_sampling_distance', 'rel_sampling_distance_obj1', 'rel_sampling_distance_obj2', 'key_point_fraction', 'key_point_fraction_obj1', 'key_point_fraction_obj2', 'pose_ref_num_steps', 'pose_ref_sub_sampling', 'pose_ref_dist_threshold_rel', 'pose_ref_dist_threshold_abs', 'model_invert_normals'}

▷ **GenParamValue** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Values of the generic parameters.
Default: []
Suggested values: `GenParamValue` ∈ {'fast', 'accurate', 'robust', 0.1, 0.25, 0.5, 1, 'true', 'false'}

▷ **Pose** (output_control) . . . . . pose ⇝ *real* / integer
Pose to transform `ObjectModel3D1` in the reference frame of `ObjectModel3D2`.

▷ **Score** (output_control) . . . . . number-array ⇝ *real*
Overlapping of the two 3D object models.

Example

```
* Generate two boxes
gen_box_object_model_3d ([0,0,0,0,0,0,0],3,2,1, ObjectModel3D1)
gen_box_object_model_3d ([0,0,0.5,15,0,0,0],3,2,1, ObjectModel3D2)
* Match them
register_object_model_3d_pair (ObjectModel3D1, ObjectModel3D2, 'matching',\
                               [], [], Pose, Score)
```

Result

`register_object_model_3d_pair` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

render_object_model_3d (: Image : ObjectModel3D, CamParam, Pose, GenParamName, GenParamValue :)

Render 3D object models to get an image.

render_object_model_3d renders the 3D object models of ObjectModel3D and returns the result in the image Image. To setup the scene to display, set CamParam and the individual Pose of the objects. Be aware that Pose can contain either one pose for each object or one pose for all objects.

The view of the output image is identical to that produced by disp_object_model_3d. The parameters and additional details are documented with disp_object_model_3d, except that the parameters *'object_index_persistence'*, and *'disp_background'* can not be set.

render_object_model_3d requires OpenGL 2.1, GLSL 1.2, and the OpenGL extensions GL_EXT_framebuffer_object and GL_EXT_framebuffer_blit. Otherwise the compatibility mode is automatically enabled. The compatibility mode requires OpenGL 1.1.

Attention

Cameras with hypercentric lenses are not supported.

Parameters

- ▷ **Image** (output_object) ..... multichannel-image ⇝ *object :* byte
  Rendered scene.
- ▷ **ObjectModel3D** (input_control) ..... object_model_3d(-array) ⇝ *handle*
  Handles of the 3D object models.
- ▷ **CamParam** (input_control) ..... campar ⇝ *real* / integer / string
  Camera parameters of the scene.
- ▷ **Pose** (input_control) ..... pose(-array) ⇝ *real* / integer
  3D poses of the objects.
- ▷ **GenParamName** (input_control) ..... string-array ⇝ *string*
  Names of the generic parameters.
  Default: []
  List of values: GenParamName ∈ {'alpha', 'attribute', 'color', 'colored', 'disp_lines', 'disp_pose', 'disp_normals', 'light_position', 'line_color', 'normal_color', 'quality', 'compatibility_mode_enable', 'point_size', 'color_attrib', 'color_attrib_start', 'color_attrib_end', 'red_channel_attrib', 'blue_channel_attrib', 'green_channel_attrib', 'rgb_channel_attrib_start', 'rgb_channel_attrib_end', 'lut'}
- ▷ **GenParamValue** (input_control) ..... string-array ⇝ *string* / integer / real
  Values of the generic parameters.
  Default: []
  List of values: GenParamValue ∈ {'true', 'false', 'coord_x', 'coord_y', 'coord_z', 'normal_x', 'normal_y', 'normal_z', 'red', 'green', 'blue', 'auto', 'faces', 'primitive', 'points', 'lines'}

Result

render_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: mutually exclusive (runs in parallel with other non-exclusive operators, but not with itself).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

rigid_trans_object_model_3d (: : ObjectModel3D, Pose : ObjectModel3DRigidTrans)

Apply a rigid 3D transformation to 3D object models.

rigid_trans_object_model_3d applies rigid 3D transformations, i.e., rotations and translations, to 3D object models and returns the handles of the transformed 3D object models. The transformations are described by the poses given in Pose, which are in the form ${}^{cst}\mathbf{P}_{mcsi}$, where *mcsi* denotes the coordinate system of the input object model and *cst* the coordinate system of the transformed model, e.g., the coordinate system of the scene (see Transformations / Poses and "Solution Guide III-C - 3D Vision"). A pose can be created using the operators create_pose, pose_invert, etc., or it can be the result of get_object_model_3d_params.

rigid_trans_object_model_3d transforms one or more 3D object models with the same pose if only one transformation matrix is passed in Pose (N:1). If a single 3D object model is passed in ObjectModel3D, it is transformed with all passed poses (1:N). If the number of poses corresponds to the number of 3D object models, every 3D object model is transformed individually with the respective pose (N:N). In those cases, N can be zero, i.e., no pose or no 3D object model can be passed to the operator. In this case, an empty tuple is returned in ObjectModel3DRigidTrans. This can be used to, for example, transform the results of find_surface_model without checking first if at least one match was returned.

Attention

rigid_trans_object_model_3d transforms the attributes of type 3D points, 3D point normals, and the prepared shape model for shape-based 3D matching, as well as 3D primitives. Precomputed data structures for 3D distance computation are not copied. All other attributes are copied without modification.

Parameters

- ▷ **ObjectModel3D** (input_control) ..... object_model_3d(-array) ⇝ *handle*
  Handles of the 3D object models.
- ▷ **Pose** (input_control) ..... pose(-array) ⇝ *real* / integer
  Poses.
- ▷ **ObjectModel3DRigidTrans** (output_control) ..... object_model_3d(-array) ⇝ *handle*
  Handles of the transformed 3D object models.

Result

rigid_trans_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

3D Metrology

sample_object_model_3d (: : ObjectModel3D, Method, SamplingParam, GenParamName, GenParamValue : SampledObjectModel3D)

Sample a 3D object model.

sample_object_model_3d creates a sampled version of the 3D object model ObjectModel3D and returns it in SampledObjectModel3D. Depending on the method used, SamplingParam controls the minimum

distance or the number of points in SampledObjectModel3D. The created 3D object model is returned in SampledObjectModel3D.

Using sample_object_model_3d is recommended if complex point clouds are to be thinned out for faster postprocessing or if primitives are to be converted to point clouds. Note that if the 3D object model is triangulated and should be simplified by preserving its original geometry as good as possible, simplify_object_model_3d should be used instead.

If the input object model ObjectModel3D contains only points, several sampling methods are available which can be selected using the parameter Method:

'fast': The default method *'fast'* adds all points from the input model which are not closer than SamplingParam to any point that was earlier added to the output model. If present, normals, XYZ-mapping and extended point attributes are copied to the output model.

'fast_compute_normals': The method *'fast_compute_normals'* selects the same points as the method *'fast'*, but additionally calculates the normals for all points that were selected. For this, the input object model must either contain normals, which are copied, or it must contain a XYZ-mapping attribute from which the normals are computed. The z-component of the calculated normal vectors is always positive. The XYZ-mapping is created by xyz_to_object_model_3d.

'accurate': The method *'accurate'* goes through the points of the 3D object model ObjectModel3D and calculates whether any other points are within a sphere with the radius SamplingParam around the examined point. If there are no other points, the original point is stored in SampledObjectModel3D. If there are other points, the center of gravity of these points (including the original point) is stored in SampledObjectModel3D. This procedure is repeated with the remaining points until there are no points left. Extended attributes of the input 3D object model are not copied, but normals and XYZ-mapping are copied. For this method, a noise removal is possible by specifying a value for *'min_num_points'* in GenParamName and GenParamValue, which removes all interpolated points that had less than the specified number of neighbor points in the original model.

'accurate_use_normals': The method *'accurate_use_normals'* requires normals in the input 3D object model and interpolates only points with similar normals. The similarity depends on the angle between the normals. The threshold of the angle can be specified in GenParamName and GenParamValue with *'max_angle_diff'*. The default value is *180* degrees. Additionally, outliers can be removed as described in the method *'accurate'*, by setting the generic parameter *'min_num_points'*.

'xyz_mapping': The method *'xyz_mapping'* can only be applied to 3D object models that contain an XYZ-mapping (for example, if it was created using xyz_to_object_model_3d). This mapping stores for each 3D point its original image coordinates. The method *'xyz_mapping'* subdivides those original images into squares with side length SamplingParam (which is given in pixel) and selects one 3D point per square.

The method behaves similar to applying zoom_image_factor onto the original XYZ-images. Note that this method does not use the 3D-coordinates of the points for the point selection, only their 2D image coordinates.

It is important to notice that for this method, the parameter SamplingParam corresponds to a distance in pixels, not to a distance in 3D space.

'xyz_mapping_compute_normals': The method *'xyz_mapping_compute_normals'* selects the same points as the method *'xyz_mapping'*, but additionally calculates the normals for all points that were selected. The z-component of the normal vectors is always positive. If the input object model contains normals, those normals are copied to the output. Otherwise, the normals are computed based on the XYZ-mapping.

'furthest_point': The method *'furthest_point'* iteratively adds the point of the input object to the output object that is furthest from all points already added to the output model. This usually leads to a reasonably uniform sampling. For this method, the desired number of points in the output model is passed in SamplingParam. If that number exceeds the number of points in the input object, then all points of the input object are returned.

The first point added to the output object is the point that is furthest away from the center of the axis aligned bounding box around the points of the input object.

'furthest_point_compute_normals': The method *'furthest_point_compute_normals'* selects the same points as the method *'furthest_point'*, but additionally calculates the normals for all points that were selected. The number of desired points in the output object is passed in SamplingParam.

To compute the normals, the input object model must either contain normals, which are copied, or it must contain a XYZ-mapping attribute from which the normals are computed. The z-component of the calculated normal vectors is always positive. The XYZ-mapping is created by xyz_to_object_model_3d.

If the input object model contains faces (triangles or polygons) or is a 3D primitive, the surface is sampled with the given distance. In this case, the method specified in `Method` is ignored. The directions of the computed normals depend on the face orientation of the model. Usually, the orientation of the faces does not vary within one CAD model, which results in a set of normals that is either pointing inwards or outwards. Note that planes and cylinders must have finite extent. If the input object model contains lines, the lines are sampled with the given distance `SamplingParam`.

The sampling process approximates surfaces by creating new points in the output object model. Therefore, any extended attributes from the input object model are discarded.

For mixed input object models, the sampling priority is (from top to bottom) faces, lines, primitives and points, i.e., only the objects of the highest priority are sampled.

The parameter `SamplingParam` accepts either one value, which is then used for all 3D object models passed in `ObjectModel3D`, or one value per input object model. If `SamplingParam` is a distance in 3D space the unit is the usual HALCON-internal unit *'m'*.

Parameters

- ▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
  Handle of the 3D object model to be sampled.
- ▷ **`Method`** (input_control) . . . . . string ⇝ *string*
  Selects between the different subsampling methods.
  Default: 'fast'
  List of values: `Method` ∈ {'fast', 'fast_compute_normals', 'accurate', 'accurate_use_normals', 'xyz_mapping', 'xyz_mapping_compute_normals', 'furthest_point', 'furthest_point_compute_normals'}
- ▷ **`SamplingParam`** (input_control) . . . . . real(-array) ⇝ *real* / integer
  Sampling distance or number of points.
  Number of elements: SamplingParam == 1 || SamplingParam == ObjectModel3D
  Default: 0.05
- ▷ **`GenParamName`** (input_control) . . . . . string-array ⇝ *string*
  Names of the generic parameters that can be adjusted.
  Default: []
  List of values: `GenParamName` ∈ {'min_num_points', 'max_angle_diff'}
- ▷ **`GenParamValue`** (input_control) . . . . . number-array ⇝ *real* / integer / string
  Values of the generic parameters that can be adjusted.
  Default: []
  Suggested values: `GenParamValue` ∈ {1, 2, 5, 10, 20, 0.1, 0.25, 0.5}
- ▷ **`SampledObjectModel3D`** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
  Handle of the 3D object model that contains the sampled points.
  Number of elements: SampledObjectModel3D == ObjectModel3D

Example

```
gen_box_object_model_3d ([0,0,0,0,0,0,0],3,2,1, ObjectModel3D)
sample_object_model_3d (ObjectModel3D, 'fast', 0.05, [], [], \
                        SampledObjectModel3D)
dev_get_window (WindowHandle)
visualize_object_model_3d (WindowHandle, SampledObjectModel3D, \
                           [], [], [], [], [], [], [], PoseOut)
```

Result

`sample_object_model_3d` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

simplify_object_model_3d (: : ObjectModel3D, Method, Amount, GenParamName, GenParamValue : SimplifiedObjectModel3D)

Simplify a triangulated 3D object model.

simplify_object_model_3d simplifies the triangulated 3D object model ObjectModel3D by removing model points and returns the result in SimplifiedObjectModel3D. Note that in contrast to sample_object_model_3d points are removed such that the original geometry of the object model is represented as good as possible. Typically, this means that edges are preserved while the point density within smooth parts is reduced. This might be helpful, for example, to speed up subsequent operator calls by using a 3D object model of reduced complexity.

The triangulation of the input 3D object model is preserved as opposed to the operator sample_object_model_3d, which samples surfaces to equidistant unconnected 3D points.

Currently, the operator offers only a single simplification method (*'preserve_point_coordinates'*), which can be set in Method. This method ensures that the points in the simplified object model SimplifiedObjectModel3D have the same coordinates as the respective points in the input object model ObjectModel3D.

simplify_object_model_3d only works for triangulated object models. Whether an object model contains a triangulation can be queried with get_object_model_3d_params (GenParamName=*'has_triangles'*). Object models that do not contain a triangulation must be triangulated beforehand, e.g., by using triangulate_object_model_3d or prepare_object_model_3d (Purpose=*'segmentation'*).

The degree of simplification can be set with Amount. By default, Amount specifies the percentage of points of the input object model that should be contained in the output object model. Thus, the smaller the value of Amount in this case is chosen the stronger the object model will be simplified.

Alternatively, the meaning of the parameter Amount can be modified. For this, the generic parameter *'amount_type'* can be set to one of the following values:

'percentage_remaining' (default): Amount specifies the percentage of points of the input object model that should be contained in the output object model.
Value range: [*0.0* ... *100.0*].

'percentage_to_remove': Amount specifies the percentage of points of the input object model that should be removed.
Value range: [*0.0* ... *100.0*].

'num_points_remaining': Amount specifies the number of points of the input object model that should be contained in the output object model.
Value range: [*0* ... number of points in the input object model].

'num_points_to_remove': Amount specifies the number of points of the input object model that should be removed.
Value range: [*0* ... number of points in the input object model].

Sometimes triangular meshes flip during the simplification, i.e., the direction of their normal vectors changes by 180 degrees. This especially happens for artificially created CAD models that consist of planar parts. To avoid this flipping, the generic parameter *'avoid_triangle_flips'* can be set to *'true'* (the default is *'false'*). Note that in this case, the run-time of simplify_object_model_3d will increase.

Note that multiple calls of simplify_object_model_3d with a lower degree of simplification might result in a different simplified object model compared to a single call with a higher degree of simplification. Also note that isolated (i.e., non-triangulated) points will be removed. This might result in a number of points in SimplifiedObjectModel3D that slightly deviates from the degree of simplification that is specified in Amount.

Parameters

- ▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
  Handle of the 3D object model that should be simplified.
- ▷ **Method** (input_control) . . . . . string ⇝ *string*
  Method that should be used for simplification.
  Default: 'preserve_point_coordinates'
  List of values: Method ∈ {'preserve_point_coordinates'}
- ▷ **Amount** (input_control) . . . . . number ⇝ *real* / integer
  Degree of simplification (default: percentage of remaining model points).
- ▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
  Names of the generic parameters.
  Default: []
  List of values: GenParamName ∈ {'amount_type', 'avoid_triangle_flips'}
- ▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / real
  Values of the generic parameters.
  Default: []
  Suggested values: GenParamValue ∈ {'percentage_remaining', 'percentage_to_remove', 'num_points_remaining', 'num_points_to_remove', 'true', 'false'}
- ▷ **SimplifiedObjectModel3D** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
  Handle of the simplified 3D object model.

Example

```
read_object_model_3d ('mvtec_bunny.om3', 'm', [], [], ObjectModel3D, Status)
visualize_object_model_3d (WindowHandle, ObjectModel3D, [], [], [], [], \
                           [], [], [], Pose)
simplify_object_model_3d (ObjectModel3D, 'preserve_point_coordinates', \
                          5.0, 'amount_type', 'percentage_remaining', \
                          SimplifiedObjectModel3D)
visualize_object_model_3d (WindowHandle, SimplifiedObjectModel3D, [], \
                           Pose, [], [], [], [], [], Pose)
```

Result

simplify_object_model_3d returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

smooth_object_model_3d (: : ObjectModel3D, Method, GenParamName, GenParamValue : SmoothObjectModel3D)

Smooth the 3D points of a 3D object model.

The operator smooth_object_model_3d smoothes the 3D points in ObjectModel3D and returns the smoothed points in SmoothObjectModel3D. Currently, the operator offers three methods for smoothing that can be selected in Method: *'mls'*, *'xyz_mapping'* and *'xyz_mapping_compute_normals'*. *'mls'* applies a Moving Least Squares (MLS) algorithm on the 3D points. As a side effect of the smoothing, the method extends SmoothObjectModel3D by corresponding normals. *'xyz_mapping'* smoothes the coordinates of the 3D points using a 2D filter and the 2D mapping contained in ObjectModel3D. *'xyz_mapping_compute_normals'* applies the same smoothing as *'xyz_mapping'*, but additionally extends SmoothObjectModel3D by normals.

Additional parameters can be set with GenParamName and GenParamValue. The parameter names settable for Method=*'mls'* use the prefix *'mls'*. Analogically, parameter names settable for Method=*'xyz_mapping'* and Method=*'xyz_mapping_compute_normals'* use the prefix *'xyz_mapping'*.

MLS smoothing

By selecting Method=*'mls'*, for each point P, the MLS smoothing algorithm fits a planar surface or a higher order polynomial surface to its k-neighborhood (the k nearest points). The surface fitting is essentially a standard *weighted least squares* parameter estimation of the plane or polynomial surface parameters, respectively. The closest neighbors of P have higher contribution than the other points, which is controlled by the following *weighting function* with a parameter σ:

$$w(P') = exp\left(-\frac{\|P' - P\|^2}{\sigma^2}\right)$$

The point is then projected on the surface. This process is repeated for all points resulting in a smoothed point set. The fitted surfaces have well defined normals (i.e., they can easily be computed from the surface parameters). Therefore, the points are augmented by the corresponding normals as side effect of the smoothing.

Additional parameters can be adjusted for the *MLS smoothing* specifically using the following parameter names and values for GenParamName and GenParamValue:

'mls_kNN': Specify the number of nearest neighbors k that are used to fit the MLS surface to each point.

Suggested values: *40*, *60*, *80*, *100*, *400*.

Default: *60*.

'mls_order': Specify the order of the MLS polynomial surface. For *'mls_order'=1* the surface is a plane.

Suggested values: *1*, *2*,*3*.

Default: *2*.

'mls_abs_sigma': Specify the weighting parameter σ as a fixed absolute value in meter. The value to be selected depends on the scale of the point data. As a rule of thumb, σ can be selected to be the typical distance between a point P and its $k/2$-th neighbor $P_{k/2}$. Note that setting an absolute weighting parameter for point data with varying density might result in different smoothing results for points that are situated in parts of the point data with different densities. This problem can be avoided by using *'mls_relative_sigma'* instead that is scale independent, which makes it also a more convenient way to specify the neighborhood weighting. Note that if *'mls_abs_sigma'* is passed, any value set in *'mls_relative_sigma'* is ignored.

Suggested values: *0.0001*, *0.001*, *0.01*, *0.1*, *1.0*.

'mls_relative_sigma': Specify a multiplication factor σ_{rel} that is used to compute σ_P for a point P by the formula:

$$\sigma_P = \sigma_{rel}\|P_{k/2} - P\|,$$

where $P_{k/2}$ is the $k/2$-th neighbor of P. Note that, unlike σ, which is a global parameter for all points, σ_P is computed for each point P and therefore adapts the weighting function to its neighborhood. This avoids

problems that might appear while trying to set a global parameter σ (*'mls_abs_sigma'*) to a point data with highly varying point density. Note however that if *'mls_abs_sigma'* is set, *'mls_relative_sigma'* is ignored.
Suggested values: *0.1*, *0.5*, *1.0*, *1.5*, *2.0*.
Default: *1.0*.

'mls_force_inwards': If this parameter is set to *'true'*, all surface normals are oriented such that they point "in the direction of the origin". Expressed mathematically, it is ensured that the scalar product between the normal vector and the vector from the respective surface point to the origin is positive. This may be necessary if the resulting `SmoothObjectModel3D` is used for surface-based matching, either as model in `create_surface_model` or as 3D scene in find_surface_model, because here, the consistent orientation of the normals is important for the matching process. If *'mls_force_inwards'* is set to *'false'*, the normal vectors are oriented arbitrarily.
List of values: *'true'*, *'false'*.
Default: *'true'*.

2D mapping smoothing

By selecting `Method`=*'xyz_mapping'* or `Method`=*'xyz_mapping_compute_normals'*, the coordinates of the 3D points are smoothed using a 2D filter and the 2D mapping contained in `ObjectModel3D`. Additionally, for `Method`=*'xyz_mapping_compute_normals'*, `SmoothObjectModel3D` is extended by normals computed from the XYZ-mapping. If no 2D mapping is available, an exception is raised. As the filter operates on the 2D depth image, using `Method`=*'xyz_mapping'* or `Method`=*'xyz_mapping_compute_normals'* is usually faster than using `Method`=*'mls'*. Invalid points (e.g., duplicated points with coordinates [0,0,0]) should be removed from the 3D object model before applying the operator, e.g., by using `select_points_object_model_3d` with attribute *'point_coord_z'* or *'num_neighbors_fast X'*.

Additional parameters can be adjusted for the *2D mapping smoothing* specifically using the following parameter names and values for `GenParamName` and `GenParamValue`:

'xyz_mapping_filter': Specify the filter used for smoothing the 2D mapping. The sizes of the corresponding filter mask are set with *'xyz_mapping_mask_width'* and *'xyz_mapping_mask_height'*.
In the default filter mode *'median_separate'*, the filter method used on the 2D image is comparable to `median_separate`. This mode is usually faster than *'median'*, but can also lead to less accurate results or artifacts at surface discontinuities.
Using filter mode *'median'*, the used filter method is comparable to `median_image`.
List of values: *'median_separate'*, *'median'*.
Default: *'median_separate'*.

'xyz_mapping_mask_width', *'xyz_mapping_mask_height'*: Specify the width and height of the used filter mask.
For *'xyz_mapping_filter'='median_separate'* or *'xyz_mapping_filter'='median'*, even values for *'xyz_mapping_mask_width'* or *'xyz_mapping_mask_height'* are increased to the next odd value automatically.
For *'xyz_mapping_filter'='median'*, the used filter mask must be quadratic (*'xyz_mapping_mask_width'* = *'xyz_mapping_mask_height'*). Thus, when setting only *'xyz_mapping_mask_width'* or *'xyz_mapping_mask_height'*, the other parameter is set to the same value automatically. If two different values are set, an error is raised.
Suggested values: *3*, *5*, *7*, *9*.
Default: *3*.

Parameters

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model containing 3D point data.

▷ **`Method`** (input_control) . . . . . string ⇝ *string*
Smoothing method.
Default: 'mls'
List of values: `Method` ∈ {'mls', 'xyz_mapping', 'xyz_mapping_compute_normals'}

▷ **`GenParamName`** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of generic smoothing parameters.
Default: []
List of values: `GenParamName` ∈ {'mls_kNN', 'mls_order', 'mls_abs_sigma', 'mls_relative_sigma', 'mls_force_inwards', 'xyz_mapping_filter', 'xyz_mapping_mask_width', 'xyz_mapping_mask_height'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of generic smoothing parameters.
Default: []
Suggested values: GenParamValue ∈ {10, 20, 40, 60, 0.1, 0.5, 1.0, 2.0, 0, 1, 2, 3, 5, 7, 9}

▷ **SmoothObjectModel3D** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model with the smoothed 3D point data.

Module

3D Metrology

surface_normals_object_model_3d (: : ObjectModel3D, Method, GenParamName, GenParamValue : ObjectModel3DNormals)

Calculate the 3D surface normals of a 3D object model.

The operator surface_normals_object_model_3d calculates the 3D surface normals for the object ObjectModel3D using the method specified by Method. The calculated normals are appended to the input object and the resulting object is returned in ObjectModel3DNormals.

For Method *'mls'*, the normals estimation method Moving Least Squares (MLS) is applied. The MLS method for normals estimation is essentially identical with the MLS method used by smooth_object_model_3d with the exception that in surface_normals_object_model_3d the 3D points are not smoothed, i.e., the original 3D points of ObjectModel3D remain unchanged. For more details on the MLS as well as a full list and descriptions of the supported MLS parameters refer to smooth_object_model_3d.

If the object ObjectModel3D contains triangles, the Method *'triangles'* can be used to obtain point normals from the normals of the triangles neighboring a point. The normals of the neighboring triangles are weighted according to the angle which the triangle encloses at the point. The triangle normals are returned in the extended attributes '&triangle_normal_x', '&triangle_normal_y' and '&triangle_normal_z'. If the extended attributes already exist, they will not be overwritten.

If the object ObjectModel3D contains a 2D mapping (for example a 3D object model that was created with xyz_to_object_model_3d), the Method *'xyz_mapping'* can be used to obtain point normals from the neighborhood of the points in the 2D mapping. In an 11x11 neighborhood of the points in the 2D mapping, a plane is fit through the corresponding 3D points. The normal of this plane then gets switched in a direction consistent with the 2D mapping, for example along the viewing direction of the sensor or in the opposite direction.

Note that for points where the normal vector cannot be estimated, it is set to the zero vector. This happens, for example, if the 3D object model contains an identical point more than *'mls_kNN'* times.

Parameters

▷ **ObjectModel3D** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model containing 3D point data.

▷ **Method** (input_control) . . . . . string ⇝ *string*
Normals calculation method.
Default: 'mls'
List of values: Method ∈ {'mls', 'triangles', 'xyz_mapping'}

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of generic smoothing parameters.
Default: []
List of values: GenParamName ∈ {'mls_kNN', 'mls_order', 'mls_abs_sigma', 'mls_relative_sigma', 'mls_force_inwards'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of generic smoothing parameters.
Default: []
Suggested values: GenParamValue ∈ {10, 20, 40, 60, 0.1, 0.5, 1.0, 2.0, 0, 1, 2, 'true', 'false'}

▷ **ObjectModel3DNormals** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model with calculated 3D normals.

Execution Information

3D Metrology

triangulate_object_model_3d (: : ObjectModel3D, Method, GenParamName, GenParamValue : TriangulatedObjectModel3D, Information)

Create a surface triangulation for a 3D object model.

The operator triangulate_object_model_3d generates a surface of triangular faces for the 3D object model ObjectModel3D and returns the resulting surface in TriangulatedObjectModel3D. Currently, the operator offers four methods for the triangulation that can be selected in Method: *'polygon_triangulation'*, *'xyz_mapping'*, *'greedy'* and *'implicit'*. *'polygon_triangulation'* is a simple method for the conversion of a polygonal to a triangular face representation in a 3D object model. *'xyz_mapping'* triangulates the points in 2D according to a 2D mapping. The other two methods are rather complex algorithms that are used to calculate triangular faces from pure 3D point data with unknown surface topology. A detailed comparison of the *'greedy'* and *'implicit'* algorithm is provided in the paragraph *"Comparison of the triangulation methods"* below.

Polygon triangulation

By selecting Method=*'polygon_triangulation'*, all polygons in ObjectModel3D are triangulated. No generic parameters are supported for this method. If no polygons are available, an exception is raised. A triangular mesh representing the same surface as ObjectModel3D is returned in TriangulatedObjectModel3D.

2D mapping triangulation

By selecting Method=*'xyz_mapping'*, the points are triangulated in 2D according to a 2D mapping contained in ObjectModel3D. The used method is the same as in prepare_object_model_3d for Purpose='segmentation'. If no 2D mapping is available, an exception is raised.

As a post-processing step, triangles whose normal differs strongly from a specified direction can be removed, refer to the description of GenParamName below. This is helpful in cases where the 2D neighborhood used for the triangulation does not reflect the 3D neighborhood well, e.g., when parts of the surface are hidden along the viewing direction of the sensor, or to remove typical noise along the viewing direction of the sensor.

By setting GenParamName to the following value, the additional parameter specific for the *2D mapping triangulation* can be set with GenParamValue:

'xyz_mapping_max_area_holes' specifies which area holes of the point coordinates are closed during a simple Delaunay triangulation. Only holes which are completely surrounded by the image region are closed. If *'xyz_mapping_max_area_holes'* is set to 0, no holes are triangulated. The parameter corresponds to the GenParamName *'max_area_holes'* of prepare_object_model_3d.

Suggested values: *1*, *10*, *100*.

Default: *10*.

'xyz_mapping_max_view_angle' specifies the maximum allowed angle difference between the triangle normal and the viewing direction of the sensor. The smaller this value is set, the fewer triangles are returned. The viewing direction of the sensor is assumed to be the z-axis in the coordinate system of `ObjectModel3D` if not specified differently using `GenParamName` set to *'xyz_mapping_max_view_dir_x'*, *'xyz_mapping_max_view_dir_y'*, and *'xyz_mapping_max_view_dir_z'*. The angle has to be specified between 0 and 90 degrees.

Suggested values: *'rad(60)'*, *'rad(85)'*, *'rad(90)'*.

Default: *'rad(90)'*.

'xyz_mapping_max_view_dir_x', *'xyz_mapping_max_view_dir_y'*, *'xyz_mapping_max_view_dir_z'* specify the viewing direction of the sensor for use with the `GenParamName` *'xyz_mapping_max_view_angle'*, in the coordinate system of `ObjectModel3D`. If not all three coordinate directions are set simultaneously or the direction equals the zero vector, an exception is raised.

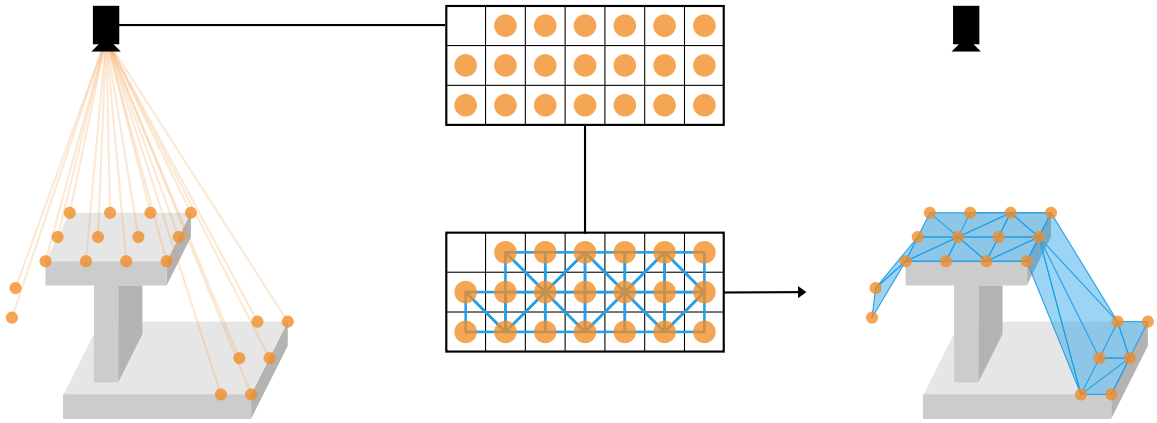
Suggested values: *[1, 0, 0]*, *[0, 0, 1]*.

Default: *[0, 0, 1]*.

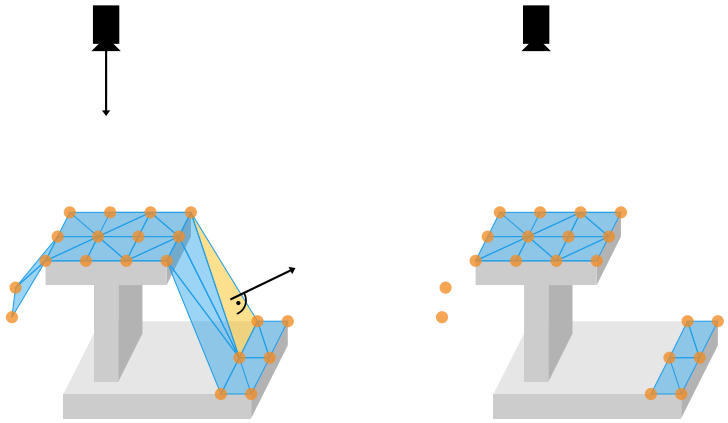
'xyz_mapping_output_all_points' controls, if all input points are returned, regardless whether they were used in the output triangulation or not. Mainly provided for reasons of backward compatibility. When *'xyz_mapping_output_all_points'* is set to *'false'*, the old point indices are stored as an extended attribute named *'original_point_indices'* in the 3D object model `TriangulatedObjectModel3D`. This attribute can subsequently be queried with `get_object_model_3d_params` or be processed with other operators that use extended attributes.

List of values: *'false'*, *'true'*.

Default: *'false'*.



(1)



(2)

(1) In order to triangulate the 3D object model, a 2D mapping of the model is used. The triangulation is based on the respective 2D neighborhood. Thereby it is possible, that unwanted triangles are created along the sensor's direction of view, e.g., because of hidden object parts or clutter data. (2) Whether or not a triangle is

returned, is decided by computing the difference between the normal direction of each triangle and the viewing direction. The maximum deviation is specified in *'xyz_mapping_max_view_angle'*.

Greedy triangulation

By selecting `Method`=*'greedy'*, a so called greedy triangulation algorithm is invoked. It requires 3D point data containing normals. If `ObjectModel3D` does not contain the normals, they are calculated internally, in an identical manner to calling `surface_normals_object_model_3d` with its default parameters before triangulation. The algorithm constructs a surface, which passes through the points and whose surface normals must be conform to the corresponding point normals up to a given tolerance. The surface is represented by triangular faces, which are constructed from triplets of *neighboring* points. In order to determine which triplets qualify for a surface triangle, the algorithm applies for each point pair the following local neighborhood test, denoted as **surface neighborhood criteria (SNC)**:

If a point P is lying on a surface, with N being the orientation (normal) of the surface, then a point P' with normal N' is considered to lay on this surface if:

1. the distance between both points is smaller or equal to r, i.e., $\Delta(P, P') \leq r$
2. both normals have similar orientation, i.e., the angle $\angle(N, N') \leq \alpha$ or - if no strict consistency of the normals is enforced - $\angle(N, -N') \leq \alpha$
3. the vector $\delta P = P' - P$ is close to orthogonal with respect to N, i.e., the angle $|90° - \angle(N, \delta P)| \leq \beta$
4. if P' does not meet 3. but it is not further away from the plane defined by $[P, N]$ than d, then it is accepted as well.

The four parameters r (see *'greedy_radius_type'* and *'greedy_radius_value'*), α (see *'greedy_neigh_orient_tol'*), β (see *'greedy_neigh_latitude_tol'*), and d (see *'greedy_neigh_vertical_tol'*) control the criteria and have the following meaning:

The parameter α essentially controls the curvature of the generated surface: for small values of α the generated surface will be locally flatter; larger values of α permit the generation of more curved surface fragments.

The other three parameters define a portion of a sphere that defines the valid SNC neighborhood. The sphere has a radius r, it is centered in P, and its equatorial plane is incident with the plane $[P, N]$. Only points that are within the sphere (first SNC criteria) are considered. Furthermore, they need to have a latitude within [-β; β] (third SNC criteria) with respect to the equator unless they are lying within the thin layer defined on the both sides of the equatorial plane by the distance parameter d (fourth SNC criteria). In contrast, points lying in any of both pole segments of the sphere (i.e., with higher latitude than β and a distance from the equatorial plane beyond d) are not considered as neighbors.

The parameter r prevents the algorithm from constructing too big triangles. This is particularly important for point sets that represent several disconnected surface pieces or a surface with holes that must not be closed. The latitude window defined by β enables neighbors which deviate from $[P, N]$ due to noise or curvature to be considered as well. Similarly, the parameter d enables neighbors right "above" or "below" the equatorial plane to be accepted, which essentially accounts for data noise.

Here is some advice for selecting the appropriate values for these parameters:

- If the resulting surface triangulation looks very disconnected or exhibits many holes, this might be a hint that r is too small and thus restricts the generation of triangles that are large enough to close the holes. Try to increase r.
- If the normals data is noisy (i.e., neighboring normals are deviating to a large extend from each other), then increase α. The source of noisy normals is typically caused either by the sensor, which delivers both the point and the normals data, or an imprecise normals estimation routine, which computes the normals from the point data.
- If the point data represents a very curved surface, i.e., it exhibits a very fine structure like, e.g., little buckles, fine waves or folds, or sharp turns, then make sure the generation of curved data is facilitated by an increasing α and/or β.
- In contrast, if the data is rather planar but has lots of outliers (i.e., points laying next to the surface, which have completely different orientations and thus most probably do not belong to it), then decrease α to exclude them from the surface generation.
- If the point data is very noisy and resembles more a crust than a single-layer surface, then increase β and/or d to make sure that neighbors for P can still be found even if they are further away from the optimal plane $[P, N]$.

- In contrast, if the data is rather noise-free, but two surfaces are running close to each other and are nearly parallel, e.g., surfaces representing the front and the back side of a thin, plate-like object, then decrease β and d to avoid interference between the surfaces.

The **greedy triangulation** algorithm starts by initializing a surface with one triangle constructed from three SNC-eligible, neighboring points. If all valid neighborhoods show local inconsistencies like collinear or 'double' points, an error will be raised. A prior call of `sample_object_model_3d` with Method set to 'fast' and a small SamplingParam will remove most local inconsistencies from `ObjectModel3D`. Having found one triangle, the algorithm then greedily constructs new triangles as long as further points can be reached by the SNC rules from any point on the surface boundaries. If no points can be reached from the current surface, but there are unprocessed points in the 3D object model, a new surface is initialized. Because the SNC rules are essentially defined only in the small local neighborhoods of the points, the resulting surface can have global topological artifacts like holes and flips. The latter occur, when - while it is growing - a surface meets itself but with inverted face orientations (i.e., the surface was *flipped* somewhere while it was growing). These artifacts are handled in special post-processing steps: *hole filling* and *flip resolving*, respectively.

Finally, a *mesh morphology* can be performed to additionally remove artifacts that occurred on the final surface boundaries. The mesh morphology consists of several mesh erosion cycles and several subsequent mesh dilation cycles. With each erosion cycle, all triangles reachable from the surface boundaries are removed and the surface boundaries shrink. Then, with each dilation cycle all triangles reachable from the surface boundaries are appended again to the surface and the boundaries expand. Note that this is only possible for triangles, which were removed by an erosion cycle before that. Therefore, once the original boundaries of the surface (i.e., those which existed before the mesh erosion cycles) are reached, the dilation cannot advance any further and hence the dilation cycles cannot be more than the erosion cycles. Applying mesh erosion and dilation subsequently is analogous to performing opening to standard HALCON regions. At last, the mesh morphology can delete surface pieces which have too few triangles.

The individual algorithm steps are summarized here:

1. Triangulation of all points reachable by SNC
2. Hole filling (see *'greedy_hole_filling'*)
3. Flip resolving (see *'greedy_fix_flips'*)
4. Mesh morphology (see *'greedy_mesh_erosion'*, *'greedy_mesh_dilation'*, and *'greedy_remove_small_surfaces'*)

By setting `GenParamName` to one of the following values, additional parameters specific for the *greedy triangulation* can be set with `GenParamValue`:

'greedy_kNN' specifies the size k of the neighborhood. While looking for reachable SNC neighbors for a surface boundary point, the algorithm considers only its closest k neighbors.

Suggested values: *20*, *30*, *40*, *50*, *60*.

Default: *40*.

'greedy_radius_type': if set to *'fixed'*,*'greedy_radius_value'* specifies the SNC radius r in meter units.

If set to *'z_factor'*, r is calculated for each point P by multiplying its z-coordinate by the value specified by *'greedy_radius_value'*. This representation of r is appropriate for data where the density of the points correlates with their distance from the sensor they were recorded with. This is typically the case with depth sensors or TOF cameras.

If set to *'auto'*, the algorithm determines internally whether to use a *'fixed'* or a *'z_factor'* radius and estimates its value. The estimated value is then multiplied by the value specified in *'greedy_radius_value'*. This way, the user specifies a scale factor for the estimated radius.

List of values: *'auto'*, *'fixed'*, *'z_factor'*.

Default: *'auto'*.

'greedy_radius_value': see *'greedy_radius_type'*.

Suggested values: *0.01*, *0.05*, *0.5*, *0.66*, *1.0*, *1.5*, *2.0*, *3.0*, *4.0*

'greedy_neigh_orient_tol': sets the SNC parameter α in degree units. α controls the surface curvature as described with the SNC rules above.

Suggested values: *10*, *20*, *30*, *40*.

Default: *30*.

'greedy_neigh_orient_consistent': enforces that the normals of two neighboring points have the same orientation (i.e., they do not show in opposite directions). If enabled, this parameter disables the second part of the SNC criteria for α, i.e., if $\angle(N, N') > \alpha$, the criteria fails even if $\angle(N, -N') \leq \alpha$.

List of values: *'true'*, *'false'*.

Default: *'false'*.

'greedy_neigh_latitude_tol': sets the SNC parameter β in degree units. β controls the surface neighborhood latitude window as described with the SNC rules above.

Suggested values: *10*, *20*, *30 40*.

Default: *30*.

'greedy_neigh_vertical_tol': sets the SNC parameter d as a factor of the radius r.

Suggested values: *0.01*, *0.1*, *0.2*, *0.3*.

Default: *0.1*.

'greedy_hole_filling': sets the length of surface boundaries (in number of point vertices) that should be considered for the hole filling. If *'false'* is specified, then the hole filling step is disabled.

Suggested values: *'false'*, *20*, *40*, *60*.

Default: *40*.

'greedy_fix_flips': enables/disables the flip resolving step of the algorithm.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'greedy_prefetch_neighbors': enables/disables prefetching of lists of the k nearest neighbors for all points. This prefetching improves the algorithm speed, but has high memory requirements ($O(kn)$, where k is the number specified by *'greedy_kNN'*, and n is the number of points in `ObjectModel3D`). For very large data, it might be impossible to preallocate such a big amount of memory, results in a memory error message. In such a case the prefetching must be disabled.

List of values: *'true'*, *'false'* **Default:** *'true'*.

'greedy_mesh_erosion': specifies the number of erosion cycles applied to the final mesh.

Suggested values: *0*, *1*, *2*, *3*.

Default: *0*.

'greedy_mesh_dilation': specifies the number of dilation cycles. The mesh dilation is applied after the mesh erosion. If *'greedy_mesh_dilation'* is set to a greater value than *'greedy_mesh_erosion'*, it will be reduced internally to the value of *'greedy_mesh_erosion'*.

Suggested values: *0*, *1*, *2*, *3* **Default:** *0*.

'greedy_remove_small_surfaces': controls the criteria for removing small surface pieces. If set to *'false'*, the small surface removal is disabled. If set to a value between *0.0* and *1.0*, all surfaces having less triangles than *'greedy_remove_small_surfaces'*×`num_triangles` will be removed, where `num_triangles` is the total number of triangles generated by the algorithm. If set to a value greater than *1*, all surfaces having less triangles than *'greedy_remove_small_surfaces'* will be removed.

Suggested values: *'false'*, *0.01*, *0.05*, *0.1*, *10*, *100*, *1000*, *10000*.

Default: *'false'*.

'greedy_timeout': using a timeout, it is possible to interrupt the operator after a defined period of time in seconds. This is especially useful in cases, where a maximum cycle time has to be ensured. The temporal accuracy of this interrupt is about 10 ms. Passing values less then zero is not valid. Setting *'greedy_timeout'* to *'false'* deactivates the timeout, which corresponds to the default. The temporal accuracy depends on several factors including the size of the model, the speed of your computer, and the *'timer_mode'* set via `set_system`.

Suggested values: *'false'*, *0.1*, *0.5*, *1*, *10*, *100*.

Default: *'false'*.

'greedy_suppress_timeout_error': by default, if a timeout occurs the operator returns a timeout error code. By setting *'greedy_suppress_timeout_error'* to *'true'* instead, the operator returns no error and the intermediate results of the triangulation are returned in `TriangulatedObjectModel3D`. With the error suppressed, the occurrence of a timeout can be checked by querying the list of values returned in `Information` (in *'verbose'* mode) by looking for the value corresponding to *'timeout_occured'*.

List of values: *'false'*, *'true'*.

Default: *'false'*.

'greedy_output_all_points': controls, if all input points are returned, regardless whether they were used in the output triangulation or not. Mainly provided for reasons of backward compatibility. When *'greedy_output_all_points'* is set to *'false'*, the old point indices are stored as an extended attribute named *'original_point_indices'* in the 3D object model `TriangulatedObjectModel3D`. This attribute can subsequently be queried with `get_object_model_3d_params` or be processed with other operators that use extended attributes.

List of values: *'false'*, *'true'*.

Default: *'false'*.

'information': specifies, which intermediate results shall be reported in `Information`. By default (*'information'*=*'num_triangles'*), the number of generated triangles is reported. For *'information'*=*'verbose'*, a list of name-value information pairs is returned. Currently, the following information is reported:

Name	Value	Description
'num_triangles'	<number of triangles>	returns the number of generated triangular faces.
'specified_radius_type'	*'auto'* | *'fixed'* | *'z_factor'* | *'none'*	returns the radius type as specified by the user.
'specified_radius_value'	<specified radius value>	returns the radius value specified by the user.
'used_radius_type'	*'fixed'* | *'z_factor'* | *'sampling'*	returns the radius type used internally; if the user specified *'auto'* for *'specified_radius_type'*, this field returns the radius type that was selected internally; if `ObjectModel3D` is a 3D primitive, the user specified radius value is internally used as a sampling step and *'used_radius_type'* returns *'sampling'*.
'used_radius_value'	<used radius value>	returns the radius value used internally; if *'used_radius_type'='fixed'*, the absolute neighborhood radius in meters is reported; if *'used_radius_type'='z_factor'*, the multiplication factor is reported, which is used to compute the neighborhood radius from the z-coordinate of the neighborhood center point; if *'used_radius_type'='sampling'*, then the sub-sampling factor is reported, which is used to generate the triangulation of 3D primitives, in particular: cylinder and sphere.
'neigh_orient_tol'	<α>	returns the surface curvature parameter α in degrees that was used for the triangulation.
'neigh_latitude_tol'	<β>	returns the angular tolerance window in degrees that was used to select surface neighbors.
'neigh_vertical_tol'	<d>	returns the neighborhood parameter d as a factor of the used radius.
'fix_flips'	*'true'* | *'false'*	returns whether the flip fixing was enabled.
'hole_filling'	*'false'* | <max hole boundary length>	returns *'false'* when the hole filling was disabled, or the specified maximal hole boundary length in number of points.
'timeout'	*'false'* | <timeout>	*'false'* when the timeout was disabled, or the specified timeout in seconds.
'timeout_occured'	*'yes'* | *'no'*	returns whether a timeout occurred.

List of values: *'num_triangles'*, *'verbose'*.
Default: *'num_triangles'*.

Implicit triangulation

By selecting `Method`=*'implicit'* an implicit triangulation algorithm based on a Poisson solver (see the paper in References) is invoked. It constructs a water-tight surface, i.e., it is completely closed. The implicit triangulation requires 3D point data containing normals. Additionally, it is required that the 3D normals are pointing strictly inwards or strictly outwards regarding the volume enclosed by the surface to be reconstructed. Unlike the *'greedy'* algorithm, the *'implicit'* algorithm does not construct the surface through the input 3D points. Instead, it constructs

a surface that approximates the original 3D data and creates a new set of 3D points lying on this surface.

First, the algorithm organizes the point data in an adaptive octree structure: the volume of the bounding box containing the point data is split in the middle in each dimension resulting in eight sub-volumes, or *octree voxels*. Voxels still containing enough point data can be split in further eight sub-voxels. Voxels that contain no or just few points must not be split further. This splitting is repeated recursively in regions of dense 3D point data until the resulting voxels contain no or just few points. The recursion level of the voxel splits, reached with the smallest voxels, is denoted as *depth* of the octree.

In the next step, the algorithm estimates the values of the so-called *implicit indicator function* of the surface, based on the assumption that the points from `ObjectModel3D` are lying on the surface of an object and the normals of the points in `ObjectModel3D` are pointing inwards that object (see the paper in References). This assumption explains the requirement of mutually consistent normal orientations. The implicit function has a value of 1 in voxel corners that are strictly inside the body and 0 for voxel corners strictly outside of it. Due to noisy data, voxel corners that are close to the boundary of the object cannot be 'labeled' unambiguously. Therefore, they receive a value between 0 and 1.

The *implicit surface* defined by the indicator function is a surface, such that each point lying on it has an indicator value of 0.5. The implicit algorithm uses a standard *marching cubes algorithm* to compute the intersection points of the implicit surface with the sides of the octree voxels. The intersection points result in the new set of 3D points spanning the surface returned in `TriangulatedObjectModel3D`. As a consequence, the resolution of the surface details reconstructed in `TriangulatedObjectModel3D` depends directly on the resolution of the octree (i.e., on its *depth*).

By setting `GenParamName` to one of the following values, additional parameters specific for the *implicit triangulation* can be set with `GenParamValue`:

'implicit_octree_depth': sets the depth of the octree. The octree depth controls the resolution of the surface generation - a higher depth leads to a higher surface resolution. The octree depth has an exponential effect on the runtime and an exponential effect on the memory requirements of the octree. Therefore, the depth is limited to *12*.

Restriction: $5 \leq$ *'implicit_octree_depth'* ≤ 12.

Suggested values: *5*, *6*, *8*, *10*, *11*, *12*.

Default: *6*.

'implicit_solver_depth': enables an alternative algorithm, which can prepare the implicit function up to a user specified octree depth, before the original algorithm takes over the rest of the computations. This algorithm requires less memory than the original one, but is a bit slower.

Restriction: *'implicit_solver_depth'* $\leq$ *'implicit_octree_depth'*.

Suggested values: *2*, *4*, *6*, *8*, *10*, *11*, *12*.

Default: *6*.

'implicit_min_num_samples': sets the minimal number of point samples required per octree voxel node. If the number of points in a voxel is less than this value, the voxel is not split any further. For noise free data, this value can be set low (e.g., between 1-5). For noisy data, this value should be set higher (e.g., 10-20), such that the noisy data is accumulated in single voxel nodes to smooth the noise.

Suggested values: *1 5*, *10*, *15*, *20*, *30*.

Default: *1*.

'information': specifies, which intermediate results shall be reported in `Information`. By default (*'information'='num_triangles'*), the number of generated triangles is reported. For *'information'='verbose'*, a list of name-value information pairs is returned. Currently, the following information is reported:

Name	Value	Description
'num_triangles'	<number of triangles>	returns the number of generated triangular faces.
'num_points'	<number of points>	returns the number of generated points.

List of values: *'num_triangles'*, *'verbose'*.

Default: *'num_triangles'*.

Comparison of the triangulation methods

In this paragraph, a simple comparison of both supported triangulation methods is provided:

Property	Greedy triangulation	Implicit triangulation
required data:	3D points with 3D normals	3D points with 3D normals, the normals must point consistently inwards
resulting surface:	open, triangulation of the input points	closed (water-tight), approximation of the input points
resulting point data:	the input point data is preserved	new point data is generated
noise handling:	moderate point and normal noise handled properly	point and normal noise handled implicitly; moderate and high noise levels are accepted
triangulation resolution:	explicit, controlled by surface neighborhood parameters	implicit, controlled by octree depth and minimal number of point samples per node
time complexity:	$O(Nk \log N)$	$O(ND^3)$
memory complexity:	$O(Nk)$, with neighborhood prefetching $O(N)$, without neighborhood prefetching	$O(D^3)$ *where:* N: *number of points* k: *size of the neighborhood* D: *depth of the octree*

Depending on the number of points in `ObjectModel3D`, noise, and specific structure of the data, both algorithms deliver different results and perform with different time and memory complexity. The greedy algorithm works fast, requires less memory, and returns a high level of details in the reconstructed surface for rather small data sets (up to, e.g., 500.000 points). Since the algorithm must basically process every single point in the data, its time performance cannot be decoupled from the point number and it can be rather time consuming for more than 500.000 points. If large point sets need to be triangulated with this method anyway, it is recommended to first sub-sample them via `sample_object_model_3d`.

In contrast, as described above, the implicit algorithm organizes all points in an underlying octree. Therefore, the details returned by it, its speed, and its memory consumption are dominated by the depth of the octree. While higher levels of surface details can only be achieved at disproportionately higher time and memory costs, the octree offers the advantage that it handles large point sets more efficiently. With the octree, the performance of the implicit algorithm depends mostly on the depth of the octree and to a lesser degree on the number of points to be processed. One further disadvantage of the implicit algorithm is its requirement that the adjacent point normals are strictly consistent. This requirement can seldom be fulfilled by usual normal estimation routines.

Parameters

▷ **`ObjectModel3D`** (input_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model containing 3D point data.

▷ **`Method`** (input_control) . . . . . string ⇝ *string*
Triangulation method.
Default: 'greedy'
List of values: `Method` ∈ {'greedy', 'implicit', 'polygon_triangulation', 'xyz_mapping'}

▷ **`GenParamName`** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic triangulation parameters.
Default: []
List of values: `GenParamName` ∈ {'information', 'implicit_octree_depth', 'implicit_solver_depth', 'implicit_min_num_samples', 'greedy_radius_type', 'greedy_radius_value', 'greedy_kNN', 'greedy_neigh_orient_tol', 'greedy_neigh_orient_consistent', 'greedy_neigh_vertical_tol', 'greedy_neigh_latitude_tol', 'greedy_hole_filling', 'greedy_fix_flips', 'greedy_mesh_erosion', 'greedy_mesh_dilation', 'greedy_remove_small_surfaces', 'greedy_prefetch_neighbors', 'greedy_timeout', 'greedy_suppress_timeout_error', 'greedy_output_all_points', 'xyz_mapping_max_area_holes', 'xyz_mapping_output_all_points', 'xyz_mapping_max_view_angle', 'xyz_mapping_max_view_dir_x', 'xyz_mapping_max_view_dir_y', 'xyz_mapping_max_view_dir_z'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of the generic triangulation parameters.
Default: []
Suggested values: GenParamValue ∈ {6, 8, 12, 'true', 'false', 'auto', 'fixed', 'z_factor', 'verbose', 'num_triangles'}

▷ **TriangulatedObjectModel3D** (output_control) . . . . . object_model_3d(-array) ⇝ *handle*
Handle of the 3D object model with the triangulated surface.

▷ **Information** (output_control) . . . . . number(-array) ⇝ *integer* / string
Additional information about the triangulation process.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

xyz_to_object_model_3d (X, Y, Z : : : ObjectModel3D)

Transform 3D points from images to a 3D object model.

The operator xyz_to_object_model_3d transforms an image triple that contains the X, Y, and Z-coordinates of 3D points to a 3D object model. Thereby, only points in the intersecting domains of all three images are used and the images need to be of same size. The size of these images can be queried from the model by get_object_model_3d_params with *'mapping_size'*. The handle of the created 3D object model is returned in ObjectModel3D. The created 3D object model contains the coordinates of the points, as well as a mapping attribute that contains the original row and column of each 3D point. Points where one of the coordinates is infinity or "Not a Number" (NaN) are ignored and not added to the 3D object model.

Parameters

▷ **X** (input_object) . . . . . singlechannelimage ⇝ *object : real*
Image with the X-Coordinates and the ROI of the 3D points.

▷ **Y** (input_object) . . . . . singlechannelimage ⇝ *object : real*
Image with the Y-Coordinates of the 3D points.

▷ **Z** (input_object) . . . . . singlechannelimage ⇝ *object : real*
Image with the Z-Coordinates of the 3D points.

▷ **ObjectModel3D** (output_control) . . . . . object_model_3d ⇝ *handle*
Handle of the 3D object model.

Result

The operator xyz_to_object_model_3d returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Chapter 5

3D Reconstruction

5.1 Binocular Stereo

```
binocular_disparity ( ImageRect1, ImageRect2 : Disparity,
    Score : Method, MaskWidth, MaskHeight, TextureThresh,
    MinDisparity, MaxDisparity, NumLevels, ScoreThresh, Filter,
    SubDisparity : )
```

Compute the disparities of a rectified image pair using correlation techniques.

`binocular_disparity` computes pixel-wise correspondences between two rectified images using correlation techniques. Different from `binocular_distance` the results are not transformed into distance values.

The algorithm requires a reference image `ImageRect1` and a search image `ImageRect2` which must be rectified, i.e., corresponding epipolar lines are parallel and lie on identical image rows ($r_1 = r_2$). In case this assumption is violated the images can be rectified by using the operators `calibrate_cameras`, `gen_binocular_rectification_map`, and `map_image`. Hence, given a pixel in the reference image `ImageRect1` the homologous pixel in `ImageRect2` is selected by searching along the corresponding row in `ImageRect2` and matching a local neighborhood within a rectangular window of size `MaskWidth` and `MaskHeight`. The pixel correspondences are returned in the single-channel `Disparity` image $d(r_1, c_1)$ which specifies for each pixel $(r1, c1)$ of the reference image `ImageRect1` a suitable matching pixel $(r2, c2)$ of `ImageRect2` according to the equation $c_2 = c_1 + d(r_1, c_1)$. A quality measure for each disparity value is returned in `Score`, containing the best result of the matching function S of a reference pixel. For the matching, the gray values of the original unprocessed images are used.

The used matching function is defined by the parameter `Method` allocating three different kinds of correlation:

- *'sad'*: Summed Absolute Differences

  $$S(r,c,d) = \frac{1}{N} \sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} \mid g_1(r',c') - g_2(r',c'+d) \mid,$$

  with $0 \leq S(r,c,d) \leq 255$.
- *'ssd'*: Summed Squared Differences

  $$S(r,c,d) = \frac{1}{N} \sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_1(r',c') - g_2(r',c'+d))^2,$$

  with $0 \leq S(r,c,d) \leq 65025$.
- *'ncc'*: Normalized Cross Correlation

  $$S(r,c,d) = \frac{\sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_1(r',c') - \bar{g_1}(r,c))(g_2(r',c'+d) - \bar{g_2}(r,c+d))}{\sqrt{\left(\sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_1(r',c') - \bar{g_1}(r,c))^2\right)\left(\sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_2(r',c'+d) - \bar{g_2}(r,c+d))^2\right)}},$$

  with $-1.0 \leq S(r,c,d) \leq 1.0$.

with

$r1$, $c1$, $r2$, $c2$: row and column coordinates of the corresponding pixels of the two input images,

$g1$, $g2$: gray values of the unprocessed input images,

$N = (2m+1)(2n+1)$: size of correlation window

$\bar{g}(r,c) = \frac{1}{N} \sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} g(r',c')$: mean value within the correlation window of width $2m+1$ and height $2n+1$.

Note that the methods *'sad'* and *'ssd'* compare the gray values of the pixels within a mask window directly, whereas *'ncc'* compensates for the mean gray value and its variance within the mask window. Therefore, if the two images differ in brightness and contrast, this method should be preferred. For images with similar brightness and contrast *'sad'* and *'ssd'* are to be preferred as they are faster because of less complex internal computations.

It should be noted, that the quality of correlation for rising S is falling in methods *'sad'* and *'ssd'* (the best quality value is 0) but rising in method *'ncc'* (the best quality value is 1.0).

The size of the correlation window, referenced by $2m+1$ and $2n+1$, has to be odd numbered and is passed in `MaskWidth` and `MaskHeight`. The search space is confined by the minimum and maximum disparity value `MinDisparity` and `MaxDisparity`. Due to pixel values not defined beyond the image border the resulting domain of `Disparity` and `Score` is not set along the image border within a margin of height (`MaskHeight`-1)/2 at the top and bottom border and of width (`MaskWidth`-1)/2 at the left and right border. For the same reason, the maximum disparity range is reduced at the left and right image border.

Since matching turns out to be highly unreliable when dealing with poorly textured areas, the minimum statistical spread of gray values within the correlation window can be defined in `TextureThresh`. This threshold is applied on both input images `ImageRect1` and `ImageRect2`. In addition, `ScoreThresh` guarantees the matching quality and defines the maximum (*'sad'*,*'ssd'*) or, respectively, minimum (*'ncc'*) score value of the correlation function. Setting `Filter` to *'left_right_check'*, moreover, increases the robustness of the returned matches, as the result relies on a concurrent direct and reverse match, whereas *'none'* switches it off.

The number of pyramid levels used to improve the time response of `binocular_disparity` is determined by `NumLevels`. Following a coarse-to-fine scheme disparity images of higher levels are computed and segmented into rectangular subimages of similar disparity to reduce the disparity range on the next lower pyramid level. `TextureThresh` and `ScoreThresh` are applied on every level and the returned domain of the `Disparity` and `Score` images arises from the intersection of the resulting domains of every single level. Generally, pyramid structures are the more advantageous the more the disparity image can be segmented into regions of homogeneous disparities and the bigger the disparity range is specified. As a drawback, coarse pyramid levels might loose important texture information which can result in deficient disparity values.

Finally, the value *'interpolation'* for parameter `SubDisparity` performs subpixel refinement of disparities. It is switched off by setting the parameter to *'none'*.

Parameters

- ▷ **`ImageRect1`** (input_object) ..... singlechannelimage ⇝ *object :* byte
  Rectified image of camera 1.
- ▷ **`ImageRect2`** (input_object) ..... singlechannelimage ⇝ *object :* byte
  Rectified image of camera 2.
- ▷ **`Disparity`** (output_object) ..... singlechannelimage ⇝ *object :* real
  Disparity map.
- ▷ **`Score`** (output_object) ..... singlechannelimage ⇝ *object :* real
  Evaluation of the disparity values.
- ▷ **`Method`** (input_control) ..... string ⇝ *string*
  Matching function.
  Default: 'ncc'
  List of values: `Method` ∈ {'sad', 'ssd', 'ncc'}
- ▷ **`MaskWidth`** (input_control) ..... integer ⇝ *integer*
  Width of the correlation window.
  Default: 11
  Suggested values: `MaskWidth` ∈ {5, 7, 9, 11, 21}
  Restriction: 3 <= MaskWidth && odd(MaskWidth)

▷ **MaskHeight** (input_control) . . . . . integer ⇝ *integer*
Height of the correlation window.
Default: 11
Suggested values: MaskHeight ∈ {5, 7, 9, 11, 21}
Restriction: 3 <= MaskHeight && odd(MaskHeight)

▷ **TextureThresh** (input_control) . . . . . real ⇝ *real* / integer
Variance threshold of textured image regions.
Default: 0.0
Suggested values: TextureThresh ∈ {0.0, 10.0, 30.0}
Restriction: 0.0 <= TextureThresh

▷ **MinDisparity** (input_control) . . . . . integer ⇝ *integer*
Minimum of the expected disparities.
Default: -30
Value range: -32768 ≤ MinDisparity ≤ 32767

▷ **MaxDisparity** (input_control) . . . . . integer ⇝ *integer*
Maximum of the expected disparities.
Default: 30
Value range: -32768 ≤ MaxDisparity ≤ 32767

▷ **NumLevels** (input_control) . . . . . integer ⇝ *integer*
Number of pyramid levels.
Default: 1
Suggested values: NumLevels ∈ {1, 2, 3, 4}
Restriction: 1 <= NumLevels

▷ **ScoreThresh** (input_control) . . . . . real ⇝ *real* / integer
Threshold of the correlation function.
Default: 0.5
Suggested values: ScoreThresh ∈ {-1.0, 0.0, 0.3, 0.5, 0.7}

▷ **Filter** (input_control) . . . . . string(-array) ⇝ *string*

binocular_disparity_mg (ImageRect1, ImageRect2 : Disparity, Score : GrayConstancy, GradientConstancy, Smoothness, InitialGuess, CalculateScore, MGParamName, MGParamValue :)

Compute the disparities of a rectified stereo image pair using multigrid methods.

`binocular_disparity_mg` calculates the disparity between two rectified stereo images `ImageRect1` and `ImageRect2` and returns it in `Disparity`. In contrast to `binocular_disparity`, a variational approach based on multigrid methods is used. This approach returns disparity values also for image parts that contain no texture. In contrast to `binocular_distance_mg`, the results are not transformed into distance values.

The input images must be a pair of rectified stereo images, i.e., corresponding points must have the same vertical coordinate. The images can have different widths, but must have the same height. The runtime of the operator is approximately linear in the size of the images.

The disparity is the amount by which each point in the first image `ImageRect1` needs to be moved to reach its corresponding point in the second image `ImageRect2`. Two points are called corresponding if they are the image of the same point in the original scene. The calculated disparity field is dense and estimates the disparity also for points that do not have a corresponding point. The disparity is calculated only for those lines that are part of the domains of both input images. More exactly, the domain of the disparity map is calculated as the intersection of heights of the smallest enclosing rectangles of the domains of the input images.

The calculated disparity field is usually not perfect. If the parameter `CalculateScore` is set to *'true'*, a quality measure for the disparity is estimated for each pixel and returned in `Score`, which is a gray value image with a range from 0 to 10, where 0 is the best quality and 10 the worst. For this, the reverse disparity field from the second to the first image is calculated and compared to the returned disparity field. Because of this, the runtime roughly doubles when computing the score.

The operator uses a variational approach, where an energy value is assigned to each possible disparity field. Disparity fields with a lower energy are better than those with a high energy. The operator calculates a disparity field with the minimum energy and returns it.

The energy assigned to a disparity field consists of a data term and a smoothness term. The data term models the fact that corresponding points are images of the same part of the scene and thus have equal gray values. The smoothness term models the fact that the imaged scene and with it its disparity field is piecewise smooth, which leads to an interpolation of the disparity into areas with low information from the data term, e.g., areas with no texture.

The details of the assumptions are as follows:

Constancy of the gray values: It is assumed that corresponding points have the same gray value, i.e., that $I_1(x,y) = I_2(x+u(x,y),y)$.

Constancy of the gray value gradients: It is assumed that corresponding points have the same gray value gradient, i.e., that $\nabla I_1(x,y) = \nabla I_2(x+u(x,y),y))$. Discrepancies from this assumption are modeled using the L_2 norm of the difference of the two gradients. The gray value gradient has the advantage of being invariant to additive illumination changes between the two images.

Statistical robustness in the data term: To reduce the influence of outliers, i.e., points that violate the constancy assumptions, they are penalized in a statistically robust manner via the total variation $\Psi(x) = \sqrt{x+\epsilon^2}$, where $\epsilon = 0.01$ is a fixed regularization constant.

Smoothness of the disparity field: It is assumed that the resulting disparity field is piecewise smooth. This is modeled by the L_2 norm of the derivative of the disparity field.

Statistical robustness in the smoothness term: Analogously to the data term, the statistically robust total variation is applied to the smoothness term to reduce the influence of outliers. This is especially important for preserving edges in the disparity field that appear on object boundaries.

The energy functional is the integral of a linear combination of the above terms over the area of the first image. The coefficients of the linear combination are parameters of the operator and allow a fine tuning of the model to a specific situation. `GrayConstancy` determines the influence of the gray value constancy, `GradientConstancy` the influence of the constancy of the gray value gradient, and `Smoothness` the influence of the smoothness term. The first two parameters need to be adapted to the gray value interval of the images. The proposed parameters are valid for images with a gray value range of 0 to 255.

Let $I_1(x,y)$ be the gray value of the first image at the coordinates (x,y), $I_2(x,y)$ the gray value of the second image, and $u(x,y)$ the value of the disparity at the coordinate (x,y). Then, the energy functional is then given by

$$\begin{aligned} E = \int \Psi \quad (\quad & \texttt{GrayConstancy} \cdot \underbrace{(I_2(x+u(x,y),y) - I_1(x,y))^2}_{\text{gray value constancy}} + \\ & \texttt{GradientConstancy} \cdot \underbrace{|\nabla I_2(x+u(x,y)) - \nabla I_1(x,y)|^2)}_{\text{gradient constancy}} \\ + \quad & \texttt{Smoothness} \cdot \Psi \underbrace{(|\nabla u(x,y)|^2)}_{\text{smoothness}} \, dx\, dy \end{aligned}$$

It is assumed that the disparity field u that minimizes the functional E satisfies the above assumptions and is thus a good approximation of the disparity between the two images.

The above functional is minimized by finding the roots of the Euler-Lagrange equation (ELE) of the integral. This is comparable to finding the extremal values of a one-dimensional function by searching the roots of its derivative. The ELE is a nonlinear partial differential equation over the region of the integral, which needs to be 0 for extrema of E. Since the functional typically does not have any maxima, the corresponding roots of the ELE correspond to the minima of the functional.

The following techniques are used to find the roots of the ELE:

Fixed point iteration: The ELE is solved by converting it to a fixed point iteration that iteratively approaches the solution. The number of iterations can be used to balance between speed and accuracy of the solution. Each step of the fixed point iteration consists of solving a linear partial differential equation.

Coarse-to-fine process: A Gaussian image pyramid of the stereo images is created. The ELE is first solved on a coarse level of the pyramid and the solution is taken as the initial value of the fixed point iteration of the next level. This has a number of advantages and disadvantages:

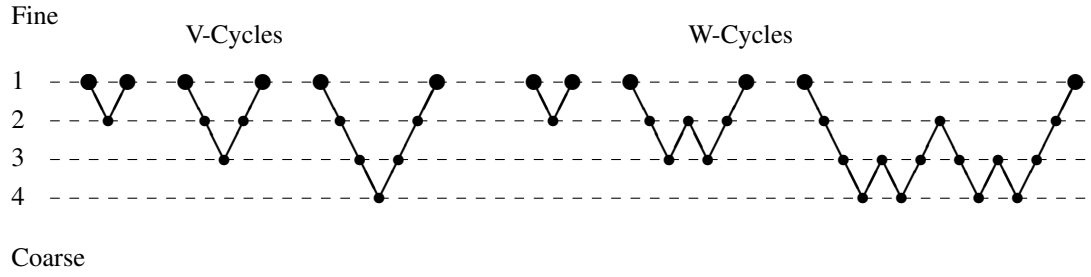
1. Since the fixed point iteration of the next level receives a good initial value, fewer iterations are necessary to archive a good accuracy. The iteration must perform only small corrections of the disparity.

2. Large disparities on the original images become small disparities on the coarse grid levels and can thus be calculated more easily.

3. The robustness against noise in the images is increased because most kinds of noise disappear on the coarse version of the images.

4. Problems arise with small structures that have a large disparity difference to their surroundings since they disappear on coarse versions of the image and thus the disparity of the surroundings is calculated. This error will not be corrected on the finer levels of the image pyramid since only small corrections are calculated there.

Multigrid methods: The linear partial differential equations that arise in the fixed point iteration at each pyramid level are converted into a linear system of equations through linearization. These linear systems are solved using iterative solvers. Multigrid methods are among the most efficient solvers for the kind of linear systems that arise here. They use the fact that classic iterative solvers, like the Gauss-Seidel solver, quickly reduce the high frequency parts of the error, but only slowly reduce the low frequency parts. Multigrid methods thus calculate the error on a coarser grid where the low frequency part of the error appears as high frequencies and can be reduced quickly by the classical solvers. This is done hierarchically, i.e., the computation of the error on a coarser resolution level itself uses the same strategy and efficiently computes its error (i.e., the error of the error) by correction steps on an even coarser resolution level. Depending on whether one or two error correction steps are performed per cycle, a so called V or W cycle is obtained. The corresponding strategies for stepping through the resolution hierarchy are as follows for two to four resolution levels:



Here, iterations on the original problem are denoted by large markers, while small markers denote iterations on error correction problems.

Algorithmically, a correction cycle can be described as follows:

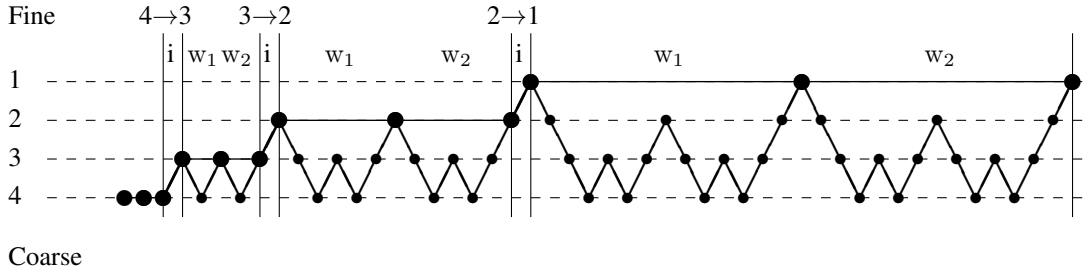
1. In the first step, several (few) iterations using an interactive linear or nonlinear basic solver are performed (e.g., a variant of the Gauss-Seidel solver). This step is called pre-relaxation step.

2. In the second step, the current error is computed to correct the current solution (the solution after step 1). For efficiency reasons, the error is calculated on a coarser resolution level. This step, which can be performed iteratively several times, is called coarse grid correction step.

3. In a final step, again several (few) iterations using the interactive linear or nonlinear basic solver of step 1 are performed. This step is called post-relaxation step.

In addition, the solution can be initialized in a hierarchical manner. Starting from a very coarse variant of the original linear equation system, the solution is successively refined. To do so, interpolated solutions of coarser variants of the equation system are used as the initialization of the next finer variant. On each resolution level itself, the V or W cycles described above are used to efficiently solve the linear equation system on that resolution level. The corresponding multigrid methods are called full multigrid methods in the literature. The full multigrid algorithm can be visualized as follows:

Full multigrid algorithm



This example represents a full multigrid algorithm that uses two W correction cycles per resolution level of the hierarchical initialization. The interpolation steps of the solution from one resolution level to the next are denoted by i and the two W correction cycles by w_1 and w_2. Iterations on the original problem are denoted by large markers, while small markers denote iterations on error correction problems.

Depending on the selected multigrid solver, a number of parameters for fine tuning the solver are available and are described in the following.

The parameter `InitialGuess` gives a initial value for the initialization of the fixed point iteration on the coarsest grid. Usually 0 is sufficient, but to avoid local minima other values can be used.

Using the parameters `MGParamName` and `MGParamValue`, the solver is controlled, i.e., the coarse-to-fine process, the fixed point iteration, and the multigrid solver. It is usually sufficient to use one of the predefined parameter sets, which are available by setting `MGParamName` = *'default_parameters'* and `MGParamValue` = *'very_accurate'*, *'accurate'*, *'fast_accurate'*, or *'fast'*.

If the parameters should be specified individually, `MGParamName` and `MGParamValue` must be set to tuples of the same length. The values corresponding to the parameters specified in `MGParamName` must be specified at the corresponding position in `MGParamValue`. The parameters are evaluated in the given order. Therefore, it is possible to first select a group of default parameters (see above) and then change only some of the parameters. in the following, the possible parameters are described.

`MGParamName` = *'mg_solver'* sets the solver for the linear system. Possible values for `MGParamValue` are *'multigrid'* for a simple multigrid solver, *'full_multigrid'* for a full multigrid solver, and *'gauss_seidel'* for the plain Gauss-Seidel solver. The multigrid methods have the advantage of a faster convergence, but incur the overhead of coarsening the linear system.

`MGParamName` = *'mg_cycle_type'* selects the type of recursion for the multigrid solvers. Possible values for `MGParamValue` are *'v'* for a V-Cycle, *'w'* for a W-Cycle, and *'none'* for no recursion.

`MGParamName` = *'mg_pre_relax'* sets the number of iterations of the pre-relaxation step in multigrid solvers, or the number of iterations for the Gauss-Seidel solver, depending on which is selected.

`MGParamName` = *'mg_post_relax'* sets the number of iterations of the post-relaxation step.

Increasing the number of pre- and post-relaxation steps increases the computation time asymptotically linearly. However, no additional restriction and prolongation operations (zooming down and up of the error correction images) are performed. Consequently, a moderate increase in the number of relaxation steps only leads to a slight increase in the computation times.

`MGParamName` = *'initial_level'* sets the coarsest level of the image pyramid where the coarse-to-fine process starts. The value can be positive, in which case it directly gives the initial level. Level 0 is the finest level with the original images. If the value is negative, then it is used relative to the maximum number of pyramid levels. The coarsest available pyramid level is the one where both images have a size of at least 4 pixels in both directions. As described below, the default value of *'initial_level'* is *-2*. This facilitates the calculation of the correct disparity for images that have very large disparities. In some cases, e.g., for repeating textures, this may lead to the fact that too large disparities are calculated for some parts of the image. In this case, *'initial_level'* should be set to a smaller value.

The standard parameters zoom the image with a factor of 0.6 per pyramid level. If a guess of the maximum disparity d exists, then the initial level s should be selected so that 0.6^{-s} is greater than d.

`MGParamName` = *'iterations'* sets the number of iterations of the fixed point iteration per pyramid level. The exact number of iterations is $steps = \min(10, \text{iterations} + \text{level}^2)$, where level is the current level in the image pyramid. If this value is set to 0, then no iteration is performed on the finest pyramid level 0. Instead, the result of

level 1 is scaled to the original image size and returned, which can be used if speed is crucial. The runtime of the operator is approximately linear in the number of iterations.

MGParamName = *'pyramid_factor'* determines the factor by which the images are scaled when creating the image pyramid for the coarse-to-fine process. The width and height of the next smaller image is scaled by the given factor. The value must lie between 0.1 and 0.9.

The predefined parameter sets for MGParamName = *'default_parameters'* contain the following values:

'default_parameters' = *'very_accurate'*: *'mg_solver'* = *'full_multigrid'*, *'mg_cycle_type'* = *'w'*, *'mg_pre_relax'* = 5, *'mg_post_relax'* = 5, *'initial_level'* = -2, *'iterations'* = 5, *'pyramid_factor'* = 0.6.

'default_parameters' = *'accurate'*: *'mg_solver'* = *'full_multigrid'*, *'mg_cycle_type'* = *'w'*, *'mg_pre_relax'* = 5, *'mg_post_relax'* = 5, *'initial_level'* = -2, *'iterations'* = 2, *'pyramid_factor'* = 0.6.

'default_parameters' = *'fast_accurate'*: *'mg_solver'* = *'full_multigrid'*, *'mg_cycle_type'* = *'v'*, *'mg_pre_relax'* = 2, *'mg_post_relax'* = 2, *'initial_level'* = -2, *'iterations'* = 1, *'pyramid_factor'* = 0.6. These are the default parameters of the algorithm if the default parameter set is not specified.

'default_parameters' = *'fast'*: *'mg_solver'* = *'full_multigrid'*, *'mg_cycle_type'* = *'v'*, *'mg_pre_relax'* = 1, *'mg_post_relax'* = 1, *'initial_level'* = -2, *'iterations'* = 0, *'pyramid_factor'* = 0.6.

Weaknesses of the operator: Large jumps in the disparity, which correspond to large jumps in the distance of the observed objects, are smoothed rather strongly. This leads to problems with thin objects that have a large distance to their background.

Distortions can occur at the left and right border of the image in the parts that are visible in only one of the images.

Additionally, general problems of stereo vision should be avoided, including horizontally repetitive patterns, areas with little texture as well as reflections.

Parameters

▷ **ImageRect1** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Rectified image of camera 1.

▷ **ImageRect2** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Rectified image of camera 2.

▷ **Disparity** (output_object) ..... singlechannelimage(-array) ⇝ *object :* real
Disparity map.

▷ **Score** (output_object) ..... singlechannelimage(-array) ⇝ *object :* real
Score of the calculated disparity if CalculateScore is set to *'true'*.

▷ **GrayConstancy** (input_control) ..... real ⇝ *real*
Weight of the gray value constancy in the data term.
Default: 1.0
Suggested values: GrayConstancy ∈ {0.0, 1.0, 2.0, 10.0}
Restriction: GrayConstancy >= 0.0

▷ **GradientConstancy** (input_control) ..... real ⇝ *real*
Weight of the gradient constancy in the data term.
Default: 30.0
Suggested values: GradientConstancy ∈ {0.0, 1.0, 5.0, 10.0, 30.0, 50.0, 70.0}
Restriction: GradientConstancy >= 0.0

▷ **Smoothness** (input_control) ..... real ⇝ *real*
Weight of the smoothness term in relation to the data term.
Default: 5.0
Suggested values: Smoothness ∈ {1.0, 3.0, 5.0, 10.0}
Restriction: Smoothness > 0.0

▷ **InitialGuess** (input_control) ..... real ⇝ *real*
Initial guess of the disparity.
Default: 0.0
Suggested values: InitialGuess ∈ {-30.0, -20.0, -10.0, 0.0, 10.0, 20.0, 30.0}

▷ **CalculateScore** (input_control) ..... string ⇝ *string*
Should the quality measure should be returned in Score?
Default: 'false'
Suggested values: CalculateScore ∈ {'true', 'false'}

▷ **MGParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Parameter name(s) for the multigrid algorithm.
Default: 'default_parameters'
List of values: MGParamName ∈ {'default_parameters', 'mg_solver', 'mg_cycle_type', 'mg_pre_relax', 'mg_post_relax', 'initial_level', 'pyramid_factor', 'iterations'}

▷ **MGParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
Parameter value(s) for the multigrid algorithm.
Default: 'fast_accurate'
Suggested values: MGParamValue ∈ {'very_accurate', 'accurate', 'fast_accurate', 'fast', 'v', 'w', 'none', 'gauss_seidel', 'multigrid', 'full_multigrid', 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, -1, -2, -3, -4, -5}

Example

```
read_image (BaseballL, 'stereo/epipolar/baseball_l')
read_image (BaseballR, 'stereo/epipolar/baseball_r')
binocular_disparity_mg (BaseballL, BaseballR, Disparity, Score, \
                        0.25, 30, 5, 0, 'true', \
                        'default_parameters','fast_accurate')
```

Result

If the parameter values are correct, binocular_disparity_mg returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

binocular_disparity_ms (ImageRect1, ImageRect2 : Disparity, Score : MinDisparity, MaxDisparity, SurfaceSmoothing, EdgeSmoothing, GenParamName, GenParamValue :)

Compute the disparities of a rectified stereo image pair using multi-scanline optimization.

binocular_disparity_ms calculates the disparity between two rectified stereo images ImageRect1 and ImageRect2 using multi-scanline optimization. The resulting disparity image is returned in Disparity. In contrast to binocular_distance_ms, the results are not transformed into distance values.

For this task, the three operators binocular_disparity, binocular_disparity_mg, and binocular_disparity_ms can be used. binocular_disparity returns robust results in regions of

sufficient texture but fails where there is none. binocular_disparity_mg interpolates low-texture regions but blurs discontinuities. binocular_disparity_ms preserves discontinuities and interpolates partially.

binocular_disparity_ms requires a reference image ImageRect1 and a search image ImageRect2 which both must be rectified, i.e., corresponding pixels must have the same row coordinate. If this assumption is violated, the images can be rectified by using the operators calibrate_cameras, gen_binocular_rectification_map, and map_image.

ImageRect1 and ImageRect2 can have different widths but must have the same height. Given a pixel in ImageRect1, the homologous pixel in ImageRect2 is selected by searching along the corresponding row in ImageRect2 and matching both pixels based on a similarity measure. The disparity is the number of pixels by which each pixel in ImageRect1 needs to be moved to reach the homologous pixel in ImageRect2.

The search space is confined by the minimum and maximum disparity values MinDisparity and MaxDisparity. If the minimum and maximum disparity values are set to an empty tuple, they are automatically set to the maximum possible range for the given images ImageRect1.

To calculate the disparities from the similarity measure, the intermediate results are optimized by a multi-scanline method. The optimization increases the robustness in low-texture areas without blurring discontinuities in the disparity image. The optimization is controlled by the parameters SurfaceSmoothing and EdgeSmoothing. SurfaceSmoothing controls the smoothness within surfaces. High values suppress disparity differences of one pixel. EdgeSmoothing controls the occurrence and the shape of edges. Low values allow many edges, high values lead to fewer and rounder edges. For both parameters, reasonable values usually range between 0 and 100. If both parameters are set to zero, no optimization is performed.

The calculation of the disparities can be controlled by generic parameters. The following generic parameters GenParamName and the corresponding values GenParamValue are supported:

'consistency_check' Activates an optional post-processing step to increase robustness. Concurrent direct and reverse matches between reference patterns in ImageRect1 and ImageRect2 are required for a disparity value to be returned. The check is switched off by setting GenParamValue to *'false'*.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'disparity_offset' Adapts the quality of the coarse-to-fine approach at discontinuities. The higher the value set in GenParamValue, the more runtime is required.

Suggested values: *2*, *3*, *4*.

Default: *3*.

'method': Determines the method used to calculate the disparities. The following parameters GenParamValue can be set:

- *'accurate'*: Most accurate calculation method, but requires more runtime and memory compared to the remaining methods.
- *'fast'*: Uses a coarse-to-fine scheme to improve the runtime. The coarse-to-fine scheme works in a similar way to the scheme explained in binocular_disparity.
  The coarse-to-fine method requires significantly less memory and is significantly faster than the *'accurate'* method, especially for large images or a large range of MinDisparity and MaxDisparity. The coarse-to-fine scheme has the further advantage that it automatically estimates the range of MinDisparity and MaxDisparity while traversing through the pyramid. As a consequence, neither MinDisparity nor MaxDisparity needs to be set. However, the generated disparity images are less accurate for the *'fast'* method than for the default *'accurate'* approach. Especially at sharp disparity jumps the *'fast'* method preserves discontinuities less accurately.
- *'very_fast'*: Also uses a coarse-to-fine scheme to improve the runtime even further. However, this approach makes numerous assumptions that may lead to a smoothing of the disparities at discontinuities. Per default, the number of levels of the coarse-to-fine scheme is estimated automatically. It is possible to set the number of levels explicitly (see *'num_levels'*).

The runtime of the operator is approximately linear to the image width, the image height, and the disparity range. Consequently, the disparity range should be chosen as narrow as possible for large images. The runtime of the coarse-to-fine scheme (which is used for *'fast'* or *'very_fast'*) is approximately linear to the image width and the image height. For small images and small disparity ranges the runtime of the coarse-to-fine scheme may be larger than that of the *'accurate'* scheme.

List of values: *'accurate'*, *'fast'*, *'very_fast'*.

Default: *'accurate'*.

'num_levels': Determines the number of pyramid levels that are used for the coarse-to-fine scheme. By setting `GenParamValue` to *'auto'*, the number of pyramid levels is automatically calculated.

Suggested values: *2*, *3*, *'auto'*.

Default: *'auto'*.

'similarity_measure': Sets the similarity measure to be used. For both options *'census_dense'* (default) and *'census_sparse'*, the similarity measure is based on the Census transform. A Census transformed image contains for every pixel information about the intensity topology within a support window around it.

- *'census_dense'*: Uses a dense 9 x 7 pixels window and is more suitable for fine structures.
- *'census_sparse'*: Uses a sparse 15 x 15 pixels window where only a subset of the pixels is evaluated. Is more robust in low-texture areas.

List of values: *'census_dense'*, *'census_sparse'*.

Default: *'census_dense'*.

'sub_disparity': Activates sub-pixel refinement of disparities when set to *'true'*. Can be deactivated by setting *'false'*.

List of values: *'true'*, *'false'*.

Default: *'true'*.

The resulting disparity is returned in the single-channel image `Disparity`. A quality measure for each disparity value is returned in `Score`, containing the best (lowest) result of the optimized similarity measure of a reference pixel.

Parameters

▷ **`ImageRect1`** (input_object) ..... singlechannelimage ⇝ *object :* byte
Rectified image of camera 1.

▷ **`ImageRect2`** (input_object) ..... singlechannelimage ⇝ *object :* byte
Rectified image of camera 2.

▷ **`Disparity`** (output_object) ..... singlechannelimage ⇝ *object :* real
Disparity map.

▷ **`Score`** (output_object) ..... singlechannelimage ⇝ *object :* real
Score of the calculated disparity.

▷ **`MinDisparity`** (input_control) ..... integer ⇝ *integer*
Minimum of the expected disparities.
Default: -30
Value range: -32768 ≤ `MinDisparity` ≤ 32768
Restriction: MinDisparity <= MaxDisparity

▷ **`MaxDisparity`** (input_control) ..... integer ⇝ *integer*
Maximum of the expected disparities.
Default: 30
Value range: -32768 ≤ `MaxDisparity` ≤ 32768
Restriction: MinDisparity <= MaxDisparity

▷ **`SurfaceSmoothing`** (input_control) ..... integer ⇝ *integer*
Smoothing of surfaces.
Default: 50
Suggested values: `SurfaceSmoothing` ∈ {20, 50, 100}
Restriction: SurfaceSmoothing >= 0

▷ **`EdgeSmoothing`** (input_control) ..... integer ⇝ *integer*
Smoothing of edges.
Default: 50
Suggested values: `EdgeSmoothing` ∈ {20, 50, 100}
Restriction: EdgeSmoothing >= 0

▷ **`GenParamName`** (input_control) ..... attribute.name(-array) ⇝ *string*
Parameter name(s) for the multi-scanline algorithm.
Default: []
List of values: `GenParamName` ∈ {'method', 'similarity_measure', 'consistency_check', 'sub_disparity', 'num_levels', 'disparity_offset'}

▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *string*
Parameter value(s) for the multi-scanline algorithm.
Default: []
Suggested values: GenParamValue ∈ {'accurate', 'fast', 'very_fast', 'census_dense', 'census_sparse', 'true', 'false', 'auto'}

Example

```
read_image (BaseballL, 'stereo/epipolar/baseball_l')
read_image (BaseballR, 'stereo/epipolar/baseball_r')
binocular_disparity_ms (BaseballL, BaseballR, Disparity, Score, \
                        -40, -10, 50, 50, [], [])
```

Result

If the parameter values are correct, binocular_disparity_ms returns the value 2 (H_MSG_TRUE). If the input is empty (no input images are available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

binocular_distance (ImageRect1, ImageRect2 : Distance, Score : CamParamRect1, CamParamRect2, RelPoseRect, Method, MaskWidth, MaskHeight, TextureThresh, MinDisparity, MaxDisparity, NumLevels, ScoreThresh, Filter, SubDistance :)

Compute the distance values for a rectified stereo image pair using correlation techniques.

binocular_distance computes the distance values for a rectified stereo image pair using correlation techniques. The operator first calculates the disparities between the two images ImageRect1 and ImageRect2 similar to binocular_disparity. The resulting disparities are transformed into distance values of the corresponding 3D world points to the rectified stereo camera system as in disparity_to_distance. The distances are returned in the single-channel image Distance in which each gray value represents the distance of the respective 3D world point to the stereo camera system.

The algorithm requires a reference image ImageRect1 and a search image ImageRect2 which must be rectified, i.e., corresponding epipolar lines are parallel and lie on identical image rows ($r_1 = r_2$). In case this assumption is violated the images can be rectified by using the operators calibrate_cameras, gen_binocular_rectification_map and map_image. Hence, given a pixel in the reference image ImageRect1 the homologous pixel in ImageRect2 is selected by searching along the corresponding row

in ImageRect2 and matching a local neighborhood within a rectangular window of size MaskWidth and MaskHeight. For each defined reference pixel the pixel correspondences are transformed into distances of the world points defined by the intersection of the lines of sight of a corresponding pixel pair to the $z = 0$ plane of the rectified stereo system.

For this transformation the rectified internal camera parameters CamParamRect1 of camera 1 and CamParamRect2 of camera 2, and the pose with the external parameters RelPoseRect have to be defined. Latter one is of the form ${}^{ccsR1}\mathbf{P}_{ccsR2}$ and characterizes the relative pose of both cameras to each other. More precisely, it specifies the point transformation from the rectified camera system 2 (*ccsR2*) into the rectified camera system 1 (*ccsR1*), see Transformations / Poses and "Solution Guide III-C - 3D Vision". These parameters can be obtained from the operator calibrate_cameras and gen_binocular_rectification_map. After all, a quality measure for each distance value is returned in Score, containing the best result of the matching function S of a reference pixel. For the matching, the gray values of the original unprocessed images are used.

- *'sad'*: Summed Absolute Differences
  $S(r,c,d) = \frac{1}{N} \sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} | g_1(r',c') - g_2(r',c'+d) |,$
  with $0 \leq S(r,c,d) \leq 255$.
- *'ssd'*: Summed Squared Differences
  $S(r,c,d) = \frac{1}{N} \sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_1(r',c') - g_2(r',c'+d))^2,$
  with $0 \leq S(r,c,d) \leq 65025$.
- *'ncc'*: Normalized Cross Correlation
  $S(r,c,d) = \frac{\sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_1(r',c') - \bar{g_1}(r,c))(g_2(r',c'+d) - \bar{g_2}(r,c+d))}{\sqrt{\left(\sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_1(r',c') - \bar{g_1}(r,c))^2\right)\left(\sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} (g_2(r',c'+d) - \bar{g_2}(r,c+d))^2\right)}},$
  with $-1.0 \leq S(r,c,d) \leq 1.0$.

with

$r1$, $c1$, $r2$, $c2$: row and column coordinates of the corresponding pixels of the two input images,

$g1$, $g2$: gray values of the unprocessed input images,

$N = (2m+1)(2n+1)$: size of correlation window

$\bar{g}(r,c) = \frac{1}{N} \sum_{r'=r-m}^{r+m} \sum_{c'=c-n}^{c+n} g(r',c')$: mean value within the correlation window of width $2m+1$ and height $2n+1$.

Note that the methods *'sad'* and *'ssd'* compare the gray values of the pixels within a mask window directly, whereas *'ncc'* compensates for the mean gray value and its variance within the mask window. Therefore, if the two images differ in brightness and contrast, this method should be preferred. For images with similar brightness and contrast *'sad'* and *'ssd'* are to be preferred as they are faster because of less complex internal computations. See binocular_disparity for further details.

It should be noted that the quality of correlation for rising S is falling in methods *'sad'* and *'ssd'* (the best quality value is 0) but rising in method *'ncc'* (the best quality value is 1.0).

The size of the correlation window ($2m+1$ and $2n+1$) has to be odd numbered and is passed in MaskWidth and MaskHeight. The search space is confined by the minimum and maximum disparity value MinDisparity and MaxDisparity. Due to pixel values not defined beyond the image border the resulting domain of Distance and Score is generally not set along the image border within a margin of height MaskHeight/2 at the top and bottom border and of width MaskWidth/2 at the left and right border. For the same reason, the maximum disparity range is reduced at the left and right image border.

Since matching turns out to be highly unreliable when dealing with poorly textured areas, the minimum variance within the correlation window can be defined in TextureThresh. This threshold is applied on both input images ImageRect1 and ImageRect2. In addition, ScoreThresh guarantees the matching quality and defines the maximum (*'sad'*,*'ssd'*) or, respectively, minimum (*'ncc'*) score value of the correlation function. Setting Filter to *'left_right_check'*, moreover, increases the robustness of the returned matches, as the result relies on a concurrent direct and reverse match, whereas *'none'* switches it off.

The number of pyramid levels used to improve the time response of binocular_distance is determined by NumLevels. Following a coarse-to-fine scheme disparity images of higher levels are computed and segmented into rectangular subimages to reduce the disparity range on the next lower pyramid level. TextureThresh and ScoreThresh are applied on every level and the returned domain of the Distance and Score images arises from the intersection of the resulting domains of every single level. Generally, pyramid structures are the more advantageous the more the distance image can be segmented into regions of homogeneous distance values and the bigger the disparity range must be specified. As a drawback, coarse pyramid levels might loose important texture information which can result in deficient distance values.

Finally, the value *'interpolation'* for parameter SubDistance increases the refinement and accuracy of the distance values. It is switched off by setting the parameter to *'none'*.

Attention

If using cameras with telecentric lenses, the Distance is not defined as the distance of a point to the camera but as the distance from the point to the plane, defined by the y-axes of both cameras and their baseline (see gen_binocular_rectification_map).

For a stereo setup of mixed type (i.e., for a stereo setup in which one of the original cameras is a perspective camera and the other camera is a telecentric camera; see gen_binocular_rectification_map), the rectifying plane of the two cameras is in a position with respect to the object that would lead to very unintuitive distances. Therefore, binocular_distance does not support a stereo setup of mixed type. For stereo setups of mixed type, please use reconstruct_surface_stereo, in which the reference coordinate system can be chosen arbitrarily. Alternatively, binocular_disparity and disparity_image_to_xyz might be used.

Additionally, stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

- ▷ **ImageRect1** (input_object) ..... singlechannelimage ⇝ *object :* byte
  Rectified image of camera 1.
- ▷ **ImageRect2** (input_object) ..... singlechannelimage ⇝ *object :* byte
  Rectified image of camera 2.
- ▷ **Distance** (output_object) ..... singlechannelimage ⇝ *object :* real
  Distance image.
- ▷ **Score** (output_object) ..... singlechannelimage ⇝ *object :* real
  Evaluation of a distance value.
- ▷ **CamParamRect1** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters of the rectified camera 1.
- ▷ **CamParamRect2** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters of the rectified camera 2.
- ▷ **RelPoseRect** (input_control) ..... pose ⇝ *real* / integer
  Point transformation from the rectified camera 2 to the rectified camera 1.
  Number of elements: 7
- ▷ **Method** (input_control) ..... string ⇝ *string*
  Matching function.
  Default: 'ncc'
  List of values: Method ∈ {'sad', 'ssd', 'ncc'}
- ▷ **MaskWidth** (input_control) ..... integer ⇝ *integer*
  Width of the correlation window.
  Default: 11
  Suggested values: MaskWidth ∈ {5, 7, 9, 11, 21}
  Restriction: 3 <= MaskWidth && odd(MaskWidth)
- ▷ **MaskHeight** (input_control) ..... integer ⇝ *integer*
  Height of the correlation window.
  Default: 11
  Suggested values: MaskHeight ∈ {5, 7, 9, 11, 21}
  Restriction: 3 <= MaskHeight && odd(MaskHeight)
- ▷ **TextureThresh** (input_control) ..... real ⇝ *real* / integer
  Variance threshold of textured image regions.
  Default: 0.0
  Suggested values: TextureThresh ∈ {0.0, 2.0, 5.0, 10.0}
  Restriction: 0.0 <= TextureThresh

▷ **MinDisparity** (input_control) ..... integer ⇝ *integer*
Minimum of the expected disparities.
Default: 0
Value range: -32768 ≤ MinDisparity ≤ 32767

▷ **MaxDisparity** (input_control) ..... integer ⇝ *integer*
Maximum of the expected disparities.
Default: 30
Value range: -32768 ≤ MaxDisparity ≤ 32767

▷ **NumLevels** (input_control) ..... integer ⇝ *integer*
Number of pyramid levels.
Default: 1
Suggested values: NumLevels ∈ {1, 2, 3, 4}
Restriction: 1 <= NumLevels

▷ **ScoreThresh** (input_control) ..... real ⇝ *real* / integer
Threshold of the correlation function.
Default: 0.0
Suggested values: ScoreThresh ∈ {0.0, 2.0, 5.0, 10.0}

▷ **Filter** (input_control) ..... string(-array) ⇝ *string*
Downstream filters.
Default: 'none'
List of values: Filter ∈ {'none', 'left_right_check'}

▷ **SubDistance** (input_control) ..... string(-array) ⇝ *string*
Distance interpolation.
Default: 'none'
List of values: SubDistance ∈ {'none', 'interpolation'}

binocular_distance_mg (ImageRect1, ImageRect2 : Distance, Score : CamParamRect1, CamParamRect2, RelPoseRect, GrayConstancy, GradientConstancy, Smoothness, InitialGuess, CalculateScore, MGParamName, MGParamValue :)

Compute the distance values for a rectified stereo image pair using multigrid methods.

binocular_distance_mg computes the distance values for a rectified stereo image pair using multigrid methods. The operator first calculates the disparities between two rectified images ImageRect1 and ImageRect2 similar to binocular_disparity_mg. The resulting disparity values are then transformed into distance values of the corresponding 3D world points to the rectified stereo camera system as in disparity_to_distance. The distances are returned in the single-channel image Distance in which each gray value represents the distance of the respective 3D world point to the stereo camera system. Different from binocular_distance this operator uses a variational approach based on multigrid methods. This approach returns distance values also for image parts that contain no texture.

The input images ImageRect1 and ImageRect2 must be a pair of rectified stereo images, i.e., corresponding points must have the same row coordinate. In case this assumption is violated the images can be rectified by using the operators calibrate_cameras, gen_binocular_rectification_map and map_image.

For the transformation of the disparity to the distance, the internal camera parameters of the rectified camera 1 CamParamRect1 and of the rectified camera 2 CamParamRect2, as well as the relative pose of the cameras RelPoseRect must be specified. The relative pose defines a point transformation from the rectified camera system 2 to the rectified camera system 1. These parameters can be obtained from the operators calibrate_cameras and gen_binocular_rectification_map.

A detailed description of the algorithm and of the remaining parameters can be found in the documentation of binocular_disparity_mg.

Attention

If using cameras with telecentric lenses, the Distance is not defined as the distance of a point to the camera but as the distance from the point to the plane, defined by the y-axes of both cameras and their baseline (see gen_binocular_rectification_map).

For a stereo setup of mixed type (i.e., for a stereo setup in which one of the original cameras is a perspective camera and the other camera is a telecentric camera; see gen_binocular_rectification_map), the rectifying plane of the two cameras is in a position with respect to the object that would lead to very unintuitive distances. Therefore, binocular_distance_mg does not support a stereo setup of mixed type. For stereo setups of mixed type, please use reconstruct_surface_stereo, in which the reference coordinate system can be chosen arbitrarily. Alternatively, binocular_disparity_mg and disparity_image_to_xyz might be used.

Additionally, stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

binocular_distance_ms (ImageRect1, ImageRect2 : Distance, Score : CamParamRect1, CamParamRect2, RelPoseRect, MinDisparity, MaxDisparity, SurfaceSmoothing, EdgeSmoothing, GenParamName, GenParamValue :)

Compute the distance values for a rectified stereo image pair using multi-scanline optimization.

binocular_distance_ms computes the distance values for a rectified stereo image pair using multi-scanline optimization. The operator first calculates the disparities between two rectified images ImageRect1 and ImageRect2 similar to binocular_disparity_ms. The resulting disparity values are then transformed into distance values of the corresponding 3D world points to the rectified stereo camera system as in disparity_to_distance. The distances are returned in the single-channel image Distance in which each gray value represents the distance of the respective 3D world point to the stereo camera system.

binocular_disparity_ms requires a reference image ImageRect1 and a search image ImageRect2 which both must be rectified, i.e., corresponding pixels must have the same row coordinate. If this assumption is violated, the images can be rectified by using the operators calibrate_cameras, gen_binocular_rectification_map, and map_image.

For the transformation of the disparity to the distance, the internal camera parameters of the rectified camera 1 CamParamRect1 and of the rectified camera 2 CamParamRect2, as well as the relative pose of the cameras RelPoseRect must be specified. The relative pose defines a point transformation from the rectified camera system 2 to the rectified camera system 1. These parameters can be obtained from the operators calibrate_cameras and gen_binocular_rectification_map.

A detailed description of the remaining parameters can be found in the documentation of binocular_disparity_ms.

Attention

If using cameras with telecentric lenses, the Distance is not defined as the distance of a point to the camera but as the distance from the point to the plane, defined by the y-axes of both cameras and their baseline (see gen_binocular_rectification_map).

For a stereo setup of mixed type (i.e., for a stereo setup in which one of the original cameras is a perspective camera and the other camera is a telecentric camera; see gen_binocular_rectification_map), the rectifying plane of the two cameras is in a position with respect to the object that would lead to very unintuitive distances. Therefore, binocular_distance_ms does not support a stereo setup of mixed type. For stereo setups of mixed type, please use reconstruct_surface_stereo, in which the reference coordinate system can be

chosen arbitrarily. Alternatively, binocular_disparity_ms and disparity_image_to_xyz might be used.

Additionally, stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

3D Metrology

disparity_image_to_xyz (Disparity : X, Y, Z : CamParamRect1, CamParamRect2, RelPoseRect :)

Transform a disparity image into 3D points in a rectified stereo system.

Given the disparity image Disparity of a rectified binocular stereo system, disparity_image_to_xyz computes the corresponding 3D points. Their coordinates relative to the rectified camera 1 are stored as gray values in the images X, Y, and Z, i.e., the pixels at the position (Row,Column) in X, Y, and Z contain the x, y, and z coordinate, respectively, of the pixel (Row,Column) in the disparity image.

The rectified binocular camera system is specified by its internal camera parameters CamParamRect1 of the rectified camera 1 and CamParamRect2 of the rectified camera 2, and the external parameters RelPoseRect. The latter one is a pose in the form ${}^{ccsR1}\mathbf{P}_{ccsR2}$, thus it defines the relative pose of the rectified camera coordinate system 2 (*ccsR2*) relative to the rectified camera coordinate system 1 (*ccsR1*) (see Transformations / Poses and "Solution Guide III-C - 3D Vision"). These camera parameters can be obtained from the operators calibrate_cameras and gen_binocular_rectification_map.

Attention

Stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

- ▷ **Disparity** (input_object) ..... singlechannelimage(-array) ⇝ *object :* real
  Disparity image.
- ▷ **X** (output_object) ..... singlechannelimage(-array) ⇝ *object :* real
  X coordinates of the points in the rectified camera system 1.
- ▷ **Y** (output_object) ..... singlechannelimage(-array) ⇝ *object :* real
  Y coordinates of the points in the rectified camera system 1.
- ▷ **Z** (output_object) ..... singlechannelimage(-array) ⇝ *object :* real
  Z coordinates of the points in the rectified camera system 1.
- ▷ **CamParamRect1** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters of the rectified camera 1.
- ▷ **CamParamRect2** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters of the rectified camera 2.
- ▷ **RelPoseRect** (input_control) ..... pose ⇝ *real* / integer
  Pose of the rectified camera 2 in relation to the rectified camera 1.
  Number of elements: 7

Example

```
disparity_image_to_xyz (ImageDisparity, ImgX, ImgY, ImgZ, RectCamParL, \
                        RectCamParR, RectLPosRectR)
get_region_points (ImageDisparity, Rows, Columns)
get_grayval (ImgX, Rows, Columns, XValues)
get_grayval (ImgY, Rows, Columns, YValues)
get_grayval (ImgZ, Rows, Columns, ZValues)
```

Result

The operator `disparity_image_to_xyz` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input image available) is set via the operator `set_system ('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

3D Metrology

disparity_to_distance (: : CamParamRect1, CamParamRect2, RelPoseRect, Disparity : Distance)

Transform a disparity value into a distance value in a rectified binocular stereo system.

`disparity_to_distance` transforms a disparity value into a distance of an object point to the binocular stereo system. The cameras of this system must be rectified and are defined by the rectified internal parameters `CamParamRect1` of camera 1 and `CamParamRect2` of camera 2, and the external parameters `RelPoseRect`. Latter specifies the relative pose of both cameras to each other by defining a point transformation from rectified camera system 2 to rectified camera system 1. These parameters can be obtained from the operator `calibrate_cameras` and `gen_binocular_rectification_map`. The disparity value `Disparity` is defined by the column difference of the image coordinates of two corresponding points on an epipolar line according to the equation $d = c_2 - c_1$(see also `binocular_disparity`). This value characterises a set of 3D object points of an equal distance to a plane being parallel to the rectified image plane of the stereo system. The distance to the subset plane $z = 0$ which is parallel to the rectified image plane and contains the optical centers of both cameras is returned in `Distance`.

Attention

If using cameras with telecentric lenses, the `Distance` is not defined as the distance of a point to the camera but as the distance from the point to the plane, defined by the y-axes of both cameras and their baseline (see `gen_binocular_rectification_map`).

For a stereo setup of mixed type (i.e., for a stereo setup in which one of the original cameras is a perspective camera and the other camera is a telecentric camera; see `gen_binocular_rectification_map`), the rectifying

plane of the two cameras is in a position with respect to the object that would lead to very unintuitive distances. Therefore, disparity_to_distance does not support stereo setups of mixed type. For stereo setups of mixed type, disparity_to_point_3d should be used instead.

Additionally, stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

- ▷ **CamParamRect1** (input_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal camera parameters of camera 1.
- ▷ **CamParamRect2** (input_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal camera parameters of camera 2.
- ▷ **RelPoseRect** (input_control) . . . . . pose ⇝ *real* / integer
  Point transformation from the rectified camera 2 to the rectified camera 1.
  Number of elements: 7
- ▷ **Disparity** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Disparity between the images of the world point.
- ▷ **Distance** (output_control) . . . . . real(-array) ⇝ *real*
  Distance of a world point to the rectified camera system.

Result

disparity_to_distance returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

disparity_to_point_3d (: : CamParamRect1, CamParamRect2, RelPoseRect, Row1, Col1, Disparity : X, Y, Z)

Transform an image point and its disparity into a 3D point in a rectified stereo system.

Given an image point of the rectified camera 1, specified by its image coordinates (Row1,Col1), and its disparity in a rectified binocular stereo system, disparity_to_point_3d computes the corresponding three dimensional object point. The disparity value Disparity defines the column difference of the image coordinates of two corresponding features on an epipolar line according to the equation $d = c_2 - c_1$. The rectified binocular camera system is specified by its internal camera parameters CamParamRect1 of camera 1 and CamParamRect2 of camera 2, and the external parameters RelPoseRect defining the pose of the rectified camera 2 in relation to the rectified camera 1. These camera parameters can be obtained from the operators calibrate_cameras and gen_binocular_rectification_map. The 3D point is returned in Cartesian coordinates (X,Y,Z) of the rectified camera system 1.

Attention

Stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

- ▷ **CamParamRect1** (input_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal camera parameters of camera 1.
- ▷ **CamParamRect2** (input_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal camera parameters of camera 2.
- ▷ **RelPoseRect** (input_control) . . . . . pose ⇝ *real* / integer
  Pose of the rectified camera 2 in relation to the rectified camera 1.
  Number of elements: 7
- ▷ **Row1** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Row coordinate of a point in the rectified image 1.
- ▷ **Col1** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Column coordinate of a point in the rectified image 1.
- ▷ **Disparity** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Disparity of the images of the world point.
- ▷ **X** (output_control) . . . . . real(-array) ⇝ *real*
  X coordinate of the 3D point.
- ▷ **Y** (output_control) . . . . . real(-array) ⇝ *real*
  Y coordinate of the 3D point.
- ▷ **Z** (output_control) . . . . . real(-array) ⇝ *real*
  Z coordinate of the 3D point.

Result

`disparity_to_point_3d` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

3D Metrology

distance_to_disparity (: : CamParamRect1, CamParamRect2, RelPoseRect, Distance : Disparity)

Transform a distance value into a disparity in a rectified stereo system.

`distance_to_disparity` transforms a distance of a 3D point to the binocular stereo system into a disparity value. The cameras of this system must be rectified and are defined by the rectified internal parameters `CamParamRect1` of the camera 1 and `CamParamRect2` of the camera 2 and the external parameters `RelPoseRect`. The latter specifies the relative pose of both camera systems to each other by defining a point transformation from the rectified camera system 2 to the rectified camera system 1. These parameters can be obtained from the operator `calibrate_cameras` and `gen_binocular_rectification_map`. The distance value is passed in `Distance` and the resulting disparity value `Disparity` is defined by the column difference of the image coordinates of two corresponding features on an epipolar line according to the equation $d = c_2 - c_1$.

Attention

If using cameras with telecentric lenses, the `Distance` is not defined as the distance of a point to the camera

but as the distance from the point to the plane, defined by the y-axes of both cameras and their baseline (see gen_binocular_rectification_map).

For stereo setups of mixed type (i.e., for a stereo setup in which one of the original cameras is a perspective camera and the other camera is a telecentric camera; see gen_binocular_rectification_map), the rectifying plane of the two cameras is in a position with respect to the object that would lead to very unintuitive distances. Therefore, distance_to_disparity does not support stereo setups of mixed type.

Additionally, stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

- ▷ **CamParamRect1** (input_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal camera parameters of camera 1.
- ▷ **CamParamRect2** (input_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal camera parameters of camera 2.
- ▷ **RelPoseRect** (input_control) . . . . . pose ⇝ *real* / integer
  Point transformation from the rectified camera 2 to the rectified camera 1.
  Number of elements: 7
- ▷ **Distance** (input_control) . . . . . real(-array) ⇝ *real*
  Distance of a world point to camera 1.
- ▷ **Disparity** (output_control) . . . . . number(-array) ⇝ *real* / integer
  Disparity between the images of the point.

Result

distance_to_disparity returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

binocular_disparity

Module

3D Metrology

essential_to_fundamental_matrix (: : EMatrix, CovEMat, CamMat1, CamMat2 : FMatrix, CovFMat)

Compute the fundamental matrix from an essential matrix.

The fundamental matrix is the entity describing the epipolar constraint in image coordinates (C,R) and the essential matrix is its counterpart for 3D direction vectors (X,Y,1):

$$\begin{pmatrix} C_2 \\ R_2 \\ 1 \end{pmatrix}^T \cdot \texttt{FMatrix} \cdot \begin{pmatrix} C_1 \\ R_1 \\ 1 \end{pmatrix} = 0 \quad \text{and} \quad \begin{pmatrix} X_2 \\ Y_2 \\ 1 \end{pmatrix}^T \cdot \texttt{EMatrix} \cdot \begin{pmatrix} X_1 \\ Y_1 \\ 1 \end{pmatrix} = 0 \quad .$$

Image coordinates result from 3D direction vectors by multiplication with the camera matrix $CamMat$:

$$\begin{pmatrix} col \\ row \\ 1 \end{pmatrix} = CamMat \cdot \begin{pmatrix} X \\ Y \\ 1 \end{pmatrix} \quad .$$

Therefore, the fundamental matrix FMatrix is calculated from the essential matrix EMatrix and the camera matrices CamMat1, CamMat2 by the following formula:

$$\texttt{FMatrix} \quad = \quad \texttt{CamMat2}^{-T} \cdot \texttt{EMatrix} \cdot \texttt{CamMat1}^{-1} \quad .$$

The transformation of the essential matrix to the fundamental matrix goes along with the propagation of the covariance matrices CovEMat to CovFMat. If CovEMat is empty CovFMat will be empty too.

The conversion operator essential_to_fundamental_matrix is used especially for a subsequent visualization of the epipolar line structure via the fundamental matrix, which depicts the underlying stereo geometry.

Parameters

▷ **EMatrix** (input_control) . . . hom_mat2d ⇝ *real* / integer
Essential matrix.

▷ **CovEMat** (input_control) . . . number-array ⇝ *real* / integer
9×9 covariance matrix of the essential matrix.
Default: []

▷ **CamMat1** (input_control) . . . hom_mat2d ⇝ *real* / integer
Camera matrix of the 1. camera.

▷ **CamMat2** (input_control) . . . hom_mat2d ⇝ *real* / integer
Camera matrix of the 2. camera.

▷ **FMatrix** (output_control) . . . hom_mat2d ⇝ *real*
Computed fundamental matrix.

▷ **CovFMat** (output_control) . . . real-array ⇝ *real*
9×9 covariance matrix of the fundamental matrix.

Execution Information

Module

3D Metrology

gen_binocular_proj_rectification (: Map1, Map2 : FMatrix, CovFMat, Width1, Height1, Width2, Height2, SubSampling, Mapping : CovFMatRect, H1, H2)

Compute the projective rectification of weakly calibrated binocular stereo images.

A binocular stereo setup is called weakly calibrated if the fundamental matrix, which describes the projective relation between the two images, is known. Rectification is the process of finding a suitable set of transformations, that transform both images such that all corresponding epipolar lines become collinear and parallel to the horizontal axes. The rectified images can be thought of as acquired by a stereo configuration where the left and right image plane are identical and the difference between both image centers is a horizontal translation. Note that rectification can only be performed if both of the epipoles are located outside the images.

Typically, the fundamental matrix is calculated beforehand with match_fundamental_matrix_ransac and FMatrix is the basis for the computation of the two homographies H1 and H2, which describe the rectifications for the left image and the right image respectively. Since a projective rectification is an underdetermined problem, additional constraints are defined: the algorithm chooses the set of homographies that minimizes the projective distortion induced by the homographies in both images. For the computation of this cost function the

dimensions of the images must be provided in Width1, Height1, Width2, Height2. After rectification the fundamental matrix is always of the canonical form

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix} .$$

In the case of a known covariance matrix CovFMat of the fundamental matrix FMatrix, the covariance matrix CovFMatRect of the above rectified fundamental matrix is calculated. This can help for an improved stereo matching process because the covariance matrix defines in terms of probabilities the image domain where to find a corresponding match.

Similar to the operator gen_binocular_rectification_map the output images Map1 and Map2 describe the transformation, also called mapping, of the original images to the rectified ones. The parameter Mapping specifies whether bilinear interpolation (*'bilinear_map'*) should be applied between the pixels in the input image or whether the gray value of the nearest neighboring pixel should be taken (*'nn_map'*). The size and resolution of the maps and of the transformed images can be adjusted by the parameter SubSampling, which applies a sub-sampling factor to the original images. For example, a factor of two will halve the image sizes. If just the two homographies are required Mapping can be set to *'no_map'* and no maps will be returned. For speed reasons, this option should be used if for a specific stereo configuration the images must be rectified only once. If the stereo setup is fixed, the maps should be generated only once and both images should be rectified with map_image; this will result in the smallest computational cost for on-line rectification.

When using the maps, the transformed images are of the same size as their maps. Each pixel in the map contains the description of how the new pixel at this position is generated. The images Map1 and Map2 are single channel images if Mapping is set to *'nn_map'* and five channel images if it is set to *'bilinear_map'*. In the first channel, which is of type int4, the pixels contain the linear coordinates of their reference pixels in the original image. With Mapping equal to *'no_map'* this reference pixel is the nearest neighbor to the back-transformed pixel coordinates of the map. In the case of bilinear interpolation the reference pixel is the next upper left pixel relative to the back-transformed coordinates. The following scheme shows the ordering of the pixels in the original image next to the back-transformed pixel coordinates, where the reference pixel takes the number 2.

2	3
4	5

The channels 2 to 5, which are of type uint2, contain the weights of the relevant pixels for the bilinear interpolation.

Based on the rectified images, the disparity be computed using binocular_disparity. In contrast to stereo with fully calibrated cameras, using the operator gen_binocular_rectification_map and its successors, metric depth information can not be derived for weakly calibrated cameras. The disparity map gives just a qualitative depth ordering of the scene.

Parameters

▷ **Map1** (output_object) ..... image(-array) ⇝ *object :* int4 / uint2
Image coding the rectification of the 1. image.

▷ **Map2** (output_object) ..... image(-array) ⇝ *object :* int4 / uint2
Image coding the rectification of the 2. image.

▷ **FMatrix** (input_control) ..... hom_mat2d ⇝ *real* / integer
Fundamental matrix.

▷ **CovFMat** (input_control) ..... number-array ⇝ *real* / integer
9×9 covariance matrix of the fundamental matrix.
Default: []

▷ **Width1** (input_control) ..... integer ⇝ *integer*
Width of the 1. image.
Default: 512
Suggested values: Width1 ∈ {128, 256, 512, 1024}
Restriction: Width1 > 0

▷ **Height1** (input_control) ..... integer ⇝ *integer*
Height of the 1. image.
Default: 512
Suggested values: Height1 ∈ {128, 256, 512, 1024}
Restriction: Height1 > 0

▷ **Width2** (input_control) ..... integer ⇝ *integer*
Width of the 2. image.
Default: 512
Suggested values: Width2 ∈ {128, 256, 512, 1024}
Restriction: Width2 > 0

▷ **Height2** (input_control) ..... integer ⇝ *integer*
Height of the 2. image.
Default: 512
Suggested values: Height2 ∈ {128, 256, 512, 1024}
Restriction: Height2 > 0

▷ **SubSampling** (input_control) ..... number ⇝ *integer* / real
Subsampling factor.
Default: 1
List of values: SubSampling ∈ {1, 2, 3, 1.5}

▷ **Mapping** (input_control) ..... string ⇝ *string*
Type of mapping.
Default: 'no_map'
List of values: Mapping ∈ {'no_map', 'nn_map', 'bilinear_map'}

▷ **CovFMatRect** (output_control) ..... number-array ⇝ *real*
9×9 covariance matrix of the rectified fundamental matrix.

▷ **H1** (output_control) ..... hom_mat2d ⇝ *real*
Projective transformation of the 1. image.

▷ **H2** (output_control) ..... hom_mat2d ⇝ *real*
Projective transformation of the 2. image.

gen_binocular_rectification_map (: Map1, Map2 : CamParam1, CamParam2, RelPose, SubSampling, Method, MapType : CamParamRect1, CamParamRect2, CamPoseRect1, CamPoseRect2, RelPoseRect)

Generate transformation maps that describe the mapping of the images of a binocular camera pair to a common rectified image plane.

Given a pair of stereo images, rectification determines a transformation of each image plane in a way that pairs of conjugate epipolar lines become collinear and parallel to the horizontal image axes. This is required for an efficient calculation of disparities or distances with operators such as binocular_disparity or binocular_distance. The rectified images can be thought of as acquired by a new stereo rig, obtained by rotating and, in case of telecentric area scan and line scan cameras, translating the original cameras. The projection centers (i.e., in the telecentric case, the direction of the optical axes) are maintained. For perspective cameras, the image planes are additionally transformed into a common plane, which means that the focal lengths are set equal, and the optical axes are parallel. For a stereo setup of mixed type (i.e., one perspective and one telecentric camera), the image planes are also transformed into a common plane, as described below.

To achieve the transformation map for rectified images gen_binocular_rectification_map requires the internal camera parameters CamParam1 of camera 1 and CamParam2 of camera 2, as well as the relative pose RelPose, ${}^{ccs1}\mathbf{P}_{ccs2}$, defining a point transformation from camera coordinate system 2 (*ccs2*) into camera coordinate system 1 (*ccs1*), see Transformations / Poses and “Solution Guide III-C - 3D Vision”. These parameters can be obtained, e.g., from the operator calibrate_cameras.

The internal camera parameters, modified by the rectification, are returned in CamParamRect1 for camera 1 and CamParamRect2 for camera 2, respectively. The rotation and, in case of telecentric cameras, translation of the rectified camera in relation to the original camera is specified by CamPoseRect1 and CamPoseRect2, respectively. These poses are in the form ${}^{ccsX}\mathbf{P}_{ccsRX}$ with *ccsX*: camera coordinate system of camera X and *ccsRX*: camera coordinate system of camera X for the rectified image. Finally, RelPoseRect returns ${}^{ccsR1}\mathbf{P}_{ccsR2}$, the

relative pose of the rectified camera coordinate system 2 (*ccsR2*) relative to the rectified camera coordinate system 1 (*ccsR1*).

Rectification Method

For perspective area scan cameras, `RelPoseRect` only has a translation in x. Generally, the transformations are defined in a way that the rectified camera 1 is left of the rectified camera 2. This means that the optical center of camera 2 has a positive x coordinate of the rectified coordinate system of camera 1.

The projection onto a common plane has many degrees of freedom, which are implicitly restricted by selecting a certain method in `Method`:

- *'viewing_direction'* uses the baseline as the x-axis of the common image plane. The mean of the viewing directions (z-axes) of the two cameras is used to span the x-z plane of the rectified system. The resulting rectified z-axis is the orientation of the common image plane and as such located in this plane and orthogonal to the baseline. In many cases, the resulting rectified z-axis will not differ much from the mean of the two old z-axes. The new focal length is determined in such a way that the old principal points have the same distance to the new common image plane. The different z-axes directions are illustrated in the schematic below.

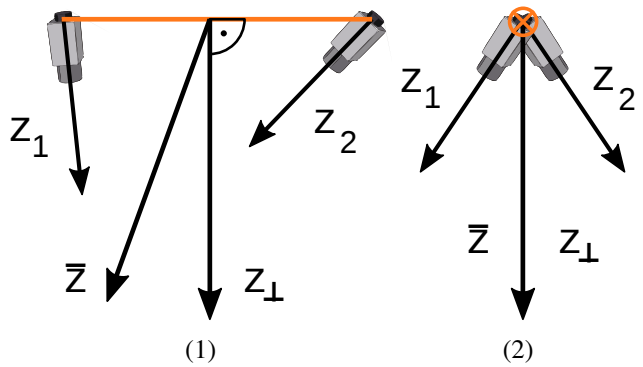

Illustration for the different z-axes directions using *'viewing_direction'*. (1): View facing the base line (in orange). (2): View along the base line (pointing into the page, in orange).

- *'geometric'* specifies the orientation of the common image plane by the cross product of the baseline and the line of intersection of the original image planes. The new focal length is determined in such a way that the old principal points have the same distance to the new common image plane.

For telecentric area scan and line scan cameras, the parameter `Method` is ignored. The relative pose of both cameras is not uniquely defined in such a system since the cameras return identical images no matter how they are translated along their optical axis. Yet, in order to define an absolute distance measurement to the cameras, a standard position of both cameras is considered. This position is defined as follows: Both cameras are translated along their optical axes until their distance is one meter and until the line between the cameras (baseline) forms the same angle with both optical axes (i.e., the baseline and the optical axes form an isosceles triangle). The optical axes remain unchanged. The relative pose of the rectified cameras `RelPoseRect` may be different from the relative pose of the original cameras `RelPose`.

For a stereo setup of mixed type (i.e., one perspective and one telecentric camera), the parameter `Method` is ignored. The rectified image plane is determined uniquely from the geometry of the perspective camera and the relative pose of the two cameras. The normal of the rectified image plane is the vector that points from the projection center of the perspective camera to the point on the optical axis of the telecentric camera that has the shortest distance from the projection center of the perspective camera. This is also the z-axis of the rectified perspective camera. The geometric base of the mixed camera system is a line that passes through the projection center of the perspective camera and has the same direction as the z-axis of the telecentric camera, i.e., the base is parallel to the viewing direction of the telecentric camera. The x-axis of the rectified perspective camera is given by the base and the y-axis is constructed to form a right-handed coordinate system. To rectify the telecentric camera, its optical axis must be shifted to the base and the image plane must be tilted by $90°$ or $-90°$. To achieve this, a special type of object-side telecentric camera that is able to handle this special rectification geometry (indicated by a negative image plane distance `ImagePlaneDist`) must be used for the rectified telecentric camera. The representation of this special camera type should be regarded as a black box because it is used only for rectification purposes in HALCON (for this reason, it is not documented in `camera_calibration`). The rectified telecentric camera has the same orientation as the original telecentric camera, while its origin is translated to a point on the base.

Rectification Maps

The mapping functions for the images of camera 1 and camera 2 are returned in the images `Map1` and `Map2`. `MapType` is used to specify the type of the output maps. If *'nearest_neighbor'* is chosen, both maps consist of one image containing one channel, in which for each pixel of the resulting image the linearized coordinate of the pixel of the input image is stored that is the nearest neighbor to the transformed coordinates. If *'bilinear'* interpolation is chosen, both maps consists of one image containing five channels. In the first channel for each pixel in the resulting image the linearized coordinates of the pixel in the input image is stored that is in the upper left position relative to the transformed coordinates. The four other channels contain the weights of the four neighboring pixels of the transformed coordinates which are used for the bilinear interpolation, in the following order:

2	3
4	5

The second channel, for example, contains the weights of the pixels that lie to the upper left relative to the transformed coordinates. If *'coord_map_sub_pix'* is chosen, both maps consist of one vector field image, in which for each pixel of the resulting image the subpixel precise coordinates in the input image are stored.

The size and resolution of the maps and of the transformed images can be adjusted by the `SubSampling` parameter which applies a sub-sampling factor to the original images.

If you want to re-use the created map in another program, you can save it as a multi-channel image with the operator `write_image`, using the format *'tiff'*.

Attention

Stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

- ▷ **`Map1`** (output_object) . . . . . (multichannel-)image ⇝ *object :* int4 / uint2 / vector_field
  Image containing the mapping data of camera 1.
- ▷ **`Map2`** (output_object) . . . . . (multichannel-)image ⇝ *object :* int4 / uint2 / vector_field
  Image containing the mapping data of camera 2.
- ▷ **`CamParam1`** (input_control) . . . . . campar ⇝ *real* / integer / string
  Internal parameters of camera 1.
- ▷ **`CamParam2`** (input_control) . . . . . campar ⇝ *real* / integer / string
  Internal parameters of camera 2.
- ▷ **`RelPose`** (input_control) . . . . . pose ⇝ *real* / integer
  Point transformation from camera 2 to camera 1.
  Number of elements: 7
- ▷ **`SubSampling`** (input_control) . . . . . real ⇝ *real*
  Subsampling factor.
  Default: 1.0
  Suggested values: `SubSampling` ∈ {0.5, 0.66, 1.0, 1.5, 2.0, 3.0, 4.0}
- ▷ **`Method`** (input_control) . . . . . string ⇝ *string*
  Type of rectification.
  Default: 'viewing_direction'
  List of values: `Method` ∈ {'viewing_direction', 'geometric'}
- ▷ **`MapType`** (input_control) . . . . . string ⇝ *string*
  Type of mapping.
  Default: 'bilinear'
  List of values: `MapType` ∈ {'nearest_neighbor', 'bilinear', 'coord_map_sub_pix'}
- ▷ **`CamParamRect1`** (output_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal parameters of camera 1.
- ▷ **`CamParamRect2`** (output_control) . . . . . campar ⇝ *real* / integer / string
  Rectified internal parameters of camera 2.
- ▷ **`CamPoseRect1`** (output_control) . . . . . pose ⇝ *real* / integer
  Point transformation from the rectified camera 1 to the original camera 1.
  Number of elements: 7
- ▷ **`CamPoseRect2`** (output_control) . . . . . pose ⇝ *real* / integer
  Point transformation from the rectified camera 1 to the original camera 1.
  Number of elements: 7

▷ **RelPoseRect** (output_control) . . . . . pose ⇝ *real* / integer
Point transformation from the rectified camera 2 to the rectified camera 1.
Number of elements: 7

Example

```
* Set internal and external stereo parameters.
* Note that, typically, these values are the result of a prior
* calibration.
gen_cam_par_area_scan_division (0.01, -665, 5.2e-006, 5.2e-006, \
                                622, 517, 1280, 1024, CamParam1)

3D Metrology

intersect_lines_of_sight (: : CamParam1, CamParam2, RelPose, Row1, Col1, Row2, Col2 : X, Y, Z, Dist)

Get a 3D point from the intersection of two lines of sight within a binocular camera system.

Given two lines of sight from different cameras, specified by their image points (Row1,Col1) of camera 1 and (Row2,Col2) of camera 2, intersect_lines_of_sight computes the 3D point of intersection of these lines. The binocular camera system is specified by its internal camera parameters CamParam1 of the projective camera 1 and CamParam2 of the projective camera 2, and the external parameters RelPose. Latter one is of the form ${}^{ccs1}\mathbf{P}_{ccs2}$ and characterizes the relative pose of both cameras to each other, thus defining a point transformation from camera coordinate system 2 (*ccs2*) into camera coordinate system 1 (*ccs1*), see Transformations / Poses and "Solution Guide III-C - 3D Vision". These camera parameters can be obtained, e.g., from the operator calibrate_cameras, if the coordinates of the image points (Row1,Col1) and (Row2,Col2) refer to the respective original image coordinate system. In case of rectified image coordinates (e.g., obtained from rectified images), the rectified camera parameters must be passed, as they are returned by the operator gen_binocular_rectification_map. The 'point of intersection' is defined by the point with the shortest distance to both lines of sight. This point is returned in Cartesian coordinates (X,Y,Z) of camera system 1 and its distance to the lines of sight is passed in Dist.

Attention

Stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported.

Parameters

- ▷ **CamParam1** (input_control) ..... campar ⇝ *real* / integer / string
  Internal parameters of the projective camera 1.
- ▷ **CamParam2** (input_control) ..... campar ⇝ *real* / integer / string
  Internal parameters of the projective camera 2.
- ▷ **RelPose** (input_control) ..... pose ⇝ *real* / integer
  Point transformation from camera 2 to camera 1.
  Number of elements: 7
- ▷ **Row1** (input_control) ..... number(-array) ⇝ *real* / integer
  Row coordinate of a point in image 1.
- ▷ **Col1** (input_control) ..... number(-array) ⇝ *real* / integer
  Column coordinate of a point in image 1.
- ▷ **Row2** (input_control) ..... number(-array) ⇝ *real* / integer
  Row coordinate of the corresponding point in image 2.
- ▷ **Col2** (input_control) ..... number(-array) ⇝ *real* / integer
  Column coordinate of the corresponding point in image 2.
- ▷ **X** (output_control) ..... real(-array) ⇝ *real*
  X coordinate of the 3D point.
- ▷ **Y** (output_control) ..... real(-array) ⇝ *real*
  Y coordinate of the 3D point.
- ▷ **Z** (output_control) ..... real(-array) ⇝ *real*
  Z coordinate of the 3D point.
- ▷ **Dist** (output_control) ..... real(-array) ⇝ *real*
  Distance of the 3D point to the lines of sight.

Result

intersect_lines_of_sight returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Module

3D Metrology

match_essential_matrix_ransac (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, CamMat1, CamMat2, GrayMatchMethod, MaskSize, RowMove, ColMove, RowTolerance, ColTolerance, Rotation, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : EMatrix, CovEMat, Error, Points1, Points2)

Compute the essential matrix for a pair of stereo images by automatically finding correspondences between image points.

Given a set of coordinates of characteristic points (Rows1, Cols1) and (Rows2, Cols2) in the stereo images Image1 and Image2 along with known internal camera parameters, specified by the camera matrices CamMat1 and CamMat2, match_essential_matrix_ransac automatically determines the geometry of the stereo setup and finds the correspondences between the characteristic points. The geometry of the stereo setup is represented by the essential matrix EMatrix and all corresponding points have to fulfill the epipolar constraint.

The operator match_essential_matrix_ransac is designed to deal with a linear camera model. The internal camera parameters are passed by the arguments CamMat1 and CamMat2, which are 3×3 upper triangular matrices describing an affine transformation. The relation between a vector (X,Y,1), representing the direction from the camera to the viewed 3D space point and its (projective) 2D image coordinates (col,row,1) is:

$$\begin{pmatrix} col \\ row \\ 1 \end{pmatrix} = CamMat \cdot \begin{pmatrix} X \\ Y \\ 1 \end{pmatrix} \quad \text{where} \quad CamMat = \begin{pmatrix} f/s_x & s & c_x \\ 0 & f/s_y & c_y \\ 0 & 0 & 1 \end{pmatrix} .$$

Note the column/row ordering in the point coordinates which has to be compliant with the x/y notation of the camera coordinate system. The focal length is denoted by f, s_x, s_y are scaling factors, s describes a skew factor and (c_x, c_y) indicates the principal point. Mainly, these are the elements known from the camera parameters as used for example in calibrate_cameras. Alternatively, the elements of the camera matrix can be described in a different way, see e.g. stationary_camera_self_calibration. Multiplied by the inverse of the camera matrices the direction vectors in 3D space are obtained from the (projective) image coordinates. For known camera matrices the epipolar constraint is given by:

$$\begin{pmatrix} X_2 \\ Y_2 \\ 1 \end{pmatrix}^T \cdot EMatrix \cdot \begin{pmatrix} X_1 \\ Y_1 \\ 1 \end{pmatrix} = 0 .$$

The matching process is based on characteristic points, which can be extracted with point operators like points_foerstner or points_harris. The matching itself is carried out in two steps: first, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images. Then, the RANSAC algorithm is applied to find the essential matrix that maximizes the number of correspondences under the epipolar constraint.

The size of the mask windows is MaskSize $\times$ MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A thus found matching is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the speed of the algorithm, the search area for the matching operations can be limited. Only points within a window of $2 \cdot$ RowTolerance $\times 2 \cdot$ ColTolerance points are considered. The offset of the center of the search window in the second image with respect to the position of the current point in the first image is given by RowMove and ColMove.

If the second camera is rotated around the optical axis with respect to the first camera the parameter Rotation may contain an estimate for the rotation angle or an angle interval in radians. A good guess will increase the quality of the gray value matching. If the actual rotation differs too much from the specified estimate the matching will typically fail. In this case, an angle interval should be specified, and Rotation is a tuple with two elements. The larger the given interval the slower the operator is since the RANSAC algorithm is run over all angle increments within the interval.

After the initial matching is completed a randomized search algorithm (RANSAC) is used to determine the essential matrix EMatrix. It tries to find the essential matrix that is consistent with a maximum number of correspondences. For a point to be accepted, the distance to its corresponding epipolar line must not exceed the threshold DistanceThreshold.

The parameter EstimationMethod decides whether the relative orientation between the cameras is of a special type and which algorithm is to be applied for its computation. If EstimationMethod is either *'normalized_dlt'* or *'gold_standard'* the relative orientation is arbitrary. Choosing *'trans_normalized_dlt'* or *'trans_gold_standard'* means that the relative motion between the cameras is a pure translation. The typical application for this special motion case is the scenario of a single fixed camera looking onto a moving conveyor belt. In order to get a unique solution in the correspondence problem the minimum required number of corresponding points is six in the general case and three in the special, translational case.

The essential matrix is computed by a linear algorithm if *'normalized_dlt'* or *'trans_normalized_dlt'* is chosen. With *'gold_standard'* or *'trans_gold_standard'* the algorithm gives a statistically optimal result, and returns the covariance of the essential matrix CovEMat as well. Here, *'normalized_dlt'* and *'gold_standard'* stand for direct-linear-transformation and gold-standard-algorithm respectively. Note, that in general the found correspondences differ depending on the deployed estimation method.

The value Error indicates the overall quality of the estimation procedure and is the mean Euclidean distance in pixels between the points and their corresponding epipolar lines.

Point pairs consistent with the mentioned constraints are considered to be in correspondences. Points1 contains the indices of the matched input points from the first image and Points2 contains the indices of the corresponding points in the second image.

For the operator match_essential_matrix_ransac a special configuration of scene points and cameras exists: if all 3D points lie in a single plane and additionally are all closer to one of the two cameras then the solution in the essential matrix is not unique but twofold. As a consequence both solutions are computed and returned by the operator. This means that the output parameters EMatrix, CovEMat and Error are of double length and the values of the second solution are simply concatenated behind the values of the first one.

The parameter RandSeed can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If RandSeed is set to a positive number the operator yields the same result on every call with the same parameters because the internally used random number generator is initialized with the RandSeed. If RandSeed = *0* the random number generator is initialized with the current time. In this case the results may not be reproducible. The value set for the HALCON system variable *'seed_rand'* (see set_system) does not affect the results of match_essential_matrix_ransac.

Parameters

- ▷ **Image1** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 1.
- ▷ **Image2** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 2.
- ▷ **Rows1** (input_control) . . . . . number-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 1.
  Restriction: length(Rows1) >= 6 || length(Rows1) >= 3
- ▷ **Cols1** (input_control) . . . . . number-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 1.
  Restriction: length(Cols1) == length(Rows1)
- ▷ **Rows2** (input_control) . . . . . number-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 2.
  Restriction: length(Rows2) >= 6 || length(Rows2) >= 3
- ▷ **Cols2** (input_control) . . . . . number-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 2.
  Restriction: length(Cols2) == length(Rows2)

▷ **CamMat1** (input_control) . . . . . hom_mat2d ⇝ *real* / integer
Camera matrix of the 1st camera.

▷ **CamMat2** (input_control) . . . . . hom_mat2d ⇝ *real* / integer
Camera matrix of the 2nd camera.

▷ **GrayMatchMethod** (input_control) . . . . . string ⇝ *string*
Gray value comparison metric.
Default: 'ssd'
List of values: GrayMatchMethod ∈ {'ssd', 'sad', 'ncc'}

▷ **MaskSize** (input_control) . . . . . integer ⇝ *integer*
Size of gray value masks.
Default: 10
Suggested values: MaskSize ∈ {3, 7, 15}
Value range: 1 ≤ MaskSize

▷ **RowMove** (input_control) . . . . . integer ⇝ *integer*
Average row coordinate shift of corresponding points.
Default: 0
Value range: 0 ≤ RowMove ≤ 200

▷ **ColMove** (input_control) . . . . . integer ⇝ *integer*
Average column coordinate shift of corresponding points.
Default: 0
Value range: 0 ≤ ColMove ≤ 200

▷ **RowTolerance** (input_control) . . . . . integer ⇝ *integer*
Half height of matching search window.
Default: 200
Value range: 1 ≤ RowTolerance

▷ **ColTolerance** (input_control) . . . . . integer ⇝ *integer*
Half width of matching search window.
Default: 200
Value range: 1 ≤ ColTolerance

▷ **Rotation** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
Estimate of the relative orientation of the right image with respect to the left image.
Default: 0.0
Suggested values: Rotation ∈ {0.0, 0.1, -0.1, 0.7854, 1.571, 3.142}

▷ **MatchThreshold** (input_control) . . . . . number ⇝ *integer* / real
Threshold for gray value matching.
Default: 10
Suggested values: MatchThreshold ∈ {10, 20, 50, 100, 0.9, 0.7}

▷ **EstimationMethod** (input_control) . . . . . string ⇝ *string*
Algorithm for the computation of the essential matrix and for special camera orientations.
Default: 'normalized_dlt'
List of values: EstimationMethod ∈ {'normalized_dlt', 'gold_standard', 'trans_normalized_dlt', 'trans_gold_standard'}

▷ **DistanceThreshold** (input_control) . . . . . number ⇝ *real* / integer
Maximal deviation of a point from its epipolar line.
Default: 1
Value range: 0.5 ≤ DistanceThreshold ≤ 5
Restriction: DistanceThreshold > 0

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **EMatrix** (output_control) . . . . . hom_mat2d ⇝ *real*
Computed essential matrix.

▷ **CovEMat** (output_control) . . . . . real-array ⇝ *real*
9×9 covariance matrix of the essential matrix.

▷ **Error** (output_control) . . . . . real(-array) ⇝ *real*
Root-Mean-Square of the epipolar distance error.

▷ **Points1** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 2.

Module

3D Metrology

match_fundamental_matrix_distortion_ransac (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, GrayMatchMethod, MaskSize, RowMove, ColMove, RowTolerance, ColTolerance, Rotation, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : FMatrix, Kappa, Error, Points1, Points2)

Compute the fundamental matrix and the radial distortion coefficient for a pair of stereo images by automatically finding correspondences between image points.

Given a set of coordinates of characteristic points (Rows1, Cols1) and (Rows2, Cols2) in the stereo images Image1 and Image2, which must be of identical size, match_fundamental_matrix_distortion_ransac automatically finds the correspondences between the characteristic points and determines the geometry of the stereo setup. For unknown cameras the geometry of the stereo setup is represented by the fundamental matrix FMatrix and the radial distortion coefficient Kappa (κ). All corresponding points must fulfill the epipolar constraint:

$$\begin{pmatrix} c_2 \\ r_2 \\ 1 \end{pmatrix}^T \cdot \texttt{FMatrix} \cdot \begin{pmatrix} c_1 \\ r_1 \\ 1 \end{pmatrix} = 0 \ .$$

Here, (r_1, c_1) and (r_2, c_2) denote image points that are obtained by undistorting the input image points with the division model (see Calibration):

$$r = \frac{\tilde{r}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)} \qquad c = \frac{\tilde{c}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)}$$

Here, $(\tilde{r}_1, \tilde{c}_1) = (\texttt{Rows1} - 0.5(h-1), \texttt{Cols1} - 0.5(w-1))$
and $(\tilde{r}_2, \tilde{c}_2) = (\texttt{Rows2} - 0.5(h-1), \texttt{Cols2} - 0.5(w-1))$

denote the distorted image points, specified relative to the image center, and w and h denote the width and height of the input images. Thus, match_fundamental_matrix_distortion_ransac assumes that the principal point of the camera, i.e., the center of the radial distortions, lies at the center of the image.

The returned Kappa can be used to construct camera parameters that can be used to rectify images or points (see change_radial_distortion_cam_par, change_radial_distortion_image, and change_radial_distortion_points):

$$\begin{aligned} \texttt{CamPar} \quad = \quad & [\textit{'area\_scan\_telecentric\_division'}, 0.0, \texttt{Kappa}, 1.0, 1.0, \\ & 0.5(w-1), 0.5(h-1), w, h] \end{aligned}$$

Note the column/row ordering in the point coordinates above: since the fundamental matrix encodes the projective relation between two stereo images embedded in 3D space, the x/y notation must be compliant with the camera coordinate system. Therefore, (x,y) coordinates correspond to (column,row) pairs.

The matching process is based on characteristic points, which can be extracted with point operators like points_foerstner or points_harris. The matching itself is carried out in two steps: first, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images. Then, the RANSAC algorithm is applied to find the fundamental matrix and radial distortion coefficient that maximizes the number of correspondences under the epipolar constraint.

The size of the mask windows used for the matching is MaskSize×MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A matching thus found is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the speed of the algorithm the search area for the match candidates can be limited to a rectangle by specifying its size and offset. Only points within a window of $2 \cdot$ RowTolerance $\times\, 2 \cdot$ ColTolerance points are considered. The offset of the center of the search window in the second image with respect to the position of the current point in the first image is given by RowMove and ColMove.

If the second camera is rotated around the optical axis with respect to the first camera, the parameter Rotation may contain an estimate for the rotation angle or an angle interval in radians. A good guess will increase the quality of the gray value matching. If the actual rotation differs too much from the specified estimate, the matching will typically fail. In this case, an angle interval should be specified and Rotation is a tuple with two elements. The larger the given interval is the slower is the operator is since the RANSAC algorithm is run over all (automatically determined) angle increments within the interval.

After the initial matching has been completed, a randomized search algorithm (RANSAC) is used to determine the fundamental matrix FMatrix and the radial distortion coefficient Kappa. It tries to find the parameters that are consistent with a maximum number of correspondences. For a point to be accepted, the distance in pixels to its corresponding epipolar line must not exceed the threshold DistanceThreshold.

The parameter EstimationMethod decides whether the relative orientation between the cameras is of a special type and which algorithm is to be applied for its computation. If EstimationMethod is either *'linear'* or *'gold_standard'*, the relative orientation is arbitrary. If the left and right cameras are identical and the relative orientation between them is a pure translation, EstimationMethod can be set to *'trans_linear'* or *'trans_gold_standard'*. The typical application for this special motion case is the scenario of a single fixed camera looking onto a moving conveyor belt. In order to get a unique solution for the correspondence problem, the minimum required number of corresponding points is nine in the general case and four in the special translational case.

The fundamental matrix is computed by a linear algorithm if EstimationMethod is set to *'linear'* or *'trans_linear'*. This algorithm is very fast. For the pure translation case (EstimationMethod = *'trans_linear'*), the linear method returns accurate results for small to moderate noise of the point coordinates and for most distortions (except for very small distortions). For a general relative orientation of the two cameras (EstimationMethod = *'linear'*), the linear method only returns accurate results for very small noise of the point coordinates and for sufficiently large distortions. For EstimationMethod = *'gold_standard'* or *'trans_gold_standard'*, a mathematically optimal but slower optimization is used, which minimizes the geometric reprojection error of reconstructed projective 3D points. For a general relative orientation of the two cameras, in general EstimationMethod = *'gold_standard'* should be selected.

The value `Error` indicates the overall quality of the estimation procedure and is the mean symmetric Euclidean distance in pixels between the points and their corresponding epipolar lines.

Point pairs consistent with the above constraints are considered to be corresponding points. `Points1` contains the indices of the matched input points from the first image and `Points2` contains the indices of the corresponding points in the second image.

The parameter `RandSeed` can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If `RandSeed` is set to a positive number, the operator returns the same result on every call with the same parameters because the internally used random number generator is initialized with `RandSeed`. If `RandSeed` = *0*, the random number generator is initialized with the current time. In this case the results may not be reproducible. The value set for the HALCON system variable *'seed_rand'* (see `set_system`) does not affect the results of `match_fundamental_matrix_distortion_ransac`.

Parameters

- ▷ **`Image1`** (input_object) . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 1.
- ▷ **`Image2`** (input_object) . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 2.
- ▷ **`Rows1`** (input_control) . . . point.y-array ⇝ *real* / integer
  Input points in image 1 (row coordinate).
  Restriction: length(Rows1) >= 9 || length(Rows1) >= 4
- ▷ **`Cols1`** (input_control) . . . point.x-array ⇝ *real* / integer
  Input points in image 1 (column coordinate).
  Restriction: length(Cols1) == length(Rows1)
- ▷ **`Rows2`** (input_control) . . . point.y-array ⇝ *real* / integer
  Input points in image 2 (row coordinate).
  Restriction: length(Rows2) >= 9 || length(Rows2) >= 4
- ▷ **`Cols2`** (input_control) . . . point.x-array ⇝ *real* / integer
  Input points in image 2 (column coordinate).
  Restriction: length(Cols2) == length(Rows2)
- ▷ **`GrayMatchMethod`** (input_control) . . . string ⇝ *string*
  Gray value match metric.
  Default: 'ncc'
  List of values: `GrayMatchMethod` ∈ {'ncc', 'ssd', 'sad'}
- ▷ **`MaskSize`** (input_control) . . . integer ⇝ *integer*
  Size of gray value masks.
  Default: 10
  Suggested values: `MaskSize` ∈ {3, 7, 15}
  Value range: 1 ≤ MaskSize
- ▷ **`RowMove`** (input_control) . . . integer ⇝ *integer*
  Average row coordinate offset of corresponding points.
  Default: 0
- ▷ **`ColMove`** (input_control) . . . integer ⇝ *integer*
  Average column coordinate offset of corresponding points.
  Default: 0
- ▷ **`RowTolerance`** (input_control) . . . integer ⇝ *integer*
  Half height of matching search window.
  Default: 200
  Restriction: RowTolerance >= 1
- ▷ **`ColTolerance`** (input_control) . . . integer ⇝ *integer*
  Half width of matching search window.
  Default: 200
  Restriction: ColTolerance >= 1
- ▷ **`Rotation`** (input_control) . . . angle.rad(-array) ⇝ *real* / integer
  Estimate of the relative rotation of the second image with respect to the first image.
  Default: 0.0
  Suggested values: `Rotation` ∈ {0.0, 0.1, -0.1, 0.7854, 1.571, 3.142}

▷ **MatchThreshold** (input_control) . . . . . number ⇝ *integer / real*
Threshold for gray value matching.
Default: 0.7
Suggested values: MatchThreshold ∈ {0.9, 0.7, 0.5, 10, 20, 50, 100}

▷ **EstimationMethod** (input_control) . . . . . string ⇝ *string*
Algorithm for the computation of the fundamental matrix and for special camera orientations.
Default: 'gold_standard'
List of values: EstimationMethod ∈ {'linear', 'gold_standard', 'trans_linear', 'trans_gold_standard'}

▷ **DistanceThreshold** (input_control) . . . . . number ⇝ *real / integer*
Maximal deviation of a point from its epipolar line.
Default: 1
Restriction: DistanceThreshold > 0

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **FMatrix** (output_control) . . . . . hom_mat2d ⇝ *real*
Computed fundamental matrix.

▷ **Kappa** (output_control) . . . . . real ⇝ *real*
Computed radial distortion coefficient.

▷ **Error** (output_control) . . . . . real ⇝ *real*
Root-Mean-Square epipolar distance error.

▷ **Points1** (output_control) . . . . . integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) . . . . . integer-array ⇝ *integer*
Indices of matched input points in image 2.

match_fundamental_matrix_ransac (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, GrayMatchMethod, MaskSize, RowMove, ColMove, RowTolerance, ColTolerance, Rotation, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : FMatrix, CovFMat, Error, Points1, Points2)

Compute the fundamental matrix for a pair of stereo images by automatically finding correspondences between image points.

Given a set of coordinates of characteristic points (Rows1, Cols1) and (Rows2, Cols2) in the stereo images Image1 and Image2, match_fundamental_matrix_ransac automatically finds the correspondences between the characteristic points and determines the geometry of the stereo setup. For unknown cameras the geometry of the stereo setup is represented by the fundamental matrix FMatrix and all corresponding points have to fulfill the epipolar constraint, namely:

$$\begin{pmatrix} \text{Cols2} \\ \text{Rows2} \\ 1 \end{pmatrix}^T \cdot \text{FMatrix} \cdot \begin{pmatrix} \text{Cols1} \\ \text{Rows1} \\ 1 \end{pmatrix} = 0 \quad .$$

Note the column/row ordering in the point coordinates: because the fundamental matrix encodes the projective relation between two stereo images embedded in 3D space, the x/y notation has to be compliant with the camera coordinate system. So, (x,y) coordinates correspond to (column,row) pairs.

The matching process is based on characteristic points, which can be extracted with point operators like points_foerstner or points_harris. The matching itself is carried out in two steps: first, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images. Then, the RANSAC algorithm is applied to find the fundamental matrix that maximizes the number of correspondences under the epipolar constraint.

The size of the mask windows is MaskSize × MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A thus found matching is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the speed of the algorithm the search area for the matching operations can be limited. Only points within a window of $2 \cdot$ RowTolerance $\times 2 \cdot$ ColTolerance points are considered. The offset of the center of the search window in the second image with respect to the position of the current point in the first image is given by RowMove and ColMove.

If the second camera is rotated around the optical axis with respect to the first camera the parameter Rotation may contain an estimate for the rotation angle or an angle interval in radians. A good guess will increase the quality of the gray value matching. If the actual rotation differs too much from the specified estimate the matching will typically fail. In this case, an angle interval should be specified and Rotation is a tuple with two elements. The larger the given interval the slower the operator is since the RANSAC algorithm is run over all angle increments within the interval.

After the initial matching is completed a randomized search algorithm (RANSAC) is used to determine the fundamental matrix FMatrix. It tries to find the matrix that is consistent with a maximum number of correspondences. For a point to be accepted, the distance to its corresponding epipolar line must not exceed the threshold DistanceThreshold.

The parameter EstimationMethod decides whether the relative orientation between the cameras is of a special type and which algorithm is to be applied for its computation. If EstimationMethod is either *'normalized_dlt'* or *'gold_standard'* the relative orientation is arbitrary. If left and right camera are identical and the relative orientation between them is a pure translation then choose EstimationMethod equal to *'trans_normalized_dlt'* or *'trans_gold_standard'*. The typical application for this special motion case is the scenario of a single fixed camera looking onto a moving conveyor belt. In order to get a unique solution in the correspondence problem the minimum required number of corresponding points is eight in the general case and three in the special, translational case.

The fundamental matrix is computed by a linear algorithm if *'normalized_dlt'* or *'trans_normalized_dlt'* is chosen. With *'gold_standard'* or *'trans_gold_standard'* the algorithm gives a statistically optimal result, and returns as well the covariance of the fundamental matrix CovFMat. Here, *'normalized_dlt'* and *'gold_standard'* stand for direct-linear-transformation and gold-standard-algorithm respectively.

The value Error indicates the overall quality of the estimation procedure and is the mean Euclidean distance in pixels between the points and their corresponding epipolar lines.

Point pairs consistent with the mentioned constraints are considered to be in correspondences. Points1 contains the indices of the matched input points from the first image and Points2 contains the indices of the corresponding points in the second image.

The parameter RandSeed can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If RandSeed is set to a positive number the operator yields the same result on every call with the same parameters because the internally used random number generator is initialized with the RandSeed. If RandSeed $=$ *0* the random number generator is initialized with the current time. In this case the results may not be reproducible. The value set for the HALCON system variable *'seed_rand'* (see set_system) does not affect the results of match_fundamental_matrix_ransac.

Parameters

- ▷ **Image1** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 1.
- ▷ **Image2** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 2.
- ▷ **Rows1** (input_control) . . . . . number-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 1.
  Restriction: length(Rows1) >= 8 || length(Rows1) >= 3
- ▷ **Cols1** (input_control) . . . . . number-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 1.
  Restriction: length(Cols1) == length(Rows1)
- ▷ **Rows2** (input_control) . . . . . number-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 2.
  Restriction: length(Rows2) >= 8 || length(Rows2) >= 3
- ▷ **Cols2** (input_control) . . . . . number-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 2.
  Restriction: length(Cols2) == length(Rows2)

▷ **GrayMatchMethod** (input_control) . . . . . string ⇝ *string*
Gray value comparison metric.
Default: 'ssd'
List of values: GrayMatchMethod ∈ {'ssd', 'sad', 'ncc'}

▷ **MaskSize** (input_control) . . . . . integer ⇝ *integer*
Size of gray value masks.
Default: 10
Suggested values: MaskSize ∈ {3, 7, 15}
Value range: 1 ≤ MaskSize

▷ **RowMove** (input_control) . . . . . integer ⇝ *integer*
Average row coordinate shift of corresponding points.
Default: 0
Value range: 0 ≤ RowMove ≤ 200

▷ **ColMove** (input_control) . . . . . integer ⇝ *integer*
Average column coordinate shift of corresponding points.
Default: 0
Value range: 0 ≤ ColMove ≤ 200

▷ **RowTolerance** (input_control) . . . . . integer ⇝ *integer*
Half height of matching search window.
Default: 200
Value range: 1 ≤ RowTolerance

▷ **ColTolerance** (input_control) . . . . . integer ⇝ *integer*
Half width of matching search window.
Default: 200
Value range: 1 ≤ ColTolerance

▷ **Rotation** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
Estimate of the relative orientation of the right image with respect to the left image.
Default: 0.0
Suggested values: Rotation ∈ {0.0, 0.1, -0.1, 0.7854, 1.571, 3.142}

▷ **MatchThreshold** (input_control) . . . . . number ⇝ *integer* / real
Threshold for gray value matching.
Default: 10
Suggested values: MatchThreshold ∈ {10, 20, 50, 100, 0.9, 0.7}

▷ **EstimationMethod** (input_control) . . . . . string ⇝ *string*
Algorithm for the computation of the fundamental matrix and for special camera orientations.
Default: 'normalized_dlt'
List of values: EstimationMethod ∈ {'normalized_dlt', 'gold_standard', 'trans_normalized_dlt', 'trans_gold_standard'}

▷ **DistanceThreshold** (input_control) . . . . . number ⇝ *real* / integer
Maximal deviation of a point from its epipolar line.
Default: 1
Value range: 0.5 ≤ DistanceThreshold ≤ 5
Restriction: DistanceThreshold > 0

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **FMatrix** (output_control) . . . . . hom_mat2d ⇝ *real*
Computed fundamental matrix.

▷ **CovFMat** (output_control) . . . . . real-array ⇝ *real*
9×9 covariance matrix of the fundamental matrix.

▷ **Error** (output_control) . . . . . real ⇝ *real*
Root-Mean-Square of the epipolar distance error.

▷ **Points1** (output_control) . . . . . integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) . . . . . integer-array ⇝ *integer*
Indices of matched input points in image 2.

3D Metrology

match_rel_pose_ransac (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, CamPar1, CamPar2, GrayMatchMethod, MaskSize, RowMove, ColMove, RowTolerance, ColTolerance, Rotation, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : RelPose, CovRelPose, Error, Points1, Points2)

Compute the relative orientation between two cameras by automatically finding correspondences between image points.

Given a set of coordinates of characteristic points (Rows1,Cols1) and (Rows2,Cols2) in the stereo images Image1 and Image2 along with known internal camera parameters CamPar1 and CamPar2, match_rel_pose_ransac automatically determines the geometry of the stereo setup and finds the correspondences between the characteristic points. The geometry of the stereo setup is represented by the relative pose RelPose and all corresponding points have to fulfill the epipolar constraint. RelPose indicates the relative pose of camera 1 with respect to camera 2 (See create_pose for more information about poses and their representations.). This is in accordance with the explicit calibration of a stereo setup using the operator calibrate_cameras. Now, let R, t be the rotation and translation of the relative pose. Then, the essential matrix E is defined as $E = ([t]_\times R)^T$, where $[t]_\times$ denotes the 3×3 skew-symmetric matrix realizing the cross product with the vector t. The pose can be determined from the epipolar constraint:

$$\begin{pmatrix} X_2 \\ Y_2 \\ 1 \end{pmatrix}^T \cdot ([t]_\times R)^T \cdot \begin{pmatrix} X_1 \\ Y_1 \\ 1 \end{pmatrix} = 0 \quad \text{where} \quad [t]_\times = \begin{pmatrix} 0 & -t_z & t_y \\ t_z & 0 & -t_x \\ -t_y & t_x & 0 \end{pmatrix} .$$

Note, that the essential matrix is a projective entity and thus is defined up to a scaling factor. From this follows that the translation vector of the relative pose can only be determined up to scale too. In fact, the computed translation vector will always be normalized to unit length. As a consequence, a subsequent three-dimensional reconstruction of the scene, using for instance vector_to_rel_pose, can be carried out only up to a single global scaling factor.

The operator match_rel_pose_ransac is designed to deal with a camera model, that includes lens distortions. This is in contrast to the operator match_essential_matrix_ransac, which encompasses only straight line preserving cameras. The camera parameters are passed in CamPar1 and CamPar2. The 3D direction vectors $(X_1, Y_1, 1)$ and $(X_2, Y_2, 1)$ are calculated from the point coordinates (Rows1,Cols1) and (Rows2,Cols2) by inverting the process of projection (see Calibration).

The matching process is based on characteristic points, which can be extracted with point operators like points_foerstner or points_harris. The matching itself is carried out in two steps: first, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images. Then, the RANSAC algorithm is applied to find the relative pose that maximizes the number of correspondences under the epipolar constraint.

The size of the mask windows is MaskSize $\times$ MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A thus found matching is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the speed of the algorithm, the search area for the matching operations can be limited. Only points within a window of $2 \cdot$ RowTolerance $\times 2 \cdot$ ColTolerance points are considered. The offset of the center of the search window in the second image with respect to the position of the current point in the first image is given by RowMove and ColMove.

If the second camera is rotated around the optical axis with respect to the first camera the parameter Rotation may contain an estimate for the rotation angle or an angle interval in radians. A good guess will increase the quality of the gray value matching. If the actual rotation differs too much from the specified estimate the matching will typically fail. In this case, an angle interval should be specified, and Rotation is a tuple with two elements. The larger the given interval the slower the operator is since the RANSAC algorithm is run over all angle increments within the interval.

After the initial matching is completed a randomized search algorithm (RANSAC) is used to determine the relative pose RelPose. It tries to find the relative pose that is consistent with a maximum number of correspondences. For a point to be accepted, the distance to its corresponding epipolar line must not exceed the threshold DistanceThreshold.

The parameter EstimationMethod decides whether the relative orientation between the cameras is of a special type and which algorithm is to be applied for its computation. If EstimationMethod is either *'normalized_dlt'* or *'gold_standard'* the relative orientation is arbitrary. Choosing *'trans_normalized_dlt'* or *'trans_gold_standard'* means that the relative motion between the cameras is a pure translation. The typical application for this special motion case is the scenario of a single fixed camera looking onto a moving conveyor belt. In order to get a unique solution in the correspondence problem the minimum required number of corresponding points is six in the general case and three in the special, translational case.

The relative pose is computed by a linear algorithm if *'normalized_dlt'* or *'trans_normalized_dlt'* is chosen. With *'gold_standard'* or *'trans_gold_standard'* the algorithm gives a statistically optimal result, and returns as well the covariance of the relative pose CovRelPose. Here, *'normalized_dlt'* and *'gold_standard'* stand for direct-linear-transformation and gold-standard-algorithm respectively. Note, that in general the found correspondences differ depending on the deployed estimation method.

The value Error indicates the overall quality of the estimation procedure and is the mean Euclidean distance in pixels between the points and their corresponding epipolar lines.

Point pairs consistent with the mentioned constraints are considered to be in correspondences. Points1 contains the indices of the matched input points from the first image and Points2 contains the indices of the corresponding points in the second image.

For the operator match_rel_pose_ransac a special configuration of scene points and cameras exists: if all 3D points lie in a single plane and additionally are all closer to one of the two cameras then the solution in the essential matrix is not unique but twofold. As a consequence both solutions are computed and returned by the operator. This means that the output parameters RelPose, CovRelPose and Error are of double length and the values of the second solution are simply concatenated behind the values of the first one.

The parameter RandSeed can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If RandSeed is set to a positive number the operator yields the same result on every call with the same parameters because the internally used random number generator is initialized with the RandSeed. If RandSeed $=$ *0* the random number generator is initialized with the current time. In this case the results may not be reproducible. The value set for the HALCON system variable *'seed_rand'* (see set_system) does not affect the results of match_rel_pose_ransac.

Parameters

▷ **Image1** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image 1.

▷ **Image2** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image 2.

▷ **Rows1** (input_control) . . . . . number-array ⇝ *real* / integer
Row coordinates of characteristic points in image 1.
Restriction: length(Rows1) >= 6 || length(Rows1) >= 3

▷ **Cols1** (input_control) . . . . . number-array ⇝ *real* / integer
Column coordinates of characteristic points in image 1.
Restriction: length(Cols1) == length(Rows1)

▷ **Rows2** (input_control) . . . . . number-array ⇝ *real* / integer
Row coordinates of characteristic points in image 2.
Restriction: length(Rows2) >= 6 || length(Rows2) >= 3

▷ **Cols2** (input_control) . . . . . number-array ⇝ *real* / integer
Column coordinates of characteristic points in image 2.
Restriction: length(Cols2) == length(Rows2)

▷ **CamPar1** (input_control) . . . . . campar ⇝ *real* / integer / string
Parameters of the 1st camera.

▷ **CamPar2** (input_control) . . . . . campar ⇝ *real* / integer / string
Parameters of the 2nd camera.

▷ **GrayMatchMethod** (input_control) . . . . . string ⇝ *string*
Gray value comparison metric.
Default: 'ssd'
List of values: `GrayMatchMethod` ∈ {'ssd', 'sad', 'ncc'}

▷ **MaskSize** (input_control) . . . . . integer ⇝ *integer*
Size of gray value masks.
Default: 10
Suggested values: `MaskSize` ∈ {3, 7, 15}
Value range: 1 ≤ MaskSize

▷ **RowMove** (input_control) . . . . . integer ⇝ *integer*
Average row coordinate shift of corresponding points.
Default: 0
Value range: 0 ≤ `RowMove` ≤ 200

▷ **ColMove** (input_control) . . . . . integer ⇝ *integer*
Average column coordinate shift of corresponding points.
Default: 0
Value range: 0 ≤ `ColMove` ≤ 200

▷ **RowTolerance** (input_control) . . . . . integer ⇝ *integer*
Half height of matching search window.
Default: 200
Value range: 1 ≤ RowTolerance

▷ **ColTolerance** (input_control) . . . . . integer ⇝ *integer*
Half width of matching search window.
Default: 200
Value range: 1 ≤ ColTolerance

▷ **Rotation** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
Estimate of the relative orientation of the right image with respect to the left image.
Default: 0.0
Suggested values: `Rotation` ∈ {0.0, 0.1, -0.1, 0.7854, 1.571, 3.142}

▷ **MatchThreshold** (input_control) . . . . . number ⇝ *integer* / real
Threshold for gray value matching.
Default: 10
Suggested values: `MatchThreshold` ∈ {10, 20, 50, 100, 0.9, 0.7}

▷ **EstimationMethod** (input_control) ..... string ⇝ *string*
Algorithm for the computation of the relative pose and for special pose types.
Default: 'normalized_dlt'
List of values: EstimationMethod ∈ {'normalized_dlt', 'gold_standard', 'trans_normalized_dlt', 'trans_gold_standard'}

▷ **DistanceThreshold** (input_control) ..... number ⇝ *real / integer*
Maximal deviation of a point from its epipolar line.
Default: 1
Value range: 0.5 ≤ DistanceThreshold ≤ 5
Restriction: DistanceThreshold > 0

▷ **RandSeed** (input_control) ..... integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **RelPose** (output_control) ..... pose ⇝ *real / integer*
Computed relative orientation of the cameras (3D pose).

▷ **CovRelPose** (output_control) ..... real-array ⇝ *real*
6 × 6 covariance matrix of the relative orientation.

▷ **Error** (output_control) ..... real(-array) ⇝ *real*
Root-Mean-Square of the epipolar distance error.

▷ **Points1** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 2.

reconst3d_from_fundamental_matrix (: : Rows1, Cols1, Rows2, Cols2, CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2, FMatrix, CovFMat : X, Y, Z, W, CovXYZW)

Compute the projective 3d reconstruction of points based on the fundamental matrix.

A pair of stereo images is called weakly calibrated if the fundamental matrix, which defines the geometric relation between the two images, is known. Given such a fundamental matrix FMatrix and a set of corresponding points (Rows1,Cols1) and (Rows2,Cols2) the operator reconst3d_from_fundamental_matrix determines the three-dimensional space points projecting onto these image points. This 3D reconstruction is purely projective

and the projective coordinates are returned by the four-vector (X,Y,Z,W). This type of reconstruction is also known as projective triangulation. If additionally the covariances CovRR1, CovRC1, CovCC1 and CovRR2, CovRC2, CovCC2 of the image points are given the covariances of the reconstructed points CovXYZW are computed too. Let n be the number of points. Then the concatenated covariances are stored in a $16 \times n$ tuple. The computation of the covariances is more precise if the covariance of the fundamental matrix CovFMat is provided.

The operator reconst3d_from_fundamental_matrix is typically used after match_fundamental_matrix_ransac to perform 3d reconstruction. This will save computational cost compared with the deployment of vector_to_fundamental_matrix.

reconst3d_from_fundamental_matrix is the projective equivalent to the Euclidean reconstruction operator intersect_lines_of_sight.

Parameters

- ▷ **Rows1** (input_control) . . . number(-array) ⇝ *real* / integer
  Input points in image 1 (row coordinate).

3D Metrology

rel_pose_to_fundamental_matrix (: : RelPose, CovRelPose, CamPar1, CamPar2 : FMatrix, CovFMat)

Compute the fundamental matrix from the relative orientation of two cameras.

Cameras including lens distortions can be modeled by the following set of parameters: the focal length f, two scaling factors s_x, s_y, the coordinates of the principal point (c_x, c_y) and the distortion coefficient κ. For a more detailed description see the chapter Calibration. Only cameras with a distortion coefficient equal to zero project straight lines in the world onto straight lines in the image. This is also true for telecentric cameras and for cameras with tilt lenses. rel_pose_to_fundamental_matrix handles telecentric lenses and tilt lenses correctly. However, for reasons of simplicity, these lens types are ignored in the formulas below. If the distortion coefficient is equal to zero, image projection is a linear mapping and the camera, i.e., the set of internal parameters, can be described by the camera matrix $CamMat$:

$$CamMat = \begin{pmatrix} f/s_x & 0 & c_x \\ 0 & f/s_y & c_y \\ 0 & 0 & 1 \end{pmatrix} .$$

Going from a nonlinear model to a linear model is an approximation of the real underlying camera. For a variety of camera lenses, especially lenses with long focal length, the error induced by this approximation can be neglected. Following the formula $E = ([t]_\times R)^T$, the essential matrix E is derived from the translation t and the rotation R of the relative pose RelPose (see also operator vector_to_rel_pose). In the linearized framework the fundamental matrix can be calculated from the relative pose and the camera matrices according to the formula presented under essential_to_fundamental_matrix:

$$\texttt{FMatrix} = CamMat2^{-T} \cdot ([t]_\times R)^T \cdot CamMat1^{-1} .$$

The transformation from a relative pose to a fundamental matrix goes along with the propagation of the covariance matrices CovRelPose to CovFMat. If CovRelPose is empty CovFMat will be empty too.

The conversion operator rel_pose_to_fundamental_matrix is used especially for a subsequent visualization of the epipolar line structure via the fundamental matrix, which depicts the underlying stereo geometry.

Parameters

▷ **RelPose** (input_control) . . . . . pose ⇝ *real* / integer
Relative orientation of the cameras (3D pose).

▷ **CovRelPose** (input_control) . . . . . number-array ⇝ *real* / integer
6×6 covariance matrix of relative pose.
Default: []

▷ **CamPar1** (input_control) . . . . . campar ⇝ *real* / integer / string
Parameters of the 1. camera.

▷ **CamPar2** (input_control) . . . . . campar ⇝ *real* / integer / string
Parameters of the 2. camera.

▷ **FMatrix** (output_control) . . . . . hom_mat2d ⇝ *real*
Computed fundamental matrix.
▷ **CovFMat** (output_control) . . . . . real-array ⇝ *real*
9×9 covariance matrix of the fundamental matrix.

3D Metrology

vector_to_essential_matrix (: : Rows1, Cols1, Rows2, Cols2, CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2, CamMat1, CamMat2, Method : EMatrix, CovEMat, Error, X, Y, Z, CovXYZ)

Compute the essential matrix given image point correspondences and known camera matrices and reconstruct 3D points.

For a stereo configuration with known camera matrices the geometric relation between the two images is defined by the essential matrix. The operator vector_to_essential_matrix determines the essential matrix EMatrix from in general at least six given point correspondences, that fulfill the epipolar constraint:

$$\begin{pmatrix} X_2 \\ Y_2 \\ 1 \end{pmatrix}^T \cdot EMatrix \cdot \begin{pmatrix} X_1 \\ Y_1 \\ 1 \end{pmatrix} = 0$$

The operator vector_to_essential_matrix is designed to deal only with a linear camera model. This is in contrast to the operator vector_to_rel_pose, that encompasses lens distortions too. The internal camera parameters are passed by the arguments CamMat1 and CamMat2, which are 3×3 upper triangular matrices describing an affine transformation. The relation between the vector (X,Y,1), defining the direction from the camera to the viewed 3D point, and its (projective) 2D image coordinates (col,row,1) is:

$$\begin{pmatrix} col \\ row \\ 1 \end{pmatrix} = CamMat \cdot \begin{pmatrix} X \\ Y \\ 1 \end{pmatrix} \quad \text{where} \quad CamMat = \begin{pmatrix} f/s_x & s & c_x \\ 0 & f/s_y & c_y \\ 0 & 0 & 1 \end{pmatrix} .$$

The focal length is denoted by f, s_x, s_y are scaling factors, s describes a skew factor and (c_x, c_y) indicates the principal point. Mainly, these are the elements known from the camera parameters as used for example in calibrate_cameras. Alternatively, the elements of the camera matrix can be described in a different way, see e.g. stationary_camera_self_calibration.

The point correspondences (Rows1,Cols1) and (Rows2,Cols2) are typically found by applying the operator match_essential_matrix_ransac. Multiplying the image coordinates by the inverse of the camera matrices results in the 3D direction vectors, which can then be inserted in the epipolar constraint.

The parameter Method decides whether the relative orientation between the cameras is of a special type and which algorithm is to be applied for its computation. If Method is either *'normalized_dlt'* or *'gold_standard'* the relative orientation is arbitrary. Choosing *'trans_normalized_dlt'* or *'trans_gold_standard'* means that the relative motion between the cameras is a pure translation. The typical application for this special motion case is the scenario

of a single fixed camera looking onto a moving conveyor belt. In this case the minimum required number of corresponding points is just two instead of six in the general case.

The essential matrix is computed by a linear algorithm if *'normalized_dlt'* or *'trans_normalized_dlt'* is chosen. With *'gold_standard'* or *'trans_gold_standard'* the algorithm gives a statistically optimal result. Here, *'normalized_dlt'* and *'gold_standard'* stand for direct-linear-transformation and gold-standard-algorithm respectively. All methods return the coordinates (X,Y,Z) of the reconstructed 3D points. The optimal methods also return the covariances of the 3D points in CovXYZ. Let n be the number of points then the 3×3 covariance matrices are concatenated and stored in a tuple of length $9n$. Additionally, the optimal methods return the covariance of the essential matrix CovEMat.

If an optimal gold-standard-algorithm is chosen the covariances of the image points (CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2) can be incorporated in the computation. They can be provided for example by the operator points_foerstner. If the point covariances are unknown, which is the default, empty tuples are input. In this case the optimization algorithm internally assumes uniform and equal covariances for all points.

The value Error indicates the overall quality of the optimization process and is the root-mean-square Euclidean distance in pixels between the points and their corresponding epipolar lines.

For the operator vector_to_essential_matrix a special configuration of scene points and cameras exists: if all 3D points lie in a single plane and additionally are all closer to one of the two cameras then the solution in the essential matrix is not unique but twofold. As a consequence both solutions are computed and returned by the operator. This means that all output parameters are of double length and the values of the second solution are simply concatenated behind the values of the first one.

Parameters

vector_to_fundamental_matrix (: : Rows1, Cols1, Rows2, Cols2, CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2, Method : FMatrix, CovFMat, Error, X, Y, Z, W, CovXYZW)

Compute the fundamental matrix given a set of image point correspondences and reconstruct 3D points.

For a stereo configuration with unknown camera parameters the geometric relation between the two images is defined by the fundamental matrix. The operator vector_to_fundamental_matrix determines the fundamental matrix FMatrix from given point correspondences (Rows1,Cols1), (Rows2,Cols2), that fulfill the epipolar constraint:

$$\begin{pmatrix} \texttt{Cols2} \\ \texttt{Rows2} \\ 1 \end{pmatrix}^T \cdot \texttt{FMatrix} \cdot \begin{pmatrix} \texttt{Cols1} \\ \texttt{Rows1} \\ 1 \end{pmatrix} = 0 \ .$$

Note the column/row ordering in the point coordinates: since the fundamental matrix encodes the projective relation between two stereo images embedded in 3D space, the x/y notation must be compliant with the camera coordinate system. Therefore, (x,y) coordinates correspond to (column,row) pairs.

For a general relative orientation of the two cameras the minimum number of required point correspondences is eight. Then, `Method` is chosen to be *'normalized_dlt'* or *'gold_standard'*. If left and right camera are identical and the relative orientation between them is a pure translation then choose `Method` equal to *'trans_normalized_dlt'* or *'trans_gold_standard'*. In this special case the minimum number of correspondences is only two. The typical application of the motion being a pure translation is that of a single fixed camera looking onto a moving conveyor belt.

The fundamental matrix is determined by minimizing a cost function. To minimize the respective error different algorithms are available, and the user can choose between the direct-linear-transformation ('normalized_dlt') and the gold-standard-algorithm ('gold_standard'). Like the motion case, the algorithm can be selected with the parameter `Method`. For `Method` = *'normalized_dlt'* or *'trans_normalized_dlt'*, a linear algorithm minimizes an algebraic error based on the above epipolar constraint. This algorithm offers a good compromise between speed and accuracy. For `Method` = *'gold_standard'* or *'trans_gold_standard'*, a mathematically optimal, but slower optimization is used, which minimizes the geometric backprojection error of reconstructed projective 3D points. In this case, in addition to the fundamental matrix its covariance matrix `CovFMat` is output, along with the projective coordinates (`X`,`Y`,`Z`,`W`) of the reconstructed points and their covariances `CovXYZW`. Let n be the number of points. Then the concatenated covariances are stored in a $16 \times n$ tuple.

If an optimal gold-standard-algorithm is chosen the covariances of the image points (`CovRR1`, `CovRC1`, `CovCC1`, `CovRR2`, `CovRC2`, `CovCC2`) can be incorporated in the computation. They can be provided for example by the operator `points_foerstner`. If the point covariances are unknown, which is the default, empty tuples are input. In this case the optimization algorithm internally assumes uniform and equal covariances for all points.

The value `Error` indicates the overall quality of the optimization procedure and is the mean Euclidean distance in pixels between the points and their corresponding epipolar lines.

If the correspondence between the points are not known, `match_fundamental_matrix_ransac` should be used instead.

Parameters

▷ **Rows1** (input_control) . . . number-array ⇝ *real* / integer
Input points in image 1 (row coordinate).
Restriction: length(Rows1) >= 8 || length(Rows1) >= 2

▷ **Cols1** (input_control) . . . number-array ⇝ *real* / integer
Input points in image 1 (column coordinate).
Restriction: length(Cols1) == length(Rows1)

▷ **Rows2** (input_control) . . . number-array ⇝ *real* / integer
Input points in image 2 (row coordinate).

vector_to_fundamental_matrix_distortion (: : Rows1, Cols1, Rows2, Cols2, CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2, ImageWidth, ImageHeight, Method : FMatrix, Kappa, Error, X, Y, Z, W)

Compute the fundamental matrix and the radial distortion coefficient given a set of image point correspondences and reconstruct 3D points.

For a stereo configuration with unknown camera parameters, the geometric relation between the two images is defined by the fundamental matrix. vector_to_fundamental_matrix_distortion determines the fundamental matrix FMatrix and the radial distortion coefficient Kappa (κ) from given point correspondences (Rows1,Cols1), (Rows2,Cols2) that fulfill the epipolar constraint:

$$\begin{pmatrix} c_2 \\ r_2 \\ 1 \end{pmatrix}^T \cdot \texttt{FMatrix} \cdot \begin{pmatrix} c_1 \\ r_1 \\ 1 \end{pmatrix} = 0 \ .$$

Here, (r_1, c_1) and (r_2, c_2) denote image points that are obtained by undistorting the input image points with the division model (see Calibration):

$$r = \frac{\tilde{r}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)} \qquad c = \frac{\tilde{c}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)}$$

Here, $(\tilde{r}_1, \tilde{c}_1) = (\texttt{Rows1} - 0.5(\texttt{ImageHeight} - 1), \texttt{Cols1} - 0.5(\texttt{ImageWidth} - 1))$
and $(\tilde{r}_2, \tilde{c}_2) = (\texttt{Rows2} - 0.5(\texttt{ImageHeight} - 1), \texttt{Cols2} - 0.5(\texttt{ImageWidth} - 1))$
denote the distorted image points, specified relative to the image center. Thus, vector_to_fundamental_matrix_distortion assumes that the principal point of the camera, i.e., the center of the radial distortions, lies at the center of the image.

The returned Kappa can be used to construct camera parameters that can be used to rectify images or points (see change_radial_distortion_cam_par, change_radial_distortion_image, and change_radial_distortion_points):

$$\begin{aligned} \texttt{CamPar} \ = \ & [\text{'}area\_scan\_telecentric\_division\text{'}, 0.0, \texttt{Kappa}, 1.0, 1.0, 0.5(\texttt{ImageWidth} - 1), \\ & 0.5(\texttt{ImageHeight} - 1), \texttt{ImageWidth}, \texttt{ImageHeight}] \end{aligned}$$

Note the column/row ordering in the point coordinates above: since the fundamental matrix encodes the projective relation between two stereo images embedded in 3D space, the x/y notation must be compliant with the camera coordinate system. Therefore, (x,y) coordinates correspond to (column,row) pairs.

For a general relative orientation of the two cameras, the minimum number of required point correspondences is nine. Then, Method must be set to *'linear'* or *'gold_standard'*. If the left and right cameras are identical and the relative orientation between them is a pure translation, Method must be set to *'trans_linear'* or *'trans_gold_standard'*. In this special case, the minimum number of correspondences is only four. The typical application of the motion being a pure translation is a single fixed camera looking onto a moving conveyor belt.

The fundamental matrix is determined by minimizing a cost function. To minimize the respective error, different algorithms are available, and the user can choose between the linear (*'linear'*) and the gold-standard algorithm (*'gold_standard'*). Like the motion type, the algorithm can be selected with the parameter Method. For Method = *'linear'* or *'trans_linear'*, a linear algorithm that minimizes an algebraic error based on the above epipolar constraint is used. This algorithm is very fast. For the pure translation case (Method = *'trans_linear'*), the linear method returns accurate results for small to moderate noise of the point coordinates and for most distortions (except for very small distortions). For a general relative orientation of the two cameras (Method = *'linear'*), the linear method only returns accurate results for very small noise of the point coordinates and for sufficiently large distortions. For Method = *'gold_standard'* or *'trans_gold_standard'*, a mathematically optimal but slower optimization is used, which minimizes the geometric reprojection error of reconstructed projective 3D points. In this case, in addition to the fundamental matrix and the distortion coefficient, the projective coordinates (X,Y,Z,W) of the reconstructed points are returned. For a general relative orientation of the two cameras, in general Method = *'gold_standard'* should be selected.

If an optimal gold-standard algorithm is chosen, the covariances of the image points (CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2) can be incorporated into the computation. They can be provided, for example, by the operator points_foerstner. If the point covariances are unknown, which is the default, empty tuples are passed. In this case, the optimization algorithm internally assumes uniform and equal covariances for all points.

The value Error indicates the overall quality of the optimization procedure and is the mean symmetric Euclidean distance in pixels between the points and their corresponding epipolar lines.

If the correspondence between the points is not known, match_fundamental_matrix_distortion_ransac should be used instead.

Parameters

▷ **Rows1** (input_control) . . . . . point.y-array ⇝ *real* / integer
Input points in image 1 (row coordinate).
Restriction: length(Rows1) >= 9 || length(Rows1) >= 4

▷ **Cols1** (input_control) . . . . . point.x-array ⇝ *real* / integer
Input points in image 1 (column coordinate).
Restriction: length(Cols1) == length(Rows1)

▷ **Rows2** (input_control) . . . . . point.y-array ⇝ *real* / integer
Input points in image 2 (row coordinate).
Restriction: length(Rows2) == length(Rows1)

▷ **Cols2** (input_control) . . . . . point.x-array ⇝ *real* / integer
Input points in image 2 (column coordinate).
Restriction: length(Cols2) == length(Rows1)

▷ **CovRR1** (input_control) . . . . . number-array ⇝ *real* / integer
Row coordinate variance of the points in image 1.
Default: []

▷ **CovRC1** (input_control) . . . . . number-array ⇝ *real* / integer
Covariance of the points in image 1.
Default: []

▷ **CovCC1** (input_control) . . . . . number-array ⇝ *real* / integer
Column coordinate variance of the points in image 1.
Default: []

▷ **CovRR2** (input_control) . . . . . number-array ⇝ *real* / integer
Row coordinate variance of the points in image 2.
Default: []

▷ **CovRC2** (input_control) . . . . . number-array ⇝ *real* / integer
Covariance of the points in image 2.
Default: []

▷ **CovCC2** (input_control) . . . . . number-array ⇝ *real* / integer
Column coordinate variance of the points in image 2.
Default: []

▷ **ImageWidth** (input_control) . . . . . integer ⇝ *integer*
Width of the images from which the points were extracted.
Restriction: ImageWidth > 0

▷ **ImageHeight** (input_control) . . . . . integer ⇝ *integer*
Height of the images from which the points were extracted.
Restriction: ImageHeight > 0

▷ **Method** (input_control) . . . . . string ⇝ *string*
Estimation algorithm.
Default: 'gold_standard'
List of values: Method ∈ {'linear', 'gold_standard', 'trans_linear', 'trans_gold_standard'}

▷ **FMatrix** (output_control) . . . . . hom_mat2d ⇝ *real*
Computed fundamental matrix.

▷ **Kappa** (output_control) . . . . . real ⇝ *real*
Computed radial distortion coefficient.

▷ **Error** (output_control) . . . . . real ⇝ *real*
Root-Mean-Square epipolar distance error.

▷ **X** (output_control) . . . . . real-array ⇝ *real*
X coordinates of the reconstructed points in projective 3D space.

▷ **Y** (output_control) . . . . . real-array ⇝ *real*
Y coordinates of the reconstructed points in projective 3D space.

▷ **Z** (output_control) . . . . . real-array ⇝ *real*
Z coordinates of the reconstructed points in projective 3D space.

▷ **W** (output_control) . . . . . real-array ⇝ *real*
W coordinates of the reconstructed points in projective 3D space.

vector_to_rel_pose (: : Rows1, Cols1, Rows2, Cols2, CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2, CamPar1, CamPar2, Method : RelPose, CovRelPose, Error, X, Y, Z, CovXYZ)

Compute the relative orientation between two cameras given image point correspondences and known camera parameters and reconstruct 3D space points.

For a stereo configuration with known camera parameters the geometric relation between the two images is defined by the relative pose. The operator vector_to_rel_pose computes the relative pose from in general at least six point correspondences in the image pair. RelPose indicates the relative pose of camera 1 with respect to camera 2 (see create_pose for more information about poses and their representations.). This is in accordance with the explicit calibration of a stereo setup using the operator calibrate_cameras. Now, let R, t be the rotation and translation of the relative pose. Then, the essential matrix E is defined as $E = ([t]_\times R)^T$, where $[t]_\times$ denotes the 3×3 skew-symmetric matrix realizing the cross product with the vector t. The pose can be determined from the epipolar constraint:

$$\begin{pmatrix} X_2 \\ Y_2 \\ 1 \end{pmatrix}^T \cdot ([t]_\times R)^T \cdot \begin{pmatrix} X_1 \\ Y_1 \\ 1 \end{pmatrix} = 0 \quad \text{where} \quad [t]_\times = \begin{pmatrix} 0 & -t_z & t_y \\ t_z & 0 & -t_x \\ -t_y & t_x & 0 \end{pmatrix} .$$

Note, that the essential matrix is a projective entity and thus is defined up to a scaling factor. From this follows that the translation vector of the relative pose can only be determined up to scale too. In fact, the computed translation vector will always be normalized to unit length. As a consequence, a three-dimensional reconstruction of the scene, here in terms of points given by their coordinates (X,Y,Z), can be carried out only up to a single global scaling factor. If the absolute 3D coordinates of the reconstruction are to be achieved the unknown scaling factor can be computed from a gauge, which has to be visible in both images. For example, a simple gauge can be given by any known distance between points in the scene.

The operator vector_to_rel_pose is designed to deal with a camera model that includes lens distortions. This is in contrast to the operator vector_to_essential_matrix, which encompasses only straight line

preserving cameras. The camera parameters are passed by the arguments CamPar1, CamPar2. The 3D direction vectors $(X_1, Y_1, 1)$ and $(X_2, Y_2, 1)$ are calculated from the point coordinates (Rows1,Cols1) and (Rows2,Cols2) by inverting the process of projection (see Calibration). The point correspondences are typically determined by applying the operator match_rel_pose_ransac.

The parameter Method decides whether the relative orientation between the cameras is of a special type and which algorithm is to be applied for its computation. If Method is either *'normalized_dlt'* or *'gold_standard'* the relative orientation is arbitrary. Choosing *'trans_normalized_dlt'* or *'trans_gold_standard'* means that the relative motion between the cameras is a pure translation. The typical application for this special motion case is the scenario of a single fixed camera looking onto a moving conveyor belt. In this case the minimum required number of corresponding points is just two instead of six in the general case.

The relative pose is computed by a linear algorithm if *'normalized_dlt'* or *'trans_normalized_dlt'* is chosen. With *'gold_standard'* or *'trans_gold_standard'* the algorithm gives a statistically optimal result. Here, *'normalized_dlt'* and *'gold_standard'* stand for direct-linear-transformation and gold-standard-algorithm respectively. All methods return the coordinates (X,Y,Z) of the reconstructed 3D points. The optimal methods also return the covariances of the 3D points in CovXYZ. Let n be the number of points then the 3×3 covariance matrices are concatenated and stored in a tuple of length $9n$. Additionally, the optimal methods return the 6×6 covariance matrix of the pose CovRelPose.

If an optimal gold-standard-algorithm is chosen the covariances of the image points (CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2) can be incorporated in the computation. They can be provided for example by the operator points_foerstner. If the point covariances are unknown, which is the default, empty tuples are input. In this case the optimization algorithm internally assumes uniform and equal covariances for all points.

The value Error indicates the overall quality of the optimization process and is the root-mean-square Euclidean distance in pixels between the points and their corresponding epipolar lines.

For the operator vector_to_rel_pose a special configuration of scene points and cameras exists: if all 3D points lie in a single plane and additionally are all closer to one of the two cameras then the solution in the relative pose is not unique but twofold. As a consequence both solutions are computed and returned by the operator. This means that all output parameters are of double length and the values of the second solution are simply concatenated behind the values of the first one.

Parameters

▷ **Rows1** (input_control) . . . . . number-array ⇝ *real* / integer
Input points in image 1 (row coordinate).
Restriction: length(Rows1) >= 6 || length(Rows1) >= 2

5.2 Depth From Focus

```
depth_from_focus ( MultiFocusImage : Depth, Confidence : Filter,
    Selection :  )
```

Extract depth using multiple focus levels.

The operator depth_from_focus extracts the depth using a focus sequence. The images of the focus sequence have to be passed as a multi channel image (MultiFocusImage). The depth for each pixel will be returned in Depth as the channel number. The parameter Confidence returns a confidence value for each depth estimation: The larger this value, the higher the confidence of the depth estimation is.

depth_from_focus selects the pixels with the best focus of all focus levels. The method used to extract these pixels is specified by the parameters Filter and Selection.

For the parameter Filter, you can choose between the values *'highpass'* and *'bandpass'*. To determine the focus within the image a high- or a bandpass filter can be applied. The larger the filter response, the more in focus is the image at this location. Compared to the highpass filter, the bandpass filter suppresses high frequencies. This is useful in particular in images containing strong noise.

Optionally, you can smooth the filtered image using the mean filter by passing two additional integer values for the mask size in the parameter Filter (e.g., ['*highpass*', *7*, *7*]). This blurs the in-focus region with neighboring pixels and thus allows to bridge small areas with no texture within the image. Note, however, that this smoothing does not suppress noise in the original image, since it is applied only after high- or bandpass filtering.

The parameter Selection determines how the optimum focus level is selected. If you pass the value *'next_maximum'*, the closest focus maximum in the neighborhood is used. In contrast, if you pass the value *'local'*, the focus level is determined based on the focus values of all focus levels of the pixel. With *'next_maximum'*, you typically achieve a slightly smoothed and more robust result.

This additional smoothing is useful if no telecentric lenses are used to take the input images. In this case, the position of an object will slightly shift within the sequence. By adding appropriate smoothing, this effect can be partially compensated.

Attention

If MultiFocusImage contains more than 255 channels (focus levels), Depth is clipped at 255, i.e. depth values higher than 255 are ignored.

If the filter mask for Filter is specified with even values, the routine uses the next larger odd values instead (this way the center of the filter mask is always explicitly determined).

If Selection is set to *'local'* and Filter is set to *'highpass'* or *'bandpass'*, depth_from_focus can be executed on OpenCL devices. If smoothing is enabled, the same restrictions and limitations as for mean_image apply.

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **MultiFocusImage** (input_object) ..... multichannel-image(-array) ⇝ *object :* byte
  Multichannel gray image consisting of multiple focus levels.
- ▷ **Depth** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Depth image.
- ▷ **Confidence** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Confidence of depth estimation.
- ▷ **Filter** (input_control) ..... string(-array) ⇝ *string* / integer
  Filter used to find sharp pixels.
  Default: 'highpass'
  Suggested values: Filter ∈ {'highpass', 'bandpass', 3, 5, 7, 9}
- ▷ **Selection** (input_control) ..... string(-array) ⇝ *string*
  Method used to find sharp pixels.
  Default: 'next_maximum'
  List of values: Selection ∈ {'next_maximum', 'local'}

Example

```
compose3(Focus0,Focus1,Focus2,&MultiFocus);
depth_from_focus(MultiFocus,&Depth,&Confidence,'highpass','next_maximum');
mean_image(Depth,&Smooth,15,15);
select_grayvalues_from_channels(MultiChannel,Smooth,SharpImage);
threshold(Confidence,HighConfidence,10,255);
reduce_domain(SharpImage,HighConfidence,ConfidentSharp);
```

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Module

3D Metrology

select_grayvalues_from_channels (MultichannelImage, IndexImage : Selected : :)

Selection of gray values of a multi-channel image using an index image.

The operator select_grayvalues_from_channels selects gray values from the different channels of MultichannelImage. The channel number for each pixel is determined from the corresponding pixel value in IndexImage. Note, IndexImage is allowed to have an arbitrary number of channels for reasons of backward compatibility, but only the first channel is considered.

Parameters

▷ **MultichannelImage** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Multi-channel gray value image.

▷ **IndexImage** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
Image, where pixel values are interpreted as channel index.
Number of elements: IndexImage == MultichannelImage || IndexImage == 1

▷ **Selected** (output_object) ..... singlechannelimage(-array) ⇝ *object :* byte
Resulting image.

Example

```
compose3(Focus0,Focus1,Focus2,&MultiFocus);
depth_from_focus(MultiFocus,&Depth,&Confidence,'highpass','next_maximum');
mean_image(Depth,&Smooth,15,15);
select_grayvalues_from_channels(MultiChannel,Smooth,SharpImage);
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

5.3 Multi-View Stereo

This chapter contains operators for multi-view 3D reconstruction.

Concept of Multi-view 3D Reconstruction

With multi-view 3D reconstruction, it is possible to generate 3D objects using 2D images from multiple cameras. It is possible to reconstruct the complete 3D surface of an object, or single 3D points.

In the following, the steps that are required to reconstruct surfaces and points are described briefly. Note that a well-calibrated camera setup is the main requirement for a precise 3D reconstruction; see Calibration for more details. Additionally, in the HDevelop example `reconstruct_surface_mixed_camera_types.hdev`, a typical calibration workflow (from the calibration data model via the camera setup model to the stereo model) is performed.

Generate stereo model: First, create the stereo model using

- create_stereo_model.

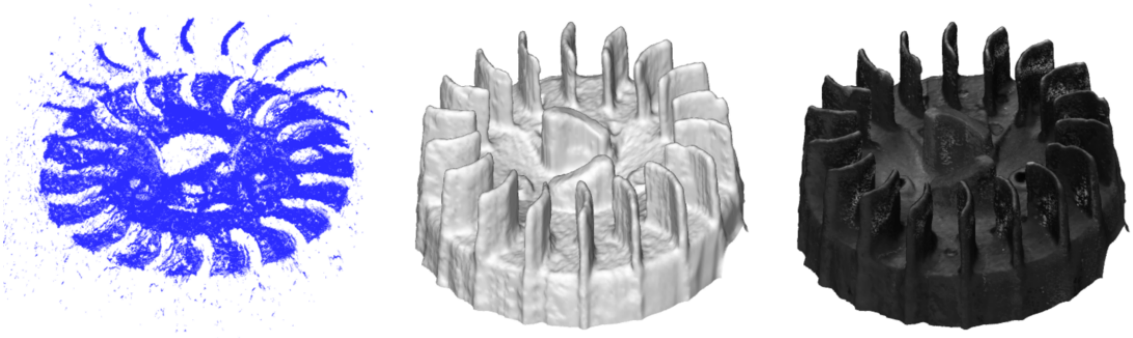
If you want to reconstruct 3D points, choose the `Method` *'points_3d'*.

3D point reconstruction with *'points_3d'*.

For the reconstruction of surfaces, the methods *'surface_pairwise'* and *'surface_fusion'* are available. For detailed information on these two methods, have a look at the reference manual entry of reconstruct_surface_stereo.

(1) (2) (3)

These three 2D images are used for the surface reconstruction as seen in the images below.



(1) (2) (3)

(1) Surface reconstruction with *'surface_pairwise'*. (2) Surface reconstruction with *'surface_fusion'*. (3) Surface reconstruction with *'surface_fusion'*, where the color information is extracted from the used 2D images. Have a look at the HDevelop example `reconstruct_surface_mixed_camera_types.hdev` to see the 3D reconstruction process.

Set the image pairs (only for surface reconstruction): For the reconstruction of 3D surfaces, multiple binocular stereo reconstructions are performed, and then combined. For the binocular reconstruction, image pairs have to be specified. For example, for the three images shown above, the image pairs might be `[0,1]` and `[1,2]`. The image pairs have to be specified using

- `set_stereo_model_image_pairs`,

and query the image pairs with

- `get_stereo_model_image_pairs`.

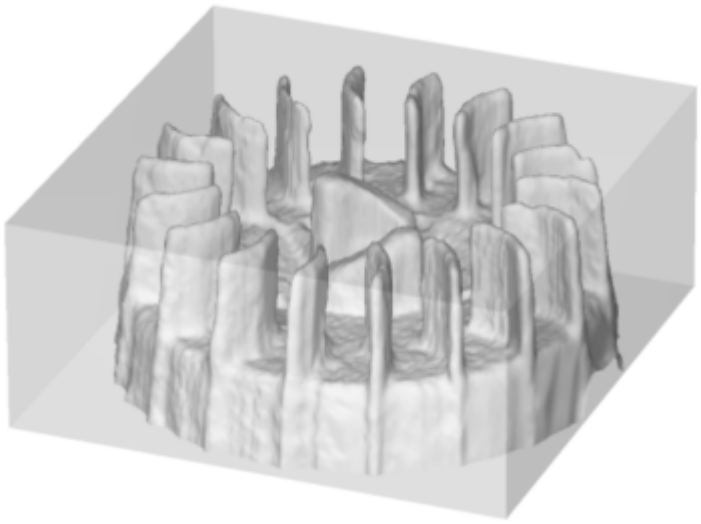
For more information, see `reconstruct_surface_stereo` as well as the above-mentioned operators.

Modify the stereo model parameters: With

- `set_stereo_model_param`,

you can optimize the settings of the 3D reconstruction for your setup.

When reconstructing surfaces, it is highly recommended to limit the 3D reconstruction using a bounding box which is as tight as possible around the object that is to be reconstructed.



The bounding box, which is set with `set_stereo_model_param`, restricts the area where the object is reconstructed, and thus can be used to reduce the runtime greatly.

When using the *'surface_fusion'* `Method` in `create_stereo_model`, it is recommended to first optimize the parameters of the *'surface_pairwise'* `Method`, since it is used as a basis. For more details on the parameters, see the examples `reconstruct_surface_stereo_pairwise_workflow.hdev` and `reconstruct_surface_stereo_fusion_workflow.hdev`.

You can query the set parameters with

- `get_stereo_model_param`.

Perform the 3D reconstruction: Then, to perform the actual reconstruction, use

- `reconstruct_points_stereo` or
- `reconstruct_surface_stereo`.

Get intermediate results (only for surface reconstruction): Note that to query these intermediate results, you must enable the *'persistence'* mode for the stereo model with `set_stereo_model_param` before performing the reconstruction.

With

- `get_stereo_model_object`,

you can access and inspect intermediate results of a surface reconstruction performed with `reconstruct_surface_stereo`. These images can be used for troubleshooting the reconstruction process.

With

- `get_stereo_model_object_model_3d`,

you can get the 3D object model that was reconstructed with `reconstruct_surface_stereo` as an intermediate result using the `Method` *'surface_fusion'*.

`clear_stereo_model` (: : StereoModelID :)

Free the memory of a stereo model.

The operator `clear_stereo_model` frees the memory of the stereo model `StereoModelID` that was created by `create_stereo_model`. After calling `clear_stereo_model`, the model can no longer be used. The handle `StereoModelID` becomes invalid.

Parameters

▷ **`StereoModelID`** (input_control) ..... stereo_model ⇝ *handle*
Handle of the stereo model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StereoModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

3D Metrology

create_stereo_model (: : CameraSetupModelID, Method, GenParamName, GenParamValue : StereoModelID)

Create a HALCON stereo model.

The operator create_stereo_model creates a HALCON stereo model and returns a handle to it in StereoModelID. The model provides functionality for reconstructing either 3D points or surfaces from a calibrated multi-view stereo camera setup specified in CameraSetupModelID (refer to Calibration / Multi-View for further details on calibration of multiple cameras).

For Method='*points_3d*', a stereo model is created that, after being configured, can be passed to reconstruct_points_stereo. The latter reconstructs 3D points by intersecting lines of sight from point correspondences, extracted from multiple calibrated images (see reconstruct_points_stereo for more details).

For Method='*surface_pairwise*' or Method='*surface_fusion*', a stereo model is created that, after being configured, can be passed to reconstruct_surface_stereo. The latter obtains disparity images from preselected image pairs in a calibrated multi-view stereo setup and fuses the collected 3D information in a single surface reconstruction (see reconstruct_surface_stereo for more details).

The parameters GenParamName and GenParamValue can be used to set general model parameters. Alternatively, these parameters can be modified with the operator set_stereo_model_param before the corresponding reconstruction operator is called (see set_stereo_model_param for more details on the available model parameters).

Parameters

▷ **CameraSetupModelID** (input_control) . . . . . camera_setup_model ⇝ *handle*
Handle to the camera setup model.

▷ **Method** (input_control) . . . . . string ⇝ *string*
Reconstruction method.
Default: 'surface_pairwise'
List of values: Method ∈ {'surface_pairwise', 'surface_fusion', 'points_3d'}

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the model parameter to be set.
Default: []
List of values: GenParamName ∈ {'bounding_box', 'persistence', 'sub_sampling_step', 'rectif_interpolation', 'rectif_method', 'disparity_method', 'binocular_method', 'binocular_num_levels', 'binocular_mask_width', 'binocular_mask_height', 'binocular_texture_thresh', 'binocular_score_thresh', 'binocular_filter', 'binocular_sub_disparity', 'binocular_mg_gray_constancy', 'binocular_mg_gradient_constancy', 'binocular_mg_smoothness', 'binocular_mg_initial_guess', 'binocular_mg_default_parameters', 'binocular_mg_solver', 'binocular_mg_cycle_type', 'binocular_mg_pre_relax', 'binocular_mg_post_relax', 'binocular_mg_initial_level', 'binocular_mg_iterations', 'binocular_mg_pyramid_factor', 'binocular_ms_surface_smoothing', 'binocular_ms_edge_smoothing', 'binocular_ms_consistency_check', 'binocular_ms_similarity_measure', 'binocular_ms_sub_disparity', 'point_meshing', 'resolution', 'surface_tolerance', 'min_thickness', 'smoothing', 'color', 'color_invisible', 'min_disparity', 'max_disparity'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Value of the model parameter to be set.
Default: []
Suggested values: GenParamValue ∈ {-1, -2, -5, 0, 0.3, 0.5, 0.9, 1, 2, 3, 'census_dense', 'census_sparse', 'binocular', 'ncc', 'none', 'sad', 'ssd', 'bilinear', 'viewing_direction', 'geometric', 'false', 'very_accurate', 'accurate', 'fast_accurate', 'fast', 'v', 'w', 'none', 'gauss_seidel', 'multigrid', 'true', 'poisson', 'isosurface', 'interpolation', 'left_right_check', 'full_multigrid', 'binocular_mg', 'binocular_ms', 'smallest_distance', 'mean_by_distance', 'line_of_sight', 'mean_by_line_of_sight', 'median'}

▷ **StereoModelID** (output_control) . . . . . stereo_model ⇝ *handle*
Handle of the stereo model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_stereo_model_param, set_stereo_model_image_pairs, reconstruct_surface_stereo, reconstruct_points_stereo

Module

3D Metrology

get_stereo_model_image_pairs (: : StereoModelID : From, To)

Return the list of image pairs set in a stereo model.

The operator get_stereo_model_image_pairs returns the list of image pairs for the stereo model StereoModelID. The camera indices of the *from* and *to* cameras in the pairs are returned in the parameters From and To, respectively (the terms "from" and "to" signal that during reconstruction the disparity "from" one image "to" the other image of the pair is computed). The indices identify cameras from the camera setup model assigned to the stereo model (see create_stereo_model).

The list of image pairs can be set with the operator set_stereo_model_image_pairs.

Parameters

▷ **StereoModelID** (input_control) ..... stereo_model ⇝ *handle*
Handle of the stereo model.

▷ **From** (output_control) ..... integer-array ⇝ *integer*
Camera indices for the *from* cameras in the image pairs.

▷ **To** (output_control) ..... integer-array ⇝ *integer*
Camera indices for the *to* cameras in the image pairs.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_stereo_model_image_pairs

Module

3D Metrology

get_stereo_model_object (: Object : StereoModelID, PairIndex, ObjectName :)

Get intermediate iconic results of a stereo reconstruction.

With the operator get_stereo_model_object you can access and inspect intermediate iconic results of a surface reconstruction performed with reconstruct_surface_stereo for the stereo model StereoModelID. In particular, this is useful for troubleshooting the reconstruction process. Note that to collect the iconic results, you must enable the *'persistence'* mode for the stereo model (see set_stereo_model_param) *before* performing the reconstruction. Iconic results are then associated with each image pair that was processed during the reconstruction (see get_stereo_model_image_pairs).

You select the image pair of interest by specifying the corresponding camera indices `[From, To]` in `PairIndex`. By setting one of the following values in `ObjectName`, the corresponding iconic objects are then returned in `Object`:

'from_image_rect', *'to_image_rect'*: Rectified image corresponding to the *from* and *to* camera, respectively. Both images can be used to inspect the quality of the internal binocular stereo image rectification.

'disparity_image': Disparity image for this pair. The quality of the disparity image has a direct impact on the final surface reconstruction.

'score_image': Score image assigned to the disparity image for this pair.

A mismatch between the rectified images, i.e., features appearing in different rows in the two images, or errors in the disparity or the score image have direct impact on the quality of the final surface reconstruction. Therefore, we recommend to correct any detected imperfections by adjusting the stereo model parameters (see `set_stereo_model_param`), in particular those which control the internal usage of `gen_binocular_rectification_map` and `binocular_disparity` (see `set_stereo_model_image_pairs` and `reconstruct_surface_stereo` for further details).

Parameters

▷ **`Object`** (output_object) ..... object(-array) ⇝ *object*
Iconic result.

▷ **`StereoModelID`** (input_control) ..... stereo_model ⇝ *handle*
Handle of the stereo model.

▷ **`PairIndex`** (input_control) ..... number(-array) ⇝ *integer* / string / real
Camera indices of the pair (`[From, To]`).
Suggested values: `PairIndex` ∈ {0, 1, 2}

▷ **`ObjectName`** (input_control) ..... string ⇝ *string*
Name of the iconic result to be returned.
Suggested values: `ObjectName` ∈ {'from_image_rect', 'to_image_rect', 'disparity_image', 'score_image'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`reconstruct_surface_stereo`

Module

3D Metrology

`get_stereo_model_object_model_3d` (: : `StereoModelID`, `GenParamName` : `ObjectModel3D`)

Get intermediate 3D object model of a stereo reconstruction

With the operator `get_stereo_model_object_model_3d` it is possible to get a 3D object model `ObjectModel3D` that was reconstructed with `reconstruct_surface_stereo` as an intermediate result using the method *'surface_fusion'*. The returned object model is equal to the result of `reconstruct_surface_stereo` using method *'surface_pairwise'*.

For this, a call to `get_stereo_model_object_model_3d` has to be performed using the value *'m3d_pairwise'* for the parameter `GenParamName`. It should be noted that the model can only be queried if the *'persistence'* mode for the stereo model (see `set_stereo_model_param`) is enabled *before* performing the reconstruction. Furthermore the object model can only be queried if the stereo model has been created using the method *'surface_fusion'*. Otherwise, an error is returned. If no object model has been created, the operator returns -1.

Parameters

▷ **StereoModelID** (input_control) . . . . . stereo_model ⇝ *handle*
Handle of the stereo model.

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Names of the model parameters.
List of values: GenParamName ∈ {'m3d_pairwise'}

▷ **ObjectModel3D** (output_control) . . . . . object_model_3d ⇝ *handle*
Values of the model parameters.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

reconstruct_surface_stereo, set_stereo_model_param

See also

set_stereo_model_param

Module

3D Metrology

get_stereo_model_param (: : StereoModelID, GenParamName : GenParamValue)

Get stereo model parameters.

The operator get_stereo_model_param can be used to inspect diverse parameters of the stereo model StereoModelID by specifying their names in GenParamName and getting their values in GenParamValue. Two types of parameters can be inspected with this operator - general and specific for surface reconstruction. Note that no specific parameters are provided for 3D point stereo reconstruction.

All parameters that can be set with set_stereo_model_param can also be queried with get_stereo_model_param - for a description see the former operator. In contrast, the following parameters are set by other operators and cannot be modified afterwards.

General parameters

'type': Type of the stereo model (currently either *'surface_pairwise'*, *'surface_fusion'* or *'points_3d'*).

'camera_setup_model': Handle to a *copy* of the camera setup model set in the stereo model. Changing properties of the copy does not affect the camera setup model stored in the stereo model.

'from_cam_param_rect N', *'to_cam_param_rect N'*: Camera parameters of the rectified *from*- and *to*-cameras of camera pair N. See set_stereo_model_image_pairs for more information about camera pairs.

'from_cam_pose_rect N', *'to_cam_pose_rect N'*: Point transformation from the rectified *from*- and *to*-cameras of camera pair N to the respective unrectified camera. See set_stereo_model_image_pairs for more information about camera pairs.

'rel_pose_rect N': Point transformation from the rectified *to*-camera to the rectified *from*-camera. See set_stereo_model_image_pairs for more information about camera pairs.

The parameters *'type'* and *'camera_setup_model'* are set when creating the stereo model with create_stereo_model. For *'from_cam_param_rect N'*, *'to_cam_param_rect N'*, *'from_cam_pose_rect N'*, *'to_cam_pose_rect N'*, and *'rel_pose_rect N'*, note that these parameters are only available *after* setting the image pairs (see set_stereo_model_image_pairs).

A note on tuple-valued model parameters

Most of the stereo model parameters are single-valued. Thus, you can provide a list (i.e., tuple) of parameter names and get a list (tuple) of values that has the same length as the output tuple. In contrast, when querying a tuple-valued parameter, a tuple of values is returned. When querying such a parameter together with other parameters, the value-to-parameter-name correspondence is not obvious anymore. Thus, tuple-valued parameters like *'bounding_box'*, *'min_disparity'* or *'max_disparity'* should always be queried in a separate call to `get_stereo_model_param`.

Parameters

▷ **StereoModelID** (input_control) . . . . . stereo_model ⇝ *handle*
Handle of the stereo model.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the parameters to be set.
List of values: `GenParamName` ∈ {'type', 'camera_setup_model', 'bounding_box', 'persistence', 'sub_sampling_step', 'rectif_interpolation', 'rectif_sub_sampling', 'rectif_method', 'disparity_method', 'binocular_method', 'binocular_num_levels', 'binocular_mask_width', 'binocular_mask_height', 'binocular_texture_thresh', 'binocular_score_thresh', 'binocular_filter', 'binocular_sub_disparity', 'binocular_mg_gray_constancy', 'binocular_mg_gradient_constancy', 'binocular_mg_smoothness', 'binocular_mg_initial_guess', 'binocular_mg_solver', 'binocular_mg_cycle_type', 'binocular_mg_pre_relax', 'binocular_mg_post_relax', 'binocular_mg_initial_level', 'binocular_mg_iterations', 'binocular_mg_pyramid_factor', 'binocular_ms_surface_smoothing', 'binocular_ms_edge_smoothing', 'binocular_ms_consistency_check', 'binocular_ms_similarity_measure', 'binocular_ms_sub_disparity', 'min_disparity', 'max_disparity', 'point_meshing', 'poisson_depth', 'poisson_solver_divide', 'poisson_samples_per_node', 'resolution', 'surface_tolerance', 'min_thickness', 'smoothing', 'color', 'color_invisible', 'from_cam_param_rect', 'to_cam_param_rect', 'from_cam_pose_rect', 'to_cam_pose_rect', 'rel_pose_rect'}

▷ **GenParamValue** (output_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of the parameters to be set.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`set_stereo_model_param`

Module

3D Metrology

reconstruct_points_stereo (: : StereoModelID, Row, Column, CovIP, CameraIdx, PointIdx : X, Y, Z, CovWP, PointIdxOut)

Reconstruct 3D points from calibrated multi-view stereo images.

The operator `reconstruct_points_stereo` reconstructs 3D points from point correspondences found in the images of a calibrated multi-view stereo setup. The calibration information for the images is provided in the camera setup model that is associated with the stereo model `StereoModelID` during its creation (see `create_stereo_model`). Note that the stereo model type must be *'points_3d'*, otherwise the operator will return an error.

The point correspondences must be passed in the parameters `Row`, `Column`, `CameraIdx`, and `PointIdx` in form of tuples of the same length. Each set `(Row[I],Column[I],CameraIdx[I],PointIdx[I])` represents the image coordinates (`Row`, `Column`) of the 3D point (`PointIdx`) in the image of a certain camera (`CameraIdx`).

The reconstructed 3D point coordinates are returned in the tuples `X`, `Y`, and `Z`, relative to the coordinate system of the camera setup model (see `create_camera_setup_model`). The tuple `PointIdxOut` contains the corresponding point indices.

The reconstruction algorithm works as follows: First, it identifies point correspondences for a given 3D point by collecting all sets with the same `PointIdx`. Then, it uses the `Row`, `Column`, and `CameraIdx` information from the collected sets to project lines of sight from each camera through the corresponding image point `[Row,Column]`. If there are at least 2 lines of sight for the point `PointIdx`, they are intersected and the result is stored as the set `(X[J],Y[J],Z[J],PointIdxOut[J])`. The intersection is performed with a least-squares algorithm, without taking into account potentially invalid lines of sight (e.g., if an image point was falsely specified as corresponding to a certain 3D point).

To compute the covariance matrices for the reconstructed 3D points, statistical information about the extracted image coordinates, i.e., the covariance matrices of the image points (see , e.g., `points_foerstner`) are needed as input and must be passed in the parameter `CovIP`. Otherwise, if no covariance matrices for the 3D points are needed or no covariance matrices for the image points are available, an empty tuple can be passed in `CovIP`. Then no covariance matrix for the reconstructed 3D points is computed.

The covariance matrix of an image point is:

$$\texttt{CovIP} = \begin{bmatrix} (sigma\_r)^2 & sigma\_rc \\ sigma\_rc & (sigma\_c)^2 \end{bmatrix}$$

The covariance matrices are symmetric `2x2` matrices, whose entries in the main diagonal represent the variances of the image point in row-direction and column-direction, respectively. For each image point, a covariance matrix must be passed in `CovIP` in form of a tuple with 4 elements:

$$[(sigma\_r)^2, sigma\_rc, sigma\_rc, (sigma\_c)^2].$$

Thus, `|CovIP|=4*|Row|` and `CovIP[I*4:I*4+3]` is the covariance matrix for the `I`-th image point.

The computed covariance matrix for a successfully reconstructed 3D point is represented by a symmetric `3x3` matrix:

$$\texttt{CovWP} = \begin{bmatrix} (sigma\_x)^2 & sigma\_xy & sigma\_xz \\ sigma\_yx & (sigma\_y)^2 & sigma\_yz \\ sigma\_zx & sigma\_zy & (sigma\_z)^2 \end{bmatrix}$$

The diagonal entries represent the variances of the reconstructed 3D point in x-, y-, and z-direction. The computed matrices are returned in the parameter `CovWP` in form of tuples each with 9 elements:

$$[(sigma\_x)^2, sigma\_xy, sigma\_xz, sigma\_yx, (sigma\_y)^2, sigma\_yz, sigma\_zx, sigma\_zy, (sigma\_z)^2].$$

Thus, `|CovWP|=9*|X|` and `CovWP[J*9:J*9+8]` is the covariance matrix for the `J`-th 3D point. Note that if the camera setup associated with the stereo model contains the covariance matrices for the camera parameters, these covariance matrices are considered in the computation of `CovWP` too.

If the stereo model has a valid bounding box set (see `set_stereo_model_param`), the resulting points are clipped to this bounding box, i.e., points outside it are not returned. If the bounding box associated with the stereo model is invalid, it is ignored and all points that could be reconstructed are returned.

Parameters

- ▷ **StereoModelID** (input_control) ..... stereo_model ⇝ *handle*
  Handle of the stereo model.
- ▷ **Row** (input_control) ..... number(-array) ⇝ *real* / integer
  Row coordinates of the detected points.
- ▷ **Column** (input_control) ..... number(-array) ⇝ *real* / integer
  Column coordinates of the detected points.
- ▷ **CovIP** (input_control) ..... number-array ⇝ *real* / integer
  Covariance matrices of the detected points.
  Default: []

▷ **CameraIdx** (input_control) ..... number ⇝ *integer*
Indices of the observing cameras.
Suggested values: CameraIdx ∈ {0, 1, 2}

▷ **PointIdx** (input_control) ..... number ⇝ *integer*
Indices of the observed world points.
Suggested values: PointIdx ∈ {0, 1, 2}

▷ **X** (output_control) ..... real(-array) ⇝ *real*
X coordinates of the reconstructed 3D points.

▷ **Y** (output_control) ..... number(-array) ⇝ *real*
Y coordinates of the reconstructed 3D points.

▷ **Z** (output_control) ..... number(-array) ⇝ *real*
Z coordinates of the reconstructed 3D points.

▷ **CovWP** (output_control) ..... number(-array) ⇝ *real*
Covariance matrices of the reconstructed 3D points.

▷ **PointIdxOut** (output_control) ..... number(-array) ⇝ *integer*
Indices of the reconstructed 3D points.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

reconstruct_surface_stereo, intersect_lines_of_sight

Module

3D Metrology

reconstruct_surface_stereo (
Images : : StereoModelID : ObjectModel3D)

Reconstruct surface from calibrated multi-view stereo images.

The operator reconstruct_surface_stereo reconstructs a surface from multiple Images, acquired with a calibrated multi-view setup associated with a stereo model StereoModelID. The reconstructed surface is stored in the handle ObjectModel3D.

Preparation and requirements

A summary of the preparation of a stereo model for surface reconstruction:

1. Obtain calibrated camera setup model (use calibrate_cameras or create_camera_setup_model) and configure it.
2. Create a stereo model with create_stereo_model by selecting Method=*'surface_pairwise'* or *'surface_fusion'* (see 'Reconstruction algorithm').
3. Configure the rectification parameters with set_stereo_model_param and afterwards set the image pairs with set_stereo_model_image_pairs.
4. Configure the bounding box for the system with set_stereo_model_param (GenParamName=*'bounding_box'*).
5. Configure parameters of pairwise reconstruction with set_stereo_model_param.
6. For models with Method=*'surface_fusion'* configure parameters of the fusion algorithm with set_stereo_model_param.
7. Acquire images with the calibrated cameras setup and collect them in an image array Images.
8. Perform surface reconstruction with reconstruct_surface_stereo.
9. Query and analyze intermediate results with get_stereo_model_object and get_stereo_model_object_model_3d.

10. Readjust the parameters of the stereo model to improve the results with respect to quality and runtime with set_stereo_model_param.

A **camera setup model** is associated with the stereo model StereoModelID upon its creation with create_stereo_model. The camera setup must contain *calibrated information* about the cameras, with which the images in the image array Images were acquired: the I-th image from the array corresponds to the camera with index I-1 from the camera setup; the number of images in the array must be the same as the number of cameras in the camera setup. The Images must represent a static scene or they must be taken simultaneously, otherwise, the reconstruction of the surface might be impossible.

A well-calibrated camera setup is the main requirement for a precise surface reconstruction. Therefore, special attention should be paid to obtaining a precise calibration of the cameras in the multi-view stereo setup used. HALCON provides calibration of a multi-view setup with the operator calibrate_cameras. The resulting calibrated camera setup can be accessed with a successive call to get_calib_data. Alternatively, for camera setups with known parameters a calibrated camera setup can be created with create_camera_setup_model.

The proper selection of **image pairs** (see set_stereo_model_image_pairs) has an important role for the general quality of the surface reconstruction. On the one hand, camera pairs with a small base line (small distance between the camera centers) are better suited for the binocular stereo disparity algorithms. On the other hand, in order to derive more accurate depth information of the scene, pairs with a long base line should be preferred. Camera pairs should provide different points of view, such that if one pair does not *see* a certain area of the surface, it is covered by another pair. Please note that the number of pairs linearly affects the runtime of the pairwise reconstruction. Therefore, use "as many as needed and just as few as possible" image pairs in order to handle the trade-off between completeness of the surface reconstruction and reconstruction runtime.

A **bounding box** is associated with the stereo model StereoModelID. For the surface stereo reconstruction, it is required that the bounding box is valid (see set_stereo_model_param for further details). The reconstruction algorithm needs the bounding box for three reasons:

- First, if MinDisparity and MaxDisparity were not set manually using the operators create_stereo_model or set_stereo_model_param, it uses the projection of the bounding box into both images of each image pair in order to estimate the values for MinDisparity and MaxDisparity, which in turn are used in the internal call to binocular_disparity and binocular_disparity_ms. In the case of using binocular_disparity_mg as disparity method, suitable values for the parameters InitialGuess and *'initial_level'* are derived from the above-mentioned parameters. However, the automatic estimation for this method is only used if called with default values for the two parameters. Otherwise, the values as set by the user with set_stereo_model_param are used.
- Secondly, the default parameters for the fusion of pairwise reconstructions are calculated based on the bounding box. They are reset in case the bounding box is changed. The bounding box should be tight around the volume of interest. Else, the runtime will increase unnecessarily and drastically.
- Thirdly, the surface fragments lying outside the bounding box are clipped and are not returned in ObjectModel3D. A too large bounding box results in a large difference between MinDisparity and MaxDisparity and this usually slows down the execution of binocular_disparity, binocular_disparity_ms or binocular_disparity_mg and therefore reconstruct_surface_stereo. A too small bounding box might result in clipping valid surface areas.

Note that the method *'surface_fusion'* will try to produce a closed surface. If the object is only observed and reconstructed from one side, the far end of the bounding box usually determines where the object is cut off.

Setting parameters of pairwise reconstruction before setting parameters of fusion is essential since the pairwise reconstruction of the object is input for the fusion algorithm. For a description of parameters, see set_stereo_model_param. The choice of *'disparity_method'* has a major influence. The objects in the scene should expose certain surface properties in order to make the scene suitable for the dense surface reconstruction. First, the surface reflectance should exhibit Lambertian properties as closely as possible (i.e., light falling on the surface is scattered such that its apparent brightness is the same regardless of the angle of view). Secondly, the surface should exhibit enough texture, but no repeating patterns.

get_stereo_model_object can be used to view **intermediate results**, in particular rectified, disparity and score images. get_stereo_model_object_model_3d can be used to view the result of pairwise reconstruction for models with Method='surface_fusion'. See the paragraph "Troubleshooting for the configuration of a stereo model" on how to use the obtained results.

Reconstruction algorithm

The operator reconstruct_surface_stereo performs multiple binocular stereo reconstructions and subsequently combines the results. The image pairs of this pairwise reconstruction are specified in StereoModelID as pairs of cameras of an associated calibrated multi-view setup.

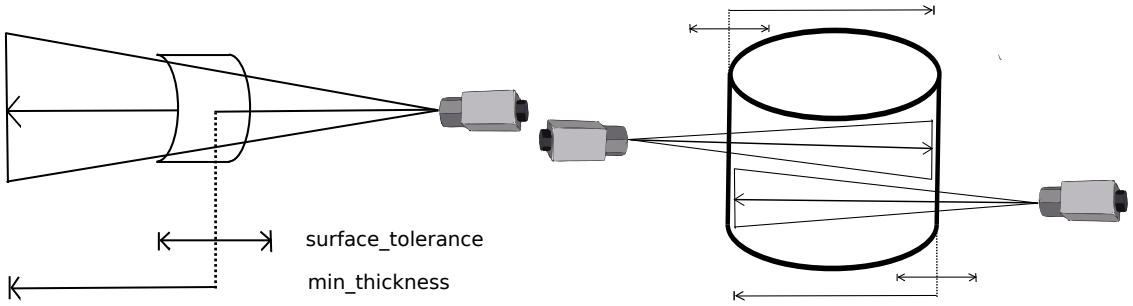
For each image pair, the images are rectified before internally one of the operators binocular_disparity, binocular_disparity_mg or binocular_disparity_ms is called. The disparity information is then converted to points in the coordinate system of the *from*-camera by an internal call of disparity_image_to_xyz. In the next step, the points are transformed into the common coordinate system that is specified in the camera setup model associated with StereoModelID and stored in a common point cloud together with the points extracted from other image pairs.

'surface_pairwise' If the stereo model is of type *'surface_pairwise'* (compare create_stereo_model), the point cloud obtained as described above is directly returned in ObjectModel3D. For each point, the normal vector is calculated by fitting a plane through the neighboring 3D points. In contrast to surface_normals_object_model_3d, the neighboring points are not determined in 3D but simply in 2D by using the neighboring points in the X, Y, and Z images. The normal vector of each 3D point is then set to the normal vector of the respective plane. Additionally, the score of the calculated disparity is attached to every reconstructed 3D point and stored as an extended attribute. Furthermore, transformed coordinate images can be sub-sampled. If only one image pair is processed and no point meshing is enabled, reconstruct_surface_stereo stores a 'xyz_mapping' attribute in ObjectModel3D, which reveals the mapping of the reconstructed 3D points to coordinates of the first image of the pair. This attribute is required by operators like segment_object_model_3d or object_model_3d_to_xyz (with Type=*'from_xyz_map'*). In contrast to the single pair case, if two or more image pairs are processed, reconstruct_surface_stereo does not store the 'xyz_mapping' attribute since single reconstructed points would originate from different image pairs. The presence of the attribute in the output object model can be verified by calling get_object_model_3d_params with GenParamName=*'has_xyz_mapping'*.

The so-obtained point cloud can be additionally meshed in a post-processing step. The object model returned in ObjectModel3D then contains the description of the mesh. The used meshing algorithm depends on the type of the stereo model. For a stereo model of type *'surface_pairwise'*, only a Poisson solver is supported which can be activated by setting the parameter *'point_meshing'* to *'poisson'*. It creates a water-tight mesh, therefore surface regions with missing data are covered by an interpolated mesh.

'surface_fusion' If the stereo model is of type *'surface_fusion'*, the point cloud obtained as described above is processed further. The goal is to obtain a preferably smooth surface while keeping form fidelity. To this end, the bounding box is sampled and each sample point is assigned a distance to a so-called isosurface (consisting of points with distance 0). The final distance values (and thus the isosurface) are obtained by minimizing an error function based on the points resulting from pairwise reconstruction. This leads to a fusion of the reconstructed point clouds of all camera pairs (see the second paper in References below).

The calculation of the isosurface can be influenced by set_stereo_model_param with the parameters *'resolution'*, *'surface_tolerance'*, *'min_thickness'* and *'smoothing'*. The distance between sample points in the bounding box (in each coordinate direction) can be set by the parameter *'resolution'*. The parameter *'smoothing'* regulates the 'jumpiness' of the distance function by weighting the two terms in the error function: Fidelity to the initial point clouds obtained by pairwise reconstruction on the one hand, total variation of the distance function on the other hand. Note that the actual value of *'smoothing'* for a given data set to be visually pleasing has to be found by trial and error. Too small values lead to integrating many outliers into the surface even if the object surface then exhibits many jumps. Too large values lead to loss of fidelity towards the point cloud of pairwise reconstruction. Fidelity to the initial surfaces obtained by pairwise reconstruction is not maintained in the entire bounding box, but only in cones of sight of cameras to the initial surface. A sample point in such a cone is considered surely outside of the object (in front of the surface) or surely inside the object (behind the surface) with respect to the given camera if its distance to the initial surface exceeds a given value which can be set by the parameter *'surface_tolerance'*. The length of considered cones behind the initial surface can roughly be set by the parameter *'min_thickness'* (see set_stereo_model_param for more details). *'min_thickness'* always has to be larger than or equal to *'surface_tolerance'*.



The parameters *'surface_tolerance'* and *'min_thickness'* regulate the fidelity to the initial surface obtained by pairwise reconstruction. Points in a cone of sight of a camera are considered surely outside of the object (in front of the surface) or surely inside the object (behind the surface) with respect to the given camera if their distance to the initial surface exceeds *'surface_tolerance'*. Points behind the surface (viewed from the given camera) are only considered to lie inside the object if their distance to the initial surface does not exceed *'min_thickness'*.

Each 3D point of the object model returned in `ObjectModel3D` is extracted from the isosurface where the distance function equals zero. Its normal vector is calculated from the gradient of the distance function. While the method *'surface_fusion'* requires the setting of more parameters than simple pairwise reconstruction, post-processing of the obtained point cloud representing the object surface will probably get a lot simpler. In particular, suppression of outliers, smoothing, equidistant sub-sampling and hole filling can be handled nicely and often in high quality by this method. The same can be said about the possible internal meshing of the output surface, see the next paragraph. Note that the algorithm will try to produce a closed surface. If the object is only observed and reconstructed from one side, the far end of the bounding box usually determines where the object is cut off. The method *'surface_fusion'* may take considerably longer than simple pairwise reconstruction, depending mainly on the parameter *'resolution'*.

Additionally, the so-obtained point cloud can be meshed in a post-processing step. The object model returned in `ObjectModel3D` then contains the description of the mesh. For a stereo model of type *'surface_fusion'*, the algorithm 'marching tetrahedra' is used which can be activated by setting the parameter *'point_meshing'* to *'isosurface'*. The wanted meshed surface is extracted as the isosurface where the distance function equals zero. Note that there are more points in `ObjectModel3D` if meshing of the isosurface is enabled even if the used *'resolution'* is the same.

Coloring the 3D object model

It is possible to provide color information for 3D object models that have been reconstructed with `reconstruct_surface_stereo` from the input images. The computation of the color depends on the chosen method set with `set_stereo_model_param` (see explanation in the list there). Each 3D point is assigned a color value consisting of a red, green and blue channel which are stored as attributes named *'red'*, *'green'* and *'blue'* in the output 3D object model `ObjectModel3D`. These attributes can for example be used in the procedure `visualize_object_model_3d` with `GenParamName` = *'red_channel_attrib'*, *'green_channel_attrib'* and *'blue_channel_attrib'*. They can also be queried with `get_object_model_3d_params` or be processed with `select_points_object_model_3d` or other operators that use extended attributes. If the reconstruction has been performed using gray value images, the color value for the three channels is identical. If multi-channel images are used, the reconstruction is performed using the first channel only. The remaining channels are solely used for the calculation of the color values.

If stereo models of type *'surface_fusion'* are used, the reconstruction will contain points without a direct correspondence to points in the images. These points are not seen by any of the cameras of the stereo system and are therefore "invisible". A color value for these points is derived by assigning the value of the nearest visible neighbor. Normally, the nearest neighbor search is not very time-consuming and can remain active. However, it may happen that the value for the parameter *'resolution'* is considerably finer than the available image resolution. In this case, many invisible 3D points are reconstructed making the nearest neighbor search very time consuming. In order to avoid an increased runtime, it is recommended to either adapt the value of *'resolution'* or to switch off the calculation for invisible points. This can be done by calling `set_stereo_model_param` with `GenParamName`=*'color_invisible'* and `GenParamValue`= *'false'*. In this case, invisible points are assigned 255 as gray value.

Troubleshooting for the configuration of a stereo model

The proper configuration of a stereo model is not always easy. Please follow the workflow above. If the reconstruction results are not satisfactory, please consult the following hints and ideas:

Run in persistence mode If you enable the *'persistence'* mode of stereo model (call set_stereo_model_param with GenParamName=*'persistence'*) a successive call to reconstruct_surface_stereo will store intermediate iconic results, which provide additional information. They can be accessed by get_stereo_model_object_model_3d and get_stereo_model_object.

Check the quality of the calibration

- If the camera setup was obtained by calibrate_cameras, it stores some quality information about the camera calibration in form of standard deviations of the camera internal parameters. This information is then carried in the camera setup model associated with the stereo model. It can be queried by first calling get_stereo_model_param with GenParamName=*'camera_setup_model'* and then inspecting the camera parameter standard deviations by calling get_camera_setup_param with GenParamName=*'params_deviations'*. Unusually big standard deviation values might indicate a bad camera calibration.
- After setting the stereo model *'persistence'* mode, we recommend inspecting the rectified images for each image pair. The rectified images are returned by get_stereo_model_object with a camera index pair [From, To] specifying the pair of interest in the parameter PairIndex and the values *'from_image_rect'* and *'to_image_rect'* in ObjectName, respectively. If the images are properly rectified, all corresponding image features must appear in the same row in both rectified images. A discrepancy of several rows is a serious indication for a bad camera calibration.

Inspect the used bounding box Make sure that the bounding box is tight around the volume of interest. If the parameters *'min_disparity'* and *'max_disparity'* are not set manually by using create_stereo_model or set_stereo_model_param, the algorithm uses the projection of the bounding box into both images of each image pair in order to estimate the values for MinDisparity and MaxDisparity, which in turn are used in the internal call to binocular_disparity and binocular_disparity_ms. These values can be queried using get_stereo_model_param and if needed, can be adapted using set_stereo_model_param. If the disparity values are set manually, the bounding box is only used to restrict the reconstructed 3D points. In the case of using binocular_disparity_mg as disparity method, suitable values for the parameters InitialGuess and *'initial_level'* are derived from the bounding box. However, these values can also be reset using set_stereo_model_param. Use the procedures gen_bounding_box_object_model_3d to create a 3D object model of your stereo model, and inspect it in conjunction with the reconstructed 3D object model to verify the bounding box visually.

Improve the quality of the disparity images After setting the stereo model *'persistence'* mode (see above), inspect the disparity and the score images for each image pair. They are returned by get_stereo_model_object with a camera index pair [From, To] specifying the pair of interest in the parameter PairIndex and the values *'disparity_image'* and *'score_image'* in ObjectName, respectively. If both images exhibit significant imperfection (e.g., the disparity image does not really resemble the shape of the object seen in the image), try to adjust the parameters used for the internal call to binocular_disparity (the parameters with a *'binocular_'* prefix) by modifying set_stereo_model_param until some improvement is achieved.

Alternatively, a different method to calculate the disparities can be used. Besides the above-mentioned internal call of binocular_disparity, HALCON also provides the two other methods binocular_disparity_mg and binocular_disparity_ms. These methods feature e.g., the calculation of disparities in textureless regions at an expanse of the reconstruction time if compared with cross-correlation methods. However, for these methods, it can be necessary to adapt the parameters to the underlying dataset as well. Dependent on the chosen method, the user can either set the parameters with a *'binocular_mg_'* or a *'binocular_ms_'* prefix until some improvement is achieved.

A detailed description of the provided methods and their parameters can be found in binocular_disparity, binocular_disparity_mg or binocular_disparity_ms, respectively.

Fusion parameters If the result of pairwise reconstruction as inspected by get_stereo_model_object_model_3d can not be improved anymore, begin to adapt the fusion parameters. For a description of parameters see also set_stereo_model_param. Note that the pairwise reconstruction is sometimes not discernible when the fusion algorithm can still tweak it into something sensible. In any case, pairwise reconstruction should yield enough points as input for the fusion algorithm.

Runtime

In order to improve the runtime, consider the following hints:

Extent of the bounding box The bounding box should be tight around the volume of interest. Else, the runtime will increase unnecessarily and - for the method *'surface_fusion'* - drastically.

Reduce the domain of the input images Reducing the domain of the input images (e.g., with `reduce_domain`) to the relevant part of the image may heavily speed up the algorithm, especially for large images.

Sub-sampling in the rectification step The stereo model parameter *'rectif_sub_sampling'* (see `set_stereo_model_param`) controls the sub-sampling in the rectification step. Setting this factor to a value > 1.0 will reduce the resolution of the rectified images compared to the original images. This factor has a direct impact on the succeeding performance of the chosen disparity method, but it causes loss of image detail. The parameter *'rectif_interpolation'* could have also some impact, but typically not a significant one.

Disparity parameters There is a trade-off between completeness of the pairwise surface reconstruction on the one hand and reconstruction runtime on the other. The stereo model offers three different methods to calculate the disparity images. Dependent on the chosen method, the stereo model provides a particular set of parameters that enables a precise adaption of the method to the used dataset. If the method `binocular_disparity` is selected, only parameters with a *'binocular_'* prefix can be set. For the method `binocular_disparity_mg`, all settable parameters have to exhibit the prefix *'binocular_mg_'*, whereas for the method `binocular_disparity_ms` only parameters with *'binocular_ms_'* are applicable.

Parameters using the method `binocular_disparity`:

- `NumLevels`
- `MaskWidth`
- `MaskHeight`
- `Filter`
- `SubDisparity`

Each of these parameters of `binocular_disparity` has a corresponding stereo model parameter written in snake case and with the prefix *'binocular_'*, and has, some more or others less, impact on the performance. Adapting them properly could improve the performance. performance.

Parameters using the method `binocular_disparity_mg`:

- `GrayConstancy`
- `GradientConstancy`
- `Smoothness`
- `InitialGuess`
- *'mg_solver'*
- *'mg_cycle_type'*
- *'mg_pre_relax'*
- *'mg_post_relax'*
- *'initial_level'*
- *'iterations'*
- *'pyramid_factor'*

Each of these parameters of `binocular_disparity_mg` has a corresponding stereo model parameter written in snake case and with the prefix *'binocular_mg_'*, and has, some more or others less, impact on the performance and the result. Adapting them properly could improve the performance.

Parameters using the method `binocular_disparity_ms`:

- `SurfaceSmoothing`
- `EdgeSmoothing`
- *'consistency_check'*
- *'similarity_measure'*

- *'sub_disparity'*

Each of these parameters of binocular_disparity_ms has a corresponding stereo model parameter written in snake case and with the prefix *'binocular_ms_'*, and has, some more or others less, impact on the performance and the result. Adapting them properly could improve the performance.

Reconstruct only points with high disparity score Besides adapting the sub-sampling it is also possible to exclude points of the 3D reconstruction because of their computed disparity score. In order to do this, the user should first query the score images for the disparity values by calling get_stereo_model_object using GenParamName = *'score_image'*. Dependent on the distribution of these values, the user can decide whether disparities with a score beneath a certain threshold should be excluded from the reconstruction. This can be achieved with set_stereo_model_param using either GenParamName = *'binocular_score_thresh'*. The advantage of excluding points of the reconstruction is a slight speed-up since it is not necessary to process the entire dataset. As an alternative to the above-mentioned procedure, it is also possible to exclude points after executing reconstruct_surface_stereo by filtering reconstructed 3D points. The advantage of this is that at the expense of a slightly increased runtime, a second call to reconstruct_surface_stereo is not necessary.

Sub-sampling of X,Y,Z data For the method *'surface_pairwise'*, you can use a larger sub-sampling step for the X,Y,Z data in the last step of the reconstruction algorithm by modifying GenParamName=*'sub_sampling_step'* with set_stereo_model_param. The reconstructed data will be much sparser, thus speeding up the post-processing.

Fusion parameters For the method *'surface_fusion'*, enlarging the parameter *'resolution'* will speed up the execution considerably.

Parameters

▷ **Images** (input_object) ..... singlechannelimage-array ⇝ *object :* byte
An image array acquired by the camera setup associated with the stereo model.

▷ **StereoModelID** (input_control) ..... stereo_model ⇝ *handle*
Handle of the stereo model.

▷ **ObjectModel3D** (output_control) ..... object_model_3d ⇝ *handle*
Handle to the resulting surface.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

3D Metrology

set_stereo_model_image_pairs (: : StereoModelID, From, To :)

Specify image pairs to be used for surface stereo reconstruction.

The operator set_stereo_model_image_pairs stores a list of image pairs for a stereo model StereoModelID of type *'surface_pairwise'* or *'surface_fusion'*. Calling the operator for a model of another type will raise an error. In the mode *'surface_pairwise'* or *'surface_fusion'*, surfaces are reconstructed by computing disparity images for image pairs. You specify these image pairs by passing tuples of camera indices in the parameters From and To. Then, e.g., the disparity image from the camera with index From[0] to the camera with index To[0] is computed and so on.

The camera indices must be valid for the camera setup model assigned to the stereo model (see create_stereo_model), otherwise an error is returned. If an image pairs list already exists in the stereo model, it is substituted by the current one.

Besides storing the list of image pairs, the operator set_stereo_model_image_pairs prepares a pair of rectification image maps for each image pair, which are used repeatedly in successive calls to reconstruct_surface_stereo to rectify the images to a normalized binocular stereo pair; refer to gen_binocular_rectification_map for further details. Three of the gen_binocular_rectification_map parameters are exported as stereo model parameters and can be modified by set_stereo_model_param or just inspected by get_stereo_model_param:

'rectif_interpolation': Interpolation mode corresponding to the parameter MapType of gen_binocular_rectification_map.

'rectif_sub_sampling': sub-sampling factor corresponding to the parameter SubSampling of gen_binocular_rectification_map.

'rectif_method': Rectification method corresponding to the parameter Method of gen_binocular_rectification_map.

Note that after modifying these parameters, set_stereo_model_image_pairs must be executed again for the changes to take effect.

The current list of image pairs in the model can be inspected by get_stereo_model_image_pairs.

Parameters

▷ **StereoModelID** (input_control) ..... stereo_model ⇝ *handle*
Handle of the stereo model.

▷ **From** (input_control) ..... integer-array ⇝ *integer*
Camera indices for the *from* cameras in the image pairs.
Number of elements: From > 0

▷ **To** (input_control) ..... integer-array ⇝ *integer*
Camera indices for the *to* cameras in the image pairs.
Number of elements: To == From

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StereoModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

set_stereo_model_param (: : StereoModelID, GenParamName, GenParamValue :)

Set stereo model parameters.

The operator set_stereo_model_param can be used to set diverse parameters for the stereo model StereoModelID. Several types of parameters can be set with this operator depending on type of the stereo model which was specified in create_stereo_model. Note that no specific parameters are provided for *'points_3d'*.

General parameters:

By setting GenParamName to one of the following values, general stereo model parameters can be set to the value passed in GenParamValue:

'bounding_box': A tuple [x1,y1,z1,x2,y2,z2] specifying two opposite corner points P1=[x1,y1,z1] and P2=[x2,y2,z2] of a bounding box for the reconstructions. The bounding box defines a box in the space in the coordinate frame of the camera setup model used for the reconstruction (specified by CameraSetupModelID in create_stereo_model). The reconstruction algorithms then clip any resulting reconstruction to this bounding box.

Furthermore, if the parameters *'min_disparity'* and *'max_disparity'* are not set manually by using create_stereo_model or set_stereo_model_param, the operator reconstruct_surface_stereo requires a valid bounding box for the estimation of the minimal and maximal disparity parameters for the pairwise disparity estimation (see set_stereo_model_image_pairs for more details).

Note that the values of parameters for the fusion of surfaces are reset to default values each time the bounding box is reset.

You can use the procedure estimate_bounding_box_3d_reconstruction to get initial values for the bounding box of your 3D reconstruction. This bounding box is based on the pose of a reference calibration plate and the cones of sight of the cameras. Later, the bounding box should be set as tight as possible around the object that is to be to be reconstructed.

Additionally, the procedures gen_bounding_box_object_model_3d and gen_camera_setup_object_model_3d can be used to visualize your camera setup.

For a valid bounding box, P1 must be the point on the front lower left corner and P2 on the back upper right corner of the bounding box, i.e., x1<x2, y1<y2 and z1<z2. While the surface reconstruction (see reconstruct_surface_stereo) will terminate in the case of an invalid bounding box, the 3D point reconstruction algorithm (see reconstruct_points_stereo) simply ignores it, and it reconstructs all points (it can), without clipping them. Thus, you can turn off the result clipping for the 3D points reconstruction by passing the tuple [0,0,0,0,0,-1].

Note that because *'bounding_box'* is a tuple-valued parameter, it cannot be set in a single call of set_stereo_model_param together with other model parameters (see the paragraph "A note on tuple-valued model parameters" below).

Tuple format: [x1,y1,z1,x2,y2,z2]

'persistence': Enables (GenParamValue=*1*) or disables (GenParamValue=*0*) the *'persistence'* mode of the stereo model. When in persistence mode, the model stores intermediate results of the reconstruction (only for reconstruct_surface_stereo), which can be inspected later by get_stereo_model_object and get_stereo_model_object_model_3d.

Note that the model might need significant memory space in this mode. This can worsen the performance of the reconstruction algorithms and even lead to running out of memory, in particular for setups with many cameras and/or large images. Therefore, we recommend to enable this mode only for inspection and debugging a reconstruction with small data sets.

List of values: *0* , *1*.

Default: *0*.

Parameters for the surface reconstruction using 'surface_pairwise' or 'surface_fusion':

By setting GenParamName to one of the following values, additional parameters specific for surface reconstruction can be set with GenParamValue for a stereo model of type *'surface_pairwise'* or *'surface_fusion'*:

'color': By setting this parameter to one of the following values, the coloring of the reconstructed 3D object model is either enabled or disabled (*'none'*). See reconstruct_surface_stereo on how to access the resulting color information.

'median' The color value of a 3D point is the median of the color values of all cameras where the 3D point is visible.

'smallest_distance' The color value of a 3D point corresponds to the color value of the camera that exhibits the smallest distance to this 3D point.

'mean_weighted_distances' All cameras that contribute to the reconstruction of a 3D point are weighted according to their distance to the 3D point. Cameras with a smaller distance receive a higher weight, whereas cameras with a larger distance get a lower weight. The color value of a 3D point is then computed by averaging the weighted color values of the cameras.

'line_of_sight' The color value of a 3D point corresponds to the color value of the camera that exhibits the smallest angle between the point normal and the line of sight.

'mean_weighted_lines_of_sight' All cameras that contribute to the reconstruction of a 3D point are weighted according to their angle between the point normal and the line of sight. Cameras with a smaller angle receive a higher weight. The color value of a 3D point is then computed by averaging the weighted color values of the cameras.

List of values: *'none'*, *'smallest_distance'*, *'mean_weighted_distances'*, *'line_of_sight'*, *'mean_weighted_lines_of_sight'*, *'median'*.

Default: *'none'*.

'color_invisible': If stereo models of type *'surface_fusion'* are used, the reconstruction will contain points without a direct correspondence to points in the images. These points are not seen by any of the cameras of the stereo system and are therefore "invisible". A color value for these points has to be calculated using the color of points in the vicinity. Coloring these "invisible" points can be switched off by setting this parameter to *'false'*. In this case invisible points are assigned 255 as gray value. Normally, coloring of "invisible" points is not very time-consuming and can remain active. However, it may happen that the value for the parameter *'resolution'* is considerably finer than the available image resolution. In this case, many invisible 3D points are reconstructed making the nearest neighbor search very time consuming. In order to avoid an increased runtime, it is recommended to either adapt the value of *'resolution'* or to switch off the calculation for invisible points. Please note that for stereo models of type *'surface_pairwise'*, this parameter will not have any effect.

List of values: *'true'*, *'false'*.

Default: *'true'*.

'rectif_interpolation': Interpolation mode for the rectification maps (see set_stereo_model_image_pairs). Note that after changing this parameter, you must call set_stereo_model_image_pairs again for the changes to take effect.

List of values: *'none'*, *'bilinear'*.

Default: *'bilinear'*.

'rectif_sub_sampling': Sub-sampling factor for the rectification maps (see set_stereo_model_image_pairs). Note that after changing this parameter, you must call set_stereo_model_image_pairs again for the changes to take effect.

Suggested values: *0.5*, *0.66*, *1.0*, *1.5*, *2.0*, *3.0*, *4.0*.

Default: *1.0*.

'rectif_method': Rectification method for the rectification maps (see set_stereo_model_image_pairs). Note that after changing this parameter, you must call set_stereo_model_image_pairs again for the changes to take effect.

List of values: *'viewing_direction'*, *'geometric'*.

Default: *'viewing_direction'*.

'disparity_method': Method used to create disparity images from the image pairs (see reconstruct_surface_stereo). Currently, the three methods *'binocular'*, *'binocular_mg'* and *'binocular_ms'* are supported. Dependent on the chosen method, the HALCON operator

binocular_disparity, binocular_disparity_mg or binocular_disparity_ms is called internally.

List of values: *'binocular'*, *'binocular_mg'*, *'binocular_ms'*.

Default: *'binocular'*.

'min_disparity', *'max_disparity'*: Minimum and maximum disparity values that are used in the operator reconstruct_surface_stereo. The number of minimum and maximum disparity values must correspond to the number of image pairs. If *'min_disparity'* and *'max_disparity'* are not set by the operator set_stereo_model_param, the disparity values are estimated internally by using the underlying bounding box.

Note that because *'min_disparity'* and *'max_disparity'* are tuple-valued parameters, they cannot be set in a single call of set_stereo_model_param together with other model parameters (see the paragraph "A note on tuple-valued model parameters" below).

'binocular_score_thresh': For the methods *'binocular_mg'* and *'binocular_ms'* the disparities that have a score above the passed threshold are excluded from further processing steps and do not end up in the reconstructed 3D point cloud. For the method *'binocular'* the disparities below the passed threshold are excluded.

For stereo models with the method *'binocular'*: **List of values:** positive and negative integer or float value.
Default: *0.5*.

For stereo models with the method *'binocular_mg'* **or** *'binocular_ms'*: **List of values:** integer or float value greater or equal to 0.0.
Default: *-1*.

Depending on the selected disparity method, a set of different parameters is available for the user. These parameters allow a fine tuning to the used data set. More information about the parameters can be found in the respective operator reference of binocular_disparity, binocular_disparity_mg or binocular_disparity_ms.

Set of parameters for stereo models with method = *'binocular'*

'binocular_method': Sets the desired matching method.
List of values: *'ncc'*, *'sad'*, *'ssd'*.
Default: *'ncc'*.

'binocular_num_levels': Number of used image pyramids. **List of values:** integer value greater or equal to 1.
Default: *1*.

'binocular_mask_width': Width of the correlation window.
List of values: Odd integer value greater or equal to 3.
Default: *11*.

'binocular_mask_height': Height of the correlation window.
List of values: Odd integer value greater or equal to 3.
Default: *11*.

'binocular_texture_thresh': Variance threshold of textured image regions.
List of values: integer or float value greater or equal to 0.0.
Default: *0.0*.

'binocular_filter': Downstream filters.
List of values: *'none'*, *'left_right_check'*.
Default: *'none'*.

'binocular_sub_disparity': Subpixel interpolation of disparities.
List of values: *'none'*, *'interpolation'*.
Default: *'none'*.

Set of parameters for stereo models with method = *'binocular_mg'*

'binocular_mg_gray_constancy': Weight of the gray value constancy in the data term.
List of values: integer or float value greater or equal to *0.0*.
Default: *1.0*.

'binocular_mg_gradient_constancy': Weight of the gradient constancy in the data term.
List of values: integer or float value greater or equal to *0.0*.
Default: *30.0*.

'binocular_mg_smoothness': Weight of the smoothness term in relation to the data term.
List of values: integer or float value greater *0.0*.
Default: *5.0*.

'binocular_mg_initial_guess': Initial guess of the disparity.
List of values: integer or float value.
Default: *0.0*.

The subsequent parameters control the behavior of the used multigrid method.

'binocular_mg_default_parameters': Sets predefined values for the following parameters of the used multigrid method: *'binocular_mg_solver'*, *'binocular_mg_cycle_type'*, *'binocular_mg_pre_relax'*, *'binocular_mg_post_relax'*, *'binocular_mg_initial_level'*, *'binocular_mg_iterations'*, *'binocular_mg_pyramid_factor'*. The exact values of these parameters can be found in the operator reference of `binocular_disparity_mg`.
List of values: *'very_accurate'*, *'accurate'*, *'fast_accurate'*, *'fast'*.
Default: *'fast_accurate'*.

'binocular_mg_solver': Solver for the linear system.
List of values: *'multigrid'*, *'full_multigrid'*, *'gauss_seidel'*.
Default: *'full_multigrid'*.

'binocular_mg_cycle_type': Selects the type of recursion for the multigrid solvers.
List of values: *'v'*,*'w'*, *'none'*.
Default: *'v'*.

'binocular_mg_pre_relax': Sets the number of iterations of the pre-relaxation step in multigrid solvers, or the number of iterations for the Gauss-Seidel solver, depending on which is selected.
List of values: integer or float value greater *0.0*.
Default: *1*.

'binocular_mg_post_relax': Sets the number of iterations of the post-relaxation step.
List of values: integer or float value.
Default: *1*.

'binocular_mg_initial_level': Sets the coarsest level of the image pyramid where the coarse-to-fine process starts.
List of values: integer value.
Default: *-2*.

'binocular_mg_iterations': Sets the number of iterations of the fixed point iteration per pyramid level.
List of values: integer or float value greater or equal to *0*.
Default: *1*

'binocular_mg_pyramid_factor': Determines the factor by which the images are scaled when creating the image pyramid for the coarse-to-fine process.
List of values: integer or float value between *0.1* and *0.9*.
Default: *0.6*.

Set of parameters for stereo models with method = *'binocular_ms'*

'binocular_ms_surface_smoothing': Smoothing of surfaces.
List of values: integer value greater or equal to *0*.
Default: *50*.

'binocular_ms_edge_smoothing': Smoothing of edges.
List of values: integer value greater or equal to *0*.
Default: *50*.

'binocular_ms_consistency_check': This parameter increases the robustness of the returned matches since the result relies on a concurrent direct and reverse match.
List of values: *'true'*, *'false'*.
Default: *'true'*.

'binocular_ms_similarity_measure': Sets the method of the similarity measure.
List of values: *'census_dense'*, *'census_sparse'*.
Default: *'census_dense'*.

'binocular_ms_sub_disparity': Enables or disables the sub-pixel refinement of disparities.
List of values: *'true'*, *'false'*.
Default: *'true'*.

'point_meshing': Enables the post-processing step for meshing the reconstructed surface points. For a stereo model of type *'surface_pairwise'*, a Poisson solver is supported. For a stereo model of type *'surface_fusion'*, a meshing of the isosurface is supported (see `reconstruct_surface_stereo` for more details).

List of values: *'none'*, *'poisson'*, *'isosurface'*.

Default: *'none'*.

If the Poisson-based meshing is enabled, the following parameters can be set:

- *'poisson_depth'*: Depth of the solver octree. More detail (i.e., a higher resolution) of the resulting mesh is achieved with deeper trees. However, this requires more time and memory.
  Suggested values:
  6, *8*, *10*.
  Default: *8*.
  Restriction: *3 <= 'poisson_depth' <= 12*
- *'poisson_solver_divide'*: Depth of block Gauss-Seidel solver used for solving the Poisson equation. At the price of a small time overhead, this parameter reduces the memory consumption of the underlying meshing algorithm. Proposed values are depths by 0 to 2 smaller compared to the main octree depth.
  Suggested values: *6*, *8*, *10*.
  Default: *8*.
  Restriction: *3 <= 'poisson_solver_divide' <= 'poisson_depth'*
- *'poisson_samples_per_node'*: Minimum number of points that should fall in a single octree leaf. This parameter is used to handle noisy data, e.g., noise-free data can be distributed over many leaves, whereas more noisy data should be stored in a single leaf to compensate for the noise. As a side effect, bigger values of this parameter distribute the data in fewer leaves, which results in a smaller octree, which means a speedup but possibly less detail of the reconstruction.
  Suggested values: *1*, *5*, *10*, *30*, *40*.
  Default: *30*.

Parameters only for 'surface_pairwise':

By setting `GenParamName` to one of the following values, additional parameters specific for surface reconstruction can be set with `GenParamValue` for a stereo model of type *'surface_pairwise'*:

'sub_sampling_step': sub-sampling step for the X, Y and Z image data resulting from the pairwise disparity estimation, before this data is used in its turn for the surface reconstruction (see `reconstruct_surface_stereo`).

Suggested values: *1*, *2*, *3*.

Default: *2*.

Parameters only for 'surface_fusion':

By setting `GenParamName` to one of the following values, additional parameters specific for surface reconstruction can be set with `GenParamValue` for a stereo model of type *'surface_fusion'*:

'resolution': Distance of neighboring sample points in each coordinate direction in discretization of bounding box. *'resolution'* is set in [m]. See `reconstruct_surface_stereo` for more details.

Too small values will unnecessarily increase the runtime. Too large values will lead to a reconstruction with too few details. Per default, it is set to a coarse resolution depending on the bounding box. The parameter will be reset if the bounding box is reset.

'smoothing' may need to be adapted when *'resolution'* is changed.

'surface_tolerance' should always be a bit larger than *'resolution'* in order to avoid effects of discretization.

Suggested values: *0.001*, *0.01*

'surface_tolerance': Specifies how much noise around the input point cloud should be combined to a surface. Points in a cone of sight of a camera are considered surely outside of the object (in front of the surface) or surely inside the object (behind the surface) with respect to the given camera if their distance to the initial surface exceeds *'surface_tolerance'*. *'surface_tolerance'* is set in [m]. See `reconstruct_surface_stereo` for more details and a figure.

Too small values lead to an uneven surface. Too large values smudge distinct surfaces into one. Per default, it is set to three times *'resolution'*. The parameter will be reset if the bounding box is reset.

'surface_tolerance' should always be a bit larger than *'resolution'* in order to avoid effects of discretization. *'min_thickness'* always has to be larger than or equal to *'surface_tolerance'*. If *'min_thickness'* is set too

small, *'surface_tolerance'* is automatically set to the same value as *'min_thickness'*. If *'surface_tolerance'* is set too big, an error is raised.

Suggested values: *0.003*, *0.03*

Restriction: *'surface_tolerance'* < *'min_thickness'*

'min_thickness': Length of considered cone of sight of a camera behind the initial surface obtained by pairwise reconstruction. Points behind the surface (viewed from the given camera) are only considered to lie inside the object if their distance to the initial surface does not exceed *'min_thickness'*. *'min_thickness'* is set in [m]. See `reconstruct_surface_stereo` for more details and a figure.

If lines of sight are expected to intersect the closed object only once (cameras all observe the object head-on from one side), this parameter should remain at the very large default setting.

If lines of sight are expected to intersect the object more often (cameras observe the object from different sides), only the interior of the object of interest should be marked as lying behind the surface. Thus, a first guess for the parameter could be less than the thickness of your object.

The method *'surface_fusion'* will try to produce a closed surface. If you observe several distinct objects from only one side, you may want to reduce the parameter *'min_thickness'* to restrict the depth of reconstructed objects and thus keep them from being smudged into one surface. The backside of the objects is not observed and thus its reconstruction will probably be incorrect.

Too small values can result in holes in the reconstructed point cloud or double walls. Too large values can result in a distorted point cloud or blow up the surface towards the outside of the object (if the surface is blown up beyond the bounding box, no points will be reconstructed). Per default set to the diameter of the bounding box. The parameter will be reset if the bounding box is reset.

'min_thickness' always has to be larger than or equal to *'surface_tolerance'*. If *'min_thickness'* is set too small, *'surface_tolerance'* is automatically set to the same value as *'min_thickness'*. If *'surface_tolerance'* is set too big, an error is raised.

Suggested values: *0.005*, *0.05*.

'smoothing': The parameter *'smoothing'* determines how important a small total variation of the distance function is compared to data fidelity. Thus, *'smoothing'* regulates the 'jumpiness' of the resulting surface (see `reconstruct_surface_stereo` for more details).

Note that the actual value of *'smoothing'* for a given data set to be visually pleasing has to be found by try and error. Too small values lead to integrating many outliers into the surface even if the surface then exhibits many jumps. Too large values lead to lost fidelity towards the point clouds of pairwise reconstruction (how the algorithm views distances to the input point clouds depends heavily on *'surface_tolerance'* and *'min_thickness'*).

The parameter will be reset if the bounding box is reset. *'smoothing'* may need to be adapted when *'resolution'* is changed.

Suggested values: *15.0*, *1.0*, *0.1*.

Default: *1.0*.

All parameters except *'binocular_mg_default_parameters'* can be read back by `get_stereo_model_param`.

A note on tuple-valued model parameters

Most of the stereo model parameters are single-valued. Thus, you can provide a list (i.e., tuple) of parameter names and a list (tuple) of values that has the same length as the input tuple. In contrast, when setting a tuple-valued parameter, you must pass a tuple of values. When setting such a parameter together with other parameters, the value-to-parameter-name correspondence is not obvious anymore. Thus, tuple-valued parameters like *'bounding_box'*, *'min_disparity'* or *'max_disparity'* should always be set in a separate call to `set_stereo_model_param`.

Parameters

▷ **`StereoModelID`** (input_control) ..... stereo_model ⇝ *handle*
Handle of the stereo model.

▷ **`GenParamName`** (input_control) ..... attribute.name(-array) ⇝ *string*
Names of the parameters to be set.
List of values: `GenParamName` ∈ {'bounding_box', 'persistence', 'sub_sampling_step', 'rectif_interpolation', 'rectif_sub_sampling', 'rectif_method', 'disparity_method', 'binocular_method', 'binocular_num_levels', 'binocular_mask_width', 'binocular_mask_height', 'binocular_texture_thresh', 'binocular_score_thresh', 'binocular_filter', 'binocular_sub_disparity', 'binocular_mg_gray_constancy', 'binocular_mg_gradient_constancy', 'binocular_mg_smoothness', 'binocular_mg_initial_guess',

'binocular_mg_default_parameters', 'binocular_mg_solver', 'binocular_mg_cycle_type', 'binocular_mg_pre_relax', 'binocular_mg_post_relax', 'binocular_mg_initial_level', 'binocular_mg_iterations', 'binocular_mg_pyramid_factor', 'binocular_ms_surface_smoothing', 'binocular_ms_edge_smoothing', 'binocular_ms_consistency_check', 'binocular_ms_similarity_measure', 'binocular_ms_sub_disparity', 'point_meshing', 'poisson_depth', 'poisson_solver_divide', 'poisson_samples_per_node', 'resolution', 'surface_tolerance', 'min_thickness', 'smoothing', 'color', 'color_invisible', 'min_disparity', 'max_disparity'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / integer / string
Values of the parameters to be set.
Suggested values: GenParamValue ∈ {1, -2, -5, 0, 0.3, 0.5, 0.9, 1, 2, 3, 'census_dense', 'census_sparse', 'binocular', 'ncc', 'none', 'sad', 'ssd', 'bilinear', 'false', 'viewing_direction', 'geometric', 'very_accurate', 'accurate', 'fast_accurate', 'fast', 'v', 'w', 'none', 'gauss_seidel', 'multigrid', 'true', 'poisson', 'isosurface', 'interpolation', 'left_right_check', 'full_multigrid', 'binocular_mg', 'binocular_ms', 'smallest_distance', 'mean_weighted_distances', 'line_of_sight', 'mean_weighted_lines_of_sight', 'median'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- StereoModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

estimate_al_am (Image : : : Albedo, Ambient)

Estimate the albedo of a surface and the amount of ambient light.

estimate_al_am estimates the Albedo of a surface, i.e. the percentage of light reflected by the surface, and the amount of ambient light Ambient by using the maximum and minimum gray values of the image.

Attention

It is assumed that the image contains at least one point for which the reflection function assumes its minimum, e.g., points in shadows. Furthermore, it is assumed that the image contains at least one point for which the reflection function assumes its maximum. If this is not the case, wrong values will be estimated.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte
Image for which albedo and ambient are to be estimated.

▷ **Albedo** (output_control) . . . . . real(-array) ⇝ *real*
Amount of light reflected by the surface.

▷ **Ambient** (output_control) . . . . . real(-array) ⇝ *real*
Amount of ambient light.

Result

`estimate_al_am` always returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

estimate_sl_al_lr (Image : : : Slant, Albedo)

Estimate the slant of a light source and the albedo of a surface.

`estimate_sl_al_lr` estimates the `Slant` of a light source, i.e., the angle between the light source and the positive z-axis, and the albedo of the surface in the input image `Image`, i.e. the percentage of light reflected by the surface, using the algorithm of Lee and Rosenfeld.

Attention

The `Albedo` is assumed constant for the entire surface depicted in the image.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
Image for which slant and albedo are to be estimated.

▷ **Slant** (output_control) ..... angle.deg(-array) ⇝ *real*
Angle between the light sources and the positive z-axis (in degrees).

▷ **Albedo** (output_control) ..... real(-array) ⇝ *real*
Amount of light reflected by the surface.

Result

`estimate_sl_al_lr` always returns the value `2` (`H_MSG_TRUE`).

Execution Information

3D Metrology

photometric_stereo (Images : HeightField, Gradient, Albedo : Slants, Tilts, ResultType, ReconstructionMethod, GenParamName, GenParamValue :)

Reconstruct a surface according to the photometric stereo technique.

`photometric_stereo` can be used to separate the three-dimensional shape of an object from its two-dimensional texture, e.g., its print image. The operator requires at least three images of the same object taken with different and known directions of illumination. Note, that the point of view of the camera must be the same for all images.

The three-dimensional shape of the object is primarily computed as the local gradients of the three-dimensional surface. Those gradients can be further integrated to obtain a height field, i.e., an image in which the pixel values correspond to a relative height. The two-dimensional texture is called albedo and corresponds to the local light absorption and reflection characteristics of the surface exclusive of any shading effect.

Typical applications of photometric stereo

Typical applications of photometric stereo are to detect small inconsistencies in a surface that represent, e.g., defects, or to exclude the influence of the direction of light from images that are used, e.g., for the print inspection of non flat characters. Note that photometric stereo is not suitable for the reconstruction of absolute heights, i.e., it is no alternative to typical 3D reconstruction algorithms like depth from focus or sheet of light.

Limitations of photometric stereo

`photometric_stereo` is based on the algorithm of Woodham and therefore assumes on the one hand that the camera performs an orthoscopic projection. That is, you must use a telecentric lens or a lens with a long focal distance. On the other hand, it assumes that each of the light sources delivers a parallel and uniform beam of light. That is, you must use telecentric illumination sources with uniform intensity or, as an alternative, distant point light sources. Additionally, the object must have Lambertian reflectance characteristics, i.e., it must reflect incoming light in a diffuse way. Objects or regions of an object that have specular reflectance characteristics (i.e., mirroring or glossy surfaces) cannot be processed correctly and thus lead to erroneous results.

The acquisition setup

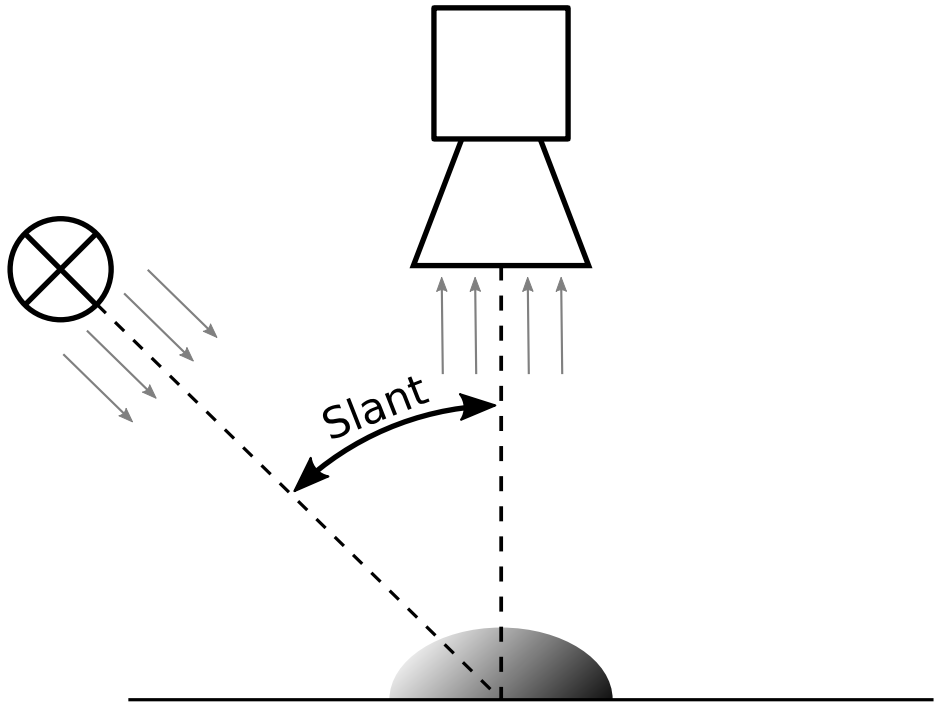
The camera with a telecentric lens must be placed orthogonally, i.e., perpendicular, to the scene that should be reconstructed. The orientation of the camera with respect to the scene must not change during the acquisition of the images. In contrast, the orientation of the illumination with respect to the camera must change for at least three gray value images.

Specifying the directions of illumination

For each image, the directions of illumination must be specified as angles within the parameters `Slants` and `Tilts`, which describe the direction of the illumination in relation to the scene. To understand the meaning of the

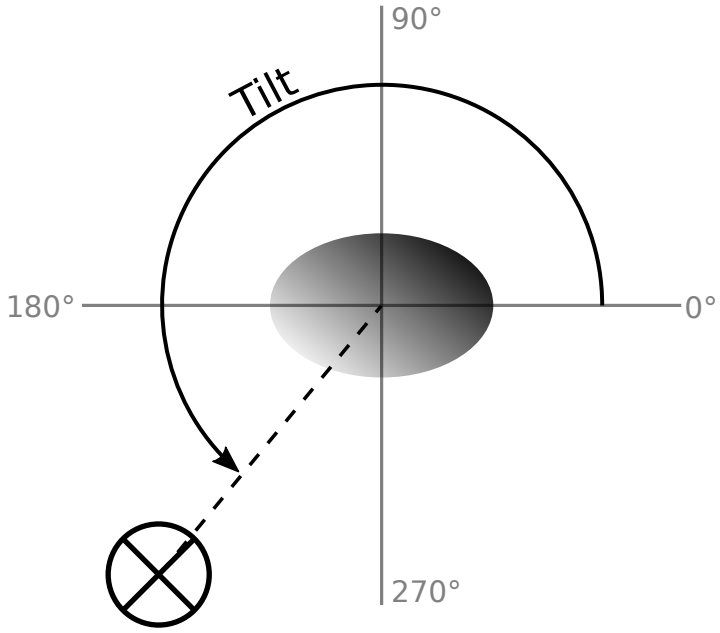
parameters Slants and Tilts, remember that the illumination source is assumed to produce parallel light rays, the camera has a telecentric lens, and the camera is placed orthogonal to the scene to reconstruct:

Slants The Slants angle is the angle between the optical axis of the camera and the direction of the illumination.



Side view

Tilts The Tilts angle is measured within the object plane or any plane that is parallel to it, e.g., the image plane. In particular, it describes the angle between the direction that points from the center of the image to the right and the direction of light that is projected into the plane. That is, when looking at the image (or the corresponding scene), a tilt angle of 0 means that the light comes from the right, a tilt angle of 90 means that the light is coming from the top, a tilt angle of 180 means that the light is coming from the left, etc.



Top view

As stated before, photometric stereo requires at least three images with different directions of illumination. However, the three-dimensional geometry of objects typically leads to shadow casting. In the shadow regions, the number of effectively available directions of illumination is reduced, which leads to ambiguities. To nevertheless get a robust result, redundancy is needed. Therefore, typically more than three light sources with different directions should be used. But note that an increasing number of illumination directions also leads to a higher number

of images to be processed and therefore to a higher processing time. In most applications, a number of four to six light sources is reasonable. As a rule of thumb, the slant angles should be chosen between 30° and 60°. The tilt angles typically should be equally distributed around the object to be measured. Please note that the directions of illumination must be selected such that they do not lie in the same plane (i.e., the illumination directions must be independent), otherwise the computing fails and an exception is thrown.

Input images and domains of definition

The input images must be provided in an image array (`Images`). Each image must have been taken with a different direction of illumination as stated above. If the images are primarily stored in a multi-channel image, they can be easily converted to an image array using `image_to_channels`. As an alternative, the image array can be created using `concat_obj`.

`photometric_stereo` relies on the evaluation of the "photometric information", i.e., the gray values stored in the images. Therefore, this information should be unbiased and accurate. We recommend to ensure that the camera that is used to acquire the images has a linear characteristic. You can use the operator `radiometric_self_calibration` to determine the characteristic of your camera and the operator `lut_trans` to correct the gray value information in case of a non linear characteristic. Additionally, if accurate measurements are required, we recommend to utilize the full dynamic range of the camera since this leads to more accurate gray value information. For the same reason, using images with a bit depth higher than 8 (e.g., uint2 images instead of byte images) leads to a better accuracy.

The domain of definition of the input images determines which algorithm is used internally to process the `Images`. Three algorithms are available:

- If all images have a full domain, the fastest algorithm is used. This mode is recommended for most applications.
- If the input images share the same reduced domain of definition, only the pixels within the domain are processed. This mode can be used to exclude areas of the object from all images. Typically, areas are excluded that are known to show non-Lambertian reflectance characteristics or that are of no interest, e.g., holes in the surface.
- If images with distinct domains of definition are provided, only the gray values that are contained in the domains are used in the respective images. Then, only those pixels are processed that have independent slant and tilt angles in at least three images. This mode is suitable, e.g., to exclude specific regions of individual images from the processing. These can be, e.g., areas of the object for which is known that they show non-Lambertian reflectance characteristics or regions for which is known that they contain biased photometric information, e.g., shadows. To exclude such regions leads to more accurate results. Please note that this last mode requires significantly more processing time than the modes that use the full domain or the same domain for all images.

Output images

The operator can return the images for the reconstructed `Gradient`, `Albedo`, and the `HeightField` of the surface:

- The `Gradient` image is a vector field that contains the partial derivative of the surface. Note that `Gradient` can be used as input to `reconstruct_height_field_from_gradient`. For visualization purposes, instead of the surface gradients normalized surface normals can be returned. Then, `ResultType` must be set to *'normalized_surface_normal'* (legacy: *'normalized_gradient'*) instead of *'gradient'*. Here, the row and column components represent the row and column components of the normalized surface normal. If `ResultType` is set to *'all'*, the default mode, i.e., *'gradient'* and not *'normalized_surface_normal'* is used.
- The `Albedo` image describes the ratio of reflected radiation to incident radiation and has a value between one (white surface) and zero (black surface). Thus, the albedo is a characteristic of the surface. For example, for a printed surface it corresponds to the print image exclusive of any influences of the incident light (shading).
- The `HeightField` image is an image in which the pixel values correspond to a relative height.

By default, all of these iconic objects are returned, i.e., the parameter `ResultType` is set to *'all'*. In case that only some of these results are needed, the parameter `ResultType` can be set to a tuple specifying only the required results among the values *'gradient'*, *'albedo'*, and *'height_field'*. Note that in certain applications like surface inspection tasks only the `Gradient` or `Albedo` images are required. Here, one can significantly

increase the processing speed by not reconstructing the surface, i.e., by passing only *'gradient'* and *'albedo'* but not *'height_field'* to ResultType.

Note that internally photometric_stereo first determines the gradient values and, if required, integrates these values in order to obtain the height field. This integration is performed by the same algorithms that are provided by the operator reconstruct_height_field_from_gradient and that can be controlled by the parameters ReconstructionMethod, GenParamName, and GenParamValue. Please, refer to the operator reconstruct_height_field_from_gradient for more information on these parameters. If ResultType is set such that *'height_field'* is not one of the results, the parameters ReconstructionMethod, GenParamName, and GenParamValue are ignored.

Attention

Note that photometric_stereo assumes square pixels. Additionally, it assumes that the heights are computed on a lattice with step width 1 in object space. If this is not the case, i.e., if the pixel size of the camera projected into the object space differs from 1, the returned height values must be multiplied by the actual step width (value of the pixel size projected into the object space). The size of the pixel in object space is computed by dividing the size of the pixel in the camera by the magnification of the (telecentric) lens.

Parameters

▷ **Images** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2
Array with at least three input images with different directions of illumination.

▷ **HeightField** (output_object) . . . . . image ⇝ *object :* real
Reconstructed height field.

▷ **Gradient** (output_object) . . . . . image ⇝ *object :* vector_field
The gradient field of the surface.

▷ **Albedo** (output_object) . . . . . image ⇝ *object :* real
The albedo of the surface.

▷ **Slants** (input_control) . . . . . angle.deg-array ⇝ *real* / integer
Angle between the camera and the direction of illumination (in degrees).
Default: 45.0
Suggested values: Slants ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Slants ≤ 180.0 (lin)
Minimum increment: 0.01
Recommended increment: 10.0

▷ **Tilts** (input_control) . . . . . angle.deg-array ⇝ *real* / integer
Angle of the direction of illumination within the object plane (in degrees).
Default: 45.0
Suggested values: Tilts ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Tilts ≤ 360.0 (lin)
Minimum increment: 0.01
Recommended increment: 10.0

▷ **ResultType** (input_control) . . . . . string-array ⇝ *string*
Types of the requested results.
Default: 'all'
List of values: ResultType ∈ {[], 'all', 'height_field', 'gradient', 'normalized_surface_normal', 'albedo'}

▷ **ReconstructionMethod** (input_control) . . . . . string ⇝ *string*
Type of the reconstruction method.
Default: 'poisson'
List of values: ReconstructionMethod ∈ {'fft_cyclic', 'rft_cyclic', 'poisson'}

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of the generic parameters.
Default: []
List of values: GenParamName ∈ {'optimize_speed', 'caching'}

▷ **GenParamValue** (input_control) . . . . . integer-array ⇝ *integer* / real / string
Values of the generic parameters.
Default: []
List of values: GenParamValue ∈ {'standard', 'patient', 'exhaustive', 'use_cache', 'no_cache', 'free_cache'}

Result

If the parameters are valid, `photometric_stereo` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`optimize_fft_speed`

Module

3D Metrology

reconstruct_height_field_from_gradient (
Gradient : HeightField : ReconstructionMethod, GenParamName,
GenParamValue :)

Reconstruct a surface from surface gradients.

`reconstruct_height_field_from_gradient` reconstructs a surface from the surface gradients that are given in `Gradient`. The surface is returned as a height field, i.e., an image in which the gray value of each image point corresponds to a relative height.

The reconstruction is done by integrating the gradients by different algorithms that can be selected in the parameter `ReconstructionMethod`. Because gradient fields are typically non-integrable due to noise, the various algorithms return a solution in a least-squares sense. The algorithms differ in the way how they model the boundary condition. Currently three algorithms are supported: *'fft_cyclic'*, *'rft_cyclic'* and *'poisson'*.

Reconstruction with Fast Fourier transforms

The variants *'fft_cyclic'* and *'rft_cyclic'* assume that the image function is cyclic at the boundaries. Note that due to the assumed cyclic image function artifacts may occur at the image boundaries. Thus, in most cases, we recommend to use the *'poisson'* algorithm instead.

The difference between *'fft_cyclic'* and *'rft_cyclic'* is that the rft version has faster processing times and requires less memory than the fft version. While theoretically fft and rft should return the same result, the fft version is numerically slightly more accurate. As `reconstruct_height_field_from_gradient` internally uses a fast Fourier transform, the run time of the operator can be influenced by a previous call to `optimize_fft_speed` or `optimize_rft_speed`, respectively.

Reconstruction according to Poisson

The *'poisson'* algorithm assumes that the image has constant gradients at the image border. In most cases, it is the recommended reconstruction method for `reconstruct_height_field_from_gradient`. Its run time can only be optimized by setting `GenParamName` to *'optimize_speed'* and `GenParamValue` to *'standard'*, *'patient'*, or *'exhaustive'*. These parameters are described in more detail with the description of `optimize_fft_speed`.

Note that by default, the *'poisson'* algorithm uses a cache that depends on the image size and that speeds up the reconstruction significantly, provided that all images have the same size. The cache is allocated at the first time when the *'poisson'* algorithm is called. Therefore the first call always takes longer than subsequent calls. The additionally needed memory corresponds to the memory needed for the specific size of one image. Please note that when calling the operator with different image sizes, the cache needs to be reallocated, which leads to a longer processing time. In this case it may be preferable to not use the cache. To switch off the caching, you must set the parameter `GenParamName` to *'caching'* and the parameter `GenParamValue` to *'no_cache'*. The cache can explicitly be deallocated by setting `GenParamName` to *'caching'* and `GenParamValue` to *'free_cache'*. However, in the majority of cases, we recommend to use the cache, i.e., to use the default setting for the parameter *'caching'*.

Saving and loading optimization parameters

The optimization parameters for all algorithms can be saved and loaded by `write_fft_optimization_data` and `read_fft_optimization_data`.

Non obvious applications

Please note that the operator `reconstruct_height_field_from_gradient` has various non-obvious applications, especially in the field called gradient domain manipulation technique. In many applications, the gradient values that are passed as input to the operator do not have the semantics of surface gradients (i.e., the first derivatives of the height values), but are rather the first derivatives of other kinds of parameters, typically gray values (then, the gradients have the semantics of gray value edges). When processing these gradient images by various means, e.g., by adding or subtracting images, or by a filtering, the original gradient values are altered and the subsequent call to `reconstruct_height_field_from_gradient` delivers a modified image, in which, e.g., unwanted edges are removed or the contrast has been changed locally. Typical applications are noise removal, seamless fusion of images, or high dynamic range compression.

Attention

`reconstruct_height_field_from_gradient` takes into account the values of all pixels in `Gradient`, not only the values within its domain. If `Gradient` does not have a full domain, one could cut out the relevant square part of the gradient field and generate a smaller image with full domain.

Parameters

- ▷ **`Gradient`** (input_object) ..... singlechannelimage ⇝ *object :* vector_field
  The gradient field of the image.
- ▷ **`HeightField`** (output_object) ..... image ⇝ *object :* real
  Reconstructed height field.
- ▷ **`ReconstructionMethod`** (input_control) ..... string ⇝ *string*
  Type of the reconstruction method.
  Default: 'poisson'
  List of values: `ReconstructionMethod` ∈ {'fft_cyclic', 'rft_cyclic', 'poisson'}
- ▷ **`GenParamName`** (input_control) ..... string-array ⇝ *string*
  Names of the generic parameters.
  Default: []
  List of values: `GenParamName` ∈ {'optimize_speed', 'caching'}
- ▷ **`GenParamValue`** (input_control) ..... integer-array ⇝ *integer* / real / string
  Values of the generic parameters.
  Default: []
  List of values: `GenParamValue` ∈ {'standard', 'patient', 'exhaustive', 'use_cache', 'no_cache', 'free_cache'}

Result

If the parameters are valid `reconstruct_height_field_from_gradient` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

`sfs_mod_lr` `( Image : Height : Slant, Tilt, Albedo, Ambient : )`

Reconstruct a surface from a gray value image.

sfs_mod_lr reconstructs a surface (i.e. the relative height of each image point) using the modified algorithm of Lee and Rosenfeld. The surface is reconstructed from the input image Image, and the light source given by the parameters Slant, Tilt, Albedo and Ambient, and is assumed to lie infinitely far away in the direction given by Slant and Tilt. The parameter Albedo determines the albedo of the surface, i.e. the percentage of light reflected in all directions. Ambient determines the amount of ambient light falling onto the surface. It can be set to values greater than zero if, for example, the white balance of the camera was badly adjusted at the moment the image was taken.

Attention

sfs_mod_lr assumes that the heights are to be extracted on a lattice with step width 1. If this is not the case, the calculated heights must be multiplied with the step width after the call to sfs_mod_lr. A Cartesian coordinate system with the origin in the lower left corner of the image is used internally. sfs_mod_lr can only handle byte-images.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte
Shaded input image.

▷ **Height** (output_object) . . . . . image(-array) ⇝ *object :* real
Reconstructed height field.

▷ **Slant** (input_control) . . . . . angle.deg ⇝ *real* / integer
Angle between the light source and the positive z-axis (in degrees).
Default: 45.0
Suggested values: Slant ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Slant ≤ 180.0 (lin)
Minimum increment: 0.01
Recommended increment: 10.0

▷ **Tilt** (input_control) . . . . . angle.deg ⇝ *real* / integer
Angle between the light source and the x-axis after projection into the xy-plane (in degrees).
Default: 45.0
Suggested values: Tilt ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Tilt ≤ 360.0 (lin)
Minimum increment: 0.01
Recommended increment: 10.0

▷ **Albedo** (input_control) . . . . . number ⇝ *real* / integer
Amount of light reflected by the surface.
Default: 1.0
Suggested values: Albedo ∈ {0.1, 0.5, 1.0, 5.0}
Value range: 0.0 ≤ Albedo ≤ 5.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Albedo >= 0.0

▷ **Ambient** (input_control) . . . . . number ⇝ *real* / integer
Amount of ambient light.
Default: 0.0
Suggested values: Ambient ∈ {0.1, 0.5, 1.0}
Value range: 0.0 ≤ Ambient ≤ 1.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Ambient >= 0.0

Result

If all parameters are correct sfs_mod_lr returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

sfs_orig_lr (Image : Height : Slant, Tilt, Albedo, Ambient :)

Reconstruct a surface from a gray value image.

sfs_orig_lr reconstructs a surface (i.e. the relative height of each image point) using the original algorithm of Lee and Rosenfeld. The surface is reconstructed from the input image Image. The light source is to be given by the parameters Slant, Tilt, Albedo and Ambient, and is assumed to lie infinitely far away in the direction given by Slant and Tilt. The parameter Albedo determines the albedo of the surface, i.e. the percentage of light reflected in all directions. Ambient determines the amount of ambient light falling onto the surface. It can be set to values greater than zero if, for example, the white balance of the camera was badly adjusted at the moment the image was taken.

Attention

sfs_orig_lr assumes that the heights are to be extracted on a lattice with step width 1. If this is not the case, the calculated heights must be multiplied with the step width after the call to sfs_orig_lr. A Cartesian coordinate system with the origin in the lower left corner of the image is used internally. sfs_orig_lr can only handle byte-images.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte
Shaded input image.

▷ **Height** (output_object) . . . . . image(-array) ⇝ *object :* real
Reconstructed height field.

▷ **Slant** (input_control) . . . . . angle.deg ⇝ *real* / integer

sfs_pentland (Image : Height : Slant, Tilt, Albedo, Ambient :)

Reconstruct a surface from a gray value image.

sfs_pentland reconstructs a surface (i.e. the relative height of each image point) using the algorithm of Pentland. The surface is reconstructed from the input image Image. The light source must be given by the parameters Slant, Tilt, Albedo and Ambient, and is assumed to lie infinitely far away in the direction given by Slant and Tilt. The parameter Albedo determines the albedo of the surface, i.e. the percentage of light reflected in all directions. Ambient determines the amount of ambient light falling onto the surface. It can be set to values greater than zero if, for example, the white balance of the camera was badly adjusted at the moment the image was taken.

Attention

sfs_pentland assumes that the heights are to be extracted on a lattice with step width 1. If this is not the case, the calculated heights must be multiplied with the step width after the call to sfs_pentland. A Cartesian coordinate system with the origin in the lower left corner of the image is used internally. sfs_pentland can only handle byte-images.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte
Shaded input image.

▷ **Height** (output_object) . . . . . image(-array) ⇝ *object :* real
Reconstructed height field.

▷ **Slant** (input_control) . . . . . angle.deg ⇝ *real* / integer
Angle between the light source and the positive z-axis (in degrees).
Default: 45.0
Suggested values: Slant ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Slant ≤ 180.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Tilt** (input_control) . . . . . angle.deg ⇝ *real* / integer
Angle between the light source and the x-axis after projection into the xy-plane (in degrees).
Default: 45.0
Suggested values: Tilt ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Tilt ≤ 360.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Albedo** (input_control) . . . . . number ⇝ *real* / integer
Amount of light reflected by the surface.

Possible Successors

shade_height_field

Module

3D Metrology

shade_height_field (ImageHeight : ImageShade : Slant, Tilt, Albedo, Ambient, Shadows :)

Shade a height field.

shade_height_field computes a shaded image from the height field ImageHeight as if the image were illuminated by an infinitely far away light source. It is assumed that the surface described by the height field has Lambertian reflection properties determined by Albedo and Ambient. The parameter Shadows determines whether shadows are to be calculated.

Attention

shade_height_field assumes that the heights are given on a lattice with step width 1. If this is not the case, the heights must be divided by the step width before the call to shade_height_field. Otherwise, the derivatives used internally to compute the orientation of the surface will be estimated to steep or too flat. Example: The height field is given on 100*100 points on the square [0,1]*[0,1]. Then the heights must be divided by 1/100 first. A Cartesian coordinate system with the origin in the lower left corner of the image is used internally.

Parameters

▷ **ImageHeight** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / int4 / real
Height field to be shaded.

▷ **ImageShade** (output_object) . . . . . image(-array) ⇝ *object :* byte
Shaded image.

▷ **Slant** (input_control) . . . . . angle.deg ⇝ *real* / integer
Angle between the light source and the positive z-axis (in degrees).
Default: 0.0
Suggested values: Slant ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Slant ≤ 180.0 (lin)
Minimum increment: 0.01
Recommended increment: 10.0

▷ **Tilt** (input_control) . . . . . angle.deg ⇝ *real* / integer
Angle between the light source and the x-axis after projection into the xy-plane (in degrees).
Default: 0.0
Suggested values: Tilt ∈ {1.0, 5.0, 10.0, 20.0, 40.0, 60.0, 90.0}
Value range: 0.0 ≤ Tilt ≤ 360.0 (lin)
Minimum increment: 0.01
Recommended increment: 10.0

▷ **Albedo** (input_control) . . . . . number ⇝ *real* / integer
Amount of light reflected by the surface.
Default: 1.0
Suggested values: Albedo ∈ {0.1, 0.5, 1.0, 5.0}
Value range: 0.0 ≤ Albedo ≤ 5.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Albedo >= 0.0

▷ **Ambient** (input_control) . . . . . number ⇝ *real* / integer
Amount of ambient light.
Default: 0.0
Suggested values: Ambient ∈ {0.1, 0.5, 1.0}
Value range: 0.0 ≤ Ambient ≤ 1.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1
Restriction: Ambient >= 0.0

▷ **Shadows** (input_control) . . . . . string ⇝ *string*
Should shadows be calculated?
Default: 'false'
Suggested values: Shadows ∈ {'true', 'false'}

Result

If all parameters are correct shade_height_field returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

sfs_mod_lr, sfs_orig_lr, sfs_pentland, photometric_stereo

Module

Foundation

uncalibrated_photometric_stereo (Images : NormalField, Gradient, Albedo : ResultType :)

Reconstruct a surface from several, differently illuminated images.

uncalibrated_photometric_stereo can be used to extract high-frequency surface details from a given object with no prior knowledge about the illumination, geometry and reflectance of the object. The geometry of interest can be for example dents, folds or scratches. The operator can usually not be used for measuring the overall shape of an object. The operator returns the normals NormalField of the surface as a 3-channel image with each image encoding a component of the normal. This is used as a visualization of the result as a color coded image. Further, it returns the Gradient and the Albedo of the surface. Which result should be calculated can be controlled with ResultType. This operator is related to photometric_stereo, but does not require known (i.e. previously calibrated) light directions. Note that photometric_stereo is faster and more accurate, but needs the light direction information. For sensible results an orthographic projection of the camera is assumed for both the calibrated and uncalibrated case. This is typically reached by using a telecentric lens or at least a lens with a long focal distance.

The operator requires at least three images of the same object, taken with a static, non-moving camera and different lighting directions for each image. For best results, the object should exhibit Lambertian reflection properties, no inter-reflection or shadow castings.

Parameters

- ▷ **Images** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2
  The input images with different illumination.
- ▷ **NormalField** (output_object) ..... image(-array) ⇝ *object :* real
  The normal field of the surface.
- ▷ **Gradient** (output_object) ..... image ⇝ *object :* vector_field
  The gradient field of the surface .
- ▷ **Albedo** (output_object) ..... image ⇝ *object :* real
  The albedo of the surface.
- ▷ **ResultType** (input_control) ..... string-array ⇝ *string*
  The result type.
  Default: 'all'
  List of values: ResultType ∈ {[], 'all', 'normal_field', 'gradient', 'normalized_gradient', 'albedo'}

Example

```
* read severally illuminated images
FName := 'photometric_stereo/pharma_braille_0' + [1:4] + '.png'
read_image(Images, FName)
* extract surface normals, gradients and albedo from images
uncalibrated_photometric_stereo(Images, NormalField, Gradient, Albedo, 'all')
derivate_vector_field (Gradient, Result, 0.1, 'mean_curvature')
reconstruct_height_field_from_gradient (Gradient, HeightField, 'poisson', \
                                        [], [])
```

Result

The operator uncalibrated_photometric_stereo returns the NormalField for the given images as well as the appropriate gradients for each pixel and the Albedo of the object.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

5.5 Sheet of Light

apply_sheet_of_light_calibration (
Disparity : : SheetOfLightModelID :)

Apply the calibration transformations to the input disparity image.

The operator apply_sheet_of_light_calibration reads the disparity image Disparity, stores it to the sheet-of-light model specified by SheetOfLightModelID and applies the calibration transformation to this image, in order to compute the calibrated coordinates of the reconstructed 3D surface points. The resulting calibrated coordinates can be retrieved from the model by using the operator get_sheet_of_light_result. The corresponding 3D object model can be retrieved with get_sheet_of_light_result_object_model_3d. Note that prior to the next call of apply_sheet_of_light_calibration for a disparity image of smaller height, reset_sheet_of_light_model should be called.

The disparity image Disparity may have been acquired previously by using the operator measure_profile_sheet_of_light or by an image acquisition device, which directly provides disparity values and works according to the sheet-of-light technique.

In order to compute the calibrated coordinates, the parameters listed below must have been set for the sheet-of-light model with the help of the operator set_sheet_of_light_param:

'calibration': extent of the calibration transformation which shall be applied to the disparity image. *'calibration'* must be set to *'xz'*, *'xyz'* or *'offset_scale'*. Refer to set_sheet_of_light_param for details on this parameter.

'camera_parameter': the internal parameters of the camera used for the measurement. This pose is required when the calibration extent has been set to *'xyz'* or *'xz'*.

'camera_pose': the pose of the world coordinate system relative to the camera coordinate system. This pose is required when the calibration extent has been set to *'xyz'* or *'xz'*.

'lightplane_pose': the pose of the light-plane coordinate system relative to the world coordinate system. The light-plane coordinate system must be chosen so that its plane z=0 coincides with the light plane described by the light line projector. This pose is required when the calibration extent has been set to *'xyz'* or *'xz'*.

'movement_pose': a pose representing the movement of the object between two successive profile images with respect to the measurement system built by the camera and the laser. This pose is required when the calibration extent has been set to *'xyz'*. It is ignored when the calibration extent has been set to *'xz'*.

'scale': with this parameter you can scale the 3D coordinates X, Y and Z that result when applying the calibration transformations to the disparity image. *'scale'* must be specified as the ratio *desired unit/original unit*. The original unit is determined by the coordinates of the calibration object. If the original unit is meters (which is the case if you use the standard calibration plate), you can set the desired unit directly by selecting 'm', 'cm', 'mm' or 'um' for the parameter Scale. By default, *'scale'* is set to 1.0.

Parameters

▷ **Disparity** (input_object) ..... singlechannelimage ⇝ *object : real*
Height or range image to be calibrated.

▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

Example

```
* ...
* Read an already acquired disparity map from file
read_image (Disparity, 'sheet_of_light/connection_rod_disparity.tif')
*
* Create a model and set the required parameters
gen_rectangle1 (ProfileRegion, 120, 75, 195, 710)
create_sheet_of_light_model (ProfileRegion, ['min_gray','num_profiles', \
                             'ambiguity_solving'], [70,290,'first'], \
                              SheetOfLightModelID)
set_sheet_of_light_param (SheetOfLightModelID, 'calibration', 'xyz')
set_sheet_of_light_param (SheetOfLightModelID, 'scale', 'mm')
set_sheet_of_light_param (SheetOfLightModelID, 'camera_parameter', \
                          CameraParameter)
set_sheet_of_light_param (SheetOfLightModelID, 'camera_pose', CameraPose)
set_sheet_of_light_param (SheetOfLightModelID, 'lightplane_pose', \
                          LightPlanePose)
set_sheet_of_light_param (SheetOfLightModelID, 'movement_pose', \
                          MovementPose)
*
* Apply the calibration transforms and
* get the resulting calibrated coordinates
apply_sheet_of_light_calibration (Disparity, SheetOfLightModelID)
get_sheet_of_light_result (X, SheetOfLightModelID, 'x')
get_sheet_of_light_result (Y, SheetOfLightModelID, 'y')
get_sheet_of_light_result (Z, SheetOfLightModelID, 'z')
*
```

Result

The operator `apply_sheet_of_light_calibration` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SheetOfLightModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Successors

`get_sheet_of_light_result`, `get_sheet_of_light_result_object_model_3d`

Module

3D Metrology

calibrate_sheet_of_light (: : SheetOfLightModelID : Error)

Calibrate a sheet-of-light setup with a 3D calibration object.

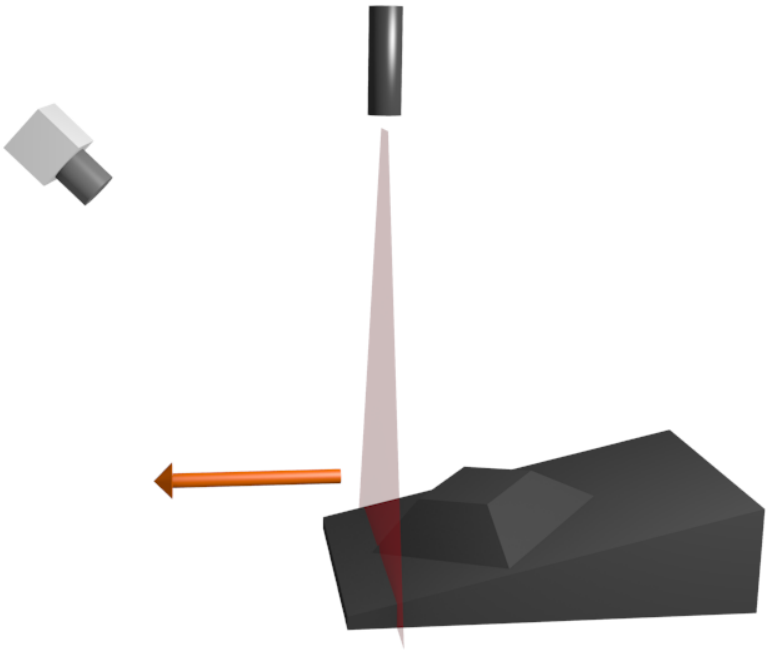
`calibrate_sheet_of_light` calibrates the sheet-of-light setup `SheetOfLightModelID` from one disparity image of a 3D calibration object and returns the back projection error of the optimization in `Error`.

Overview

The calibration of a sheet-of-light setup with `calibrate_sheet_of_light` is simpler than the calibration of a sheet-of-light setup with standard HALCON calibration plates, which is shown in the HDevelop example

calibrate_sheet_of_light_calplate.hdev. It is only necessary to obtain one uncalibrated reconstruction, i.e., a disparity image, of a special 3D calibration object to calibrate the sheet-of-light model.

In the following, the steps that are necessary for the calibration are described.



Calibration of a sheet-of-light setup

Supply of a 3D calibration object

A special 3D calibration object must be provided. This calibration object must correspond to the CAD model created with create_sheet_of_light_calib_object. The 3D calibration object has an inclined plane on which a truncated pyramid is located. It has a thinner side, which is hereinafter referred to as front side. The thicker side is referred to as back side of the calibration object.

The dimensions of the calibration object should be chosen such that the calibration object covers the complete measuring volume. Be aware, that only parts on the 3D calibration object above HeightMin (see create_sheet_of_light_calib_object) are taken into account.

The CAD model, which is written as a DXF file, also serves as description file of the calibration object.

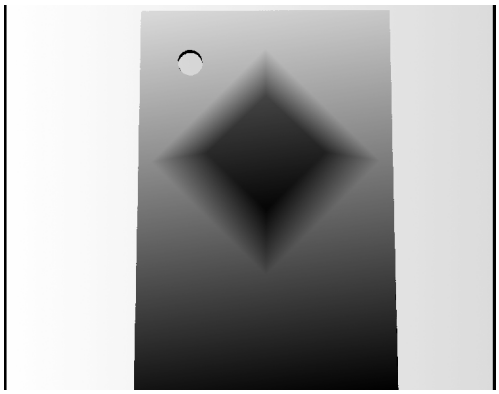
Preparation of the sheet-of-light model

To prepare a sheet-of-light model for the calibration, the following steps must be performed.

- Create a sheet-of-light model with create_sheet_of_light_model and adapt the default parameters to your specific measurement task.
- Set the initial parameters of the camera with set_sheet_of_light_param. So far, only pinhole cameras with the division model are supported, i.e., only cameras of type *'area_scan_division'*.
- Set the description file of the calibration object (created with create_sheet_of_light_calib_object) with set_sheet_of_light_param.

Uncalibrated reconstruction of the 3D calibration object

The 3D calibration object must be reconstructed with the (uncalibrated) sheet-of-light model prepared above, i.e., a disparity image of the 3D calibration object must be created.



Disparity image of a calibration object

For this, the calibration object must be oriented such that either its front side or its back side intersect the light plane first (i.e., the movement vector should be parallel to the Y axis of the calibration object, see create_sheet_of_light_calib_object). As far as possible, the domain of the disparity image of the calibration object should be restricted to the calibration object. Besides, the domain of the disparity image should have no holes on the truncated pyramid. All four sides of the truncated pyramid must be clearly visible.

Calibration of the sheet-of-light setup

The calibration is then performed with calibrate_sheet_of_light. The returned Error is the RMS of the distance of the reconstructed points to the calibration object in meters.

For sheet-of-light models calibrated with calibrate_sheet_of_light, in rare cases the parameters might yield an unrealistic setup. However, the quality of measurements performed with the calibrated parameters is not affected.

Parameters

▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

▷ **Error** (output_control) ..... number ⇝ *real*
Average back projection error of the optimization.

Example

```
* Calibrate a sheet-of-light model with a 3D calibration object
gen_rectangle1 (Rectangle, 300, 0, 800, 1023)
CameraParam := ['area_scan_division', 0.016, 0, 4.65e-6, 4.65e-6, \
                640.0, 512.0, 1280, 1024]
create_sheet_of_light_model (Rectangle, 'min_gray', 50, SheetOfLightModelID)
set_sheet_of_light_param (SheetOfLightModelID, 'camera_parameter', \
                          CameraParam)
set_sheet_of_light_param (SheetOfLightModelID, 'calibration_object', \
                         'calib_object.dxf')
* Uncalibrated reconstruction of the calibration object
for ProfileIndex := 1 to 1000 by 1
    grab_image_async (Image, AcqHandle, -1)
    measure_profile_sheet_of_light (Image, SheetOfLightModelID, [])
endfor
* Calibration of the sheet-of-light-model
calibrate_sheet_of_light (SheetOfLightModelID, Error)
* Now get a calibrated reconstruction of the calibration object
get_sheet_of_light_result_object_model_3d (SheetOfLightModelID, \
                                           ObjectModel3D)
```

Result

The operator calibrate_sheet_of_light returns the value 2 (H_MSG_TRUE) if the calibration was successful. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- SheetOfLightModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_sheet_of_light_model`, `set_sheet_of_light_param`, `set_profile_sheet_of_light`, `measure_profile_sheet_of_light`

Possible Successors

`set_profile_sheet_of_light`, `apply_sheet_of_light_calibration`

Module

3D Metrology

clear_sheet_of_light_model (: : SheetOfLightModelID :)

Delete a sheet-of-light model and free the allocated memory.

The operator `clear_sheet_of_light_model` deletes a sheet-of-light model that was created by `create_sheet_of_light_model`. All memory used by the model is freed. The handle of the model is passed in `SheetOfLightModelID`. After the operator call it is invalid.

Parameters

▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

Result

The operator `clear_sheet_of_light_model` returns the value `2` (`H_MSG_TRUE`) if a valid handle is passed and the referred sheet-of-light model can be freed correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SheetOfLightModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

`create_sheet_of_light_model`

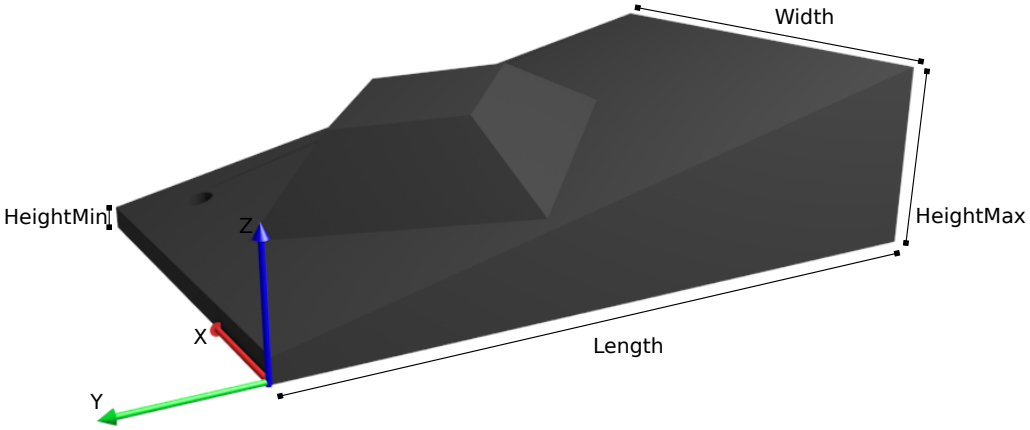
Module

3D Metrology

create_sheet_of_light_calib_object (: : Width, Length, HeightMin, HeightMax, FileName :)

Create a calibration object for sheet-of-light calibration.

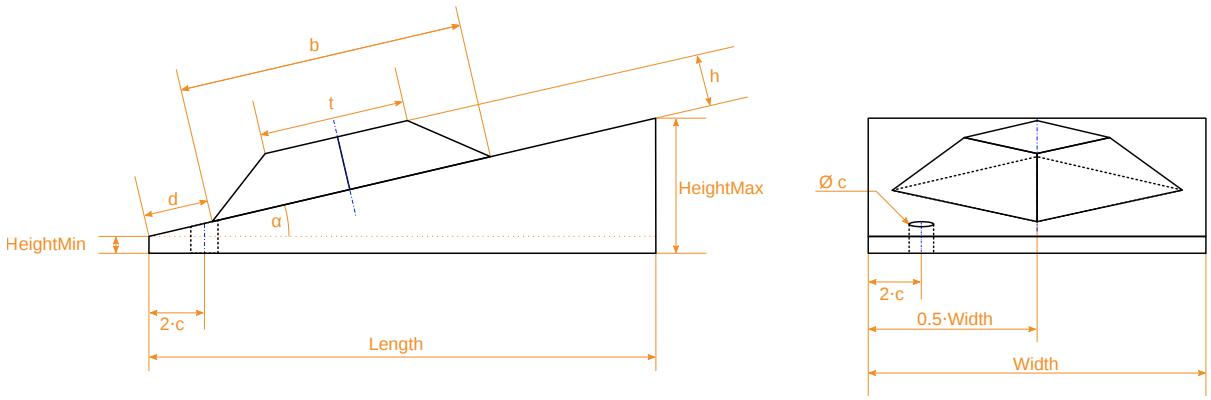
`create_sheet_of_light_calib_object` creates a CAD model of a calibration object for sheet-of-light calibration with `calibrate_sheet_of_light` and stores it in `FileName`.



A calibration object for sheet-of-light calibration

The calibration object consists of a ramp with a truncated pyramid rotated by 45 degrees. The calibration object contains an orientation mark in the form of a circular hole. The dimensions of the calibration target in `Width`, `Length`, `HeightMin`, and `HeightMax` must be given in meters. `Length` must be at least 10% larger than `Width`. The Z coordinate of the highest point on the truncated pyramid is at most `HeightMax`. The calibration object might not be found by `calibrate_sheet_of_light` if the height difference between the truncated pyramid and the ramp is too small. In this case, adjust `HeightMin` and `HeightMax` accordingly or increase the sampling rate when acquiring the calibration data.

The dimensions of the calibration object should be chosen such that it is possible to cover the measuring volume of the sheet-of-light setup. In addition, when selecting the `Length` of the calibration object, the speed of the sheet-of-light setup should be considered such that the calibration object is sampled with enough profile measurements.



Technical drawing of the calibration object, where `c` is the diameter of the orientation mark, `d` is the distance of the pyramid from the front of the calibration object, `h` is the height of the truncated pyramid, `b` is the length of the diagonal of the pyramid at the bottom, `t` is the corresponding length at the top, and α is the angle of the ramp as seen in the drawing. You can calculate these dimensions with the procedure `get_sheet_of_light_calib_object_dimensions`.

Set the parameter *'calibration_object'* to `FileName` with `set_sheet_of_light_param` to use the generated calibration object in a subsequent call to `calibrate_sheet_of_light`.

Note that MVTec does not offer 3D calibration objects. Instead, use `create_sheet_of_light_calib_object` to generate a customized CAD model of a calibration object. This CAD model can then be used to produce the calibration object. Milled aluminum is an established material for this. However, depending on the required precision, its thermal stability may be a problem. Note that the surface should be bright. Its color may have to be adjusted depending on the color of the laser to provide a

sufficient contrast to the color of the laser. Additionally, the surface must not be translucent nor reflective. To achieve this, you can anodize or lacquer it. Please note that when lacquering it, the accuracy might be decreased due to the applied paintwork. However, a surface that is too rough leads to a decreasing precision as well. It is advisable to have the produced calibration object remeasured to determine whether the required accuracy can be achieved. The accuracy of the calibration object should be ten times higher than the required accuracy of measurement. After having the object measured, the results can be manually inserted into the DXF file that can then be used for the calibration with `calibrate_sheet_of_light`.

Parameters

▷ **`Width`** (input_control) . . . . . number ⇝ *real*
Width of the object.
Default: 0.1

▷ **`Length`** (input_control) . . . . . number ⇝ *real*
Length of the object.
Default: 0.15

▷ **`HeightMin`** (input_control) . . . . . number ⇝ *real*
Minimum height of the ramp.
Default: 0.005

▷ **`HeightMax`** (input_control) . . . . . number ⇝ *real*
Maximum height of the ramp.
Default: 0.04

▷ **`FileName`** (input_control) . . . . . filename.write ⇝ *string*
Filename of the model of the calibration object.
Default: 'calib_object.dxf'
File extension: `.dxf`

Result

The operator `create_sheet_of_light_calib_object` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

3D Metrology

`create_sheet_of_light_model` `( ProfileRegion : : GenParamName, GenParamValue : SheetOfLightModelID )`

Create a model to perform 3D-measurements using the sheet-of-light technique.

The operator `create_sheet_of_light_model` creates a model to perform 3D-Measurements using the sheet-of-light technique.

The sheet-of-light technique performs a three-dimensional reconstruction of the surface of an opaque and diffuse reflecting solid by using an area scan camera and a light line projector (typically a laser line projector). The camera and the line projector must be mounted so that their main axis form an angle of triangulation. The value of the angle of triangulation is typically chosen between 30° and 60°. The projected light line defines a plane in space. This plane intersects the surface of the solid under measurement and builds a profile of the surface visible for the camera. By moving the solid in front of the measurement system (i.e., the combination of the camera and the line projector), it is possible to record the whole surface of the solid. As an alternative, the measurement system can also be moved over the surface under measurement. Please note that the profiles must be oriented roughly horizontal in the profile images, because they are processed column by column.

If geometrical information about the measurement setup is available, it is possible to compute true three-dimensional coordinates of the reconstructed surface. For an overview of the required geometrical (i.e., calibration)

information, refer to the operator set_sheet_of_light_param. If such information is not available, the result of the measurement is a disparity image, where each pixel holds a record of the subpixel precise position of the detected profile.

The operator returns a handle to the sheet-of-light model in SheetOfLightModelID, which is used for all further operations on the sheet-of-light model, like modifying parameters of the model, measuring profiles, applying calibration transformations or accessing the results of measurements.

Mandatory input iconic parameters

In order to perform measurements, you will have to set the following input iconic parameter:

ProfileRegion: defines the region of the profile images, which will be processed by the operator measure_profile_sheet_of_light. This region should be rectangular and can be generated e.g., by using the operator gen_rectangle1. If the region passed to ProfileRegion is not rectangular, its smallest enclosing rectangle (bounding box) will be used. Note that ProfileRegion is only taken into account by the operator measure_profile_sheet_of_light and is ignored when disparity images are processed.

Default settings of the sheet-of-light model parameters

The default settings of the sheet-of-light model were chosen to perform non-calibrated measurements in a basic configuration. The following list provides an overview of the parameter values used by default (refer to set_sheet_of_light_param for a detailed description of all supported generic parameters):

'method' is set to *'center_of_gravity'*

'min_gray': is set to 100

'num_profiles' is set to 512

'ambiguity_solving' is set to *'first'*

'score_type' is set to *'none'*

'calibration' is set to *'none'*

Modify the sheet-of-light model parameters

We recommend to adapt the default parameters to your specific measurement task, in order to enhance the quality of the measurement or to shorten the runtime. You will also have to modify the default values of the model parameters if you need calibrated results.

create_sheet_of_light_model provides the generic parameters GenParamName and GenParamValue to modify the default value of most of the model parameters. Note that model parameters can also be set by using the operator set_sheet_of_light_param. Nevertheless, with this second operator only one parameter can be set at the same time, whereas it is possible to set more than one parameter at the time with create_sheet_of_light_model. Refer to set_sheet_of_light_param for a detailed description of all supported generic parameters.

Please note that the following model parameters can not be set with the operator create_sheet_of_light_model, and thus have to be set with the operator set_sheet_of_light_param: *'camera_parameter'*, *'camera_pose'*, *'lightplane_pose'*, and *'movement_pose'*.

It is possible to query the value of the model parameters with the operator get_sheet_of_light_param. The names of all supported model parameters are returned by the operator query_sheet_of_light_params.

Use the simplified sheet-of-light model parameters

In case of a simple setup or if not a real metric calibration is necessary, the transformation of the observed disparities into 3D values can be controlled using a simplified parameter set of the sheet-of-light model:

By setting the calibration with the set_sheet_of_light_param to *'offset_scale'*, the poses and camera parameter are changed to such values, that an offset of one pixel corresponds to one unit in the 3D result. This allows to create a 3D object model and 3D images from an uncalibrated sheet-of-light model.

The transformation from disparity to 3D coordinates can be controlled by six parameters: *'scale_x'*, *'scale_y'*, *'scale_z'*, *'offset_x'*, *'offset_y'*, *'offset_z'*. Refer to set_sheet_of_light_param for a detailed description of all supported generic parameters.

Use of a handle in multiple threads

Please note that you have to take special care when using a handle of a sheet-of-light-model SheetOfLightModelID in multiple threads. One and the same handle cannot be used concurrently in different threads if they modify the handle. Thus, you have to be careful especially if the threads call operators that change the data of the handle. You can find an according hint in the *'Attention'* section of the operators. Anyway, if you still want to use the same handle in operators that concurrently write into the handle in different threads you have to synchronize the threads to assure that they do not access the same handle simultaneously. If you are not sure if the usage of the same handle is thread-safe, please see the *'Attention'* section of the respective reference manual entry if it contains a warning pointing to this problem. However, different handles can be used independently and safely in different threads.

Parameters

- ▷ **ProfileRegion** (input_object) ..... region ⇝ *object*
  Region of the images containing the profiles to be processed. If the provided region is not rectangular, its smallest enclosing rectangle will be used.
- ▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
  Names of the generic parameters that can be adjusted for the sheet-of-light model.
  Default: 'min_gray'
  List of values: GenParamName ∈ {'min_gray', 'method', 'ambiguity_solving', 'score_type', 'num_profiles', 'calibration', 'scale', 'scale_x', 'scale_y', 'scale_z', 'offset_x', 'offset_y', 'offset_z'}
- ▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *integer* / real / string
  Values of the generic parameters that can be adjusted for the sheet-of-light model.
  Default: 50
  Suggested values: GenParamValue ∈ {'default', 'center_of_gravity', 'last', 'first', 'brightest', 'none', 'intensity', 'width', 'offset_scale', 50, 100, 150, 180}
- ▷ **SheetOfLightModelID** (output_control) ..... sheet_of_light_model ⇝ *handle*
  Handle for using and accessing the sheet-of-light model.

Example

```
* Create the rectangular region in which the profiles are measured.
gen_rectangle1 (ProfileRegion, 120, 75, 195, 710)
*
* Create a model in order to measure profiles according to
* the sheet-of-light technique. Simultaneously set some
* parameters for the model.
create_sheet_of_light_model (ProfileRegion, ['min_gray','num_profiles', \
                             'ambiguity_solving','score_type'], \
                             [70,290,'first','width'], \
  SheetOfLightModelID)
*
* Measure the profile from successive images
for Index := 1 to 290 by 1
    read_image (ProfileImage, 'sheet_of_light/connection_rod_'+Index$'.3')
    dev_display (ProfileImage)
    dev_display (ProfileRegion)
    measure_profile_sheet_of_light (ProfileImage, SheetOfLightModelID, [])
endfor
*
* Get the resulting disparity and score images
get_sheet_of_light_result (Disparity, SheetOfLightModelID, 'disparity')
get_sheet_of_light_result (Score, SheetOfLightModelID, 'score')
*
* Close the sheet-of-light handle once the measurement
* has been performed
```

Result

The operator create_sheet_of_light_model returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

deserialize_sheet_of_light_model (: : SerializedItemHandle : SheetOfLightModelID)

Deserialize a sheet-of-light model.

deserialize_sheet_of_light_model deserializes a sheet-of-light model that was serialized by serialize_sheet_of_light_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized model is defined by the handle SerializedItemHandle. The deserialized values are stored in a new sheet-of-light model with the handle SheetOfLightModelID.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **SheetOfLightModelID** (output_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

Result

The operator deserialize_sheet_of_light_model returns the value 2 (H_MSG_TRUE) if the sheet-of-light model can be correctly deserialized. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_sheet_of_light_param (: : SheetOfLightModelID, GenParamName : GenParamValue)

Get the value of a parameter, which has been set in a sheet-of-light model.

The operator get_sheet_of_light_param is used to query the values of the different parameters of a sheet-of-light model. The names of the desired parameters are passed in the generic parameter GenParamName, the corresponding values are returned in GenParamValue. All these parameters can be set and changed at any time with the operator set_sheet_of_light_param.

It is not possible to query the values of several parameters with a single operator call. In order to request the values of several parameters you have to successively call of the operator get_sheet_of_light_param.

The values of the following model parameters can be queried:

Measurement of the profiles:

'method': defines the method used to determine the position of the profile. The values *'default'* and *'center_of_gravity'* both refer to the same method, whereby the position of the profile is determined column by column with subpixel accuracy by computing the center of gravity of the gray values g_i of all pixels fulfilling the condition:

$$g_i \geq 'min\_gray'$$

'min_gray': the smallest gray values taken into account for the measurement of the position of the profile (see *'method'* above).

'num_profiles': number of profiles for which memory has been allocated within the sheet-of-light model. By default, *'num_profiles'* is set to 512. If this number of profiles is exceeded during the measurement, memory will be reallocated automatically at runtime. Since the reallocation process requires some time, we recommend to set *'num_profiles'* to a reasonable value before the measurement is started.

'ambiguity_solving': this model parameter determines which candidate shall be chosen, if the determination of the position of the light line is ambiguous.

'first': the first encountered candidate is returned. This method is the fastest.

'last': the last encountered candidate is returned.

'brightest': for each candidate, the brightness of the profile is computed and the candidate having the highest brightness is returned. The brightness is computed according to:

$$brightness = \frac{1}{n} \sum_{i=0}^{n} g_i \ ,$$

where g_i is the gray value of the pixel and n the number of pixels taken into consideration to determine the position of the profile.

'score_type': this model parameter selects which type of score will be calculated during the measurement of the disparity. The score values give an advice on the quality of the computed disparity.

'none': no score is computed.

'width': for each pixel of the disparity, a score value is set to the local width of the profile (i.e., the number of pixels used to compute the position of the profile).

'intensity': for each pixel of the disparity, a score value is evaluated by computing the local intensity of the profile according to:

$$score = \frac{1}{n} \sum_{i=0}^{n} g_i$$

where g_i is the gray value of the pixel and n the number of pixels taken into consideration to determine the position of the profile.

Calibration of the measurement:

'calibration': extent of the calibration transformation which shall be applied to the disparity image:

'none': no calibration transformation is applied.

'xz': the calibration transformations which describe the geometrical properties of the measurement system (camera and light line projector) are taken into account, but the movement of the object during the measurement is not taken into account.

'xyz': the calibration transformations which describe the geometrical properties of the measurement system (camera and light line projector) as well as the transformation which describe the movement of the object during the measurement are taken into account.

'offset_scale': a simplified set of parameters to describe the setup, that can be used with default parameters or can be controlled by six parameters. Three of the parameters describe an anisotropic scaling: *'scale_x'* describes the scaling of a pixel in column direction into the new x-axis, *'scale_y'* describes the linear movement between two profiles, and *'scale_z'* describes the scaling of to measured disparities into the new z-axis. The other three parameters describe the offset of the frame of reference of the resulting x,y,z values (*'offset_x'*, *'offset_y'*, *'offset_z'*).

'camera_parameter': the internal parameters of the camera used for the measurement. Those parameters are required when the calibration extent has been set to *'xz'* or *'xyz'*.

'camera_pose': the pose of the world coordinate system relative to the camera coordinate system. This pose is required when the calibration extent has been set to *'xz'* or *'xyz'*.

'lightplane_pose': the pose of the light-plane coordinate system relative to the world coordinate system. The light-plane coordinate system must be chosen so that its plane z=0 coincides with the light plane described by the light line projector. This pose is required when the calibration extent has been set to *'xz'* or *'xyz'*.

'movement_pose': a pose representing the movement of the object between two successive profile images with respect to the measurement system built by the camera and the laser. This pose is required when the calibration extent has been set to *'xyz'*.

'scale': with this parameter you can scale the 3D coordinates X, Y and Z that result when applying the calibration transformations to the disparity image. *'scale'* must be specified as the ratio *desired unit/original unit*. The original unit is determined by the coordinates of the calibration object. If you use the standard calibration plate the original unit is meter. This parameter can only be set if the calibration extent has been set to *'offset_scale'*, *'xz'* or *'xyz'*. By default, *'scale'* is set to 1.0.

'scale_x': This value defines the width of a pixel in 3D space. The value is only applicable if the calibration extend is set to *'offset_scale'*. By default, *'scale_x'* is set to *1.0*.

'scale_y': This value defines the linear movement between two profiles in 3D space. The value is only applicable if the calibration extend is set to *'offset_scale'*. By default, *'scale_y'* is set to *10.0*.

'scale_z': This value defines the height of disparities in 3D space. The value is only applicable if the calibration extend is set to *'offset_scale'*. By default, *'scale_z'* is set to *1.0*.

'offset_x': This value defines the x offset of reference frame for 3D results. The value is only applicable if the calibration extend is set to *'offset_scale'*. By default, *'offset_x'* is set to *0.0*.

'offset_y': This value defines the y offset of reference frame for 3D results. The value is only applicable if the calibration extend is set to *'offset_scale'*. By default, *'offset_y'* is set to *0.0*.

'offset_z': This value defines the z offset of reference frame for 3D results. The value is only applicable if the calibration extend is set to *'offset_scale'*. By default, *'offset_z'* is set to *0.0*.

Parameters

▷ **SheetOfLightModelID** (input_control) . . . . . sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter that shall be queried.
Default: 'method'
List of values: GenParamName ∈ {'min_gray', 'method', 'ambiguity_solving', 'score_type', 'num_profiles', 'calibration', 'camera_parameter', 'camera_pose', 'lightplane_pose', 'movement_pose', 'scale', 'scale_x', 'scale_y', 'scale_z', 'offset_x', 'offset_y', 'offset_z'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Value of the model parameter that shall be queried.

Result

The operator get_sheet_of_light_param returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

3D Metrology

get_sheet_of_light_result (: ResultValue : SheetOfLightModelID, ResultName :)

Get the iconic results of a measurement performed with the sheet-of light technique.

The operator get_sheet_of_light_result provides access to the results of the calibrated and uncalibrated measurements performed with a given sheet-of-light model. The different kinds of results can be selected by setting the value of the parameter ResultName as described below:

Non-calibrated results:

'disparity': the measured disparity i.e., the subpixel row value at which the profile was detected is returned for each pixel. The disparity values can be considered as non-calibrated pseudo-range values.

'score': the score values computed according to the value of the parameter *'score_type'* is returned. If the parameter *'score_type'* has been set to *'none'*, no score value is computed during the measurement, therefore the returned image is empty. Refer to create_sheet_of_light_model and set_sheet_of_light_param for details on the possible values of the model parameter *'score_type'*.

Calibrated results:

'x': The calibrated X-coordinates of the reconstructed surface is returned as an image.

'y': The calibrated Y-coordinates of the reconstructed surface is returned as an image.

'z': The calibrated Z-coordinates of the reconstructed surface is returned as an image.

Please, note that the pixel values of the images returned when setting ResultName to *'x'*, *'y'* or *'z'* have the semantic of coordinates with respect to the world coordinate system that is implicitly defined during the calibration of the system. The unit of the returned coordinates depends on the value of the parameter *'scale'*. (see create_sheet_of_light_model and set_sheet_of_light_param for details on the possible values of the model parameter *'scale'*.)

The operator get_sheet_of_light_result returns an empty object if the desired result has not been computed.

Parameters

▷ **ResultValue** (output_object) ..... singlechannelimage ⇝ *object : real*
Desired measurement result.

▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model to be used.

▷ **ResultName** (input_control) ..... string(-array) ⇝ *string*
Specify which result of the measurement shall be provided.
Default: 'disparity'
List of values: ResultName ∈ {'disparity', 'score', 'x', 'y', 'z'}

Result

The operator get_sheet_of_light_result returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

3D Metrology

get_sheet_of_light_result_object_model_3d (
: : SheetOfLightModelID : ObjectModel3D)

Get the result of a calibrated measurement performed with the sheet-of-light technique as a 3D object model.

The operator get_sheet_of_light_result_object_model_3d returns the result of a fully calibrated sheet-of-light measurement as a 3D object model. The handle of the sheet-of-light model with which the measurement is performed must be passed to SheetOfLightModelID. The calibration extent of the sheet-of-light model (*'calibration'*) must have been set to *'xyz'* or *'offset_scale'* before applying the measurement, otherwise the computed coordinates cannot be returned as a 3D object model and an exception is raised.

The handle of the 3D object model resulting from the measurement is returned in ObjectModel3D. For the 3D points within this 3D object model no triangular meshing is available, therefore no faces are stored in the 3D object model. If a 3D object model with triangular meshing is required for the subsequent processing, use the operator get_sheet_of_light_result in order to retrieve the *'x'*, *'y'*, and *'z'* coordinates from the sheet-of-light model and then call the operator xyz_to_object_model_3d with suitable parameters. Refer to xyz_to_object_model_3d for more information about 3D object models.

The unit of the returned coordinates depends on the value of the parameter *'scale'* that was set for the sheet-of-light model before applying the measurement. See create_sheet_of_light_model and set_sheet_of_light_param for details on the possible values of the model parameter *'scale'*. The operator get_sheet_of_light_result_object_model_3d returns a handle to an empty 3D object model if the desired result has not been measured yet.

Parameters

▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
Handle for accessing the sheet-of-light model.

▷ **ObjectModel3D** (output_control) ..... object_model_3d ⇝ *handle*
Handle of the resulting 3D object model.

Result

The operator get_sheet_of_light_result_object_model_3d returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

clear_object_model_3d

Module

3D Metrology

measure_profile_sheet_of_light (
ProfileImage : : SheetOfLightModelID, MovementPose :)

Process the profile image provided as input and store the resulting disparity to the sheet-of-light model.

The operator measure_profile_sheet_of_light processes the ProfileImage and stores the resulting disparity values to the sheet-of-light model. Please note that ProfileImage will only be processed in the region defined by ProfileRegion as set with the operator create_sheet_of_light_model. Since ProfileImage is processed column by column, the profile must be oriented roughly horizontal.

Influence of different model parameters

If the model parameter *'score_type'* has been set to *'intensity'* or *'width'*, score values are also computed and stored into the model. Refer to set_sheet_of_light_param for details on the possible values of *'score_type'*.

If the model parameter *'calibration'* has been set to *'xz'*, *'xyz'*, or *'offset_scale'* and all parameters required to determine the calibration transformation have been set to the sheet-of-light model, the calibration transformations will be automatically applied to the disparity values after the measurement. Refer to set_sheet_of_light_param for details on setting the calibration parameters to the sheet-of-light model.

Setting MovementPose

MovementPose describes the movement of the object between the acquisition of the previous profile and the acquisition of the current profile.

If the model parameter *'calibration'* has been set to *'none'* or *'xz'* (see set_sheet_of_light_param) the movement of the object is not taken into consideration by the calibration transformation. Therefore, MovementPose is ignored, and it can be set to an empty tuple.

If the model parameter *'calibration'* has been set to *'xyz'*, the pose describing the movement of the object must be specified to the sheet-of-light model. This can be done here with MovementPose or with the parameter *'movement_pose'* in the operator set_sheet_of_light_param.

If the model parameter *'calibration'* has been set to *'offset_scale'*, a movement can be specified, but it should be considered, that the space to which this transformation is applied is most probably not metrically.

If the movement of the object between the recording of two successive profiles is constant, we recommend to set MovementPose here to an empty tuple, and to set the constant pose via the parameter *'movement_pose'* in the operator set_sheet_of_light_param. This configuration is often encountered, for example when the object under measurement is moved by a conveyor belt and measured by a fixed measurement system.

If the movement of the object between the recording of two successive profiles is not constant, for example because the measurement system is moved over the object by a robot, you must set MovementPose here for each call of measure_profile_sheet_of_light.

MovementPose must be expressed in the world coordinate system that is implicitly defined during the calibration of the measurement system.

Parameters

- ▷ **ProfileImage** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
  Input image.
- ▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
  Handle of the sheet-of-light model.
- ▷ **MovementPose** (input_control) ..... number-array ⇝ *integer* / real
  Pose describing the movement of the scene under measurement between the previously processed profile image and the current profile image.

Result

The operator measure_profile_sheet_of_light returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SheetOfLightModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

query_sheet_of_light_params (: : SheetOfLightModelID, QueryName : GenParamName)

For a given sheet-of-light model get the names of the generic iconic or control parameters that can be used in the different sheet-of-light operators.

The operator query_sheet_of_light_params returns the names of the generic parameters that are supported by the following operators create_sheet_of_light_model, set_sheet_of_light_param, get_sheet_of_light_param and get_sheet_of_light_result. The parameter QueryName is used to select the desired **parameter group**:

'create_model_params': create_sheet_of_light_model – Parameters for adjusting the sheet-of-light model during its creation.

'set_model_params': set_sheet_of_light_param – Parameters for adjusting the parameters of an available sheet-of-light model.

'get_model_params': get_sheet_of_light_param – Parameters for querying the values of the parameters of a sheet-of-light model.

'get_result_objects': get_sheet_of_light_result – Parameters for accessing the iconic objects resulting from the measurement.

The returned parameter list does not depend on the current state of the model or its results.

Parameters

▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

▷ **QueryName** (input_control) ..... attribute.name ⇝ *string*
Name of the parameter group.
Default: 'create_model_params'
List of values: QueryName ∈ {'create_model_params', 'set_model_params', 'get_model_params', 'get_result_objects'}

▷ **GenParamName** (output_control) ..... attribute.value-array ⇝ *string*
List containing the names of the supported generic parameters.

Result

The operator query_sheet_of_light_params returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

Module

3D Metrology

read_sheet_of_light_model (: : FileName : SheetOfLightModelID)

Read a sheet-of-light model from a file and create a new model.

The operator read_sheet_of_light_model reads the sheet-of-light model from the file FileName and creates a new model that is an identical copy of the saved model. The parameter SheetOfLightModelID returns the handle of the new model. The model file FileName must have been created by the operator write_sheet_of_light_model. The default HALCON file extension for sheet-of-light model is 'solm'.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the sheet-of-light model file.
Default: 'sheet_of_light_model.solm'
File extension: .solm

▷ **SheetOfLightModelID** (output_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

Result

The operator read_sheet_of_light_model returns the value 2 (H_MSG_TRUE) if the named file was found and correctly read. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

write_sheet_of_light_model

Module

3D Metrology

reset_sheet_of_light_model (: : SheetOfLightModelID :)

Reset a sheet-of-light model.

The operator reset_sheet_of_light_model resets a sheet-of-light model that was created by create_sheet_of_light_model. All indices and result arrays used by the model are reset. The parameters of the model remain unchanged. The handle of the model is passed in SheetOfLightModelID.

Parameters

▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

Result

The operator reset_sheet_of_light_model returns the value 2 (H_MSG_TRUE) if a valid handle is passed and the sheet-of-light model can be reset correctly. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SheetOfLightModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

clear_sheet_of_light_model

Module

3D Metrology

serialize_sheet_of_light_model (
: : SheetOfLightModelID : SerializedItemHandle)

Serialize a sheet-of-light model.

serialize_sheet_of_light_model serializes a sheet-of-light model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_sheet_of_light_model is converted to a serialized item. The sheet-of-light model is defined by the handle SheetOfLightModelID. The serialized model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_sheet_of_light_model.

Parameters

▷ **SheetOfLightModelID** (input_control) . . . . . sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

The operator serialize_sheet_of_light_model returns the value 2 (H_MSG_TRUE) if the passed handle of the sheet-of-light model is valid and if the model can be serialized into the serialized item. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_profile_sheet_of_light (
ProfileDisparityImage : : SheetOfLightModelID, MovementPoses :)

Set sheet of light profiles by measured disparities.

set_profile_sheet_of_light adds sheet-of-light profiles to the sheet-of-light model SheetOfLightModelID. The profiles are specified as rows in a disparity image in ProfileDisparityImage. Each of the profiles can have an individual Pose set in MovementPoses which is interpreted as relative movement to the previous row. If no pose is set, the default transformation is used, which can be set by set_sheet_of_light_param. If only one pose is set, this pose will become the default transformation.

Parameters

- ▷ **ProfileDisparityImage** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
  Disparity image that contains several profiles.
- ▷ **SheetOfLightModelID** (input_control) ..... sheet_of_light_model ⇝ *handle*
  Handle of the sheet-of-light model.
- ▷ **MovementPoses** (input_control) ..... number-array ⇝ *integer* / real
  Poses describing the movement of the scene under measurement between the previously processed profile image and the current profile image.

Result

The operator set_profile_sheet_of_light returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SheetOfLightModelID

set_sheet_of_light_param (: : SheetOfLightModelID, GenParamName, GenParamValue :)

Set selected parameters of the sheet-of-light model.

The operator set_sheet_of_light_param is used to set or change a single parameter of a sheet-of-light model in order to adapt the model to a particular measurement task. All parameters, except the internal camera parameters *'camera_parameters'* and the following poses *'camera_pose'*, *'lightplane_pose'*, and *'movement_pose'* can also be set while creating a sheet-of-light model with create_sheet_of_light_model. The current configuration of the sheet-of-light model can be queried with the operator get_sheet_of_light_param. A list with the names of all parameters that can be set for the sheet-of-light model is returned by query_sheet_of_light_params.

The following overview lists the different generic parameters with the respective value ranges and default values:

Measurement of the profiles:

'method': defines the method used to determine the position of the profile. The values *'default'* and *'center_of_gravity'* both refer to the same method, whereby the position of the profile is determined column

by column with subpixel accuracy by computing the center of gravity of the gray values g_i of all pixels fulfilling the condition:

$$g_i \geq 'min\_gray'$$

'min_gray': lowest gray values taken into account for the measurement of the position of the profile (see *'center_of_gravity'*).

Suggested values: 20, *50*, *100*, *128*, *200*, *220*, *250*

Default: 100

'num_profiles': number of profiles for which memory has been allocated within the sheet-of-light model. By default, *'num_profiles'* is set to 512. If this number of profiles is exceeded, memory will be reallocated automatically during the measurement.

Suggested values: 1, *2*, *50*, *100*, *512*, *1024*, *3000*

Default: 512

'ambiguity_solving': method applied to determine which candidate shall be chosen if the determination of the position of the profile is ambiguous.

'first': the first encountered candidate is returned. This method is the fastest.

'last': the last encountered candidate is returned.

'brightest': for each candidate, the brightness of the profile is computed and the candidate having the highest brightness is returned. The brightness is computed according to:

$$brightness = \frac{1}{n} \sum_{i=0}^{n} g_i \ ,$$

where g_i is the gray value of the pixel and n the number of pixels taken into consideration to determine the position of the profile.

Default: 'first'

'score_type': method used to calculate a score for the measurement of the position of the profile.

'none': no score is computed.

'width': for each pixel of the disparity, the score value is set to the number of pixels used to determine the disparity value.

'intensity': for each pixel of the disparity, a score value is evaluated by computing the local intensity of the profile according to:

$$score = \frac{1}{n} \sum_{i=0}^{n} g_i$$

where g_i is the gray value of the pixel and n the number of pixels taken into consideration to determine the position of the profile.

Default: 'none'

Calibration of the measurement:

'calibration': extent of the calibration transformation which shall be applied to the disparity image:

'none': no calibration transformation is applied.

'xz': the calibration transformations which describe the geometrical properties of the measurement system (camera and light line projector) are taken into account, but the movement of the object during the measurement is not taken into account.

'xyz': the calibration transformations which describe the geometrical properties of the measurement system (camera and light line projector) as well as the transformation which describe the movement of the object during the measurement are taken into account.

'offset_scale': a simplified set of parameters to describe the setup, that can be used with default parameters or can be controlled by six parameters. Three of the parameters describe an anisotropic scaling: *'scale_x'* describes the scaling of a pixel in column direction into the new x-axis, *'scale_y'* describes the linear movement between two profiles, and *'scale_z'* describes the scaling of to measured disparities into the new z-axis. The other three parameters describe the offset of the frame of reference of the resulting x,y,z values (*'offset_x'*, *'offset_y'*, *'offset_z'*).

Default: 'none'

'camera_parameter': the internal parameters of the camera used for the measurement. Those parameters are required if the calibration extent has been set to *'xz'* or *'xyz'*. If `calibrate_sheet_of_light` shall be used for calibration, this parameter is used to set the initial camera parameters.

'calibration_object': the calibration object used for calibration with `calibrate_sheet_of_light`. If `calibrate_sheet_of_light` shall be used for calibration, this parameter must be set to the filename of a calibration object created with `create_sheet_of_light_calib_object`.

'camera_pose': the pose that transforms the camera coordinate system into the world coordinate system, i.e., the pose that could be used to transform point coordinates from the world coordinate system into the camera coordinate system. This pose is required if the calibration extent has been set to *'xz'* or *'xyz'*.

Note that the world coordinate system is implicitly defined by setting the *'camera_pose'*.

'lightplane_pose': the pose that transforms the light plane coordinate system into the world coordinate system, i.e., the pose that could be used to transform point coordinates from the world coordinate system into the light plane coordinate system. The light plane coordinate system must be chosen such that the plane z=0 coincides with the light plane. This pose is required if the calibration extent has been set to *'xz'* or *'xyz'*.

'movement_pose': a pose representing the movement of the object between two successive profile images with respect to the measurement system built by the camera and the laser. This pose must be expressed in the world coordinate system. It is required if the calibration extent has been set to *'xyz'*.

'scale': with this value you can scale the 3D coordinates X, Y and Z that result when applying the calibration transformations to the disparity image. The model parameter *'scale'* must be specified as the ratio *desired unit/original unit*. The original unit is determined by the coordinates of the calibration object. If the original unit is meters (which is the case if you use the standard calibration plate), you can set *'scale'* to the desired unit directly by selecting *'m'*, *'cm'*, *'mm'*, *'microns'*, or *'um'*. This parameter can only be set if the calibration extent has been set to *'offset_scale'*, *'xz'* or *'xyz'*.

Suggested values: 'm', 'cm', 'mm', 'microns', 'um', 1.0, 0.01, 0.001, 1.0e-6

Default value: 1.0

'scale_x': This value defines the width of a pixel in the 3D space. This parameter can only be set if the calibration extent has been set to *'offset_scale'*.

Suggested values: 10.0, 1.0, 0.01, 0.001, 1.0e-6

Default value: 1.0

'scale_y': This value defines the linear movement between two profiles in the 3D space. This parameter can only be set if the calibration extent has been set to *'offset_scale'*.

Suggested values: 100.0, 10.0, 1.0, 0.1, 1.0e-6

Default value: 10.0

'scale_z': This value defines the height of a pixel in the 3D space. This parameter can only be set if the calibration extent has been set to *'offset_scale'*.

Suggested values: 10.0, 1.0, 0.01, 0.001, 1.0e-6

Default value: 1.0

'offset_x': This value defines the x offset of reference frame for 3D results. This parameter can only be set if the calibration extent has been set to *'offset_scale'*.

Suggested values: 10.0, 0.0, 0.01, 0.001, 1.0e-6

Default value: 0.0

'offset_y': This value defines the y offset of reference frame for xyz results. This parameter can only be set if the calibration extent has been set to *'offset_scale'*.

Suggested values: 10.0, 0.0, 0.01, 0.001, 1.0e-6

Default value: 0.0

'offset_z': This value defines the z offset of reference frame for 3D results. This parameter can only be set if the calibration extent has been set to *'offset_scale'*.

Suggested values: 10.0, 0.0, 0.01, 0.001, 1.0e-6

Default value: 0.0

Parameters

▷ **SheetOfLightModelID** (input_control) . . . . . sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Name of the model parameter that shall be adjusted for the sheet-of-light model.
Default: 'method'
List of values: GenParamName ∈ {'method', 'ambiguity_solving', 'score_type', 'num_profiles', 'min_gray', 'scale', 'calibration', 'calibration_object', 'camera_parameter', 'camera_pose', 'lightplane_pose', 'movement_pose', 'scale_x', 'scale_y', 'scale_z', 'offset_x', 'offset_y', 'offset_z'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Value of the model parameter that shall be adjusted for the sheet-of-light model.
Default: 'center_of_gravity'
Suggested values: GenParamValue ∈ {'default', 'center_of_gravity', 'last', 'first', 'brightest', 'none', 'intensity', 'width', 'xz', 'xyz', 'offset_scale', 'm', 'cm', 'mm', 'um', 'microns', 1.0, 1e-2, 1e-3, 1e-6}

Result

The operator set_sheet_of_light_param returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SheetOfLightModelID

write_sheet_of_light_model (: : SheetOfLightModelID, FileName :)

Write a sheet-of-light model to a file.

The operator write_sheet_of_light_model writes the sheet-of-light model SheetOfLightModelID to the file FileName. The model can be read again with read_sheet_of_light_model. The stored data contains all generic model parameters (see set_sheet_of_light_param) and the results of calibrate_sheet_of_light.

The default HALCON file extension for sheet-of-light model is 'solm'.

Parameters

▷ **SheetOfLightModelID** (input_control) . . . . . sheet_of_light_model ⇝ *handle*
Handle of the sheet-of-light model.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of the sheet-of-light model file.
Default: 'sheet_of_light_model.solm'
File extension: .solm

Result

The operator write_sheet_of_light_model returns the value 2 (H_MSG_TRUE) if the passed handle is valid and if the model can be written into the named file. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

5.6 Structured Light

This chapter describes the usage of structured light for 3D reconstruction.

Concept of Structured Light

The basic concept behind structured light is to use a structured illumination, i.e. an illumination showing well known patterns. The way those patterns appear in the scene after hitting surfaces helps to further analyze (e.g., perform an inspection Inspection / Structured Light) or reconstruct the surfaces.

For non-specular (lambertian or diffuse) surfaces, a 3D surface can be reconstructed using a projector projecting light like an 'inverse camera'. For every projected pattern image, a camera image of the projection on the surface is acquired. Using the decoded correspondence between projector coordinates lighting the camera coordinates, as well as calibration information, the 3D surface is reconstructed.

In the following, the steps that are required to use structured light are described briefly.

Create a structured light model: In the first step, a structured light model is created with

- create_structured_light_model (ModelType='3d_reconstruction')

or read with

- read_structured_light_model.

Set the model parameters: The different structured light model parameters can then be set with

- set_structured_light_model_param

or queried with

- get_structured_light_model_param.

The pattern parameters *'pattern_width'*, *'pattern_height'*, *'pattern_orientation'*, and *'pattern_type'* specify along with the stripe parameters *'min_stripe_width'* and *'single_stripe_width'* the specifications of the pattern images to be used to illuminate the surface. Finally, the *'persistence'* parameter can be enabled to debug intermediate results.

Generate the pattern images: The pattern images are to be generated with `gen_structured_light_pattern` after setting all relevant parameters. Please ensure that the output images are as needed in the particular setup.

Use the patterns to illuminate the surface and acquire the camera images: At this stage, the pattern images are projected. The respective image of the illuminated surface is acquired by the camera for each pattern image.

When calibrating the system, images of the illuminated calibration object need to be acquired. The calibration process is shown in detail in the example program `structured_light_calibration.hdev`. The obtained calibration information can then be specified with the parameter *'camera_setup_model'* of `set_structured_light_model_param`.

Decode the acquired images: The acquired `CameraImages` can be decoded with `decode_structured_light_pattern`. Upon calling this operator, the correspondence images are created and stored in the model `StructuredLightModel`.

Get the results: The decoded *'correspondence_image'*, as well as other results can be queried with `get_structured_light_object`. For more details of the different objects that can be queried, please refer to the operator's documentation.

Perform the reconstruction: The reconstructed surface can be obtained with `reconstruct_surface_structured_light`.

Further operators

The structured light model offers various other operators that help access and update the various parameters of the model.

The operator `write_structured_light_model` enables writing the structured light model to a file. Please note that previously generated pattern images are not written in this file. A structured light model file can be read using `read_structured_light_model`.

Furthermore, it is possible to serialize and deserialize the structured light model using `serialize_structured_light_model` and `deserialize_structured_light_model`.

Further Information

See also the "`Solution Guide Basics`" for further details. For a list of operators, please refer to Inspection / Structured Light.

Chapter 6

Calibration

This chapter provides information regarding camera calibration.

General Objectives

To achieve maximum accuracy of measurement for your camera setup, you have to calibrate it accordingly. Therefore, a camera model is determined, which describes the projection of a 3D world point into a (sub-)pixel in the image.

HALCON provides a wide range of operators to approach diverse tasks related to calibration, such as

- describing and finding a calibration object (Calibration / Calibration Object),
- the projection of points from the 3D scene onto the image plane and the other way around (Calibration / Projection, Calibration / Inverse Projection),
- compensating perspective and radial distortions (Calibration / Rectification),
- handling the camera parameters (Calibration / Camera Parameters),
- performing a self-calibration (Calibration / Self-Calibration), and
- calibrating different setups consisting of
  - one camera (Calibration / Monocular),
  - multiple cameras (Calibration / Binocular, Calibration / Multi-View), or
  - a camera in combination with a robot (Calibration / Hand-Eye).

This chapter gives guidance regarding the basic concept of retrieving the internal and external parameters of your camera. The following paragraphs state how to successfully calibrate a camera. In particular, they describe

- the needed calibration object,
- the individual steps to calibrate the cameras, including
  - how to prepare the calibration input data,
  - how to perform the actual calibration with `calibrate_cameras`, and
  - how to check the success of the calibration,
- the camera parameters,
- additional information about the calibration process, including
  - how to obtain an appropriate calibration plate,
  - how to take a set of suitable images, and
  - which distortion model to use,

- the available 3D camera models and how 3D points are transformed into the image coordinate system, and
- limitations related to specific camera types.

Calibration Object

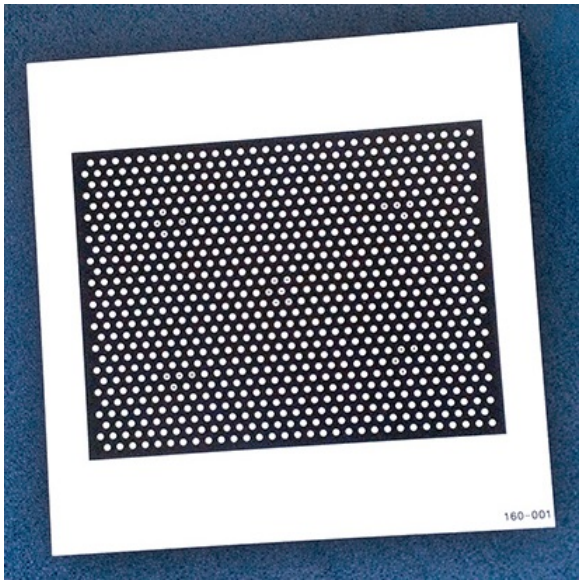
For a successful calibration of your camera setup, at least one calibration object with accurately known metric properties is needed, e.g., a HALCON calibration plate. For the calibration, take a series of images of the calibration object in different positions and orientations. The success of the calibration highly depends on the quality of the calibration object and the images. So you might want to exercise special diligence during the acquisition of the calibration images. See the section "How to take a set of suitable images?" for further information.

A calibration plate is covered by multiple calibration marks, which are extracted in the calibration images in order to retrieve their coordinates. The orientation of the plate has to be known distinctively, hence, a finder pattern is also part of the imprint.

Your distributor can provide you with two different types of standard HALCON calibration plates:

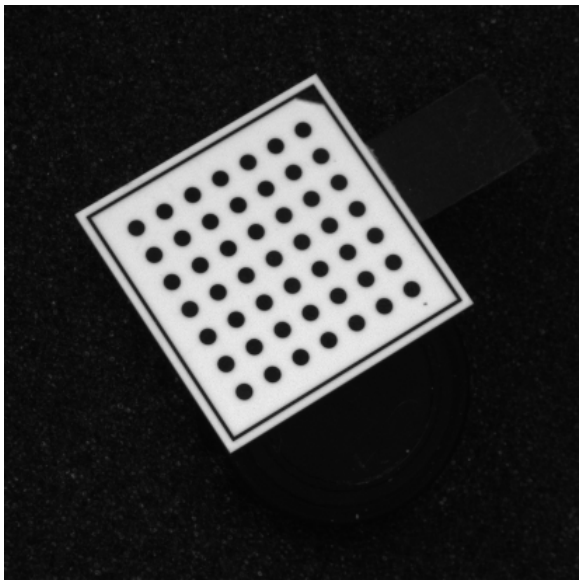
Calibration plate with hexagonally arranged marks: As finder pattern, there are special groups of mark hexagons where some of the marks contain dot-shaped holes (see `create_caltab`). One finder pattern has to be visible to locate the calibration plate. To make sure the plate is not inverted, at least a second one needs to be seen, but the plate does not have to be fully visible in the image. The origin of the coordinate system is located at the center of the central mark of the first finder pattern. The z-axis of the coordinate system is pointing into the calibration plate, its x-axis is pointing to the right, and its y-axis is pointing downwards with the direction of view along the z-axis.

When using `camera_calibration` instead of `calibrate_cameras`, this calibration plate is not applicable.



HALCON calibration plate with hexagonally arranged marks.

Calibration plate with rectangularly arranged marks: The finder pattern consists of the surrounding frame and the triangular corner marker (see `gen_caltab`). Thus, the plate has to be fully visible in the image. The origin is located in the middle of the surface of the calibration plate. The z-axis of the coordinate system is pointing into the calibration plate, its x-axis is pointing to the right, and its y-axis is pointing downwards with the direction of view along the z-axis.



HALCON calibration plate with rectangularly arranged marks.

When acquiring your calibration images, note that there are different recommendations on how to take them, depending on your used calibration plate (see section “How to take a set of suitable images?”).

Preparing the Calibration Input Data

Before calling a calibration operator (e.g., `calibrate_cameras`), you must create and adapt the calibration data model with the following steps:

1. **Create a calibration data model** with the operator `create_calib_data`, specifying the number of cameras in the setup and the number of used calibration objects.
2. **Specify the camera type and the initial internal camera parameters** with the operator `set_calib_data_cam_param`.
3. **Specify the description of all calibration objects** with the operator `set_calib_data_calib_object`.
4. **Collect observation data** with the operators `find_calib_object` or `set_calib_data_observ_points`, i.e., obtain the image coordinates of the extracted calibration marks of the calibration object and a roughly estimated pose of the calibration object relative to the observing camera.
5. **Configure the calibration process**, e.g., exclude certain camera parameters from the optimization. You can specify these parameters with the operator `set_calib_data`. For example, if the image sensor cell size of camera 0 is known precisely and only the rest of the parameters needs to be calibrated, you call

```
set_calib_data(CalibDataID, 'camera', 0, 'excluded_settings',
['sx','sy']).
```

Performing the Actual Camera Calibration and Obtaining its Results

Using all the information stored within the calibration data model, the actual calibration can be performed calling `calibrate_cameras`. Thereby, the input model is modified by optimizing the initial internal camera parameters, computing and adding further data like the external camera parameters or standard deviations. Furthermore, the standard deviations and covariances of the calibrated internal parameters and the root mean square error of the back projection are calculated in order to check the success of the calibration.

The results can then be queried with the operator `get_calib_data`.

Checking the Success of the Calibration

After a successful calibration, the root mean square error (RMSE) of the back projection of the optimization is returned in `Error` (in pixels). The error gives a general indication whether the optimization was successful as it corresponds to the average distance (in pixels) between the back projected calibration points and their extracted image coordinates.

If only a single camera is calibrated, an `Error` in the order of 0.1 pixel (the typical detection error by extraction of the coordinates of the projected calibration markers) is an indication that the optimization fits the observation data well. If `Error` strongly differs from 0.1 pixels, the calibration did not perform well. Reasons for this might be, e.g., a poor image quality, an insufficient number of calibration images, or an inaccurate calibration plate.

For information about how to check the success of the calibration using a multi-view camera setup, see the respective section in the chapter Calibration / Multi-View.

Camera Parameters

Regarding camera parameters, you can distinguish between internal and external camera parameters.

Internal camera parameters: These parameters describe the characteristics of the used camera, especially the dimension of the sensor itself and the projection properties of the used combination of lens, camera, and frame grabber. Below is an overview of all available camera types and their respective parameters `CameraParam`. In the list, "projective cameras" refers to the property that the lens performs a perspective projection on the object-side of the lens, while "telecentric cameras" refers to the property that the lens performs a telecentric projection on the object-side of the lens.

Area scan cameras have 9 to 16 internal parameters depending on the camera type.

For reasons explained below, parameters that are marked with an * asterisk are fixed and not estimated by the algorithm.

Area scan cameras with regular lenses

Projective area scan cameras with regular lenses

- *'area_scan_division'*:
  ['area_scan_division', Focus, Kappa, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_polynomial'*:
  ['area_scan_polynomial', Focus, K1, K2, K3, P1, P2, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*

Telecentric area scan cameras with regular lenses

- *'area_scan_telecentric_division'*:
  ['area_scan_telecentric_division', Magnification, Kappa, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_telecentric_polynomial'*:
  ['area_scan_telecentric_polynomial', Magnification, K1, K2, K3, P1, P2, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*

Area scan cameras with tilt lenses

Projective area scan cameras with tilt lenses

- *'area_scan_tilt_division'*:
  ['area_scan_tilt_division', Focus, Kappa, ImagePlaneDist, Tilt, Rot, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_tilt_polynomial'*:
  ['area_scan_tilt_polynomial', Focus, K1, K2, K3, P1, P2, ImagePlaneDist, Tilt, Rot, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_tilt_image_side_telecentric_division'*:
  ['area_scan_tilt_image_side_telecentric_division', Focus, Kappa, Tilt, Rot, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_tilt_image_side_telecentric_polynomial'*:
  ['area_scan_tilt_image_side_telecentric_polynomial', Focus, K1, K2, K3, P1, P2, Tilt, Rot, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight]*

Telecentric area scan cameras with tilt lenses

- *'area_scan_tilt_bilateral_telecentric_division'*:
  ['area_scan_tilt_bilateral_telecentric_division', Magnification, Kappa, Tilt, Rot, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight]*

- *'area_scan_tilt_bilateral_telecentric_polynomial'*:
  ['area_scan_tilt_bilateral_telecentric_polynomial', Magnification, K1, K2, K3, P1, P2, Tilt, Rot, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_tilt_object_side_telecentric_division'*:
  ['area_scan_tilt_object_side_telecentric_division', Magnification, Kappa, ImagePlaneDist, Tilt, Rot, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_tilt_object_side_telecentric_polynomial'*:
  ['area_scan_tilt_object_side_telecentric_polynomial', Magnification, K1, K2, K3, P1, P2, ImagePlaneDist, Tilt, Rot, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*

Area scan cameras with hypercentric lenses

Projective area scan cameras with hypercentric lenses

- *'area_scan_hypercentric_division'*:
  ['area_scan_hypercentric_division', Focus, Kappa, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*
- *'area_scan_hypercentric_polynomial'*:
  ['area_scan_hypercentric_polynomial', Focus, K1, K2, K3, P1, P2, Sx, Sy, Cx, Cy, ImageWidth, ImageHeight]*

Description of the internal camera parameters of area scan cameras:

CameraType: Type of the camera, as listed above.

Focus: Focal length of the lens (only for lenses that perform a perspective projection on the object side of the lens).
The initial value is the nominal focal length of the used lens, e.g., 0.008m.

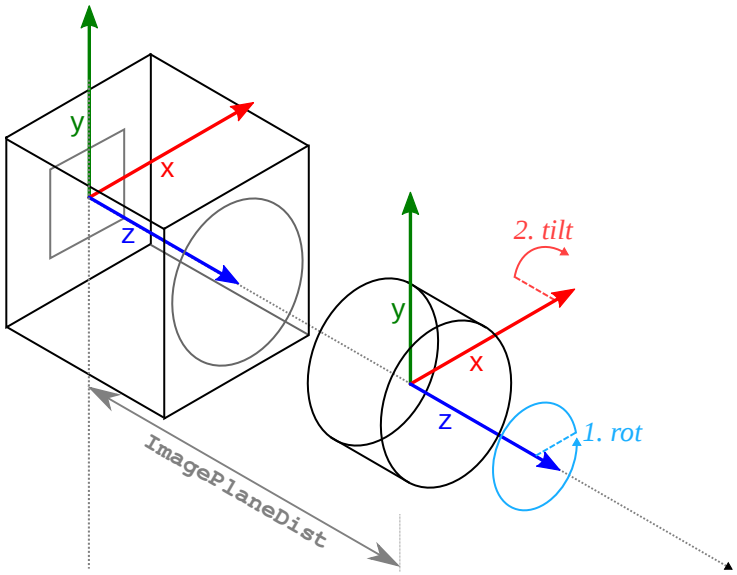
Magnification: Magnification of the lens (only for lenses that perform a telecentric projection on the object side of the lens).
The initial value is the nominal magnification of the used telecentric lens (the image size divided by the object size), e.g., 0.2.

Kappa (κ)**:** Distortion coefficient to model the radial lens distortions (only for the division model).
Use 0.0 m^{-2} as initial value.

K1, K2, K3, P1, P2: Distortion coefficients to model the radial (K_1, K_2, K_3) and decentering (P_1, P_2) lens distortions (only for the polynomial model).
Use 0.0 as initial value for all five coefficients.

ImagePlaneDist: Distance of the exit pupil of the lens to the image plane. The exit pupil is the (virtual) image of the aperture stop (typically the diaphragm), as viewed from the image side of the lens. Typical values are in the order of a few centimeters to very large values if the lens is close to being image-side telecentric.

Tilt, Rot: The tilt angle $tilt$ $(0° \leq tilt < 90°)$ describes the angle by which the optical axis is tilted with respect to the normal of the sensor plane (corresponds to a rotation around the x-axis). The rotation angle rot $(0° \leq rot < 360°)$ describes the rotation around the optical axis (z-axis). For a rotation $rot = 0°$ the optical axis gets tilted vertically down with respect to the camera housing, $rot = 90°$ corresponds to the optical axis being tilted horizontally to the left (direction of view along the z-axis), $rot = 180°$ corresponds to the optical axis being tilted vertically up, and $rot = 270°$ corresponds to the optical axis being tilted horizontally to the right by $tilt$.
These parameters are only used if a tilt lens is part of the camera setup.



The tilt of the lens is described by the parameters rot , $tilt$ and `ImagePlaneDist`. rot describes the orientation of the tilt axis in relation to the x-axis of the sensor and has to be applied first. $tilt$ describes the actual tilt of the lens. `ImagePlaneDist` is the distance of the exit pupil of the lens to the image plane.

These angles are typically roughly known based on the considerations that led to the use of the tilt lens or can be read off from the mechanism by which the lens is tilted.

Sx, Sy: Scale factors. They correspond to the horizontal and vertical distance between two neighboring cells on the sensor. Since in most cases the image signal is sampled line-synchronously, S_y is determined by the dimension of the sensor and does not need to be estimated by the calibration process.
The initial values depend on the dimensions of the used chip of the camera. See the technical specification of your camera for the actual values. Attention: These values increase if the image is subsampled!
As **projective cameras** are described through the pinhole camera model, it is impossible to determine `Focus`, S_x, and S_y simultaneously. Therefore, the algorithm will keep S_y fixed.
For **telecentric lenses**, it is impossible to determine `Magnification`, S_x, and S_y simultaneously. Therefore, the algorithm will keep S_y fixed.
For **image-side telecentric tilt lenses** (see chapter "Basics", section "Camera Model and Parameters" in the "`Solution Guide III-C 3D Vision`" for an overview of different types of tilt lenses), it is impossible to determine `Focus`, S_x, S_y, and the tilt parameters $tilt$ and rot simultaneously. Therefore, additionally to S_y, the algorithm will keep S_x fixed.
For **bilateral telecentric tilt lenses**, it is impossible to determine `Magnification`, S_x, S_y, and the tilt parameters $tilt$ and rot simultaneously. Therefore, additionally to S_y, the algorithm will keep S_x fixed.

Cx, Cy: Column (C_x) and row (C_y) coordinate of the principal point of the image (center of the radial distortion).
Use the half image width and height as initial values. Attention: These values decrease if the image is subsampled!

ImageWidth, Image Height: Width and height of the sampled image. Attention: These values decrease if the image is subsampled!

Line scan cameras have 12 or 16 internal parameters depending on the camera type.

For reasons explained below, parameters that are marked with an * asterisk are fixed and not estimated by the algorithm.

Line scan cameras with regular lenses

Projective line scan cameras with regular lenses

- *'line_scan_division'*:
  ['line_scan_division', Focus, Kappa, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight, Vx, Vy, Vz]*
- *'line_scan_polynomial'*:
  ['line_scan_polynomial', Focus, K1, K2, K3, P1, P2, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight, Vx, Vy, Vz]*

Telecentric line scan cameras with regular lenses

- *'line_scan_telecentric_division'*:
  ['line_scan_telecentric_division', Magnification, Kappa, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight, Vx, Vy, Vz*]*
- *'line_scan_telecentric_polynomial'*:
  ['line_scan_telecentric_polynomail', Magnification, K1, K2, K3, P1, P2, Sx, Sy*, Cx, Cy, ImageWidth, ImageHeight, Vx, Vy, Vz*]*

Description of the internal camera parameters of line scan cameras:

CameraType: Type of the camera, as listed above.

Focus: Focal length of the lens (only for lenses that perform a perspective projection on the object side of the lens).
The initial value is the nominal focal length of the used lens, e.g., 0.008m.

Magnification: Magnification of the lens (only for lenses that perform a telecentric projection on the object side of the lens).
The initial value is the nominal magnification of the used telecentric lens (the image size divided by the object size), e.g., 0.2.

Kappa (κ)**:** Distortion coefficient of the division model to model the radial lens distortions.
Use 0.0 m^{-2} as initial value.

K1, K2, K3, P1, P2: Distortion coefficients to model the radial (K_1, K_2, K_3) and decentering (P_1, P_2) lens distortions (only for the polynomial model).
Use 0.0 as initial value for all five coefficients.

Sx: Scale factor. Corresponds to the horizontal distance between two neighboring cells on the sensor. Note that `Focus` or `Magnification`, respectively, and S_x cannot be determined simultaneously. Therefore, S_x is kept fixed in the calibration. The initial value for S_x can be taken from the technical specifications of the camera. Attention: This value increases if the image is subsampled!

Sy: Scale factor. During the calibration, it appears only in the form $p_v = -S_y \cdot C_y$. Consequently, S_y and C_y cannot be determined simultaneously. Therefore, in the calibration, S_y is kept fixed. p_v describes the distance of the image center point from the sensor line in meters. The initial value for S_y can be taken from the technical specifications of the camera. Attention: This value increases if the image is subsampled!

Cx: Column coordinate of the image center point (center of the radial distortions). Use half of the image width as the initial value for C_x. Attention: This value decreases if the image is subsampled!

Cy: Distance of the image center point (center of the radial distortions) from the sensor line in scanlines. The initial value can normally be set to 0.

ImageWidth, ImageHeight: Width and height of the sampled image. Attention: These values decrease if the image is subsampled!

Vx, Vy, Vz: X-, Y-, and Z-component of the motion vector.
The initial values for the x-, y-, and z-component of the motion vector depend on the image acquisition setup. Assuming a camera that looks perpendicularly onto a conveyor belt and that is rotated around its optical axis such that the sensor line is perpendicular to the conveyor belt, i.e., the y-axis of the camera coordinate system is parallel to the conveyor belt, use the initial values $V_x = V_z = 0$. The initial value for V_y can then be determined, e.g., from a line scan image of an object with known size (e.g., calibration plate, ruler):

$$V_y = \frac{l[m]}{l[row]}$$

With

$$\begin{aligned} l[m] &= \text{Length of the object in object coordinates [meter]} \\ l[row] &= \text{Length of the object in image coordinates [rows]} \end{aligned}$$

If, compared to the above setup, the camera is rotated 30 degrees around its optical axis, i.e., around the z-axis of the camera coordinate system, the above determined initial values must be changed as follows:

$$\begin{aligned} V_x^z &= \sin(30^\circ)V_y \\ V_y^z &= \cos(30^\circ)V_y \\ V_z^z &= V_z = 0 \end{aligned}$$

If, compared to the first setup, the camera is rotated -20 degrees around the x-axis of the camera coordinate system, the following initial values result:

$$\begin{aligned} V_x^x &= V_x = 0 \\ V_y^x &= \cos(-20^\circ)V_y \\ V_z^x &= \sin(-20^\circ)V_y \end{aligned}$$

The quality of the initial values for V_x, V_y, and V_z are crucial for the success of the whole calibration. If they are not precise enough, the calibration may fail.
Note that for telecentric line scan cameras, the value of V_z has no influence on the image position of 3D points and therefore cannot be determined. Consequently, V_z is not optimized and left at its initial value for telecentric line scan cameras. Therefore, the initial value of V_z should be set to *0*. For setups with multiple telecentric line scan cameras that share a common motion vector (for a detailed explanation, see Calibration / Multi-View), however, V_z can be determined based on the camera poses. Therefore, in this case V_z is optimized.

Restrictions for internal camera parameters Note that the term *focal length* is not quite correct and would be appropriate only for an infinite object distance. To simplify matters, always the term *focal length* is used even if the *image distance* is meant.

For all operators that use camera parameters as input the respective parameter values are checked as to whether they fulfill the following restrictions:

$$\begin{aligned} S_x &> 0 \\ S_y &\geq 0 \\ Focus &> 0 \\ Magnification &> 0 \\ ImageWidth &> 0 \\ ImageHeight &> 0 \\ ImagePlaneDist &> 0 \\ 0 \leq tilt &< 90 \\ 0 \leq rot &< 360 \\ V_x^2 + V_y^2 + V_z^2 &\neq 0 \end{aligned}$$

For some operators the restrictions differ slightly. In particular, for operators that do not support line scan cameras the following restriction applies:

$$S_y > 0$$

External camera parameters: The following 6 parameters describe the 3D pose, i.e., the position and orientation of the world coordinate system relative to the camera coordinate system. The x- and y-axis of the camera coordinate system are parallel to the column and row axes of the image, while the z-axis is perpendicular to the image plane. For line scan cameras, the pose of the world coordinate system refers to the camera coordinate system of the first image line.

TransX: Translation along the x-axis of the camera coordinate system.

TransY: Translation along the y-axis of the camera coordinate system.

TransZ: Translation along the z-axis of the camera coordinate system.

RotX: Rotation around the x-axis of the camera coordinate system.

RotY: Rotation around the y-axis of the camera coordinate system.

RotZ: Rotation around the z-axis of the camera coordinate system.

The pose tuple contains one more element, which is the representation type of the pose. It codes the combination of the parameters `OrderOfTransform`, `OrderOfRotation`, and `ViewOfTransform`. See `create_pose` for more information about 3D poses.

When using a standard HALCON calibration plate, the world coordinate system is defined by the coordinate system of the calibration plate. See the section "Calibration Object" above for further information.

If a HALCON calibration plate is used, you can use the operator `find_calib_object` to determine initial values for all parameters. Using HALCON calibration plates with rectangularly arranged marks, a combination of the two operators `find_caltab` and `find_marks_and_pose` will have the same effect.

Parameter units: HALCON calibration plates use meters as unit. The camera parameters use corresponding units. Of course, calibration can be done using different units, but in this case the related parameters have to be adapted. Here, we list the HALCON default units for the different camera parameters:

	Parameter	**Unit**
External	RotX, RotY, RotZ	deg, deg, deg
	TransX, TransY, TransZ	m, m, m
Internal	Cx, Cy	px, px
	Focus	m
	ImagePlaneDist	m
	ImageWidth, ImageHeight	px, px
	K1, K2, K3	m^{-2}, m^{-4}, m^{-6}
	Kappa (κ)	m^{-2}
	P1, P2	m^{-1}, m^{-1}
	Magnification	- (scalar)
	Sx, Sy	m/px, m/px
	Tilt, Rot	deg, deg
	Vx, Vy, Vz	$m/scanline$, $m/scanline$, $m/scanline$

Additional Information about the Calibration Process

The use of `calibrate_cameras` leads to some questions, which are addressed in the following sections:

How to obtain an appropriate calibration plate? You can obtain high-precision calibration plates in various sizes and materials from your local distributor. These calibration plates come with associated description files and can be easily extracted with `find_calib_object`.

It is also possible to use any arbitrary object for calibration. The only requirement is that the object has characteristic points that can be robustly detected in the image and that the 3D world position of these points is known with high accuracy. See the "`Solution Guide III-C 3D Vision`" for details.

Self-printed calibration objects are usually not accurate enough for high-precision applications.

How to take a set of suitable images? With the combination of lens (fixed focus setting!), camera, and frame grabber to be calibrated, a set of images of the calibration plate must be taken (see `open_framegrabber` and `grab_image`).

Your local distributor can provide you with two different types of standard HALCON calibration plates: Calibration plates with hexagonally arranged marks (see `create_caltab`) and calibration plates with rectangularly arranged marks (see `gen_caltab`). Since these two calibration plates substantially differ from each other, in some cases additional particularities apply (see below).

The parameters and hints listed below should be considered when taking the calibration images. For a successful calibration, the setup and the used set of images should have certain qualities. These qualities may vary for the specific task and demand. In order to give guidance, values and hints suitable for a basic monocular camera setup are mentioned.

Regarding the camera setup:

- **Aperture**
  The aperture of the camera must not be changed during the acquisition of the images. If the aperture is changed after the calibration, the camera must be calibrated anew.
- **Camera pose**
  The position of the camera must not be changed during the image acquisition.
- **Focus**
  The calibration images should be sharply focused, i.e., transitions between objects should be clearly delimited. The focus, respectively the focal length, must not be changed during the image acquisition.

Regarding the placement of the calibration plates:

- **Field of view coverage and orientation**
  Within the set of calibration images, every part of the field of view should be covered by the plate at least once. The calibration plate may also fill the entire image. The orientation of the plate should vary within the set of images.
- **Tilt angles**
  The set of calibration images should also contain images with tilted calibration plates. Thereby the plate should be tilted in different directions at an angle of about 30-45°. Note, that if the recommended angle cannot be realized due to, e.g., limited depth of field, you should at least tilt your plate as steeply as possible with your setup.
- **Number of images/ calibration plate poses**
  - Plate with hexagonally arranged marks: At least 6 images (Not all, but at least 4 of them with tilted calibration plates).
  - Plate with rectangularly arranged marks: At least 15 images.

  Nevertheless, you must make sure that the poses of the calibration plates also fulfill the other requirements.
- **Inverted acquisition of the calibration plate**
  The calibration marks must not be acquired inverted. This can, e.g., happen if a calibration plate made of glass is acquired from its backside or if a line scan camera is not moving downwards with respect to the image coordinate system (i.e., V_y is negative).

Regarding image properties and content:

- **Pattern coverage**
  How much of the calibration pattern must at least be contained in the images depends on the used plate.
  - Plate with hexagonally arranged marks: At least one finder pattern needs to be visible. If at least two finder patterns are visible in the image, it is possible to detect whether the calibration plate is mirrored or not. In a mirrored case, a suitable error will be returned.
  - Plate with rectangularly arranged marks: Plate needs to be completely visible, as the finder pattern is the frame surrounding the point marks.

  Nevertheless, of course, the more of the calibration pattern is visible to the camera and the more of the field of view is filled by the calibration plate, the better.
- **Mark diameter**
  The marks of the calibration plates should have a diameter of at least 20 pixels in each image. This requirement is essential for a successful calibration.
- **Contrast**
  The contrast between the light and dark areas of the calibration plate should be at least 100 gray values (regarding byte images).

- **Overexposure**
  To avoid overexposed images, make sure that gray values of the light parts of the calibration plate do not exceed 240 (regarding byte images), especially not in the neighborhood of the calibration marks.
- **Homogeneity**
  The calibration plate should be illuminated homogeneously and reflections should be avoided. As a rule of thumb, the range of gray values of the light parts of the plate should not exceed 45 (regarding byte images).

Regarding image format and preprocessing:

- **Image format**
  Calibration images should be saved in an uncompressed format. Compression artifacts which occur, e.g., when using JPG format and high compression rates need to be avoided.
- **Preprocessing**
  Calibration images should not be preprocessed. If image properties like contrast or focus are insufficient (see above), the issues need to be resolved by adjusting the camera setup instead of processing the images ahead of the calibration.

Which distortion model should be used? Two distortion models can be used: The division model and the polynomial model. The division model uses one parameter to model the radial distortions while the polynomial model uses five parameters to model radial and decentering distortions (see the sections "Camera parameters" and "The Used 3D camera model").

The advantages of the division model are that the distortions can be applied faster, especially the inverse distortions, i.e., if world coordinates are projected into the image plane. Furthermore, if only few calibration images are used or if the field of view is not covered sufficiently, the division model typically yields more stable results than the polynomial model. The main advantage of the polynomial model is that it can model the distortions more accurately because it uses higher order terms to model the radial distortions and because it also models the decentering distortions. Note that the polynomial model cannot be inverted analytically. Therefore, the inverse distortions must be calculated iteratively, which is slower than the calculation of the inverse distortions with the (analytically invertible) division model.

Typically, the division model should be used for the calibration. If the accuracy of the calibration is not high enough, the polynomial model can be used. Note, however, that the calibration sequence used for the polynomial model must provide an even better coverage of the area in which measurements will later be performed. The distortions may be modeled inaccurately outside of the area that was covered by the calibration plate. This holds for the image border as well as for areas inside the field of view that were not covered by the calibration plate.

The Used 3D Camera Model

In general, camera calibration means the exact determination of the parameters that model the (optical) projection of any 3D world point $\mathbf{p}^w$ into a (sub-)pixel (r, c) in the image. This is important if the original 3D pose of an object must be computed from the image (e.g., for measuring industrial parts). The appropriate projection model depends on the camera type used in your setup.

For the modeling of this projection process, which is determined by the used combination of camera, lens, and frame grabber, HALCON provides the following 3D camera models:

Area scan pinhole camera: The combination of an area scan camera with a lens that effects a perspective projection on the object side of the lens and that may show radial and decentering distortions. The lens may be a tilt lens, i.e., the optical axis of the lens may be tilted with respect to the camera's sensor (this is sometimes called a Scheimpflug lens). Since hypercentric lenses also perform a perspective projection, cameras with hypercentric lenses are pinhole cameras. The models for regular (i.e., non-tilt) pinhole and image-side telecentric lenses are identical. In contrast, the models for pinhole and image-side telecentric tilt lenses differ substantially, as described below.

Area scan telecentric camera: The combination of an area scan camera with a lens that is telecentric on the object-side of the lens, i.e., that effects a parallel projection on the object-side of the lens, and that may show radial and decentering distortions. The lens may be a tilt lens. The models for regular (i.e., non-tilt) bilateral and object-side telecentric lenses are identical. In contrast, the models for bilateral and object-side telecentric tilt lenses differ substantially, as described below.

Line scan pinhole camera: The combination of a line scan camera with a lens that effects a perspective projection and that may show radial distortions. Tilt lenses are currently not supported for line scan cameras.

Line scan telecentric camera: The combination of a line scan camera with a lens that effects a telecentric projection and that may show radial distortions. Tilt lenses are currently not supported for line scan cameras.

To transform a 3D point $\mathbf{p}^w = (\mathbf{x}^w, \mathbf{y}^w, \mathbf{z}^w)^T$ which is given in world coordinates, into a 2D point $\mathbf{q}^i = (\mathbf{r}, \mathbf{c})^T$, which is given in pixel coordinates, a chain of transformations is needed:

$$\mathbf{p}^w \rightarrow \mathbf{p}^c \rightarrow \mathbf{q}^c \rightarrow \tilde{\mathbf{q}}^c \left[\rightarrow \mathbf{q}^t\right] \rightarrow \mathbf{q}^i$$

$\mathbf{p}^w$	3D world point
$\mathbf{p}^c$	Transformed into camera coordinate system
$\mathbf{q}^c$	Projected into image plane (2D point, still in metric coordinates)
$\tilde{\mathbf{q}}^c$	Lens distortion applied
$\mathbf{q}^t$	If a tilted lens is used, the point $\tilde{\mathbf{q}}^c$ is projected on the point $\mathbf{q}^t$ in the tilted image plane. In this case the distorted point $\tilde{\mathbf{q}}^c$ only lies on a virtual image plane of a system without tilt.
$\mathbf{q}^i$	Pixel coordinates

The following paragraphs describe these steps in more detail for area scan cameras and subsequently for line scan cameras. For a even more detailed description of the different 3D camera models as well as some explanatory diagrams please refer to the chapter "Basics", section "Camera Model and Parameters" in the "`Solution Guide III-C 3D Vision`".

Transformation step 1: $\mathbf{p}^w \rightarrow \mathbf{p}^c$ The point $\mathbf{p}^w$ is transformed from world into camera coordinates (points as homogeneous vectors, compare `affine_trans_point_3d`) by :

$$\begin{pmatrix} \mathbf{p}^c \\ 1 \end{pmatrix} = \begin{pmatrix} x^c \\ y^c \\ z^c \\ 1 \end{pmatrix} = \begin{bmatrix} \mathbf{R} & \mathbf{T} \\ 0\,0\,0 & 1 \end{bmatrix} \cdot \begin{pmatrix} \mathbf{p}^w \\ 1 \end{pmatrix}$$

with $\mathbf{R}$ and $\mathbf{T}$ being the rotation and translation matrices (refer to the chapter "Basics", section "3D Transformations and Poses'" in the "`Solution Guide III-C 3D Vision`" for detailed information).

Transformation step 2: $\mathbf{p}^c \rightarrow \mathbf{q}^c$ If the underlying camera model is an **area scan pinhole camera**, the projection of $\mathbf{p}^c = (\mathbf{x}^c, \mathbf{y}^c, \mathbf{z}^c)^T$ into the image plane is described by the following equation:

$$\mathbf{q}^c = \begin{pmatrix} u \\ v \end{pmatrix} = \frac{f}{\mathbf{z}^c} \begin{pmatrix} \mathbf{x}^c \\ \mathbf{y}^c \end{pmatrix}$$

where $f =$ `Focus`. For cameras with hypercentric lenses, the following equation holds instead:

$$\mathbf{q}^c = \begin{pmatrix} u \\ v \end{pmatrix} = \frac{-f}{\mathbf{z}^c} \begin{pmatrix} \mathbf{x}^c \\ \mathbf{y}^c \end{pmatrix}$$

If an **area scan telecentric camera** is used, the corresponding equation is:

$$\mathbf{q}^c = \begin{pmatrix} u \\ v \end{pmatrix} = m \begin{pmatrix} \mathbf{x}^c \\ \mathbf{y}^c \end{pmatrix}$$

where $m =$ `Magnification`.

Transformation step 3: $\mathbf{q}^c \rightarrow \tilde{\mathbf{q}}^c$ For all types of cameras, the lens distortions can be modeled either by the division model or by the polynomial model.

The **division model** uses one parameter `Kappa` to model the radial distortions.

The following equations transform the distorted image plane coordinates into undistorted image plane coordinates if the division model is used:

$$\begin{pmatrix} u \\ v \end{pmatrix} = \frac{1}{1+\kappa(\tilde{u}^2+\tilde{v}^2)} \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix}$$

These equations can be inverted analytically, which leads to the following equations that transform undistorted coordinates into distorted coordinates:

$$\tilde{\mathbf{q}}^c = \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \frac{2}{1+\sqrt{1-4\kappa(u^2+v^2)}} \begin{pmatrix} u \\ v \end{pmatrix}$$

The **polynomial model** uses three parameters (K_1, K_2, K_3) to model the radial distortions and two parameters (P_1, P_2) to model the decentering distortions.

The following equations transform the distorted image plane coordinates into undistorted image plane coordinates if the polynomial model is used:

$$\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} \tilde{u}+\tilde{u}(K_1r^2+K_2r^4+K_3r^6)+P_1(r^2+2\tilde{u}^2)+2P_2\tilde{u}\tilde{v} \\ \tilde{v}+\tilde{v}(K_1r^2+K_2r^4+K_3r^6)+2P_1\tilde{u}\tilde{v}+P_2(r^2+2\tilde{v}^2) \end{pmatrix}$$

with $r = \sqrt{\tilde{u}^2+\tilde{v}^2}$

These equations cannot be inverted analytically. Therefore, distorted image plane coordinates must be calculated from undistorted image plane coordinates numerically.

Additional transformation step for tilt lenses: $\tilde{\mathbf{q}}^c \rightarrow \mathbf{q}^t$ If the camera lens is a **tilt lens**, the tilt of the lens with respect to the image plane is described by the rotation angle rot and the tilt angle $tilt$.

In this step you have to further distinguish between different types of tilt lenses as described below. See chapter "Basics", section "Camera Model and Parameters" in the "`Solution Guide III-C 3D Vision`" for an overview of different types of tilt lenses.

For **projective tilt lenses** and **object-side telecentric tilt lenses** (which perform a perspective projection on the image side of the lens) the projection of $\tilde{\mathbf{q}}^c = (\tilde{u}, \tilde{v})^T$ into the point $\mathbf{q}^t = (\hat{u}, \hat{v})^T$, which lies in the tilted image plane, is described by a projective 2D transformation, i.e., by the homogeneous 3×3 matrix $\mathbf{H}$ (see `projective_trans_point_2d`):

$$\begin{pmatrix} \mathbf{q}^t \\ q_w^t \end{pmatrix} = \mathbf{H} \cdot \begin{pmatrix} \tilde{\mathbf{q}}^c \\ 1 \end{pmatrix}$$

where q_w^t is the additional coordinate from the projective transformation of a homogeneous point.

$$\mathbf{H} = \begin{pmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \\ h_{31} & h_{32} & h_{33} \end{pmatrix} = \begin{pmatrix} q_{11}q_{33}-q_{13}q_{31} & q_{21}q_{33}-q_{23}q_{31} & 0 \\ q_{12}q_{33}-q_{13}q_{32} & q_{22}q_{33}-q_{23}q_{32} & 0 \\ q_{13}/d & q_{23}/d & q_{33} \end{pmatrix}$$

where $d =$ `ImagePlaneDist` and

$$\begin{aligned} \mathbf{Q} &= \begin{pmatrix} q_{11} & q_{12} & q_{13} \\ q_{21} & q_{22} & q_{23} \\ q_{31} & q_{32} & q_{33} \end{pmatrix} \\ &= \begin{pmatrix} (\cos\rho)^2(1-\cos\tau)+\cos\tau & \cos\rho\sin\rho(1-\cos\tau) & \sin\rho\sin\tau \\ \cos\rho\sin\rho(1-\cos\tau) & (\sin\rho)^2(1-\cos\tau)+\cos\tau & -\cos\rho\sin\tau \\ -\sin\rho\sin\tau & \cos\rho\sin\tau & \cos\tau \end{pmatrix} \end{aligned}$$

with $\rho = rot$ and $\tau = tilt$.

For **image-side telecentric tilt lenses** and **bilateral telecentric tilt lenses** (which perform a parallel projection on the image side of the lens), the projection onto the tilted image plane is described by a linear 2D transformation, i.e., by a 2×2 matrix:

$$\mathbf{H} = \begin{pmatrix} h_{11} & h_{12} \\ h_{21} & h_{22} \end{pmatrix} = \frac{1}{q_{11}q_{22} - q_{12}q_{21}} \begin{pmatrix} q_{22} & -q_{12} \\ -q_{21} & q_{11} \end{pmatrix}$$

where $\mathbf{Q}$ is defined as above for projective lenses.

Transformation step 4: $\mathbf{q}^t \rightarrow \mathbf{q}^i$ / $\tilde{\mathbf{q}}^c \rightarrow \mathbf{q}^i$ Finally, the point $\tilde{\mathbf{q}}^c = (\tilde{u}, \tilde{v})^T$ (or $\mathbf{q}^t$ if a tilt lens is present) is transformed from the image plane coordinate system into the image coordinate system (the pixel coordinate system):

$$\mathbf{q}^i = \begin{pmatrix} r \\ c \end{pmatrix} = \begin{pmatrix} \frac{\tilde{v}}{S_y} + C_y \\ \frac{\tilde{u}}{S_x} + C_x \end{pmatrix}$$

For **line scan cameras**, also the relative motion between the camera and the object must be modeled. In HALCON, the following assumptions for this motion are made:

1. The camera moves with constant velocity along a straight line.
2. The orientation of the camera is constant.
3. The motion is equal for all images.

The motion is described by the motion vector $V = (V_x, V_y, V_z)^T$ that must be given in [meter/row] in the camera coordinate system. The motion vector describes the motion of the camera, assuming a fixed object. In fact, this is equivalent to the assumption of a fixed camera with the object traveling along $-V$.

The camera coordinate system of line scan cameras is defined as follows: The origin of the coordinate system is the center of projection (for pinhole cameras) or the center of distortion (for telecentric cameras), respectively. The z-axis is identical to the optical axis and directed so that the visible points have positive z coordinates. The y-axis is perpendicular to the sensor line and to the z-axis. It is directed so that the motion vector has a positive y-component. The x-axis is perpendicular to the y- and z-axis, so that the x-, y-, and z-axis form a right-handed coordinate system.

As the camera moves over the object during the image acquisition, also the camera coordinate system moves relatively to the object, i.e., each image line has been imaged from a different position. This means there would be an individual pose for each image line. To make things easier, in HALCON all transformations from world coordinates into camera coordinates and vice versa are based on the pose of the first image line only. The motion V is taken into account during the projection of the point $\mathbf{p}^c$ into the image. Consequently, only the pose of the first image line is computed by the operator `find_calib_object` (and stored by `calibrate_cameras` in the calibration results).

For **line scan cameras**, the transformation from world to camera coordinates ($\mathbf{p}^w \rightarrow \mathbf{p}^c$) works in the same way. Therefore, you can also apply transformation step 1 as described for area scan cameras above.

For **line scan pinhole cameras**, the projection of the point $\mathbf{p}^c$ that is given in the camera coordinate system into (sub-)pixel coordinates (r, c) in the image is modeled as follows:

Assuming

$$\mathbf{p}^c = \begin{pmatrix} x \\ y \\ z \end{pmatrix},$$

the following set of equations must be solved for m, $\tilde{u}$, and t:

$$\begin{aligned} m \cdot u(\tilde{u}, p_v) &= x - t \cdot V_x \\ m \cdot v(\tilde{u}, p_v) &= y - t \cdot V_y \\ m \cdot \text{Focus} &= z - t \cdot V_z \end{aligned}$$

were $u(\tilde{u}, \tilde{v})$ and $v(\tilde{u}, \tilde{v})$ are the undistortion functions that are described above for area scan cameras and $p_v = -S_y \cdot C_y$.

For **line scan telecentric cameras**, the following set of equations must be solved for $\tilde{u}$ and t:

$$\begin{aligned} u(\tilde{u}, p_v)/\text{Magnification} &= x - t \cdot V_x \\ v(\tilde{u}, p_v)/\text{Magnification} &= y - t \cdot V_y \end{aligned}$$

with $u(\tilde{u}, \tilde{v})$, $v(\tilde{u}, \tilde{v})$ and p_v as defined above. Note that neither z nor V_z influence the projection for telecentric cameras.

The above formulas already include the compensation for image distortions.

Finally, the point is transformed into the image coordinate system, i.e., the pixel coordinate system:

$$\mathbf{q}^i = \begin{pmatrix} r \\ c \end{pmatrix} = \begin{pmatrix} t \\ \frac{\tilde{u}}{S_x} + C_x \end{pmatrix}.$$

Further Limitations Related to Specific Camera Types

For **pinhole cameras**, if the calibration plates are parallel to each other in all images (in particular, if they all lie in the same plane), it is impossible to determine `Focus` together with all six of the external camera parameters. For example, it is impossible to determine `Focus` and the distance of the calibration plates to the camera in this case. To be able to calibrate all camera parameters uniquely, make sure that you acquire images of the calibration plate tilted in different orientations.

For **telecentric lenses**, the distance of the calibration plate from the camera cannot be determined. Therefore, the z-component of the resulting calibration plate pose is set to 1 m in the calibration results. Furthermore, as described previously, for telecentric line scan cameras, V_z cannot be determined and is left at its initial value, except for multi-camera setups that have a common motion vector, in which case V_z can be determined.

For **tilt lenses**, the greater the lens distortion is, the more accurately the tilt can be determined. For lenses with small distortions, the tilt cannot be determined robustly. Therefore, the optimized tilt parameters may differ significantly from the nominal tilt parameters of the setup. If this is the case, please check `Error`. If `Error` is small, the resulting camera parameters describe the imaging geometry consistently within the calibrated volume and can be used for accurate measurements.

For **perspective tilt lenses** and **object-side telecentric tilt lenses**, the image plane distance can only be determined uniquely if the tilt is not 0 degrees. The smaller the tilt, the less accurately the image plane distance can be determined. Therefore, the optimized image plane distance may differ significantly from the nominal image plane distance of the setup. If this is the case, please check `Error`. If `Error` is small, the resulting camera parameters describe the imaging geometry consistently within the calibrated volume and can be used for accurate measurements.

For **perspective tilt lenses** and **object-side telecentric tilt lenses** that are tilted around the horizontal or vertical axis, i.e., for which the rotation angle is 0, 90, 180, or 270 degrees, the tilt angle $tilt$, scale factor S_x, the focal length f (for perspective tilt lenses) or the magnification m (for object-side telecentric tilt lenses), and the distance of the tilted image plane from the perspective projection center d cannot be determined uniquely. In this case, S_x should be excluded from the optimization by calling

```
set_calib_data(CalibDataID, 'camera', 'general', 'excluded_settings', 'sx').
```

Additionally, note that for tilt lenses it is only possible to determine $tilt$ and rot simultaneously. This is an implementation choice that makes the optimization numerically more robust. Consequently, the parameters $tilt$ and rot are excluded simultaneously from the optimization by calling

`set_calib_data(CalibDataID, 'camera', 'general', 'excluded_settings', 'tilt')`.

Pinhole cameras with tilt lenses with large focal lengths have nearly telecentric projection characteristics. Therefore, as described before, S_x and the tilt parameters $tilt$ and rot are correlated and can only be determined imprecisely simultaneously. In this case, it is again advisable to exclude S_x from the optimization.

For telecentric lenses, there are always two possible poses of a calibration plate for a single image. Therefore, it is not possible to decide which one of the two poses is actually present in the image. This ambiguity also effects the tilt parameters $tilt$ and rot of a telecentric tilt lens. Consequently, depending on the initial parameters for $tilt$ and rot the camera calibration may return the alternative parameters instead of the nominal ones. If this is the case, please check `Error`. If `Error` is small, the resulting camera parameters describe the imaging geometry consistently within the calibrated volume and can be used for accurate measurements.

For **line scan cameras with the polynomial distortion model** (for cameras with perspective as well as telecentric lenses), the parameters P_1 and P_2 are highly correlated with other parameters in the camera model. Therefore, they typically cannot be determined reliably and should be excluded from the calibration by calling

`set_calib_data(CalibDataID, 'camera', 'general', 'excluded_settings', 'poly_tan_2')`.

6.1 Binocular

binocular_calibration (: : NX, NY, NZ, NRow1, NCol1, NRow2, NCol2, StartCamParam1, StartCamParam2, NStartPose1, NStartPose2, EstimateParams : CamParam1, CamParam2, NFinalPose1, NFinalPose2, RelPose, Errors)

Determine all camera parameters of a binocular stereo system.

In general, binocular calibration means the exact determination of the parameters that model the 3D reconstruction of a 3D point from the corresponding images of this point in a binocular stereo system. This reconstruction is specified by the internal parameters `CamParam1` of camera 1 and `CamParam2` of camera 2 describing the underlying camera model, and the external parameters `RelPose` describing the relative pose of camera system 2 in relation to camera system 1.

Thus, known 3D model points (with coordinates `NX`, `NY`, `NZ`) are projected in the image planes of both cameras (camera 1 and camera 2) and the sum of the squared distances between these projections and the corresponding measured image points (with coordinates `NRow1`, `NCol1` for camera 1 and `NRow2`, `NCol2` for camera 2) is minimized. It should be noted that all these model points must be visible in both images. The used camera model is described in Calibration. The camera model is represented (for each camera separately) by a tuple of 9 to 16 parameters that correspond to perspective or telecentric area scan or telecentric line scan cameras (see Calibration). The projection uses the initial values `StartCamParam1` and `StartCamParam2` of the internal parameters of camera 1 and camera 2, which can be obtained from the camera data sheets. In addition, the initial guesses `NStartPose1` and `NStartPose2` of the poses of the 3D calibration model in relative to the camera coordinate systems (*ccs*) of camera 1 and camera 2 are needed as well. These poses are expected in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *wcs* denotes the world coordinate system (see Transformations / Poses and "`Solution Guide III-C - 3D Vision`"). They can be determined by the operator `find_marks_and_pose`. Since this calibration algorithm simultaneously handles correspondences between measured image and known model points from different image pairs, poses (`NStartPose1`,`NStartPose2`), and measured points (`NRow1`,`NCol1`,`NRow2`, `NCol2`) must be passed concatenated in a corresponding order.

The input parameter `EstimateParams` is used to select the parameters to be estimated. Usually this parameter is set to *'all'*, i.e., all external camera parameters (translation and rotation) and all internal camera parameters are determined. Otherwise, `EstimateParams` contains a tuple of strings indicating the combination of parameters to estimate. For instance, if the internal camera parameters already have been determined (e.g., by previous calls to `binocular_calibration`), it is often desired to only determine relative the pose of the two cameras to each other (`RelPose`). In this case, `EstimateParams` can be set to *'pose_rel'*. The internal parameters can be

subsumed by the parameter values *'cam_param1'* and *'cam_param2'* as well. Note that if the polynomial model is used to model the lens distortions, the values *'k1_i'*, *'k2_i'* and *'k3_i'* can be specified individually, whereas *'p1'* and *'p2'* can only be specified in the group *'poly_tan_2_i'* (with *'i'* indicating the index of the camera). *'poly_i'* specifies the group *'k1_i'*, *'k2_i'*, *'k3_i'* and *'poly_tan_2_i'*.

The following list contains all possible strings that can be passed to the tuple:

Allowed strings for `EstimateParams`	*Determined parameters*
'all' (default)	All internal camera parameters, as well as the relative pose of both cameras and the poses of the calibration objects.
'pose'	Relative pose between the two cameras and poses of the calibration objects.
'pose_rel'	Relative pose between the two cameras.
'alpha_rel', *'beta_rel'*, *'gamma_rel'*, *'transx_rel'*, *'transy_rel'*, *'transz_rel'*	Rotation angles and translation parameters of the relative pose between the two cameras.
'pose_caltabs'	Poses of the calibration objects.
'alpha_caltabs', *'beta_caltabs'*, *'gamma_caltabs'*, *'transx_caltabs'*, *'transy_caltabs'*, *'transz_caltabs'*	Rotation angles and translation parameters of the relative poses of the calibration objects.
'cam_param1', *'cam_param2'*	All internal camera parameters of camera 1 and camera 2, respectively.
'focus1', *'magnification1'*, *'kappa1'*, *'poly_1'*, *'k1_1'*, *'k2_1'*, *'k3_1'*, *'poly_tan_2_1'*, *'image_plane_dist1'*, *'tilt1'*, *'cx1'*, *'cy1'*, *'sx1'*, *'sy1'*, *'focus2'*, *'magnification2'*, *'kappa2'*, *'poly_2'*, *'k1_2'*, *'k2_2'*, *'k3_2'*, *'poly_tan_2_2'*, *'image_plane_dist2'*, *'tilt2'*, *'cx2'*, *'cy2'*, *'sx2'*, *'sy2'*	Individual internal camera parameters of camera 1 and camera 2, respectively.
'common_motion_vector'	Determines whether two line scan cameras have a common motion vector. This is the case if the two cameras are mounted rigidly and the object is moved linearly in front of the cameras or if the two rigidly mounted cameras are moved by the same linear actuator. This is assumed to be the default. Therefore, you only need to set '~common_motion_vector' if the cameras are moving independently in different directions.

In addition, parameters can be excluded from estimation by using the prefix '~'. For example, the values *['pose_rel','~transx_rel']* have the same effect as *['alpha_rel','beta_rel','gamma_rel','transy_rel','transz_rel']*. On the other hand, *['all','~focus1']* determines all internal and external parameters except the focus of camera 1, for instance. The prefix '~' can be used with all parameter values except *'all'*.

The underlying camera model is explained in the chapter Calibration. The calibrated internal camera parameters are returned in `CamParam1` for camera 1 and in `CamParam2` for camera 2.

The external parameters are returned analogously to `camera_calibration`, the 3D transformation poses of the calibration model to the respective camera coordinate system (*ccs*) are returned in `NFinalPose1` and `NFinalPose2`. Thus, the poses are in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *wcs* denotes the world coordinate system of the 3D calibration model (see Transformations / Poses and "`Solution Guide III-C - 3D Vision`"). The relative pose ${}^{ccs1}\mathbf{P}_{ccs2}$, `RelPose`, specifies the transformation of points in *ccs2* into *ccs1*. Therewith, the final poses are related with each other (neglecting differences due to the balancing effects of the multi image calibration) by:

HomMat3D_NFinalPose2 = INV(HomMat3D_RelPose) * HomMat3D_NFinalPose1,

where HomMat3D_* denotes a homogeneous transformation matrix of the respective poses and INV() inverts a homogeneous matrix.

The computed average errors returned in `Errors` give an impression of the accuracy of the calibration. Using the determined camera parameters, they denote the average euclidean distance between the projection of the mark centers to their extracted image coordinates.

For cameras with telecentric lenses, additional conditions must be fulfilled for the setup. They can be found in the chapter Calibration.

Attention

Stereo setups that contain cameras with and without hypercentric lenses at the same time are not supported. Furthermore, stereo setups that contain area scan and line scan cameras at the same time are not supported.

Parameters

- ▷ **NX** (input_control) . . . . . number-array ⇝ *real* / integer
  Ordered Tuple with all X-coordinates of the calibration marks (in meters).
- ▷ **NY** (input_control) . . . . . number-array ⇝ *real* / integer
  Ordered Tuple with all Y-coordinates of the calibration marks (in meters).
  Number of elements: NY == NX
- ▷ **NZ** (input_control) . . . . . number-array ⇝ *real* / integer
  Ordered Tuple with all Z-coordinates of the calibration marks (in meters).
  Number of elements: NZ == NX
- ▷ **NRow1** (input_control) . . . . . number-array ⇝ *real* / integer
  Ordered Tuple with all row-coordinates of the extracted calibration marks of camera 1 (in pixels).
- ▷ **NCol1** (input_control) . . . . . number-array ⇝ *real* / integer
  Ordered Tuple with all column-coordinates of the extracted calibration marks of camera 1 (in pixels).
  Number of elements: NCol1 == NRow1
- ▷ **NRow2** (input_control) . . . . . number-array ⇝ *real* / integer
  Ordered Tuple with all row-coordinates of the extracted calibration marks of camera 2 (in pixels).
  Number of elements: NRow2 == NRow1
- ▷ **NCol2** (input_control) . . . . . number-array ⇝ *real* / integer
  Ordered Tuple with all column-coordinates of the extracted calibration marks of camera 2 (in pixels).
  Number of elements: NCol2 == NRow1
- ▷ **StartCamParam1** (input_control) . . . . . campar ⇝ *real* / integer / string
  Initial values for the internal parameters of camera 1.
- ▷ **StartCamParam2** (input_control) . . . . . campar ⇝ *real* / integer / string
  Initial values for the internal parameters of camera 2.
- ▷ **NStartPose1** (input_control) . . . . . pose(-array) ⇝ *real* / integer
  Ordered tuple with all initial values for the poses of the calibration model in relation to camera 1.
  Number of elements: NStartPose1 == 7 * NRow1 / NX
- ▷ **NStartPose2** (input_control) . . . . . pose(-array) ⇝ *real* / integer
  Ordered tuple with all initial values for the poses of the calibration model in relation to camera 2.
  Number of elements: NStartPose2 == 7 * NRow1 / NX
- ▷ **EstimateParams** (input_control) . . . . . string-array ⇝ *string*
  Camera parameters to be estimated.
  Default: 'all'
  List of values: `EstimateParams` ∈ {'all', 'pose', 'pose_caltabs', 'pose_rel', 'cam_param1', 'cam_param2', 'alpha_rel', 'beta_rel', 'gamma_rel', 'transx_rel', 'transy_rel', 'transz_rel', 'alpha_caltabs', 'beta_caltabs', 'gamma_caltabs', 'transx_caltabs', 'transy_caltabs', 'transz_caltabs', 'focus1', 'magnification1', 'kappa1', 'poly_1', 'k1_1', 'k2_1', 'k3_1', 'poly_tan_2_1', 'image_plane_dist1', 'tilt1', 'cx1', 'cy1', 'sx1', 'sy1', 'focus2', 'magnification2', 'kappa2', 'poly_2', 'k1_2', 'k2_2', 'k3_2', 'poly_tan_2_2', 'image_plane_dist2', 'tilt2', 'cx2', 'cy2', 'sx2', 'sy2', 'common_motion_vector'}
- ▷ **CamParam1** (output_control) . . . . . campar ⇝ *real* / integer / string
  Internal parameters of camera 1.
- ▷ **CamParam2** (output_control) . . . . . campar ⇝ *real* / integer / string
  Internal parameters of camera 2.
- ▷ **NFinalPose1** (output_control) . . . . . pose(-array) ⇝ *real* / integer
  Ordered tuple with all poses of the calibration model in relation to camera 1.
  Number of elements: NFinalPose1 == 7 * NRow1 / NX
- ▷ **NFinalPose2** (output_control) . . . . . pose(-array) ⇝ *real* / integer
  Ordered tuple with all poses of the calibration model in relation to camera 2.
  Number of elements: NFinalPose2 == 7 * NRow1 / NX

▷ **RelPose** (output_control) . . . . . pose ⇝ *real* / integer
Pose of camera 2 in relation to camera 1.

▷ **Errors** (output_control) . . . . . real(-array) ⇝ *real*
Average error distances in pixels.

```

Result

`binocular_calibration` returns `2` (`H_MSG_TRUE`) if all parameter values are correct and the desired parameters have been determined by the minimization algorithm. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

6.2 Calibration Object

caltab_points (: : CalPlateDescr : X, Y, Z)

Read the mark center points from the calibration plate description file.

`caltab_points` reads the mark center points from the calibration plate description file `CalPlateDescr` (see `gen_caltab` for calibration plates with rectangularly arranged marks and `create_caltab` for calibration plates with hexagonally arranged marks) and returns their coordinates in `X`, `Y` and `Z`. The mark center points are 3D coordinates in the calibration plate coordinate system and describe the 3D model of the calibration plate. The calibration plate coordinate system is located in the middle of the surface of the calibration plate for calibration plates with rectangularly arranged marks and at the center of the central mark of the first finder pattern for calibration plates with hexagonally arranged marks. Its z-axis points into the calibration plate, its x-axis to the right, and its y-axis downwards.

The mark center points are typically used as input parameters for the operator `camera_calibration`.

Parameters

▷ **CalPlateDescr** (input_control) . . . . . filename.read ⇝ *string*
File name of the calibration plate description.
Default: 'calplate_320mm.cpd'
List of values: `CalPlateDescr` ∈ {'calplate_5mm.cpd', 'calplate_10mm.cpd', 'calplate_20mm.cpd', 'calplate_40mm.cpd', 'calplate_80mm.cpd', 'calplate_160mm.cpd', 'calplate_320mm.cpd', 'calplate_640mm.cpd', 'calplate_1200mm.cpd', 'calplate_20mm_dark_on_light.cpd', 'calplate_40mm_dark_on_light.cpd', 'calplate_80mm_dark_on_light.cpd', 'caltab_650um.descr', 'caltab_2500um.descr', 'caltab_6mm.descr', 'caltab_10mm.descr', 'caltab_30mm.descr', 'caltab_100mm.descr', 'caltab_200mm.descr', 'caltab_800mm.descr', 'caltab_small.descr', 'caltab_big.descr'}
File extension: `.cpd`, `.descr`

▷ **X** (output_control) . . . . . real-array ⇝ *real*
X coordinates of the mark center points in the coordinate system of the calibration plate.

▷ **Y** (output_control) . . . . . real-array ⇝ *real*
Y coordinates of the mark center points in the coordinate system of the calibration plate.

▷ **Z** (output_control) . . . . . real-array ⇝ *real*
Z coordinates of the mark center points in the coordinate system of the calibration plate.

Example

```
* Read calibration image.
read_image(Image, 'calib/calib-3d-coord-03')
CalTabDescr := 'caltab_100mm.descr'
* Find calibration pattern.
find_caltab(Image, CalPlate1, CalTabDescr, 3, 112, 5)
* Find calibration marks and start poses.
StartCamPar := ['area_scan_division', 0.008, 0.0, 0.000011, 0.000011, \
                384, 288, 768, 576]
find_marks_and_pose(Image,CalPlate1,CalTabDescr, StartCamPar, \
                    128, 10, 18, 0.9, 15.0, 100.0, RCoord1, CCoord1, \
                    StartPose1)
* Read 3D positions of calibration marks.
caltab_points(CalTabDescr, NX, NY, NZ)
*  Calibrate camera.
camera_calibration(NX, NY, NZ, RCoord1, CCoord1, StartCamPar, \
                   StartPose1, 'all', CameraParam, FinalPose, Errors)
*  Visualize calibration result.
dev_display(Image)
disp_caltab(WindowHandle, CalTabDescr, CameraParam, FinalPose, 1.0)
```

Result

`caltab_points` returns `2` (`H_MSG_TRUE`) if all parameter values are correct and the file `CalPlateDescr` has been read successfully. If necessary, an exception is raised.

Execution Information

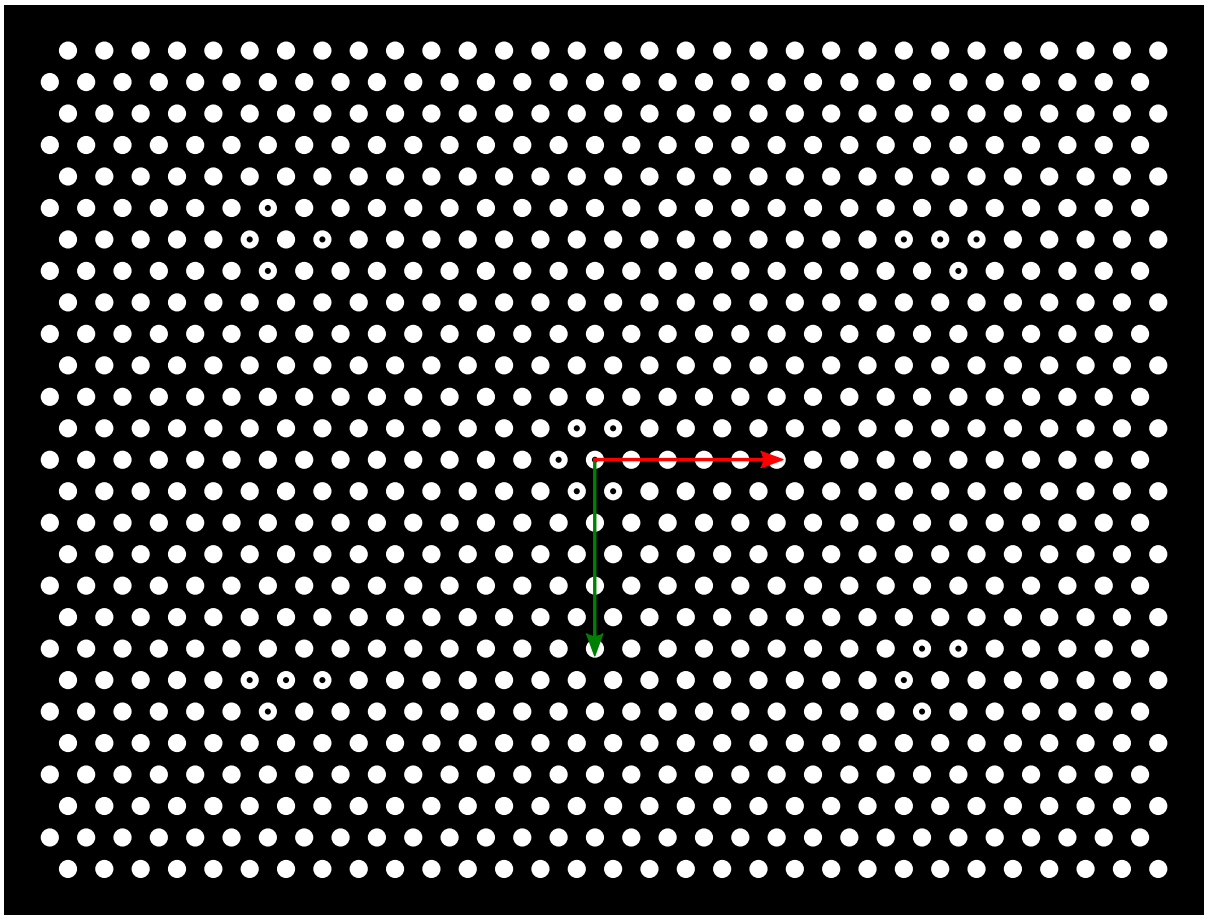
Module

Foundation

create_caltab (: : NumRows, MarksPerRow, Diameter, FinderRow, FinderColumn, Polarity, CalPlateDescr, CalPlatePSFile :)

Generate a calibration plate description file and a corresponding PostScript file for a calibration plate with hexagonally arranged marks.

`create_caltab` creates the description file of a standard HALCON calibration plate with hexagonally arranged marks. This calibration plate contains `MarksPerRow` times `NumRows` circular marks. These marks are arranged in a hexagonal lattice such that each mark (except the ones at the border) has six equidistant neighbors.



A standard HALCON calibration plate with hexagonally arranged marks and its coordinate system.

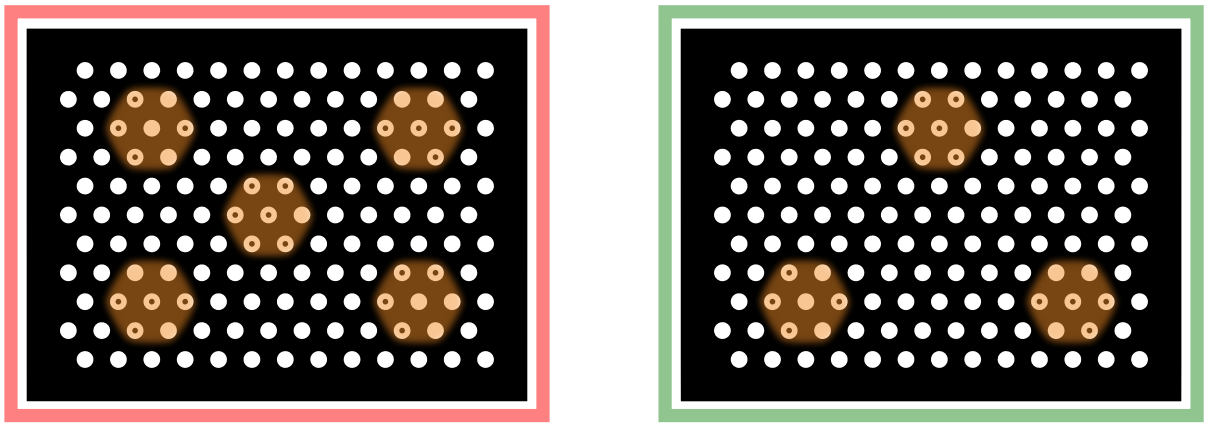
The diameter of the marks is given by the parameter `Diameter` in meters. The distance between the centers of horizontally neighboring calibration marks is given by $2 \cdot Diameter$. The distance between neighboring rows of calibration marks is given by $2 \cdot Diameter \cdot \sqrt{0.75}$. The width and the height of the generated calibration plate can be calculated with the following equations:

$$\texttt{Width} = (2 \left\lfloor \frac{\texttt{MarksPerRow}-1}{2} \right\rfloor + 3) \cdot 2 \cdot \texttt{Diameter}$$

$$\texttt{Height} = (2 \left\lfloor \frac{\texttt{NumRows}-1}{2} \right\rfloor \cdot \sqrt{3} + 5) \cdot \texttt{Diameter}$$

The calibration plate contains one to five finder patterns. A finder pattern is a special mark hexagon (i.e. a mark and its six neighbors) where either four or six marks contain a hole. Each of these up to five finder patterns is unique such that it can be used to determine the orientation of the calibration plate and the position of the finder pattern on the calibration plate. As a consequence, the calibration plate can only be found by `find_calib_object` if at least one of these finder patterns is completely visible. The position of the central mark of each finder pattern is given in `FinderRow` and `FinderColumn`. Thus, the length of the tuples given in `FinderRow` and `FinderColumn`, respectively determine the number of finder patterns on the calibration plate. Be aware that two finder patterns must not overlap. It is recommended to keep a certain distance between the finder patterns, so every mark containing a hole can be assigned to a finder pattern distinctly. As a rule of thumb, if the calibration plate contains too few marks to place all finder patterns in distinct positions, it is better to reduce the number of finder patterns so that they can be distributed more evenly. An example case is depicted below, but note that a successful detection of the patterns also depends on the used camera setup.

The coordinate system of the calibration plate is located in the center of the central mark of the first finder pattern.



The finder patterns on a calibration plate should not be too close to each other (left). If there are not enough marks on your plate to distribute the finder patterns further apart you should reduce the number of finder patterns (right).

Depending on `Polarity` the marks are either light on dark background (for *'light_on_dark'*, which is the default) or dark on light background (for *'dark_on_light'*).

The file `CalPlateDescr` contains the calibration plate description, and must be passed to all HALCON operations using the generated calibration plate (e.g., `set_calib_data_calib_object` or `sim_caltab`). The default HALCON file extension for the description of a calibration plate with hexagonally arranged marks is 'cpd'.

A calibration plate description file contains information about:

- the number of row and columns of the calibration plate
- the number of marks per row and column
- the offset of the coordinate system to the plate's surface in z-direction
- the rim of the calibration plate
- the polarity of the marks
- the number and position of finder patterns
- the x,y coordinates and radius of the calibration marks

A file generated by `create_caltab` looks like the following (comments are marked by a '#' at the beginning of a line):

```

```

Note that only the coordinates and radius of the marks in the first two rows are listed completely. The corresponding coordinates and radius of the marks in the other rows are omitted for a better overview.

The file `CalPlatePSFile` contains the corresponding PostScript description of the calibration plate, which can be used to print the calibration plate.

Attention

Depending on the accuracy of the used output device (e.g., laser printer), a printed calibration plate may not match the values in the calibration plate description file `CalPlateDescr` exactly. Thus, the coordinates of the calibration marks in the calibration plate description file may have to be corrected!

For purchased calibration plates it is recommended to use the specific calibration description file that is supplied with your calibration plate.

Parameters

▷ **NumRows** (input_control) . . . . . integer ⇝ *integer*
Number of rows.
Default: 27
Recommended increment: 1
Restriction: NumRows > 2

▷ **MarksPerRow** (input_control) . . . . . integer ⇝ *integer*
Number of marks per row.
Default: 31
Recommended increment: 1
Restriction: MarksPerRow > 2

▷ **Diameter** (input_control) . . . . . real ⇝ *real*
Diameter of the marks.
Default: 0.00258065
Suggested values: `Diameter` ∈ {0.00258065, 0.1, 0.0125, 0.00375, 0.00125}

▷ **FinderRow** (input_control) . . . . . integer(-array) ⇝ *integer*
Row indices of the finder patterns.
Default: [13,6,6,20,20]

▷ **FinderColumn** (input_control) . . . . . integer(-array) ⇝ *integer*
Column indices of the finder patterns.
Default: [15,6,24,6,24]

▷ **Polarity** (input_control) . . . . . string ⇝ *string*
Polarity of the marks
Default: 'light_on_dark'
Suggested values: `Polarity` ∈ {'light_on_dark', 'dark_on_light'}

▷ **CalPlateDescr** (input_control) . . . . . filename.write ⇝ *string*
File name of the calibration plate description.
Default: 'calplate.cpd'
List of values: `CalPlateDescr` ∈ {'calplate.cpd'}
File extension: `.cpd`

▷ **CalPlatePSFile** (input_control) . . . . . filename.write ⇝ *string*
File name of the PostScript file.
Default: 'calplate.ps'
File extension: `.ps`

Example

```
* Parameters to create the descriptor for the 160mm wide calibration
* plate.
create_caltab (27, 31, 0.00258065, [13, 6, 6, 20, 20], [15, 6, 24, 6, 24], \
              'light_on_dark', 'calplate.cpd', 'caltab.ps')
```

Result

`create_caltab` returns `2` (`H_MSG_TRUE`) if all parameter values are correct and both files have been written successfully. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`find_caltab`, `find_marks_and_pose`, `camera_calibration`, `disp_caltab`, `sim_caltab`

Module

Foundation

disp_caltab (: : WindowHandle, CalPlateDescr, CameraParam, CalPlatePose, ScaleFac :)

Project and visualize the 3D model of the calibration plate in the image.

disp_caltab is used to visualize the calibration marks and the connecting lines between the marks of the used calibration plate (CalPlateDescr) in the window specified by WindowHandle. Additionally, the x- and y-axes of the plate's coordinate system are printed on the plate's surface. For this, the 3D model of the calibration plate is projected into the image plane using the internal (CameraParam) and external camera parameters (CalPlatePose). Thereby the pose is in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *ccs* denotes the camera coordinate system and *wcs* the world coordinate system (see Transformations / Poses and "Solution Guide III-C - 3D Vision"), thus the pose of the calibration plate in camera coordinates. The underlying camera model is described in Calibration.

Typically, disp_caltab is used to verify the result of the camera calibration (see Calibration or camera_calibration) by superimposing it onto the original image. The current line width can be set by set_line_width, the current color can be set by set_color. Additionally, the font type of the labels of the coordinate axes can be set by set_font.

The parameter ScaleFac influences the number of supporting points to approximate the elliptic contours of the calibration marks. You should increase the number of supporting points, if the image part in the output window is displayed with magnification (see set_part).

Parameters

▷ **WindowHandle** (input_control) ..... window ⇝ *handle*
Window in which the calibration plate should be visualized.

▷ **CalPlateDescr** (input_control) ..... filename.read ⇝ *string*
File name of the calibration plate description.
Default: 'calplate_320.cpd'
List of values: CalPlateDescr ∈ {'calplate_5mm.cpd', 'calplate_10mm.cpd', 'calplate_20mm.cpd', 'calplate_40mm.cpd', 'calplate_80mm.cpd', 'calplate_160mm.cpd', 'calplate_320mm.cpd', 'calplate_640mm.cpd', 'calplate_1200mm.cpd', 'calplate_20mm_dark_on_light.cpd', 'calplate_40mm_dark_on_light.cpd', 'calplate_80mm_dark_on_light.cpd', 'caltab_650um.descr', 'caltab_2500um.descr', 'caltab_6mm.descr', 'caltab_10mm.descr', 'caltab_30mm.descr', 'caltab_100mm.descr', 'caltab_200mm.descr', 'caltab_800mm.descr', 'caltab_small.descr', 'caltab_big.descr'}

▷ **CameraParam** (input_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **CalPlatePose** (input_control) ..... pose ⇝ *real* / integer
External camera parameters (3D pose of the calibration plate in camera coordinates).
Number of elements: 7

▷ **ScaleFac** (input_control) ..... real ⇝ *real*
Scaling factor for the visualization.
Default: 1.0
Suggested values: ScaleFac ∈ {0.5, 1.0, 2.0, 3.0}
Recommended increment: 0.05
Restriction: 0.0 < ScaleFac

Example

```
* Read image of calibration plate.
read_image (Image, 'calib/calib_single_camera_01')
get_image_size (Image, Width, Height)
* Create and setup the calibration model.
create_calib_data ('calibration_object', 1, 1, CalibDataID)
CalPlateDescr := 'calplate_80mm.cpd'
set_calib_data_calib_object (CalibDataID, 0, CalPlateDescr)
CamParam := ['area_scan_division', 0.008, -1500, 3.7e-6, 3.7e-6, \
             640, 470, 1292, 964]
set_calib_data_cam_param (CalibDataID, 0, [], CamParam)
```

```
* Localize calibration plate in the image.
find_calib_object (Image, CalibDataID, 0, 0, 0, [], [])
get_calib_data_observ_pose (CalibDataID, 0, 0, 0, StartPose)
* Display calibration plate.
disp_caltab (WindowHandle, CalPlateDescr, CamParam, StartPose, 1)
```

Result

`disp_caltab` returns 2 (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

find_calib_object (Image : : CalibDataID, CameraIdx, CalibObjIdx, CalibObjPoseIdx, GenParamName, GenParamValue :)

Find the HALCON calibration plate and set the extracted points and contours in a calibration data model.

`find_calib_object` searches in `Image` for a HALCON calibration plate corresponding to the description of the calibration object with the index `CalibObjIdx` from the calibration data model `CalibDataID`. If a calibration plate is found, `find_calib_object` extracts the centers and the contours of its marks and estimates the pose of the plate relative to the observing camera `CameraIdx`. All collected observation data is stored in the calibration data model for the calibration object pose `CalibObjPoseIdx`. In order to ensure a successful detection of the calibration plate, at least one finder pattern has to be visible in the image. For calibration plates with hexagonally arranged marks this is a special mark hexagon where either four or six marks contain a hole, while for calibration plates with rectangularly arranged marks this is the border of the calibration plate with a triangle in one corner.

Preparation of the input data

Before the operator `find_calib_object` can be called, a calibration data model has to be defined performing the following steps:

1. **Create a calibration data model** with the operator `create_calib_data`, specifying the number of cameras in the setup and the number of used calibration objects.
2. **Specify the camera type and the initial internal camera parameters** for all cameras with the operator `set_calib_data_cam_param`. Note that only cameras of the same type can be calibrated in a single setup.
3. **Specify the description of all calibration objects** with the operator `set_calib_data_calib_object`. Note that for a successful call of `find_calib_object` a valid description file of the calibration plate is necessary. This description file has to be set beforehand via the operator `set_calib_data_calib_object`. As a consequence, the usage of a user-defined calibration object can only be made by the operator `set_calib_data_observ_points`.

Collecting observation data

`find_calib_object` is used to collect observations in a calibration data model. Beyond, it stores additional observation data that cannot be added to the model with `set_calib_data_observ_points` and that is dependent on the used calibration plate. While for calibration plates with rectangularly arranged marks (see

gen_caltab) the rim of the calibration plate is added to the observations, calibration plates with hexagonal pattern (see create_caltab) store one of their finder pattern. Additionally and irrespective of the used calibration plate, the contour of each mark is added to the calibration model.

Setting additional parameters

Using **calibration plates with hexagonally arranged marks**, the following additional parameter can be set via GenParamName and GenParamValue:

'sigma': Smoothing factor for the extraction of the mark contours. For increasing values of *'sigma'*, the filter width and thereby the amount of smoothing increases (see also edges_sub_pix for the influence of the filter width on the Canny filter).

Suggested values: *0.5*, *0.7*, *0.9*, *1.0*, *1.2*, *1.5*

Default: *1.0*

For **calibration plates with rectangularly arranged marks**, find_calib_object essentially encapsulates the sequence of three operator calls: find_caltab, find_marks_and_pose and set_calib_data_observ_points. For this kind of calibration plates the following parameters can be set using GenParamName and GenParamValue:

'alpha': Smoothing factor for the extraction of the mark contours. For increasing values of *'alpha'*, the filter width and thereby the amount of smoothing decreases (see also edges_sub_pix for the influence of the filter width on the Lanser2 filter).

Suggested values: *0.5*, *0.7*, *0.9*, *1.0*, *1.2*, *1.5*

Default: *0.9*

'gap_tolerance': Tolerance factor for gaps between the marks. If the marks appear closer to each other than expected, you might set *'gap_tolerance'* < *1.0* to avoid disturbing patterns outside the calibration plate to be associated with the calibration plate. This can typically happen if the plate is strongly tilted and positioned in front of a background that exposes mark-like patterns. If the distances between single marks vary in a wide range, e.g., if the calibration plate appears with strong perspective distortion in the image, you might set *'gap_tolerance'* > *1.0* to enforce the marks grouping (see also find_caltab).

Suggested values: *0.75*, *0.9*, *1.0*, *1.1*, *1.2*, *1.5*

Default: *1.0*

'max_diam_marks': Maximum expected diameter of the marks (needed internally by find_marks_and_pose). By default, this value is estimated by the preceding internal call to find_caltab. However, if the estimation is erroneous for no obvious reason or the internal call to find_caltab fails or is simply skipped (see *'skip_find_caltab'* below), you might have to adjust this value.

Suggested values: *50.0*, *100.0*, *150.0*, *200.0*, *300.0*

'skip_find_caltab': Skip the internal call to find_caltab. If activated, only the domain of Image reduces the search area for the internal call of find_marks_and_pose. Thus, a user defined calibration plate region can be incorporated by setting *'skip_find_caltab'*=*'false'* and reducing the Image domain to the user region.

List of values: *'false'*, *'true'*

Default: *'false'*

If using a HALCON calibration plate as calibration object, it is recommended to use find_calib_object instead of set_calib_data_observ_points where possible, since the contour information, which it stores in the calibration data model, enables a more precise calibration procedure with calibrate_cameras.

After a successful call to find_calib_object, the extracted points can be queried by get_calib_data_observ_points and the extracted contours can be accessed by get_calib_data_observ_contours.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image.

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **CameraIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observing camera.
Default: 0
Suggested values: CameraIdx ∈ {0, 1, 2}

▷ **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
Index of the calibration object.
Default: 0
Suggested values: CalibObjIdx ∈ {0, 1, 2}

▷ **CalibObjPoseIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration object.
Default: 0
Suggested values: CalibObjPoseIdx ∈ {0, 1, 2}
Restriction: CalibObjPoseIdx >= 0

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters to be set.
Default: []
List of values: GenParamName ∈ {'gap_tolerance', 'alpha', 'sigma', 'max_diam_marks', 'skip_find_caltab'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
Values of the generic parameters to be set.
Default: []
Suggested values: GenParamValue ∈ {0.5, 0.9, 1.0, 1.2, 1.5, 2.0, 'true', 'false'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Calibration

find_caltab (Image : CalPlate : CalPlateDescr, SizeGauss, MarkThresh, MinDiamMarks :)

Segment the region of a standard calibration plate with rectangularly arranged marks in the image.

find_caltab is used to determine the region of a plane calibration plate with circular marks in the input image Image. The region must correspond to a standard calibration plate with rectangularly arranged marks described in the file CalPlateDescr. The successfully segmented region is returned in CalPlate. The operator provides two algorithms. By setting appropriate integer values in SizeGauss, MarkThresh, and MinDiamMarks, respectively, you invoke the *standard algorithm*. If you pass a tuple of parameter names in SizeGauss and a corresponding tuple of parameter values in MarkThresh, or just two empty tuples, respectively, you invoke the *advanced algorithm* instead. In this case the value passed in MinDiamMarks is ignored.

Standard algorithm

First, the input image is smoothed (see gauss_image); the size of the used filter mask is given by SizeGauss. Afterwards, a threshold operator (see threshold) with a minimum gray value MarkThresh is applied. Among the extracted connected regions the most convex region with an almost correct number of holes (corresponding to the dark marks of the calibration plate) is selected. Holes with a diameter smaller than the expected size of the marks MinDiamMarks are eliminated to reduce the impact of noise. The number of marks is read from the calibration plate description file CalPlateDescr. The complete explanation of this file can be found within the description of gen_caltab.

Advanced algorithm

First, an image pyramid based on Image is built. Starting from the highest pyramid level, round regions are segmented with a dynamic threshold. Then, they are associated in groups based on their mutual proximity and it is evaluated whether they can represent marks of a potential calibration plate. The search is terminated once the expected number of marks has been identified in one group. The surrounding lighter area is returned in CalPlate.

The image pyramid makes the search independent from the size of the image and the marks. The dynamic threshold makes the algorithm immune to bad or irregular illumination. Therefore, in general, no parameter is required. Yet, you can adjust some auxiliary parameters of the advanced algorithm by passing a list of parameter names (strings) to SizeGauss and a list of corresponding parameter values to MarkThresh. Currently the following parameter is supported:

'gap_tolerance': Tolerance factor for gaps between the marks. If the marks appear closer to each other than expected, you might set *'gap_tolerance'* < *1.0* to avoid disturbing patterns outside the calibration plate to be associated with the calibration plate. This can typically happen if the plate is strongly tilted and positioned in front of a background that exposes mark-like patterns. If the distances between single marks deviate significantly, e.g., if the calibration plate appears with strong perspective distortion in the image, you might set *'gap_tolerance'* > *1.0* to enforce the grouping for the more distant marks.

Suggested values: *0.75*, *0.9*, *1.0*, *1.1*, *1.2*, *1.5*

Default: *1.0*

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object* : byte / uint2
Input image.

▷ **CalPlate** (output_object) ..... region ⇝ *object*
Output region.

▷ **CalPlateDescr** (input_control) ..... filename.read ⇝ *string*
File name of the calibration plate description.
Default: 'caltab_100.descr'
List of values: CalPlateDescr ∈ {'caltab_650um.descr', 'caltab_2500um.descr', 'caltab_6mm.descr', 'caltab_10mm.descr', 'caltab_30mm.descr', 'caltab_100mm.descr', 'caltab_200mm.descr', 'caltab_800mm.descr', 'caltab_small.descr', 'caltab_big.descr'}
File extension: .descr

▷ **SizeGauss** (input_control) ..... integer(-array) ⇝ *integer* / string
Filter size of the Gaussian.
Default: 3
List of values: SizeGauss ∈ {0, 3, 5, 7, 9, 11, 'gap_tolerance'}

▷ **MarkThresh** (input_control) ..... integer(-array) ⇝ *integer* / real
Threshold value for mark extraction.
Default: 112
Suggested values: MarkThresh ∈ {48, 64, 80, 96, 112, 128, 144, 160, 0.5, 0.9, 1.0, 1.1, 1.5}

▷ **MinDiamMarks** (input_control) ..... integer ⇝ *integer*
Expected minimal diameter of the marks on the calibration plate.
Default: 5
Suggested values: MinDiamMarks ∈ {3, 5, 9, 15, 30, 50, 70}

Example

```
* Read calibration image.
read_image(Image, 'calib/calib_distorted_01')
```

```
* Find calibration pattern.
find_caltab(Image, CalPlate, 'caltab_100mm.descr', 3, 112, 5)
```

Result

`find_caltab` returns `2` (`H_MSG_TRUE`) if all parameter values are correct and an image region is found. The behavior in case of empty input (no image given) can be set via `set_system(::'no_object_result',<Result>:)` and the behavior in case of an empty result region via `set_system(::'store_empty_region',<'true'/'false'>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

find_marks_and_pose (Image, CalPlateRegion : : CalPlateDescr, StartCamParam, StartThresh, DeltaThresh, MinThresh, Alpha, MinContLength, MaxDiamMarks : RCoord, CCoord, StartPose)

Extract rectangularly arranged 2D calibration marks from the image and calculate initial values for the external camera parameters.

`find_marks_and_pose` is used to determine the input data for a subsequent camera calibration using a calibration plate with rectangularly arranged marks (see Calibration or `camera_calibration`): First, the 2D center points [`RCoord`,`CCoord`] of the calibration marks within the region `CalPlateRegion` of the input image `Image` are extracted and ordered. Secondly, a rough estimate for the external camera parameters (`StartPose`) is computed, i.e., the 3D pose (= position and orientation) of the calibration plate relative to the camera coordinate system (see `create_pose` for more information about 3D poses).

In the input image `Image` an edge detector is applied (see `edges_image`, mode 'lanser2') to the region `CalPlateRegion`, which can be found by applying the operator `find_caltab`. The filter parameter for this edge detection can be tuned via `Alpha`. Use a smaller value for `Alpha` to achieve a stronger smoothing effect. In the edge image closed contours are searched for: The number of closed contours must correspond to the number of calibration marks as described in the calibration plate description file `CalPlateDescr` and the contours have to be elliptically shaped. Contours shorter than `MinContLength` are discarded, just as contours enclosing regions with a diameter larger than `MaxDiamMarks` (e.g., the border of the calibration plate).

For the detection of contours a threshold operator is applied on the resulting amplitudes of the edge detector. All points with a high amplitude (i.e., borders of marks) are selected.

First, the threshold value is set to `StartThresh`. If the search for the closed contours or the successive pose estimate fails, this threshold value is successively decreased by `DeltaThresh` down to a minimum value of `MinThresh`.

Each of the found contours is refined with subpixel accuracy (see `edges_sub_pix`) and subsequently approximated by an ellipse. The center points of these ellipses represent a good approximation of the desired 2D image coordinates [`RCoord`,`CCoord`] of the calibration mark center points. The order of the values within these two tuples must correspond to the order of the 3D coordinates of the calibration marks in the calibration plate description file `CalPlateDescr`, since this fixes the correspondences between extracted image marks and known model marks (given by `caltab_points`)! If a triangular orientation mark is defined in a corner of the plate by the

plate description file (see gen_caltab), the mark will be detected and the point order is returned in row-major order beginning with the corner mark in the (barycentric) negative quadrant with respect to the defined coordinate system of the plate. Else, if no orientation mark is defined, the order of the center points is in row-major order beginning at the upper left corner mark in the image.

Based on the ellipse parameters for each calibration mark, a rough estimate for the external camera parameters is finally computed. For this purpose the fixed correspondences between extracted image marks and known model marks are used. The estimate StartPose describes the pose of the calibration plate in the camera coordinate system as required by the operator camera_calibration.

Parameters

- ▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2

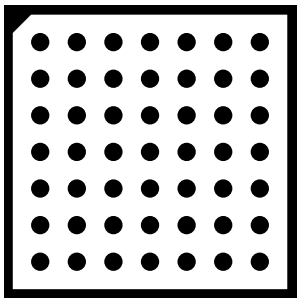
gen_caltab (: : XNum, YNum, MarkDist, DiameterRatio, CalPlateDescr, CalPlatePSFile :)

Generate a calibration plate description file and a corresponding PostScript file for a calibration plate with rectangularly arranged marks.

`gen_caltab` generates the description of a standard HALCON calibration plate with rectangularly arranged marks. This calibration plate consists of `XNum` times `YNum` black circular marks on a white plane which are surrounded by a black frame.



A standard HALCON calibration plate with rectangularly arranged marks

The marks are arranged in a rectangular grid with YNum and XNum equidistant rows and columns. The distances between these rows and columns defines the parameter MarkDist in meter. The marks' diameter can be set by the parameter DiameterRatio and is defined by the equation Diameter = MarkDist · DiameterRatio . Using a distance between marks of 0.01 m and a diameter ratio of 0.5, the width of the dark surrounding frame becomes 8 cm, and the radius of the marks is set to 2.5 mm. The coordinate system of the calibration plate is located in the barycenter of all marks, its z-axis points into the calibration plate, its x-axis to the right, and its y-axis downwards.

The black frame of the calibration plate encloses a triangular black orientation mark in the top left corner to uniquely determine the position of the calibration plate. The width and the height of the generated calibration plate can be calculated with the following equations:

$\texttt{Width} = \texttt{MarkDist} \cdot (\texttt{XNum} + 1)$

$\texttt{Height} = \texttt{MarkDist} \cdot (\texttt{YNum} + 1)$

The file CalPlateDescr contains the calibration plate description, e.g., the number of rows and columns of the calibration plate, the geometry of the surrounding frame (see find_caltab), the triangular orientation mark, an offset of the coordinate system to the plate's surface in z-direction, and the x,y coordinates and the radius of all calibration plate marks given in the calibration plate coordinate system. The definition of the orientation and the offset, indicated by t and z, is optional and can be commented out. The default HALCON file extension for the calibration plate description is 'descr'. A file generated by gen_caltab looks like the following (comments are marked by a '#' at the beginning of a line):

```

The file `CalPlatePSFile` contains the corresponding PostScript description of the calibration plate.

Attention

Depending on the accuracy of the used output device (e.g., laser printer), the printed calibration plate may not match the values in the calibration plate description file `CalPlateDescr` exactly. Thus, the coordinates of the calibration marks in the calibration plate description file may have to be corrected!

Parameters

▷ **XNum** (input_control) . . . integer ⇝ *integer*
Number of marks in x direction.
Default: 7
Suggested values: XNum ∈ {5, 7, 9}
Recommended increment: 1
Restriction: XNum > 1

▷ **YNum** (input_control) . . . integer ⇝ *integer*
Number of marks in y direction.
Default: 7
Suggested values: YNum ∈ {5, 7, 9}
Recommended increment: 1
Restriction: YNum > 1

▷ **MarkDist** (input_control) . . . real ⇝ *real*
Distance of the marks in meters.
Default: 0.0125
Suggested values: MarkDist ∈ {0.1, 0.0125, 0.00375, 0.00125}
Restriction: 0.0 < MarkDist

▷ **DiameterRatio** (input_control) . . . real ⇝ *real*
Ratio of the mark diameter to the mark distance.
Default: 0.5
Suggested values: DiameterRatio ∈ {0.5, 0.55, 0.6, 0.65}
Restriction: 0.0 < DiameterRatio < 1.0

▷ **CalPlateDescr** (input_control) . . . filename.write ⇝ *string*
File name of the calibration plate description.
Default: 'caltab.descr'
List of values: CalPlateDescr ∈ {'caltab.descr'}
File extension: .descr

▷ **CalPlatePSFile** (input_control) . . . filename.write ⇝ *string*
File name of the PostScript file.
Default: 'caltab.ps'
File extension: .ps

Example

```
* Create calibration plate with width = 80 cm.
gen_caltab( 7, 7, 0.1, 0.5, 'caltab.descr', 'caltab.ps')
```

Result

`gen_caltab` returns `2` (`H_MSG_TRUE`) if all parameter values are correct and both files have been written successfully. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`read_cam_par`, `caltab_points`

Alternatives

`create_caltab`

Module

Foundation

sim_caltab (: SimImage : CalPlateDescr, CameraParam, CalPlatePose, GrayBackground, GrayPlate, GrayMarks, ScaleFac :)

Simulate an image with calibration plate.

sim_caltab is used to generate a simulated calibration image. The calibration plate description is read from the file CalPlateDescr and will be projected into the image plane using the given camera parameters, thus internal camera parameters CameraParam and external camera parameters CalPlatePose (see also project_3d_point). Thereby the pose is expected to be in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *ccs* denotes the camera coordinate system and *wcs* the world coordinate system (see Transformations / Poses and "Solution Guide III-C - 3D Vision").

In the simulated image only the calibration plate is shown. The image background is set to the gray value GrayBackground, the calibration plate background is set to GrayPlate, and the calibration marks are set to the gray value GrayMarks. The parameter ScaleFac influences the number of supporting points to approximate the elliptic contours of the calibration marks, see also disp_caltab. Increasing the number of supporting points causes a more accurate determination of the mark boundary, but increases the computation time, too. For each pixel of the simulated image which touches a subpixel-boundary of this kind, the gray value is set linearly between GrayMarks and GrayPlate dependent on the proportion Inside/Outside.

By applying the operator sim_caltab you can generate synthetic calibration images (with known camera parameters!) to test the quality of the calibration algorithm (see Calibration).

Parameters

▷ **SimImage** (output_object) . . . . . image ⇝ *object :* byte
Simulated calibration image.

▷ **CalPlateDescr** (input_control) . . . . . filename.read ⇝ *string*
File name of the calibration plate description.
Default: 'calplate_320mm.cpd'
List of values: CalPlateDescr ∈ {'calplate_5mm.cpd', 'calplate_10mm.cpd', 'calplate_20mm.cpd', 'calplate_40mm.cpd', 'calplate_80mm.cpd', 'calplate_160mm.cpd', 'calplate_320mm.cpd', 'calplate_640mm.cpd', 'calplate_1200mm.cpd', 'calplate_20mm_dark_on_light.cpd', 'calplate_40mm_dark_on_light.cpd', 'calplate_80mm_dark_on_light.cpd', 'caltab_650um.descr', 'caltab_2500um.descr', 'caltab_6mm.descr', 'caltab_10mm.descr', 'caltab_30mm.descr', 'caltab_100mm.descr', 'caltab_200mm.descr', 'caltab_800mm.descr', 'caltab_small.descr', 'caltab_big.descr'}
File extension: .cpd, .descr

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **CalPlatePose** (input_control) . . . . . pose ⇝ *real* / integer
External camera parameters (3D pose of the calibration plate in camera coordinates).
Number of elements: 7

▷ **GrayBackground** (input_control) . . . . . integer ⇝ *integer*
Gray value of image background.
Default: 128
Suggested values: GrayBackground ∈ {0, 32, 64, 96, 128, 160}
Restriction: 0 <= GrayBackground <= 255

▷ **GrayPlate** (input_control) . . . . . integer ⇝ *integer*
Gray value of calibration plate.
Default: 80
Suggested values: GrayPlate ∈ {144, 160, 176, 192, 208, 224, 240}
Restriction: 0 <= GrayPlate <= 255

▷ **GrayMarks** (input_control) ..... integer ⇝ *integer*
Gray value of calibration marks.
Default: 224
Suggested values: GrayMarks ∈ {16, 32, 48, 64, 80, 96, 112}
Restriction: 0 <= GrayMarks <= 255

▷ **ScaleFac** (input_control) ..... real ⇝ *real*
Scaling factor to reduce oversampling.
Default: 1.0
Suggested values: ScaleFac ∈ {1.0, 0.5, 0.25, 0.125}
Recommended increment: 0.05
Restriction: 1.0 >= ScaleFac

Example

```
* Read calibration image.
read_image(Image1, 'calib-01')
* Find calibration pattern.
CameraType := 'area_scan_division'
StartCamPar := [CameraType, Focus, Kappa, Sx, Sy, Cx, Cy, \
               ImageWidth, ImageHeight]
create_calib_data ('calibration_object', 1, 1, CalibDataID)
set_calib_data_cam_param (CalibDataID, 0, [], StartCamPar)
set_calib_data_calib_object (CalibDataID, 0, 'calplate.cpd')
find_caltab(Image1, CalPlate1, 'caltab.descr', 3, 112, 5)
* Find calibration marks and initial pose.
find_calib_object (Image1, CalibDataID, 0, 0, 0, [], [])
* Camera calibration.
calibrate_cameras (CalibDataID, Error)
* Simulate calibration image.
get_calib_data (CalibDataID, 'calib_obj_pose', [0, 0], 'pose', FinalPose)
get_calib_data (CalibDataID, 'camera', 0, 'params', CameraParam)
sim_caltab(Image1Sim, 'calplate.cpd', CameraParam, FinalPose, 128, \
           80, 224, 1)
```

Result

sim_caltab returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

6.3 Camera Parameters

cam_mat_to_cam_par (: : CameraMatrix, Kappa, ImageWidth, ImageHeight : CameraParam)

Compute the internal camera parameters from a camera matrix.

cam_mat_to_cam_par computes internal camera parameters from the camera matrix CameraMatrix, the radial distortion coefficient Kappa, the image width ImageWidth, and the image height ImageHeight. The camera parameters are returned in CameraParam. The parameters CameraMatrix and Kappa can be determined with stationary_camera_self_calibration. cam_mat_to_cam_par converts this representation of the internal camera parameters into the representation used by camera_calibration. The conversion can only be performed if the skew of the image axes is set to 0 in stationary_camera_self_calibration, i.e., if the parameter *'skew'* is *not* being determined.

Parameters

- ▷ **CameraMatrix** (input_control) ..... hom_mat2d ⇝ *real*
  3×3 projective camera matrix that determines the internal camera parameters.
- ▷ **Kappa** (input_control) ..... number ⇝ *real*
  Kappa.
- ▷ **ImageWidth** (input_control) ..... extent.x ⇝ *integer*
  Width of the images that correspond to CameraMatrix.
  Restriction: ImageWidth > 0
- ▷ **ImageHeight** (input_control) ..... extent.y ⇝ *integer*
  Height of the images that correspond to CameraMatrix.
  Restriction: ImageHeight > 0
- ▷ **CameraParam** (output_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters.

Example

```
* For the input data to stationary_camera_self_calibration, please
* refer to the example for stationary_camera_self_calibration.
stationary_camera_self_calibration (4, 640, 480, 1, From, To, \
                                    HomMatrices2D, Rows1, Cols1, \
                                    Rows2, Cols2, NumMatches, \
                                    'gold_standard', \
                                    ['focus','principal_point','kappa'], \
                                    'true', CameraMatrix, Kappa, \
                                    RotationMatrices, X, Y, Z, Error)
cam_mat_to_cam_par (CameraMatrix, Kappa, 640, 480, CameraParam)
```

Result

If the parameters are valid, the operator cam_mat_to_cam_par returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

stationary_camera_self_calibration

camera_calibration, cam_par_to_cam_mat

Module

Calibration

cam_par_to_cam_mat (: : CameraParam : CameraMatrix, ImageWidth, ImageHeight)

Compute a camera matrix from internal camera parameters.

cam_par_to_cam_mat computes the camera matrix CameraMatrix as well as the image width ImageWidth, and the image height ImageHeight from the internal camera parameters CameraParam. The internal camera parameters CameraParam can be determined with camera_calibration. cam_par_to_cam_mat converts this representation of the internal camera parameters into the representation used by stationary_camera_self_calibration. The conversion can only be performed if the camera is an area scan pinhole camera and the distortion coefficients in CameraParam are 0. If necessary, change_radial_distortion_cam_par must be used to set the distortion coefficients to 0.

Parameters

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **CameraMatrix** (output_control) . . . . . hom_mat2d ⇝ *real*
3×3 projective camera matrix that corresponds to CameraParam.

▷ **ImageWidth** (output_control) . . . . . extent.x ⇝ *integer*
Width of the images that correspond to CameraMatrix.
Assertion: ImageWidth > 0

▷ **ImageHeight** (output_control) . . . . . extent.y ⇝ *integer*
Height of the images that correspond to CameraMatrix.
Assertion: ImageHeight > 0

Example

```
* For the input data to calibrate_cameras, please refer to the
* example for calibrate_cameras.
calibrate_cameras (CalibDataID, Error)
get_calib_data (CalibDataID, 'camera', 0, 'params', CameraParam)
cam_par_to_cam_mat (CameraParam, CameraMatrix, ImageWidth, ImageHeight)

* Alternatively, the following calls can be used.
change_radial_distortion_cam_par ('adaptive', CameraParam, 0, CamParamOut)
cam_par_to_cam_mat (CamParamOut, CameraMatrix, ImageWidth, ImageHeight)
```

Result

If the parameters are valid, the operator cam_par_to_cam_mat returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

camera_calibration

See also

stationary_camera_self_calibration, cam_mat_to_cam_par

Module

Calibration

deserialize_cam_par (: : SerializedItemHandle : CameraParam)

Deserialize the serialized internal camera parameters.

deserialize_cam_par deserializes the internal camera parameters, that were serialized by serialize_cam_par (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized camera parameters are defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created tuple with the handle CameraParam.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **CameraParam** (output_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters.

Result

If the parameters are valid, the operator deserialize_cam_par returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_cam_par

Module

Foundation

read_cam_par (: : CamParFile : CameraParam)

Read internal camera parameters from a file.

read_cam_par reads the internal camera parameters CameraParam from a file with name CamParFile. The file must have been written by write_cam_par.

The default HALCON file extension for the camera parameters is 'dat'.

The number of values in CameraParam depends on the specified camera type. See the description of set_calib_data_cam_param for a list of values and the chapter Calibration for details on camera types and camera parameters.

Parameters

▷ **CamParFile** (input_control) ..... filename.read ⇝ *string*
File name of internal camera parameters.
Default: 'campar.dat'
List of values: CamParFile ∈ {'campar.dat', 'campar.initial', 'campar.final'}
File extension: .dat

▷ **CameraParam** (output_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters.

Example

```
* Create sample camera parameters and write them to file.
gen_cam_par_area_scan_division (0.01, -731, 5.2e-006, 5.2e-006, \
                                654, 519, 1280, 1024, CameraParamTmp)
write_cam_par (CameraParamTmp, 'campar_tmp.dat')
* Read internal camera parameters.
read_cam_par('campar_tmp.dat', CameraParam)
```

Result

read_cam_par returns 2 (H_MSG_TRUE) if all parameter values are correct and the file has been read successfully. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

find_marks_and_pose, sim_caltab, gen_caltab, disp_caltab, camera_calibration

See also

find_caltab, find_marks_and_pose, camera_calibration, disp_caltab, sim_caltab, write_cam_par, write_pose, read_pose, project_3d_point, get_line_of_sight

Module

Foundation

serialize_cam_par (: : CameraParam : SerializedItemHandle)

Serialize the internal camera parameters.

serialize_cam_par serializes the internal camera parameters (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_cam_par is converted to a serialized item. The camera parameters are defined by the tuple CameraParam. The serialized camera parameters are returned by the handle SerializedItemHandle and can be deserialized by deserialize_cam_par.

Parameters

▷ **CameraParam** (input_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_cam_par returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_cam_par

Module

Foundation

write_cam_par (: : CameraParam, CamParFile :)

Write internal camera parameters into a file.

write_cam_par stores the internal camera parameters CameraParam into a file specified by its file name CamParFile.

The number of values in CameraParam depends on the specified camera type. See the description of set_calib_data_cam_param for a list of values and the chapter Calibration for details on camera types and camera parameters.

The default HALCON file extension for the camera parameters is 'dat'.

The internal camera parameters can be later read with read_cam_par.

Parameters

▷ **CameraParam** (input_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **CamParFile** (input_control) ..... filename.write ⇝ *string*
File name of internal camera parameters.
Default: 'campar.dat'
List of values: CamParFile ∈ {'campar.dat', 'campar.initial', 'campar.final'}
File extension: .dat

Example

```
*
* Calibrate the camera.
*
StartCamPar := ['area_scan_division', 0.016, 0, 0.0000074, 0.0000074, \
                326, 247, 652, 494]
create_calib_data ('calibration_object', 1, 1, CalibDataID)
set_calib_data_cam_param (CalibDataID, 0, [], StartCamPar)
set_calib_data_calib_object (CalibDataID, 0, 'caltab_30mm.descr')
NumImages := 10
for I := 1 to NumImages by 1
  read_image (Image, '3d_machine_vision/calib/calib_' + I$'02d')
  find_calib_object (Image, CalibDataID, 0, 0, I, [], [])
  get_calib_data_observ_contours (Caltab, CalibDataID, 'caltab', 0, 0, I)
endfor
calibrate_cameras (CalibDataID, Error)
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* Write the internal camera parameters to a file.
write_cam_par (CamParam, 'camera_parameters.dat')
```

Result

write_cam_par returns 2 (H_MSG_TRUE) if all parameter values are correct and the file has been written successfully. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

6.4 Hand-Eye

calibrate_hand_eye (: : CalibDataID : Errors)

Perform a hand-eye calibration.

The operator calibrate_hand_eye determines the 3D pose of a robot ("hand") relative to a camera or 3D sensor ("eye") based on the calibration data model CalibDataID. With the determined 3D poses, the poses of the calibration object in the camera coordinate system can be transformed into the coordinate system of the robot which can then, e.g., grasp an inspected part. There are two possible configurations of robot-camera (hand-eye) systems: The camera can be mounted on the robot or be stationary and observe the robot. Note that the term robot is used in place of a mechanism that moves objects. Thus, you can use calibrate_hand_eye to calibrate many different systems, from pan-tilt heads to multi-axis manipulators.

In essence, systems suitable for hand-eye calibration are described by a closed chain of four Euclidean transformations. In this chain two non-consecutive transformations are either known from the robot controller or computed from camera data, e.g., calibration object poses observed by a camera. The two unknown constant transformations are computed by the hand-eye calibration procedure.

A hand-eye calibration is performed similarly to the calibration of the external camera parameters (see Calibration): You acquire a set of poses of a calibration object in the camera coordinate system, and a corresponding set of poses of the tool in robot base coordinates and set them in the calibration data model CalibDataID.

In contrast to the camera calibration, the calibration object is not moved manually. This task is delegated to the robot. Basically, two hand-eye calibration scenarios can be distinguished. A robot either moves the camera (moving camera) or it moves the calibration object (stationary camera). The robot's movements are assumed to be known. They are used as an input for the hand-eye calibration and are set in the calibration data model CalibDataID using set_calib_data.

The results of a hand-eye calibration are two poses: For the moving camera scenario, the 3D pose of the tool in the camera coordinate system (*'tool_in_cam_pose'*) and the 3D pose of the calibration object in the robot base coordinate system (*'obj_in_base_pose'*) are computed. For the stationary camera scenario, the 3D pose of the robot base in the camera coordinate system (*'base_in_cam_pose'*) and the 3D pose of the calibration object in the tool coordinate system (*'obj_in_tool_pose'*) are computed. Their pose type is identical to the pose type of the input poses. If the input poses have different pose types, poses of type 0 are returned.

The two hand-eye calibration scenarios are discussed in more detail below, followed by general information about the data for and the preparation of the calibration data model.

Moving camera (mounted on a robot)

In this configuration, the calibration object remains stationary. The camera is mounted on the robot and is moved to different positions by the robot. The main idea behind the hand-eye calibration is that the information extracted from an observation of the calibration object, i.e., the pose of the calibration object relative to the camera, can be seen as a chain of poses or homogeneous transformation matrices from the calibration object via the base of the robot to its tool (end-effector) and finally to the camera:

Moving camera:

$$^{camera}\mathbf{H}_{cal} = {}^{camera}\mathbf{H}_{tool} \cdot \left({}^{base}\mathbf{H}_{tool}\right)^{-1} \cdot {}^{base}\mathbf{H}_{cal}$$

'obj_in_cam_pose' 'tool_in_cam_pose' 'tool_in_base_pose' 'obj_in_base_pose'

From the set of calibration object poses (*'obj_in_cam_pose'*) and the poses of the tool in the robot base coordinate system (*'tool_in_base_pose'*), the operator calibrate_hand_eye determines the two missing transformations at the ends of the chain, i.e., the pose of the robot tool in the camera coordinate system ($^{camera}\mathbf{H}_{tool}$, *'tool_in_cam_pose'*) and the pose of the calibration object in the robot base coordinate system ($^{base}\mathbf{H}_{cal}$, *'obj_in_base_pose'*). These two poses are constant.

In contrast, the transformation in the middle of the chain, $^{base}\mathbf{H}_{tool}$, is known but changes for each observation of the calibration object, because it describes the pose of the tool with respect to the robot base coordinate system. In the equation the inverted transformation matrix is used. The inversion is performed internally.

Note that when calibrating SCARA robots, it is not possible to determine the Z translation of *'obj_in_base_pose'*. To eliminate this ambiguity the Z translation *'obj_in_base_pose'* is internally set to 0.0 and the *'tool_in_cam_pose'* is calculated accordingly. It is necessary to determine the true translation in Z after the calibration by moving the robot to a pose of known height in the camera coordinate system. For this, the following approach can be applied: The calibration plate is placed at an arbitrary position. The robot is then moved such that the camera can observe the calibration plate. Now, an image of the calibration plate is acquired and the current robot pose is queried (*ToolInBasePose1*). From the image, the pose of the calibration plate in the camera coordinate system can be

determined (*ObjInCamPose1*). Afterwards, the tool of the robot is manually moved to the origin of the calibration plate and the robot pose is queried again (*ToolInBasePose2*). These three poses and the result of the calibration (*ToolInCamPose*) can be used to fix the Z ambiguity by using the following lines of code:

```
pose_invert(ToolInCamPose, CamInToolPose)
pose_compose(CamInToolPose, ObjInCamPose1, ObjInToolPose1)
pose_invert(ToolInBasePose1, BaseInToolPose1)
pose_compose(BaseInToolPose1, ToolInBasePose2, Tool2InTool1Pose)
ZCorrection := ObjInToolPose1[2]-Tool2InTool1Pose[2]
set_origin_pose(ToolInCamPose, 0, 0, ZCorrection,
ToolInCamPoseFinal)
```

The *'optimization_method' 'stochastic'* also estimates the uncertainty of observations. Besides the input poses described above, it also uses the extracted calibration marks and is thus only available for use with a camera and a calibration plate, not for use with a 3D sensor. For articulated robots, the hand-eye poses and camera parameters are refined simultaneously.

Stationary camera

In this configuration, the robot grasps the calibration object and moves it in front of the camera. Again, the information extracted from an observation of the calibration object, i.e., the pose of the calibration object in the camera coordinate system (e.g., the external camera parameters), are equal to a chain of poses or homogeneous transformation matrices, this time from the calibration object via the robot's tool to its base and finally to the camera:

Stationary camera:

$$^{camera}\mathbf{H}_{cal} = {}^{camera}\mathbf{H}_{base} \cdot {}^{base}\mathbf{H}_{tool} \cdot {}^{tool}\mathbf{H}_{cal}$$

'obj_in_cam_pose' 'base_in_cam_pose' 'tool_in_base_pose' 'obj_in_tool_pose'

Analogously to the configuration with a moving camera, the operator `calibrate_hand_eye` determines the two transformations at the ends of the chain, here the pose of the robot base coordinate system in camera coordinates ($^{camera}\mathbf{H}_{base}$, *'base_in_cam_pose'*) and the pose of the calibration object relative to the robot tool ($^{tool}\mathbf{H}_{cal}$, *'obj_in_tool_pose'*).

The transformation in the middle of the chain, $^{base}\mathbf{H}_{tool}$, describes the pose of the tool relative to the robot base coordinate system. The transformation $^{camera}\mathbf{H}_{cal}$ describes the pose of the calibration object relative to the camera coordinate system.

Note that when calibrating SCARA robots, it is not possible to determine the Z translation of *'obj_in_tool_pose'*. To eliminate this ambiguity the Z translation of *'obj_in_tool_pose'* is internally set to 0.0 and the *'base_in_cam_pose'* is calculated accordingly. It is necessary to determine the true translation in Z after the calibration by moving the robot to a pose of known height in the camera coordinate system. For this, the following approach can be applied: A calibration plate (that is not attached to the robot) is placed at an arbitrary position such that it can be observed by the camera. The pose of the calibration plate must then be determined in the camera coordinate system (*ObjInCamPose*). Afterwards the tool of the robot is manually moved to the origin of the calibration plate and the robot pose is queried (*ToolInBasePose*). The two poses and the result of the calibration (*BaseInCamPose*) can be used to fix the Z ambiguity by using the following lines of code:

```
pose_invert(BaseInCamPose, CamInBasePose)
pose_compose(CamInBasePose, ObjInCamPose, ObjInBasePose)
ZCorrection := ObjInBasePose[2]-ToolInBasePose[2]
set_origin_pose(BaseInCamPose, 0, 0, ZCorrection,
BaseInCamPoseFinal)
```

The *'optimization_method' 'stochastic'* also estimates the uncertainty of observations. Besides the input poses described above, it also uses the extracted calibration marks and is thus only available for use with a camera and a

calibration plate, not for use with a 3D sensor. For articulated robots, the hand-eye poses and camera parameters are refined simultaneously.

Preparing the calibration input data

Before calling `calibrate_hand_eye`, you must create and fill the calibration data model with the following steps:

1. **Create a calibration data model** with the operator `create_calib_data`, specifying the number of cameras in the setup and the number of used calibration objects. Depending on your scenario, `CalibSetup` has to be set to *'hand_eye_moving_camera'*, *'hand_eye_stationary_camera'*, *'hand_eye_scara_moving_camera'*, or *'hand_eye_scara_stationary_camera'*. These four scenarios on the one hand distinguish whether the camera or the calibration object is moved by the robot and on the other hand distinguish whether an articulated robot or a SCARA robot is calibrated. The arm of an articulated robot has three rotary joints typically covering 6 degrees of freedom (3 translations and 3 rotations). SCARA robots have two parallel rotary joints and one parallel prismatic joint covering only 4 degrees of freedom (3 translations and 1 rotation). Loosely speaking, an articulated robot is able to tilt its end effector while a SCARA robot is not.
2. **Specify the optimization method** with the operator `set_calib_data`. For the parameter `DataName='optimization_method'`, three options for `DataValue` are available, `DataValue='linear'`, `DataValue='nonlinear'` and `DataValue='stochastic'` (see paragraph 'Performing the actual hand-eye calibration').
3. **Specify the poses of the calibration object**
   (a) For each observation of the calibration object, the 3D pose can be set directly using the operator `set_calib_data_observ_pose`. This operator is intended to be used with generic 3D sensors that observe the calibration object.
   (b) The pose of the calibration object can also be estimated using camera images. The calibration object has to be set in the calibration data model `CalibDataID` with the operator `set_calib_data_calib_object`. Initial camera parameters have to be set with the operator `set_calib_data_cam_param`. If a standard HALCON calibration plate is used, the operator `find_calib_object` determines the pose of the calibration plate relative to the camera and saves it in the calibration data model `CalibDataID`.
   The operator `calibrate_hand_eye` for articulated (i.e., non-SCARA) robots in this case calibrates the camera before performing the hand-eye calibration. If *'optimization_method'* is set to *'stochastic'*, the hand-eye poses and camera parameters are then refined simultaneously. If the provided camera parameters are already calibrated, the camera calibration can be switched off by calling `set_calib_data (CalibDataID,'camera','general','excluded_settings','params')`.
   In contrast, for SCARA robots `calibrate_hand_eye` always assumes that the provided camera parameters are already calibrated. Therefore, in this case the internal camera calibration is never performed automatically during hand-eye calibration. This is because the internal camera parameters cannot be calibrated reliably without significantly tilting the calibration plate with respect to the camera. For hand-eye calibration, the calibration plate is often approximately parallel to the image plane. Therefore, for SCARA robots all camera poses are approximately parallel. Therefore, the camera must be calibrated beforehand by using a different set of calibration images.
4. **Specify the poses of the tool** in robot base coordinates. For each pose of the calibration object in the camera coordinate system, the corresponding pose of the tool in the robot base coordinate system has to be set with the operator `set_calib_data(CalibDataID,'tool', PoseNumber, 'tool_in_base_pose', ToolInBasePose)`.

Performing the actual hand-eye calibration

The operator `calibrate_hand_eye` can perform the calibration in three different ways. In all cases, all provided calibration object poses in camera coordinates and the corresponding poses of the tool in robot base coordinates are used for the calibration. The method *'stochastic'* also uses the extracted calibration marks, and is thus only available for use with a camera and a calibration plate, not for use with a 3D sensor. The method to be used is specified with `set_calib_data`.

For the parameter combination `DataName='optimization_method'` and `DataValue='linear'`, the calibration is performed using a linear algorithm which is fast but in many practical situations not accurate enough.

For the parameter DataName='*optimization_method*' and DataValue='*nonlinear*', the calibration is performed using a non-linear algorithm, which results in more accurately calibrated poses.

For the parameter DataName='*optimization_method*' and DataValue='*stochastic*', the calibration algorithm models the uncertainty of all measured observations including the input robot poses, which results in more robustly calibrated hand-eye poses. The estimation will be better the more input poses are used. However, the method is only available for use with a camera and a calibration plate, not for use with a 3D sensor. For articulated robots, the hand-eye poses and camera parameters are refined simultaneously.

Checking the success of the calibration

The operator calibrate_hand_eye returns the pose error of the complete chain of transformations in Errors. To be more precise, a tuple with four elements is returned, where the first element is the root-mean-square error of the translational part, the second element is the root-mean-square error of the rotational part, the third element is the maximum translational error and the fourth element is the maximum rotational error. Using these error measures, it can be determined, whether the calibration was successful.

The Errors are returned in the same units in which the input poses were given, i.e., the translational errors are typically given in meters and the rotational errors are always given in degrees.

If *'optimization_method'* is set to *'stochastic'*, get_calib_data can be used to obtain *'hand_eye_calib_error_corrected_tool'*, which differs from Errors only in that it uses the corrected robot tool poses instead of the input robot tool poses.

For articulated robots, get_calib_data can be used to obtain the *'camera_calib_error'* of the camera calibration, the root mean square error (RMSE) of the direct back projection of calibration mark centers into camera images. If *'optimization_method'* is set to *'stochastic'*, *'camera_calib_error_corrected_tool'* returns the back projection error via the pose chain using corrected tool poses.

Getting the calibration results

The poses that are computed with the operator calibrate_hand_eye can be queried with get_calib_data. For the moving camera scenario, the 3D pose of the tool in the camera coordinate system (*'tool_in_cam_pose'*) and the 3D pose of the calibration object in the robot base coordinate system (*'obj_in_base_pose'*) can be obtained. For the stationary camera scenario, the 3D pose of the robot base in the camera coordinate system (*'base_in_cam_pose'*) and the 3D pose of the calibration object in the coordinate system of the tool (*'obj_in_tool_pose'*) can be obtained.

Querying the input data

If the poses of the calibration object relative to a camera were computed with find_calib_object, then for articulated (i.e., non-SCARA) robots they are used in an internal camera calibration step preceding the hand-eye calibration and are calibrated as well. For *'optimization_method'* set to *'stochastic'*, the hand-eye poses and camera parameters are refined simultaneously, the poses of the calibration object are then updated relative to the resulting new camera parameters. The calibrated 3D poses can be queried using get_calib_data with the parameter ItemType='*calib_obj_pose*'.

If the poses of the calibration object were observed with a generic 3D sensor, they cannot be calibrated and are set by set_calib_data_observ_pose. These raw 3D poses can be queried using get_calib_data_observ_pose.

The corresponding 3D poses of the tool in the coordinate system of the robot base can be queried using get_calib_data.

Acquiring a suitable set of observations

The following conditions, especially if using a standard calibration plate, should be considered:

- The position of the calibration object (moving camera: relative to the robot's base; stationary camera: relative to the robot's tool) and the position of the camera (moving camera: relative to the robot's tool; stationary camera: relative to the robot's base) must not be changed between the calibration poses.
- Even though a lower limit of three calibration object poses is theoretically possible, it is recommended to acquire 10 or more poses, in which the pose of the camera or the robot hand are sufficiently different. If *'optimization_method'* is set to *'stochastic'*, at least 25 poses are recommended. The estimation will be better the more poses are used.

  For articulated (i.e., non-SCARA) robots the amount of rotation between the calibration object poses is essential and should be at least 30 degrees or better 60 degrees. The rotations between the poses must exhibit at least two different axes of rotation. Very different orientations lead to more precise results of the hand-eye

calibration. For SCARA robots there is only one axis of rotation. The amount of rotation between the images should also be large.

- For cameras, the internal camera parameters must be constant during and after the calibration. Note that changes of the image size, the focal length, the aperture, or the focus cause a change of the internal camera parameters.
- As mentioned, the camera must not be modified between the acquisition of the individual images. Please make sure that the focus is sufficient for the expected changes of the camera to calibration plate distance. Therefore, bright lighting conditions for the calibration plate are important, because then you can use smaller apertures, which result in a larger depth of focus.

Obtaining the poses of the robot tool

We recommend to create the robot poses in a separate program and save them in files using `write_pose`. In the calibration program you can then import them and set them in the calibration data model `CalibDataID`.

Via the Cartesian interface of the robot, you can typically obtain the pose of the tool in robot base coordinates in a notation that corresponds to the pose representations with the codes 0 or 2 (`OrderOfRotation` = *'gba'* or *'abg'*, see `create_pose`). In this case, you can directly use the pose values obtained from the robot as input for `create_pose`.

If the Cartesian interface of your robot describes the orientation in a different way, e.g., with the representation ZYZ ($\mathbf{R}_z(\varphi 1) \cdot \mathbf{R}_y(\varphi 2) \cdot \mathbf{R}_z(\varphi 3)$), you can create the corresponding homogeneous transformation matrix step by step using the operators `hom_mat3d_rotate` and `hom_mat3d_translate` and then convert the resulting matrix into a pose using `hom_mat3d_to_pose`. The following example code creates a pose from the ZYZ representation described above:

```
hom_mat3d_identity(HomMat3DIdent)
hom_mat3d_rotate(HomMat3DIdent, phi3, 'z', 0, 0, 0, HomMat3DRotZ)
hom_mat3d_rotate(HomMat3DRotZ, phi2, 'y', 0, 0, 0, HomMat3DRotZY)
hom_mat3d_rotate(HomMat3DRotZY, phi1, 'z', 0, 0, 0,
HomMat3DRotZYZ)
hom_mat3d_translate(HomMat3DRotZYZ, Tx, Ty, Tz, base_H_tool)
hom_mat3d_to_pose(base_H_tool, RobPose)
```

Please note that the hand-eye calibration only works if the poses of the tool in robot base coordinates are specified with high accuracy. Of the provided methods, *'optimization_method'* set to *'stochastic'* will yield the most robust results with respect to noise on the poses of the tool in robot base coordinates. The estimation will be better the more input poses are used.

Please note that this operator supports canceling timeouts and interrupts if *'optimization_method'* is set to *'stochastic'*.

Parameters

▷ **CalibDataID** (input_control) ..... calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **Errors** (output_control) ..... number-array ⇝ *real*
Average residual error of the optimization.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_calib_data, set_calib_data_cam_param, set_calib_data_calib_object, set_calib_data_observ_pose, find_calib_object, set_calib_data, remove_calib_data, remove_calib_data_observ

Possible Successors

get_calib_data

Module

Calibration

get_calib_data_observ_pose (: : CalibDataID, CameraIdx, CalibObjIdx, CalibObjPoseIdx : ObjInCameraPose)

Get observed calibration object poses from a calibration data model.

The operator get_calib_data_observ_pose reads the poses of the calibration object given in the camera coordinate system from a calibration data model CalibDataID. The observation data was previously stored by set_calib_data_observ_pose, find_calib_object, or set_calib_data_observ_points.

Note that if the model CalibDataID uses a general sensor and no calibration object (i.e., the model was created by create_calib_data with NumCameras=0 and NumCalibObjects=0), then both CameraIdx and CalibObjIdx must be set to 0.

Parameters

- ▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
  Handle of a calibration data model.
- ▷ **CameraIdx** (input_control) . . . . . number ⇝ *integer*
  Index of the observing camera.
  Default: 0
- ▷ **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
  Index of the observed calibration object.
  Default: 0
- ▷ **CalibObjPoseIdx** (input_control) . . . . . number ⇝ *integer*
  Index of the observed calibration object pose.
  Default: 0
- ▷ **ObjInCameraPose** (output_control) . . . . . pose ⇝ *real* / integer
  Stored observed calibration object pose relative to the observing camera.
  Number of elements: 7

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

hand_eye_calibration (: : X, Y, Z, Row, Col, NumPoints, RobotPoses, CameraParam, Method, QualityType : CameraPose, CalibrationPose, Quality)

Perform a hand-eye calibration.

The operator hand_eye_calibration determines the 3D pose of a robot ("hand") relative to a camera ("eye"). With this information, the results of image processing can be transformed into the coordinate system of the robot which can then, e.g., grasp an inspected part. Please note that the operator hand_eye_calibration does not support 3D sensors. A hand-eye calibration including 3D sensors is only supported by the operator calibrate_hand_eye. That operator furthermore provides a more user-friendly interface to the hand-eye calibration than the operator hand_eye_calibration, since the reference coordinate systems are explicitly indicated.

There are two possible configurations of robot-camera (hand-eye) systems: The camera can be mounted on the robot or be stationary and observe the robot. Note that the term robot is used in place for a mechanism that moves objects. Thus, you can use hand_eye_calibration to calibrate many different systems, from pan-tilt heads to multi-axis manipulators.

In essence, systems suitable for hand-eye calibration are described by a closed chain of four Euclidean transformations. In this chain two non-consecutive transformations are either known from the robot controller or computed from calibration points seen by a camera system. The two other constant transformations are computed by the hand-eye calibration procedure.

A hand-eye calibration is performed similarly to the calibration of the external camera parameters (see camera_calibration): You acquire a set of images of a calibration object, determine correspondences between known calibration points and their projection in the images and pass them to hand_eye_calibration via the parameters X, Y, Z, Row, Col, and NumPoints. If you use the standard calibration plate, the correspondences can be determined very easily with the operators find_caltab and find_marks_and_pose. Furthermore, the camera is identical for the complete calibration sequence and is specified by the internal camera parameters in CameraParam. The internal camera parameters are calibrated beforehand deploying the operator calibrate_cameras or camera_calibration.

In contrast to the camera calibration, the calibration object is not moved manually. This task is delegated to the robot, which either moves the camera (mounted camera) or the calibration object (stationary camera). The robot's movements are assumed to be known and therefore are also used as an input for the calibration (parameter RobotPoses).

The output of hand_eye_calibration are the two poses CameraPose and CalibrationPose. Their pose type is identical to the pose type of the first input robot pose.

Basically, two hand-eye configurations can be distinguished and are discussed in more detail below, followed by general information about the process of hand-eye calibration.

Moving camera (mounted on a robot)

In this configuration, the calibration object remains stationary and the camera is moved to different positions by the robot. The main idea behind the hand-eye calibration is that the information extracted from a calibration image, i.e., the pose of the calibration object relative to the camera (i.e., the external camera parameters), can be seen as a chain of poses or homogeneous transformation matrices, from the calibration object via the base of the robot to its tool (end-effector) and finally to the camera:

Moving camera:

$$ {}^{cam}\mathbf{H}_{cal} = {}^{cam}\mathbf{H}_{tool} \cdot {}^{tool}\mathbf{H}_{base} \cdot {}^{base}\mathbf{H}_{cal} $$

CameraPose RobotPoses CalibrationPose

From the set of calibration images, the operator hand_eye_calibration determines the two transformations at the ends of the chain, i.e., the pose of the robot tool in camera coordinates (${}^{cam}\mathbf{H}_{tool}$,CameraPose) and the pose of the calibration object in the robot base coordinate system (${}^{base}\mathbf{H}_{cal}$,CalibrationPose).

In contrast, the transformation in the middle of the chain, ${}^{tool}\mathbf{H}_{base}$, is known but changes for each calibration image, because it describes the pose of the robot moving the camera, or to be more exact its inverse pose (pose of

the base coordinate system in robot tool coordinates). You must specify the inverse robot poses in the calibration images in the parameter RobotPoses.

Note that when calibrating SCARA robots it is not possible to determine the Z translation of CalibrationPose. To eliminate this ambiguity the Z translation of CalibrationPose is internally set to 0.0 and the CameraPose is calculated accordingly. It is necessary to determine the true translation in Z after the calibration (see calibrate_hand_eye).

Stationary camera

In this configuration, the robot grasps the calibration object and moves it in front of the camera. Again, the information extracted from a calibration image, i.e., the pose of the calibration object in camera coordinates (the external camera parameters), are equal to a chain of poses or homogeneous transformation matrices, this time from the calibration object via the robot's tool to its base and finally to the camera:

Stationary camera:

$$^{cam}\mathbf{H}_{cal} = {}^{cam}\mathbf{H}_{base} \cdot {}^{base}\mathbf{H}_{tool} \cdot {}^{tool}\mathbf{H}_{cal}$$

CameraPose RobotPoses CalibrationPose

Analogously to the configuration with a moving camera, the operator hand_eye_calibration determines the two transformations at the ends of the chain, here the pose of the robot base coordinate system in camera coordinates ($^{cam}\mathbf{H}_{base}$,CameraPose) and the pose of the calibration object relative to the robot tool ($^{tool}\mathbf{H}_{cal}$,CalibrationPose).

The transformation in the middle of the chain, $^{base}\mathbf{H}_{tool}$, describes the pose of the robot moving the calibration object, i.e., the pose of the tool relative to the base coordinate system. You must specify the robot poses in the calibration images in the parameter RobotPoses.

Note that when calibrating SCARA robots it is not possible to determine the Z translation of CalibrationPose. To eliminate this ambiguity the Z translation of CalibrationPose is internally set to 0.0 and the CameraPose is calculated accordingly. It is necessary to determine the true translation in Z after the calibration (see calibrate_hand_eye).

Additional information about the calibration process

The following sections discuss individual questions arising from the use of hand_eye_calibration. They are intended to be a guideline for using the operator in an application, as well as to help understanding the operator.

How do I get 3D calibration points and their projections? 3D calibration points given in the world coordinate system (X, Y, Z) and their associated projections in the image (Row, Col) form the basis of the hand-eye calibration. In order to be able to perform a successful hand-eye calibration, you need at least three images of the 3D calibration points that were obtained under different poses of the manipulator. In each image at least four points must be available, in order to compute internally the pose transferring the calibration points from their world coordinate system into the camera coordinate system.

In principle, you can use arbitrary known points for the calibration. However, it is usually most convenient to use the standard calibration plate, e.g., the one that can be generated with gen_caltab. In this case, you can use the operators find_caltab and find_marks_and_pose to extract the position of the calibration plate and of the calibration marks and the operator caltab_points to read the 3D coordinates of the calibration marks (see also the description of camera_calibration).

The parameter NumPoints specifies the number of 3D calibration points used for each pose of the manipulator, i.e., for each image. With this, the 3D calibration points which are stored in a linearized fashion in X, Y, Z, and their corresponding projections (Row, Col) can be associated with the corresponding pose of the manipulator (RobotPoses). Note that in contrast to the operator camera_calibration the 3D coordinates of the calibration points must be specified for each calibration image, not only once, and thus can vary for each image of the sequence.

How do I acquire a suitable set of images? The following conditions, especially if using a standard calibration plate, should be considered:

- The position of the calibration marks (moving camera: relative to the robot's base; stationary camera: relative to the robot's tool) and the position of the camera (moving camera: relative to the robot's tool; stationary camera: relative to the robot's base) must not be changed between the images.

- The internal camera parameters (CameraParam) must be constant and must be determined in a previous camera calibration step (see camera_calibration). Note that changes of the image size, the focal length, the aperture, or the focus cause a change of the internal camera parameters.
- The theoretical lower limit of the number of image to acquire is three. Nevertheless, it is recommended to have 10 or more images at hand, in which the position of the camera or the robot hand are sufficiently different.
  For articulated (i.e., non-SCARA) robots the amount of rotation between the images is essential and should be at least 30 degrees or better 60 degrees. The rotations between the images must exhibit at least two different axes of rotation. Very different orientations lead to precise calibration results. For SCARA robots there is only one axis of rotation. The amount of rotation between the images should also be large.
- In each image, the calibration plate must be completely visible (including its border).
- Reflections or other disturbances should not impair the detection of the calibration plate and its calibration marks.
- If individual calibration marks instead of the standard calibration plate are used at least four marks must be present in each image.
- In each image, the calibration plate should at least fill one quarter of the entire image for a precise computation of the calibration to camera transformation, which is performed internally during hand-eye calibration.
- As mentioned, the camera must not be modified between the acquisition of the individual images. Please make sure that the focus is sufficient for the expected changes of the camera to calibration plate distance. Therefore, bright lighting conditions for the calibration plate are important, because then you can use smaller apertures, which result in a larger depth of focus.

How do I obtain the poses of the robot? In the parameter RobotPoses you must pass the poses of the robot in the calibration images (moving camera: pose of the robot base in robot tool coordinates; stationary camera: pose of the robot tool in robot base coordinates) in a linearized fashion. We recommend to create the robot poses in a separate program and save in files using write_pose. In the calibration program you can then read and accumulate them in a tuple as shown in the example program below. In addition, we recommend to save the pose of the robot tool in robot base coordinates independent of the hand-eye configuration. When using a moving camera, you then invert the read poses before accumulating them. This is also shown in the example program.

Via the Cartesian interface of the robot, you can typically obtain the pose of the tool in base coordinates in a notation that corresponds to the pose representations with the codes 0 or 2 (OrderOfRotation = *'gba'* or *'abg'*, see create_pose). In this case, you can directly use the pose values obtained from the robot as input for create_pose.

If the Cartesian interface of your robot describes the orientation in a different way, e.g., with the representation ZYZ ($\mathbf{R}_z(\varphi 1) \cdot \mathbf{R}_y(\varphi 2) \cdot \mathbf{R}_z(\varphi 3)$), you can create the corresponding homogeneous transformation matrix step by step using the operators hom_mat3d_rotate and hom_mat3d_translate and then convert the matrix into a pose using hom_mat3d_to_pose. The following example code creates a pose from the ZYZ representation described above:

```
hom_mat3d_identity(HomMat3DIdent)
hom_mat3d_rotate(HomMat3DIdent, phi3, 'z', 0, 0, 0,
HomMat3DRotZ)
hom_mat3d_rotate(HomMat3DRotZ, phi2, 'y', 0, 0, 0,
HomMat3DRotZY)
hom_mat3d_rotate(HomMat3DRotZY, phi1, 'z', 0, 0, 0,
HomMat3DRotZYZ)
hom_mat3d_translate(HomMat3DRotZYZ, Tx, Ty, Tz, base_H_tool)
hom_mat3d_to_pose(base_H_tool, RobPose)
```

Please note that the hand-eye calibration only works if the robot poses RobotPoses are specified with high accuracy!

What is the order of the individual parameters? The length of the tuple NumPoints corresponds to the number of different positions of the manipulator and thus to the number of calibration images. The parameter NumPoints determines the number of calibration points used in the individual positions. If the standard calibration plate is used, this means 49 points per position (image). If, for example, 15 images were acquired, NumPoints is a tuple of length 15, where all elements of the tuple have the value 49.

The number of images in the sequence, which is determined by the length of NumPoints, must also be taken into account for the tuples of the 3D calibration points and the extracted 2D marks, respectively. Hence, for 15 calibration images with 49 calibration points each, the tuples X, Y, Z, Row, and Col must contain $15 \cdot 49 = 735$ values each. These tuples are ordered according to the image the respective points lie in, i.e., the first 49 values correspond to the 49 calibration points in the first image. The order of the 3D calibration points and the extracted 2D calibration points must be the same in each image.

The length of the tuple RobotPoses also depends on the number of calibration images. If, for example, 15 images and therefore 15 poses are used, the length of the tuple RobotPoses is $15 \cdot 7 = 105$ (15 times 7 pose parameters). The first seven parameters thus determine the pose of the manipulator in the first image, and so on.

Algorithm and output parameters The parameter Method determines the type of algorithm used for the hand-eye calibration: With *'linear'* a linear algorithm is chosen, which is fast but in many practical situations not accurate enough. *'nonlinear'* selects a non-linear algorithm, which results in the most accurately calibrated poses and which is the method of choice.

For the calibration of SCARA robots the parameter Method must be set to *'scara_linear'* or *'scara_nonlinear'*, respectively. While the arm of an articulated robot has three rotary joints typically covering 6 degrees of freedom (3 translations and 3 rotations), SCARA robots have two parallel rotary joints and one parallel prismatic joint covering only 4 degrees of freedom (3 translations and 1 rotation). Loosely speaking, an articulated robot is able to tilt its end effector while a SCARA robot is not.

The parameter QualityType switches between different possibilities for assessing the quality of the calibration result returned in Quality. *'error_pose'* stands for the pose error of the complete chain of transformations. To be more precise, a tuple with four elements is returned, where the first element is the root-mean-square error of the translational part, the second element is the root-mean-square error of the rotational part, the third element is the maximum translational error and the fourth element is the maximum rotational error. With *'standard_deviation'*, a tuple with 12 elements containing the standard deviations of the two poses is returned: The first six elements refer to the camera pose and the others to the pose of the calibration points. With *'covariance'*, the full 12x12 covariance matrix of both poses is returned. Like poses, the standard deviations and the covariances are specified in the units [m] and [°]. Note that selecting *'linear'* or *'scara_linear'* for the parameter Method enables only the output of the pose error (*'error_pose'*).

Parameters

▷ **X** (input_control) . . . . . number-array ⇝ *real* / integer
Linear list containing all the x coordinates of the calibration points (in the order of the images).

▷ **Y** (input_control) . . . . . number-array ⇝ *real* / integer
Linear list containing all the y coordinates of the calibration points (in the order of the images).

▷ **Z** (input_control) . . . . . number-array ⇝ *real* / integer
Linear list containing all the z coordinates of the calibration points (in the order of the images).

▷ **Row** (input_control) . . . . . number-array ⇝ *real* / integer
Linear list containing all row coordinates of the calibration points (in the order of the images).

▷ **Col** (input_control) . . . . . number-array ⇝ *real* / integer
Linear list containing all the column coordinates of the calibration points (in the order of the images).

▷ **NumPoints** (input_control) . . . . . integer-array ⇝ *integer*
Number of the calibration points for each image.

▷ **RobotPoses** (input_control) . . . . . pose-array ⇝ *real* / integer
Known 3D pose of the robot for each image (moving camera: robot base in robot tool coordinates; stationary camera: robot tool in robot base coordinates).

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **Method** (input_control) . . . . . string ⇝ *string*
Method of hand-eye calibration.
Default: 'nonlinear'
List of values: Method ∈ {'linear', 'nonlinear', 'scara_linear', 'scara_nonlinear'}

▷ **QualityType** (input_control) . . . . . string(-array) ⇝ *string*
Type of quality assessment.
Default: 'error_pose'
List of values: QualityType ∈ {'error_pose', 'standard_deviation', 'covariance'}

▷ **CameraPose** (output_control) . . . . . pose ⇝ *real* / integer
Computed relative camera pose: 3D pose of the robot tool (moving camera) or robot base (stationary camera), respectively, in camera coordinates.

▷ **CalibrationPose** (output_control) . . . . . pose ⇝ *real* / integer
Computed 3D pose of the calibration points in robot base coordinates (moving camera) or in robot tool coordinates (stationary camera), respectively.

▷ **Quality** (output_control) . . . . . real(-array) ⇝ *real*
Quality assessment of the result.

Example

```
* Note that, in order to use this code snippet, you must provide
* the camera parameters, the calibration plate description file,
* the calibration images, and the robot poses.
read_cam_par('campar.dat', CameraParam)
CalDescr := 'caltab.descr'
caltab_points(CalDescr, X, Y, Z)
* Process all calibration images.
for i := 0 to NumImages-1 by 1
  read_image(Image, 'calib_'+i$'02d')
  * Find marks on the calibration plate in every image.
  find_caltab(Image, CalPlate, CalDescr, 3, 150, 5)
  find_marks_and_pose(Image, CalPlate, CalDescr, CameraParam, 128, 10, 18, \
                      0.9, 15, 100, RCoordTmp, CCoordTmp, StartPose)
  * Accumulate 2D and 3D coordinates of the marks.
  RCoord := [RCoord, RCoordTmp]
  CCoord := [CCoord, CCoordTmp]
  XCoord := [XCoord, X]
  YCoord := [YCoord, Y]
  ZCoord := [ZCoord, Z]
  NumMarker := [NumMarker, |RCoordTmp|]
  * Read pose of the robot tool in robot base coordinates.
  read_pose('robpose_'+i$'02d'+'.dat', RobPose)
  * Moving camera? Invert pose.
  if (IsMovingCameraConfig == 'true')
    pose_to_hom_mat3d(RobPose, base_H_tool)
    hom_mat3d_invert(base_H_tool, tool_H_base)
    hom_mat3d_to_pose(tool_H_base, RobPose)
  endif
  * Accumulate robot poses.
  RobotPoses := [RobotPoses, RobPose]
endfor
*
* Perform hand-eye calibration.
*
hand_eye_calibration(XCoord, YCoord, ZCoord, RCoord, CCoord, NumMarker, \
                     RobotPoses, CameraParam, 'nonlinear', 'error_pose', \
                     CameraPose, CalibrationPose, Error)
```

Result

The operator `hand_eye_calibration` returns the value `2` (`H_MSG_TRUE`) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

set_calib_data_observ_pose (: : CalibDataID, CameraIdx, CalibObjIdx, CalibObjPoseIdx, ObjInCameraPose :)

Set observed calibration object poses in a calibration data model.

For a calibration data model of type CalibSetup='*hand_eye_moving_cam*', '*hand_eye_stationary_cam*', '*hand_eye_scara_moving_cam*', or '*hand_eye_scara_stationary_cam*' with no calibration object (see create_calib_data), the hand-eye calibration is based on so-called observations of an arbitrary object in the camera coordinate system. In the following this object will be called calibration object. Additionally, the corresponding poses of the robot tool in the robot base coordinate system must be known. With set_calib_data_observ_pose, you store an observation of the calibration object pose in the calibration data model CalibDataID. An observation of the calibration object pose consists of the following data:

CameraIdx: Index of the observing camera

CalibObjIdx: Index of the observed calibration object

CalibObjPoseIdx: Index of the observed pose of the calibration object. You can choose it freely, without following a strict order. If you specify an index that already exists for the calibration object CalibObjIdx, the corresponding observation data is replaced by the new one.

ObjInCameraPose: Pose of the observed calibration object relative to observing camera.

Note that, since the model CalibDataID uses a general sensor and no calibration object (i.e., the model was created by create_calib_data with NumCameras=0 and NumCalibObjects=0), both CameraIdx and CalibObjIdx must be set to 0. If the model uses a camera and an calibration object (i.e., NumCameras=1 and NumCalibObjects=1), then find_calib_object or set_calib_data_observ_points must be used.

The observation pose data can be accessed later by calling get_calib_data_observ_pose using the same values for the arguments CameraIdx, CalibObjIdx, and CalibObjPoseIdx.

Parameters

▷ **CalibDataID** (input_control) ..... calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **CameraIdx** (input_control) ..... number ⇝ *integer*
Index of the observing camera.
Default: 0
Suggested values: CameraIdx ∈ {0, 1, 2}

▷ **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
Index of the calibration object.
Default: 0
Suggested values: CalibObjIdx ∈ {0, 1, 2}

▷ **CalibObjPoseIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration object.
Default: 0
Suggested values: CalibObjPoseIdx ∈ {0, 1, 2}
Restriction: CalibObjPoseIdx >= 0

▷ **ObjInCameraPose** (input_control) . . . . . pose ⇝ *real* / integer
Pose of the observed calibration object relative to the observing camera.
Number of elements: 7

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

find_marks_and_pose, set_calib_data_cam_param, set_calib_data_calib_object

Possible Successors

set_calib_data, calibrate_cameras

Alternatives

find_calib_object

Module

Calibration

6.5 Inverse Projection

get_line_of_sight (: : Row, Column, CameraParam : PX, PY, PZ, QX, QY, QZ)

Compute the line of sight corresponding to a point in the image.

get_line_of_sight computes the line of sight corresponding to a pixel (Row, Column) in the image. The line of sight is a (straight) line in the camera coordinate system, which is described by two points (PX,PY,PZ) and (QX,QY,QZ) on the line. The camera is described by the internal camera parameters CameraParam (see Calibration for details). If a pinhole camera is used, the second point lies on the focal plane, i.e., for frame cameras, the output parameter QZ is equivalent to the focal length of the camera, whereas for linescan cameras, QZ also depends on the motion of the camera with respect to the object. The equation of the line of sight is given by

$$\begin{pmatrix} X \\ Y \\ Z \end{pmatrix} = \begin{pmatrix} \mathtt{PX} \\ \mathtt{PY} \\ \mathtt{PZ} \end{pmatrix} + l \cdot \begin{pmatrix} \mathtt{QX} - \mathtt{PX} \\ \mathtt{QY} - \mathtt{PY} \\ \mathtt{QZ} - \mathtt{PZ} \end{pmatrix}$$

The advantage of representing the line of sight as two points is that it is easier to transform the line in 3D. To do so, all that is necessary is to apply the operator affine_trans_point_3d to the two points.

Parameters

▷ **Row** (input_control) . . . . . real-array ⇝ *real*
Row coordinate of the pixel.

▷ **Column** (input_control) . . . . . real-array ⇝ *real*
Column coordinate of the pixel.

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **PX** (output_control) . . . . . real-array ⇝ *real*
X coordinate of the first point on the line of sight in the camera coordinate system

▷ **PY** (output_control) . . . . . real-array ⇝ *real*
Y coordinate of the first point on the line of sight in the camera coordinate system

▷ **PZ** (output_control) . . . . . real-array ⇝ *real*
Z coordinate of the first point on the line of sight in the camera coordinate system

▷ **QX** (output_control) . . . . . real-array ⇝ *real*
X coordinate of the second point on the line of sight in the camera coordinate system

▷ **QY** (output_control) . . . . . real-array ⇝ *real*
Y coordinate of the second point on the line of sight in the camera coordinate system

▷ **QZ** (output_control) . . . . . real-array ⇝ *real*
Z coordinate of the second point on the line of sight in the camera coordinate system

Example

```
* Set internal camera parameters.
* Note the, typically, these values are the result of a prior
* calibration.
gen_cam_par_area_scan_division (0.01, 30, 4.65e-006, 4.65e-006, \
                                640, 480, 1280, 960, CameraParam)
* Inverse projection.
get_line_of_sight([50, 100], [100, 200], CameraParam, PX, PY, PZ, QX, QY, QZ)
```

Result

`get_line_of_sight` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Calibration

6.6 Monocular

camera_calibration (: : NX, NY, NZ, NRow, NCol, StartCamParam, NStartPose, EstimateParams : CameraParam, NFinalPose, Errors)

Determine all camera parameters by a simultaneous minimization process.

camera_calibration performs the calibration of a single camera. For this, known 3D model points (with coordinates NX, NY, NZ) are projected into the image and the sum of the squared distances between the projected 3D-coordinates and their corresponding image point coordinates (NRow, NCol) is minimized.

As initial values for the minimization process the external (NStartPose) and internal (StartCamParam) camera parameters are used. Thereby NStartPose is an ordered tuple with all initial values for the external camera parameters given in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *ccs* denotes the camera coordinate system and *wcs* the world coordinate system (see Transformations / Poses and "Solution Guide III-C - 3D Vision"). Individual camera parameters can be explicitly included or excluded from the minimization with EstimateParams. For a detailed description of the available camera models, the different sets of internal camera parameters, and general requirements for the setup, see Calibration.

For a successful calibration, at least one calibration object with accurately known metric properties is needed, e.g., a HALCON calibration plate. Before calling camera_calibration, take a series of images of the calibration object in different orientations and make sure that the whole field of view or measurement volume is covered. The success of the calibration highly depends on the quality of the calibration object and the images. So you might want to exercise special diligence during the acquisition of the calibration images. See the section "How to take a set of suitable images?" in Calibration for further details.

After a successful calibration, camera_calibration returns the optimized internal (CameraParam) and external (NFinalPose ${}^{ccs}\mathbf{P}_{wcs}$) camera parameters of the camera. Additionally, the root mean square error (RMSE) of the back projection of the optimization is returned in Errors (in pixels). This error gives a general indication whether the optimization was successful.

Preparation of the calibration process

How to extract the calibration marks in the images? If a HALCON calibration plate is used, you can use the operator find_calib_object to determine the coordinates of the calibration marks in each image and to compute a rough estimate for the external camera parameters. Using HALCON calibration plates with rectangularly arranged marks (see gen_caltab), a combination of the two operators find_caltab and find_marks_and_pose will have the same effect. In both cases, the hereby obtained values can directly be used as initial values for the external camera parameters (NStartPose).

Obviously, images in which the segmentation of the calibration plate (find_caltab) has failed or the calibration marks have not been determined successfully by find_marks_and_pose or find_calib_object should not be used.

How do you get the required initial values for the calibration? If you use a HALCON calibration plate, the input parameters NX, NY, and NZ are stored in the description file of the calibration plate. You can easily access them by calling the operator caltab_points. Initial values for the internal camera parameters (StartCamParam) can be obtained from the specifications of the used camera. Further information can be found in Calibration. Initial values for the poses of the calibration plate and the coordinates of the calibration marks NRow and NCol can be calculated using the operator find_calib_object. The tuple NStartPose is set by the concatenation of all these poses.

Which camera parameters are estimated? The input parameter EstimateParams is used to select which camera parameters to estimate. Usually, this parameter is set to *'all'*, i.e., all 6 external camera parameters (translation and rotation) and all internal camera parameters are determined. If the internal camera parameters already have been determined (e.g., by a previous call to camera_calibration), it is often desired to only determine the pose of the world coordinate system in camera coordinates (i.e., the external camera parameters). In this case, EstimateParams can be set to *'pose'*. This has the same effect as EstimateParams = *['alpha','beta','gamma','transx','transy','transz']*. Otherwise, EstimateParams contains a tuple of strings that indicates the combination of parameters to estimate. In addition, parameters can be excluded from estimation by using the prefix ~. For example, the values *['pose','~transx']* have the same effect as *['alpha','beta','gamma','transy','transz']*. As a different example, *['all','~focus']* determines all internal and external parameters except the focus. The prefix ~ can be used with all parameter values except *'all'*.

Which limitations exist for the determination of the camera parameters? For additional information about general limitations when determining camera parameters, please see the section "Further Limitations Related to Specific Camera Types" in the chapter Calibration.

What is the order within the individual parameters? The length of the tuple NStartPose depends on the number of calibration images, e.g., using 15 images leads to a length of the tuple NStartPose equal to $15 \cdot 7 = 105$ (15 times the 7 external camera parameters). The first 7 values correspond to the pose of the calibration plate in the first image, the next 7 values to the pose in the second image, etc.

This fixed number of calibration images must be considered within the tuples with the coordinates of the 3D model marks and the extracted 2D marks. If 15 images are used, the length of the tuples NRow and NCol is 15 times the length of the tuples with the coordinates of the 3D model marks (NX, NY, and NZ). If every image consists 49 marks, the length of the tuples NRow and NCol is $15 \cdot 49 = 735$, while the length of the tuples NX, NY, and NZ is 49. The order of the values in NRow and NCol is "image after image", i.e., using 49 marks the first 3D model point corresponds to the 1st, 50th, 99th, 148th, 197th, 246th, etc. extracted 2D mark.

What is the meaning of the output parameters? If the camera calibration process has finished successfully, the output parameters CameraParam and NFinalPose contain the adjusted values for the internal and external camera parameters. The length of the tuple NFinalPose corresponds to the length of the tuple NStartPose.

The representation types of NFinalPose correspond to the representation type of the first tuple of NStartPose (see create_pose). You can convert the representation type by convert_pose_type.

As an additional parameter, the root mean square error (RMSE) (Errors) of the back projection of the optimization is returned. This parameter reflects the accuracy of the calibration. The error value (root mean square error of the position) is measured in pixels. If only a single camera is calibrated, an Error in the order of 0.1 pixel (the typical detection error by extraction of the coordinates of the projected calibration markers) is an indication that the optimization fits the observation data well. If Errors strongly differs from 0.1 pixels, the calibration did not perform well. Reasons for this might be, e.g., a poor image quality, an insufficient number of calibration images, or an inaccurate calibration plate.

Do I have to use a planar calibration object? No. The operator camera_calibration is designed in a way that the input tuples NX, NY, NZ, NRow, and NCol can contain any 3D/2D correspondences. The order of the single parameters is explained in the paragraph "What is the order within the individual parameters?".

Thus, it makes no difference how the required 3D model marks and the corresponding 2D marks are determined. On the one hand, it is possible to use a 3D calibration object, on the other hand, you also can use any characteristic points (e.g., natural landmarks) with known position in the world. By setting EstimateParams to *'pose'*, it is thus possible to compute the pose of an object in camera coordinates! For this, at least three 3D/2D-correspondences are necessary as input. NStartPose can, e.g., be generated directly as shown in the program example for create_pose.

Attention

The minimization process of the calibration depends on the initial values of the internal (StartCamParam) and external (NStartPose) camera parameters. The computed average errors Errors give an impression of the accuracy of the calibration. The errors (deviations in x- and y-coordinates) are measured in pixels.

For line scan cameras, it is possible to set the start value for the internal camera parameter Sy to the value 0.0. In this case, it is not possible to determine the position of the principal point in y-direction. Therefore, EstimateParams must contain the term *'~cy'*. The effective distance of the principle point from the sensor line is then always $p_v = S_y \cdot C_y = 0.0$. Further information can be found in the section "Further Limitations Related to Specific Camera Types" of Calibration.

Parameters

▷ **NX** (input_control) . . . . . number-array ⇝ *real* / integer
Ordered tuple with all x coordinates of the calibration marks (in meters).

▷ **NY** (input_control) . . . . . number-array ⇝ *real* / integer
Ordered tuple with all y coordinates of the calibration marks (in meters).
Number of elements: NY == NX

▷ **NZ** (input_control) . . . . . number-array ⇝ *real* / integer
Ordered tuple with all z coordinates of the calibration marks (in meters).
Number of elements: NZ == NX

▷ **NRow** (input_control) . . . . . number-array ⇝ *real* / integer
Ordered tuple with all row coordinates of the extracted calibration marks (in pixels).

▷ **NCol** (input_control) . . . . . number-array ⇝ *real* / integer
Ordered tuple with all column coordinates of the extracted calibration marks (in pixels).
Number of elements: NCol == NRow

▷ **StartCamParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Initial values for the internal camera parameters.

▷ **NStartPose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
Ordered tuple with all initial values for the external camera parameters.
Number of elements: NStartPose == 7 * NRow / NX

▷ **EstimateParams** (input_control) . . . . . string-array ⇝ *string*
Camera parameters to be estimated.
Default: 'all'
List of values: `EstimateParams` ∈ {'all', 'pose', 'camera', 'alpha', 'beta', 'gamma', 'transx', 'transy', 'transz', 'focus', 'magnification', 'kappa', 'poly', 'k1', 'k2', 'k3', 'poly_tan_2', 'image_plane_dist', 'tilt', 'cx', 'cy', 'sx', 'sy', 'vx', 'vy', 'vz'}

▷ **CameraParam** (output_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **NFinalPose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
Ordered tuple with all external camera parameters.
Number of elements: NFinalPose == 7 * NRow / NX

▷ **Errors** (output_control) . . . . . real(-array) ⇝ *real*
Average error distance in pixels.

Example

```
* Read calibration images.
read_image(Image1, 'calib/grid_space.cal.k.000')
read_image(Image2, 'calib/grid_space.cal.k.001')
read_image(Image3, 'calib/grid_space.cal.k.002')
*  Find calibration pattern.
find_caltab(Image1, CalPlate1, 'caltab_big.descr', 3, 112, 5)
find_caltab(Image2, CalPlate2, 'caltab_big.descr', 3, 112, 5)
find_caltab(Image3, CalPlate3, 'caltab_big.descr', 3, 112, 5)
*  Find calibration marks and start poses.
StartCamPar := ['area_scan_division', 0.008, 0.0, 0.000011, 0.000011, \
                384, 288, 768, 576]
find_marks_and_pose(Image1, CalPlate1, 'caltab_big.descr', StartCamPar, \
                    128, 10, 18, 0.9, 15.0, 100.0, RCoord1, CCoord1, \
                    StartPose1)
find_marks_and_pose(Image2, CalPlate2, 'caltab_big.descr', StartCamPar, \
                    128, 10, 18, 0.9, 15.0, 100.0, RCoord2, CCoord2, \
                    StartPose2)
find_marks_and_pose(Image3, CalPlate3, 'caltab_big.descr', StartCamPar, \
                    128, 10, 18, 0.9, 15.0, 100.0, RCoord3, CCoord3, \
                    StartPose3)
*  Read 3D positions of calibration marks.
caltab_points('caltab_big.descr', NX, NY, NZ)
*  Camera calibration.
camera_calibration(NX, NY, NZ, [RCoord1, RCoord2, RCoord3], \
                   [CCoord1, CCoord2, CCoord3], StartCamPar, \
                   [StartPose1, StartPose2, StartPose3], 'all', \
                   CameraParam, NFinalPose, Errors)
*  Write internal camera parameters to file.
write_cam_par(CameraParam, 'campar.dat')
```

Result

`camera_calibration` returns `2` (`H_MSG_TRUE`) if all parameter values are correct and the desired camera parameters have been determined by the minimization algorithm. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Calibration

6.7 Multi-View

This chapter describes how to calibrate different multi-view camera setups.

In order to achieve high accuracy for your measuring tasks you need to calibrate your camera setup. In comparison to a single-camera setup, some additional requirements apply to the calibration of a multi-view camera setup. The following paragraphs provide explanations regarding the calibration of multi-view camera setups. For general information on camera calibration please refer to the chapter Calibration.

Preparing the Calibration Input Data for Multi-View Camera Setups

Before the actual calibration can be performed, a calibration data model must be prepared (as described in Calibration). For setups with multiple cameras, these additional aspects should be considered:

- The number of cameras in the setup and the number of used calibration objects can be set when calling create_calib_data.
- When specifying the camera type with set_calib_data_cam_param, note that only cameras of the same type (i.e., area scan or line scan) can be calibrated in a single setup.
- Configure the calibration process, e.g., specify the reference camera, using set_calib_data. You can also specify parameters for the complete setup or just configure parameters of individual cameras as well as calibration object poses in the setup.

Performing the Actual Camera Calibration

The calibration performed by calibrate_cameras depends on the camera types that are involved in the calibration setup. While different camera setups require specific conditions when acquiring images, the basic steps of the calibration procedure for setups including projective and/or telecentric cameras are similar:

1. **Building a chain of observation poses:** In the first step, the operator calibrate_cameras tries to build a valid chain of observation poses, that connects all cameras and calibration object poses to the reference camera. Depending on the setup, the conditions for a valid chain of poses differ. For specific information see the respective paragraphs below.

   If there is a camera that cannot be reached (i.e., it is not observing any calibration object pose that can be connected in the chain), the calibration process is terminated with an error. Otherwise, the algorithm initializes all calibration items' poses by going down this chain.

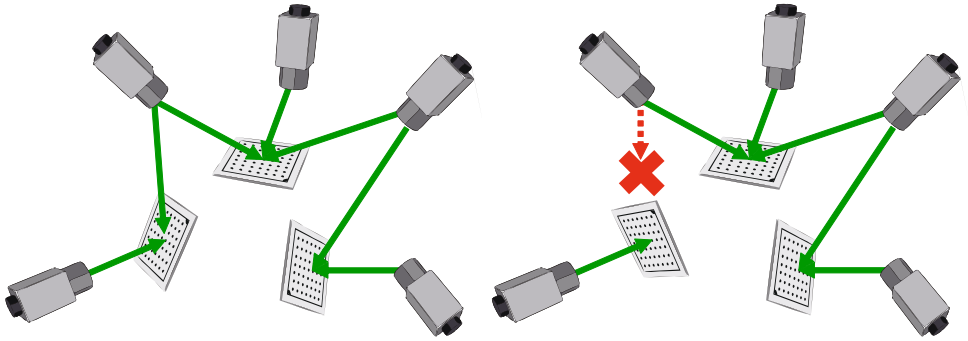
2. **First optimization:** In this step, calibrate_cameras performs the actual optimization for all optimization parameters that were not explicitly excluded from the calibration.

3. **Second optimization:** Based on the so-far calibrated cameras, the algorithm corrects all observations that contain mark contour information (see find_calib_object). Then, the calibration setup is optimized anew for the corrections to take effect. If no contour information was available, this step is skipped.

4. **Compute quality of parameter estimation:** In the last step, `calibrate_cameras` computes the standard deviations and the covariances of the calibrated internal camera parameters.

The following paragraphs give further information about the conditions specific to the camera setups.

Projective area scan cameras For a setup with projective area scan cameras, the calibration is performed in the four steps listed above. The algorithm tries to build a chain of observation poses that connects all cameras and calibration object poses to the reference camera like in the diagram below.



(1) (2)

(1) All cameras can be connected by a chain of observation poses. (2) The leftmost camera is isolated, because the left calibration plate cannot be seen by any other camera.

Possible projective area scan cameras are:

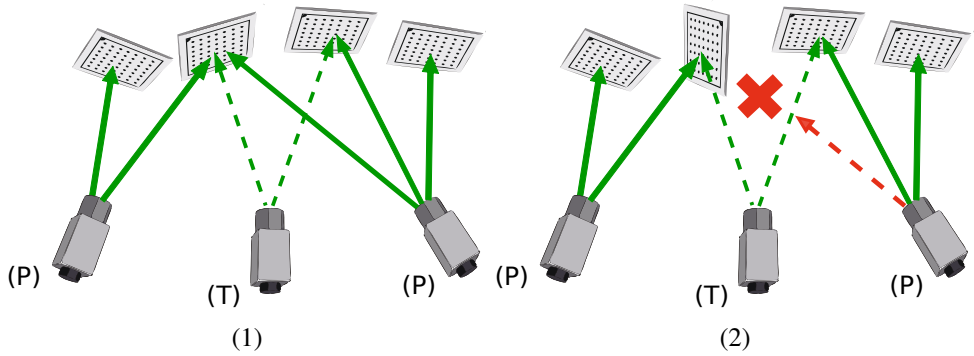
- *'area_scan_division'*
- *'area_scan_polynomial'*
- *'area_scan_tilt_division'*
- *'area_scan_tilt_polynomial'*
- *'area_scan_tilt_image_side_telecentric_division'*
- *'area_scan_tilt_image_side_telecentric_polynomial'*
- *'area_scan_hypercentric_division'*
- *'area_scan_hypercentric_polynomial'*

Telecentric area scan cameras For a setup with telecentric area scan cameras, similar to projective area scan cameras, the same four steps that are listed above are executed. In the first step (building a chain of observation poses that connects all cameras and calibration objects), additional conditions must hold. Since the pose of an object can only be determined up to a translation along the optical axis, each calibration object must be observed by at least two cameras to determine its relative location. Otherwise, its pose is excluded from the calibration. Also, since a planar calibration object appears the same from two different observation angles, the relative pose of the cameras among each other cannot be determined unambiguously. Therefore, there are always two valid alternative relative poses. Both alternatives result in a consistent camera setup which can be used for measuring. Since the ambiguity cannot be resolved, the first of the alternatives is returned. Note that, if the returned pose is not the real pose but the alternative one, then this will result in a mirrored reconstruction.

Possible telecentric area scan cameras are:

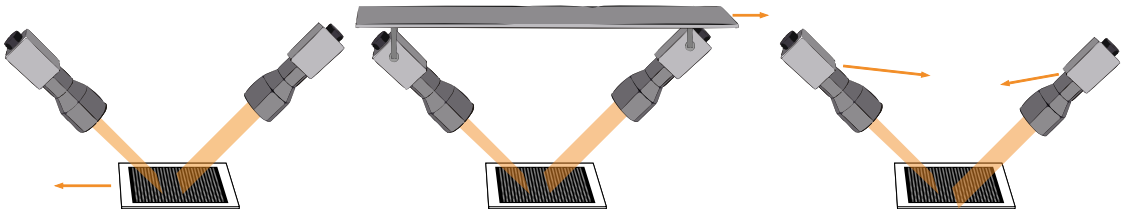
- *'area_scan_telecentric_division'*
- *'area_scan_telecentric_polynomial'*
- *'area_scan_tilt_bilateral_telecentric_division'*
- *'area_scan_tilt_bilateral_telecentric_polynomial'*
- *'area_scan_tilt_object_side_telecentric_division'*
- *'area_scan_tilt_object_side_telecentric_polynomial'*

Projective and telecentric area scan cameras For a mixed setup with projective and telecentric area scan cameras, the algorithm performs the same four steps as enumerated above. Possible ambiguities during the first step (building a chain of observation poses that connects all cameras and calibration objects), as described above for the setup with telecentric cameras, can be resolved as long as there exists a chain of observation poses consisting of all perspective cameras and a sufficient number of calibration objects. Here, sufficient number means that each telecentric camera observes at least two calibration objects of this chain.



Mixed calibration setup with perspective (P) and telecentric (T) area scan cameras. (1) All perspective cameras are connected by a chain of observation poses that only contains perspective cameras. (2) The second calibration plate (from the left) is not observed by the rightmost perspective camera. Therefore, the relative pose between both perspective cameras cannot be determined uniquely.

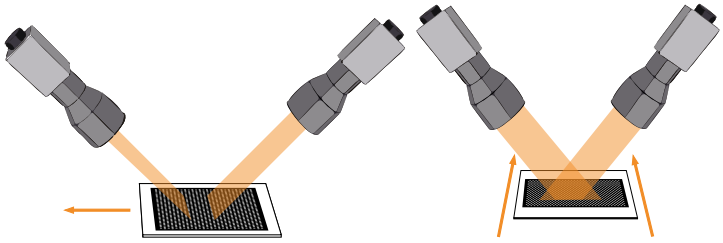
Line scan cameras Setups with telecentric line scan cameras (*'line_scan_telecentric'*) behave identically to setups with telecentric area scan cameras and the same restrictions and ambiguities that are described above apply. For this type of setup, two possible configurations can be distinguished. In the first configuration, all cameras are mounted rigidly and stationary and the object is moved linearly in front of the cameras. Alternatively, all cameras are mounted rigidly with respect to each other and are moved across the object by the same linear actuator. In both cases, all cameras share a common motion vector, which is modeled in the camera coordinate system of the reference camera and is transformed to the camera coordinate systems of all other cameras by the rotation part of the respective camera's pose. This configuration is assumed by default. In the second configuration, the cameras are moved by independent linear actuators in different directions. In this case, each camera has its own independent motion vector. The type of configuration can be selected with `set_calib_data`.



Different configurations of telecentric line scan camera setups can be distinguished: (1) Only one motion vector needs to be computed if the cameras are mounted stationary while the object is moved linearly, (2) or if the cameras are moved across the object while mounted rigidly to each other. (3) Alternatively, if the cameras are moved independently from each other, a motion vector is determined for each camera.

Note that two different stereo setups are common for telecentric line scan cameras. For both setups, a linear, constant motion is assumed for the observed object or the camera system respectively.

- For along-track setups one camera is placed in front, looking in backwards direction, while the second camera is mounted behind, looking forwards, both at an suitable angle in respect to the motion vector.
- The cameras in an across-track setup are all directed perpendicular to the motion vector, while the viewing planes are approximately coplanar. Therefore, the depth of field is rather limited. Precise measurements are only possible in areas where the depth of field of the individual cameras overlap.



(1) (2)

Stereo setups for telecentric line scan cameras: (1) Along-track setup and (2) Across-track setup.

For setups with projective line scan cameras (*'line_scan'*), the following restriction exists: only one camera can be calibrated and only one calibration object per setup can be used.

Finally, for calibration plates with rectangularly arranged marks (see `gen_caltab`) all observations must contain the projection coordinates of all calibration marks of the calibration object. For calibration plates with hexagonally arranged marks (see `create_caltab`) this restriction is not applied. You can find further information about calibration plates and the acquisition of calibration images in the section "Additional information about the calibration process" within the chapter Calibration.

Checking the Success of the Calibration

If more than one camera is calibrated simultaneously, the value of `Error` is more difficult to judge. As a rule of thumb, `Error` should be as small as possible and at least smaller than 1.0, thus indicating that a subpixel precise evaluation of the data is possible with the calibrated parameters. This value might be difficult to reach in particular configurations. For further analysis of the quality of the calibration, refer to the standard deviations and covariances of the estimated parameters.

Getting the Calibration Results

The results of the calibration, i.e., internal camera parameters, camera poses (external camera parameters), calibration objects poses etc., can be queried with `get_calib_data`.

Note that the poses of telecentric cameras can only be determined up to a displacement along the z-axis of the coordinate system of the respective camera (perpendicular to the image plane). Therefore, all camera poses are moved along this axis until they all lie on a common sphere. The center of the sphere is defined by the pose of the first calibration object. The radius of the sphere depends on the calibration setup. If projective and telecentric area scan cameras are calibrated, the radius is the maximum over all distances from the perspective cameras to the first calibration object. Otherwise, if only telecentric area scan cameras are considered, the radius is equal to 1 m.

Further Information

Learn about the calibration of multi-camera setups and many other topics in interactive online courses at our MVTec Academy .

calibrate_cameras (: : CalibDataID : Error)

Determine all camera parameters by a simultaneous minimization process.

The operator `calibrate_cameras` calculates the internal and external camera parameters of a calibration data model specified in `CalibDataID`. The calibration data model describes a setup of one or more cameras and is specified during the creation of the data model. You can find detailed information about the calibration process in the chapter reference Calibration.

The root mean square error (RMSE) of the back projection of the optimization is returned in `Error` (in pixels). The error gives a general indication whether the optimization was successful. You can find more details about the RMSE in the chapter reference mentioned above.

Parameters

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **Error** (output_control) . . . . . number ⇝ *real*
Back projection root mean square error (RMSE) of the optimization.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_calib_data`, `set_calib_data_cam_param`, `set_calib_data_calib_object`, `set_calib_data_observ_points`, `find_calib_object`, `set_calib_data`, `remove_calib_data_observ`

Possible Successors

`get_calib_data`

Module

Calibration

clear_calib_data (: : CalibDataID :)

Free the memory of a calibration data model.

The operator `clear_calib_data` frees the memory of the calibration data model `CalibDataID`. After calling `clear_calib_data`, the model can no longer be used. The handle `CalibDataID` becomes invalid.

Parameters

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Calibration

clear_camera_setup_model (: : CameraSetupModelID :)

Free the memory of a calibration setup model.

The operator clear_camera_setup_model frees the memory of a camera setup model that was created by create_camera_setup_model or read_camera_setup_model or was returned as a result by get_calib_data. After calling clear_camera_setup_model, the model can no longer be used. The handle CameraSetupModelID becomes invalid.

Parameters

▷ **CameraSetupModelID** (input_control) . . . . . camera_setup_model ⇝ *handle*
Handle of the camera setup model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CameraSetupModelID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Calibration

create_calib_data (: : CalibSetup, NumCameras,
NumCalibObjects : CalibDataID)

Create a HALCON calibration data model.

The operator create_calib_data creates a generic calibration data model that stores

- the description of a camera calibration setup,
- settings for the calibration process,
- the calibration data, and
- the results of the camera calibration or the hand-eye calibration.

In the parameter CalibSetup, you specify the calibration setup type. Currently, five types are supported. A model of the type *'calibration_object'* is used to calibrate the internal camera parameters and the camera poses of one or more cameras based on the metric information extracted from observations of calibration objects.

A model of type *'hand_eye_moving_cam'*, *'hand_eye_stationary_cam'*, *'hand_eye_scara_moving_cam'*, or *'hand_eye_scara_stationary_cam'* is used to perform a hand-eye calibration based on observations of a calibration object and corresponding poses of a robot tool in the robot base coordinate system. The latter four model types on the one hand distinguish whether the camera or the calibration object is moved by the robot and on the other hand distinguish whether an articulated robot or a SCARA robot is calibrated. The arm of an articulated robot has

three rotary joints typically covering 6 degrees of freedom (3 translations and 3 rotations). SCARA robots have two parallel rotary joints and one parallel prismatic joint covering only 4 degrees of freedom (3 translations and 1 rotation). Loosely speaking, an articulated robot is able to tilt its end effector while a SCARA robot is not.

NumCameras specifies the number of cameras that are calibrated simultaneously in the setup. NumCalibObjects specifies the number of calibration objects observed by the cameras. Please note that for camera calibrations with line scan cameras with perspective lenses only a single calibration object is allowed (NumCalibObjects=1). For hand-eye calibrations, only two setups are currently supported: either one area scan projective camera and one calibration object (NumCameras=1, NumCalibObjects=1) or a general sensor with no calibration object (NumCameras=0, NumCalibObjects=0). **Attention:** The four hand-eye calibration models do not support telecentric cameras.

CalibDataID returns a handle of the new calibration data model. You pass this handle to other operators to collect the description of the camera setup, the calibration settings, and the calibration data. For camera calibrations, you pass it to calibrate_cameras, which performs the actual camera calibration and stores the calibration results in the calibration data model. For a detailed description of the preparation process, please refer to the chapter Calibration. For hand-eye calibrations, you pass it to calibrate_hand_eye, which performs the actual hand-eye calibration and stores the calibration results in the calibration data model. For a detailed description of the preparation process, please refer to the operator calibrate_hand_eye.

Parameters

▷ **CalibSetup** (input_control) . . . . . string ⇝ *string*
Type of the calibration setup.
Default: 'calibration_object'
List of values: CalibSetup ∈ {'calibration_object', 'hand_eye_moving_cam', 'hand_eye_stationary_cam', 'hand_eye_scara_moving_cam', 'hand_eye_scara_stationary_cam'}

▷ **NumCameras** (input_control) . . . . . number ⇝ *integer*
Number of cameras in the calibration setup.
Default: 1
Restriction: NumCameras >= 0

▷ **NumCalibObjects** (input_control) . . . . . number ⇝ *integer*
Number of calibration objects.
Default: 1
Restriction: NumCalibObjects >= 0

▷ **CalibDataID** (output_control) . . . . . calib_data ⇝ *handle*
Handle of the created calibration data model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_calib_data_cam_param, set_calib_data_calib_object

Module

Calibration

create_camera_setup_model (: : NumCameras : CameraSetupModelID)

Create a model for a setup of calibrated cameras.

The operator create_camera_setup_model creates a new camera setup model and returns a handle to it in CameraSetupModelID. The camera setup comprises a fixed number of cameras, which is specified by NumCameras and cannot be changed once the model was created. For each camera, the setup stores its internal parameters, covariances of the internal parameters (optional) and a pose of the camera.

Using set_camera_setup_param, you can change the coordinate system in which the cameras are represented: You can either select a camera and convert all camera poses to be relative to this camera or you can apply a general coordinate transformation, which moves the setup's coordinate system into an arbitrary pose. Changing the coordinate system of the camera setup is particularly useful in cases, where, e.g., you want to represent the cameras in the coordinate system of an object being observed by the cameras. This concept is further demonstrated in the example below.

The internal parameters and pose of a camera are set or modified by set_camera_setup_cam_param. Further camera parameters and general setup parameters can be set by set_camera_setup_param as well. All parameters can be read back by get_camera_setup_param.

A camera setup model can be saved into a file by write_camera_setup_model and read back by read_camera_setup_model.

Parameters

▷ **NumCameras** (input_control) . . . . . integer ⇝ *integer*
Number of cameras in the setup.
Default: 2
Suggested values: NumCameras ∈ {1, 2, 3, 4}
Restriction: NumCameras >= 1

▷ **CameraSetupModelID** (output_control) . . . . . camera_setup_model ⇝ *handle*
Handle to the camera setup model.

Example

```
* Create camera setup of three cameras.
create_camera_setup_model (3, CameraSetupModelID)
gen_cam_par_area_scan_division (0.006, 0, 8.3e-6, 8.3e-6,\
              512, 384, 1024, 768, StartCamPar)
* Camera 0 is located in the origin.
set_camera_setup_cam_param (CameraSetupModelID, 0, [], StartCamPar,\
                            [0, 0, 0, 0, 0, 0, 0])

* Camera 1 is shifted 0.07 m in positive x-direction relative to
* camera 0.
set_camera_setup_cam_param (CameraSetupModelID, 1, [], StartCamPar,\
                            [0.07, 0, 0, 0, 0, 0, 0])

* Camera 2 is shifted 0.1 m in negative y-direction relative to
* camera 0.
set_camera_setup_cam_param (CameraSetupModelID, 2, [], StartCamPar,\
                            [0.0, -0.1, 0, 0, 0, 0, 0])

* There is an object, which is 0.5 away from the origin in
* z-direction, and is facing the origin.
ObjectPose := [0, 0, 0.5, 180, 0, 0, 0]
* Place the setup's origin in the object.
set_camera_setup_param (CameraSetupModelID, 'general', 'coord_transf_pose',\
                        ObjectPose)

* Now the camera poses are given relative to the object.
get_camera_setup_param (CameraSetupModelID, 0, 'pose', CamPose0)
* CamPose0 is equivalent to [0.0, 0.0, 0.5, 180.0, 0.0, 0.0, 0]

get_camera_setup_param (CameraSetupModelID, 1, 'pose', CamPose1)
* CamPose1 is equivalent to [0.07, 0.0, 0.5, 180.0, 0.0, 0.0, 0]

get_camera_setup_param (CameraSetupModelID, 2, 'pose', CamPose2)
* CamPose2 is equivalent to [0.0, 0.1, 0.5, 180.0, 0.0, 0.0, 0]
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_camera_setup_param

Module

Calibration

deserialize_calib_data (: : SerializedItemHandle : CalibDataID)

Deserialize a serialized calibration data model.

deserialize_calib_data deserializes a calibration data model, that was serialized by serialize_calib_data (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized calibration data model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created calibration data model with the handle CalibDataID.

Note that serialize_calib_data does not serialize any calibration results. Yet, calibrate_cameras can be called for a fully configured calibration model immediately after the deserialization. All calibration results are accessible afterwards.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **CalibDataID** (output_control) ..... calib_data ⇝ *handle*
Handle of a calibration data model.

Result

If the parameters are valid, the operator deserialize_calib_data returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_calib_data

Module

Calibration

deserialize_camera_setup_model (
: : SerializedItemHandle : CameraSetupModelID)

Deserialize a serialized camera setup model.

deserialize_camera_setup_model deserializes a camera setup model, that was serialized by serialize_camera_setup_model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized camera setup model is defined by the handle

SerializedItemHandle. The deserialized values are stored in an automatically created camera setup model with the handle CameraSetupModelID.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **CameraSetupModelID** (output_control) ..... camera_setup_model ⇝ *handle*
Handle to the camera setup model.

Result

If the parameters are valid, the operator deserialize_camera_setup_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_camera_setup_model

Module

Calibration

get_calib_data (: : CalibDataID, ItemType, ItemIdx, DataName : DataValue)

Query data stored or computed in a calibration data model.

With the operator get_calib_data, you can query data of the calibration data model CalibDataID.

Note that in the following, all 'pose'-related data is given in relation to the coordinate system of the model's *reference camera*, which can be set with set_calib_data and queried with get_calib_data. By default, the first camera (camera index 0) is used as reference camera.

The calibration data model contains various kinds of data. How to query specific data of the calibration data model is described for different categories of data:

- Model-related data (ItemType *'model'*)
- Camera-related data (ItemType *'camera'*)
- Data related to calibration objects (ItemType *'calib_obj'*)
- Data related to calibration object poses (ItemType *'calib_obj_pose'*)
- Hand-eye calibration related data (different values for ItemType)

Before we describe the individual data you can query in detail, we provide you with an overview on which data is available after the individual steps of the calibration processes. When calibrating cameras or a hand-eye system, several operators are called that step by step fill the calibration data model with content. In the following, for each operator a table lists the data that is added to the model. Additionally, you find information about the combinations of the values for ItemType, ItemIdx, and DataName that are needed to query the information with get_calib_data. For the different indices that are used within the tables the following abbreviations (or potential variable names) are used:

- Camera index: CameraIdx
- Calibration object index: CalibObjIdx
- Calibration object pose index: CalibObjPoseIdx

Detailed descriptions of the data that can be queried can then be found in the specific sections that handle the different categories of data individually.

To get detailed information about the calibration process of your camera setup see the chapter Calibration.

Content of Calibration Data Model When Calibrating Cameras

For each operator that extends the calibration model, a table is provided to give an overview on the respective data:

- `create_calib_data`:

Data added to the model	ItemType	ItemIdx	DataName
Type of the calibration data model	*'model'*	*'general'*	*'type'*
Number of cameras	*'model'*	*'general'*	*'num_cameras'*
Number of calibration objects	*'model'*	*'general'*	*'num_calib_objs'*

- `set_calib_data_cam_param`:

Data added to the model	ItemType	ItemIdx	DataName
Camera types	*'camera'*	CameraIdx	*'type'*
Initial internal camera parameters	*'camera'*	CameraIdx	*'init_params'*

- `set_calib_data_calib_object`:

Data added to the model	ItemType	ItemIdx	DataName
Numbers of calibration marks of the calibration objects	*'calib_obj'*	CalibObjIdx	*'num_marks'*
Coordinates of the calibration marks of the calibration objects relative to their calibration object coordinate systems	*'calib_obj'*	CalibObjIdx	*'x'*, *'y'*, *'z'*

For standard HALCON calibration plates, further calibration plate specific information is added to the model, which is not accessible with `get_calib_data` but can be obtained directly from the corresponding calibration plate description files instead (for details about the description files see `create_caltab` for a calibration plate with hexagonally arranged marks and `gen_caltab` for a calibration plate with rectangularly arranged marks).

- `find_calib_object` (for standard HALCON calibration plates):

Data added to the model	accessible with
Observed image coordinates of the calibration marks	`get_calib_data_observ_points`
Observed contours of the calibration marks	`get_calib_data_observ_contours`
Observed poses of the calibration plate relative to the camera coordinate system	`get_calib_data_observ_pose` or `get_calib_data_observ_points`

- `set_calib_data_observ_points` (for other calibration objects than the HALCON calibration plates):

Data added to the model	accessible with
Observed image coordinates of the calibration marks	`get_calib_data_observ_points`

- set_calib_data:

Data added to the model	ItemType	ItemIdx	DataName
Reference camera	*'model'*	*'general'*	*'reference_camera'*
Internal and external camera parameters to calibrate	*'camera'*	*'general'* or CameraIdx	*'calib_settings'*
Internal and external camera parameters to be excluded from the calibration	*'camera'*	*'general'* or CameraIdx	*'excluded_settings'*
For stereo setups with telecentric line scan cameras: Do the cameras have a **common motion vector**?	*'model'*	*'general'*	*'common_motion_vector'*
Calibration object pose settings to be optimized	*'calib_obj_pose'*	*'general'* or [CalibObjIdx, CalibObjPoseIdx]	*'calib_settings'*
Calibration object pose settings to be excluded from the calibration	*'calib_obj_pose'*	*'general'* or [CalibObjIdx, CalibObjPoseIdx]	*'excluded_settings'*

- calibrate_cameras:

Data added to the model	ItemType	ItemIdx	DataName
Camera setup model (needed for multi-view stereo reconstruction)	*'model'*	*'general'*	*'camera_setup_model'*
Optimized internal camera parameters	*'camera'*	CameraIdx	*'params'*
Standard deviations of the optimized internal camera parameters	*'camera'*	CameraIdx	*'params_deviations'*
Covariance matrices of the optimized internal camera parameters	*'camera'*	CameraIdx	*'params_covariances'*
Labels for the internal camera parameters	*'camera'*	CameraIdx	*'params_labels'*
Initial external camera parameters (camera poses)	*'camera'*	CameraIdx	*'init_pose'*
Optimized external camera parameters (camera poses)	*'camera'*	CameraIdx	*'pose'*
Labels for the external camera parameters (camera poses)	*'camera'*	CameraIdx	*'pose_labels'*
Initial calibration object poses	*'calib_obj_pose'*	[CalibObjIdx, CalibObjPoseIdx]	*'init_pose'*
Optimized calibration object poses	*'calib_obj_pose'*	[CalibObjIdx, CalibObjPoseIdx]	*'pose'*
Labels for the calibration object pose parameters	*'calib_obj_pose'*	[CalibObjIdx, CalibObjPoseIdx]	*'pose_labels'*

Content of Calibration Data Model When Performing Hand-Eye Calibration

For each operator that extends the calibration model when performing hand-eye calibration, a table is provided to give an overview on the respective data:

- create_calib_data:
  See the section **'Content of Calibration Data Model When Calibrating Cameras'**.
- set_calib_data:

Data added to the model	ItemType	ItemIdx	DataName
Optimization method	*'model'*	*'general'*	*'optimization_method'*
Poses of the robot tool in robot base coordinates	*'tool'*	CalibObjPoseIdx	*'tool_in_base_pose'*

- set_calib_data_observ_pose (observations obtained by 3D sensors):

Data added to the model	accessible with
Observed calibration object poses	get_calib_data_observ_pose

- set_calib_data_cam_param, set_calib_data_calib_object, and find_calib_object or set_calib_data_observ_points (observations obtained by cameras):
  See the section 'Content of Calibration Data Model When Calibrating Cameras'.

- calibrate_hand_eye:
  Moving camera scenario:

Data added to the model	ItemType	ItemIdx	DataName
Pose of robot tool in camera coordinate system	*'camera'*	*0*	*'tool_in_cam_pose'*
Pose of calibration object in robot base coordinate system	*'calib_obj'*	*0*	*'obj_in_base_pose'*
Standard deviations of the Pose of the robot tool in camera coordinate system	*'camera'*	*0*	*'tool_in_cam_pose_deviations'*
Covariance matrices of the Pose of the robot tool in camera coordinate system	*'camera'*	*0*	*'tool_in_cam_pose_covariances'*
Standard deviations of the Pose of the calibration object in robot base coordinate system	*'calib_obj'*	*0*	*'obj_in_base_pose_deviations'*
Covariance matrices of the Pose of the calibration object in robot base coordinate system	*'calib_obj'*	*0*	*'obj_in_base_pose_covariances'*

Stationary camera scenario:

Data added to the model	ItemType	ItemIdx	DataName
Pose of robot base in camera coordinate system	*'camera'*	*0*	*'base_in_cam_pose'*
Pose of calibration object in robot tool coordinate system	*'calib_obj'*	*0*	*'obj_in_tool_pose'*
Standard deviations of the Pose of the robot base in camera coordinate system	*'camera'*	*0*	*'base_in_cam_pose_deviations'*
Covariance matrices of the Pose of the robot base in camera coordinate system	*'camera'*	*0*	*'base_in_cam_pose_covariances'*
Standard deviations of the Pose of the calibration object in robot tool coordinate system	*'calib_obj'*	*0*	*'obj_in_tool_pose_deviations'*
Covariance matrices of the Pose of the calibration object in robot tool coordinate system	*'calib_obj'*	*0*	*'obj_in_tool_covariances'*

Both hand-eye scenarios:

Data added to the model	ItemType	ItemIdx	DataName
Calibrated poses of the calibration object in camera coordinate system (not available for SCARA robots)	*'calib_obj_pose'*	*[0, CalibObjPoseIdx]*	*'pose'*
Root mean square error (RMSE) of the back projection after the optimization of the camera system	*'model'*	*'general'*	*'camera_calib_error'*
Pose error of the complete chain of transformations	*'model'*	*'general'*	*'hand_eye_calib_error'*
Camera setup model (needed for multi-view stereo reconstruction)	*'model'*	*'general'*	*'camera_setup_model'*

Both hand-eye scenarios, if *'optimization_method'* is set to *'stochastic'*:

Data added to the model	ItemType	ItemIdx	DataName
Root mean square error (RMSE) of the back projection into camera images, via pose chain using corrected tool poses	*'model'*	*'general'*	*'camera_calib_error_corrected_tool'*
Pose error of the complete chain of transformations using corrected tool poses	*'model'*	*'general'*	*'hand_eye_calib_error_corrected_tool'*
Standard deviations of the input poses of the robot tool in robot base coordinates	*'tool'*	*'general'*	*'tool_translation_deviation'*, *'tool_rotation_deviation'*
Corrected poses of the robot tool in robot base coordinates	*'tool'*	CalibObjPoseIdx	*'tool_in_base_pose_corrected'*

The following sections describe the parameters for the specific categories of data in more detail.

Model-Related Data

ItemType=*'model'*: ItemIdx must be set to *'general'*.

Depending on the selection in DataName, the following model-related data is then returned in DataValue:

'type': Type of the calibration data model. Currently, the five types *'calibration_object'*, *'hand_eye_stationary_cam'*, *'hand_eye_moving_cam'*, *'hand_eye_scara_stationary_cam'*, and *'hand_eye_scara_moving_cam'* are supported.

'reference_camera': Index of the reference camera for the calibration model. All poses stored in the calibration data model are specified in the coordinate system of this reference camera.

'num_cameras': Number of cameras in the calibration data model (see create_calib_data).

'num_calib_objs': Number of calibration objects in the calibration data model (see create_calib_data).

'common_motion_vector': For stereo setups with telecentric line scan cameras, a string with a Boolean value (i.e., *'true'* or *'false'*) that determines whether the cameras have a common motion vector.

'camera_setup_model': A handle to a camera setup model containing the poses and the internal parameters for the calibrated cameras from the current calibration setup.

'camera_calib_error': The root mean square error (RMSE) of the back projection of the optimization of the camera system. Typically, this error is queried after a hand-eye calibration (`calibrate_hand_eye`) was performed, where internally the camera system is calibrated without returning the error of the camera calibration. The returned error is identical to the error returned by `calibrate_cameras`, except for *'optimization_method'* set to *'stochastic'*, which refines hand-eye poses and camera parameters simultaneously for articulated robots.

'hand_eye_calib_error': After a successful hand-eye calibration, the pose error of the complete chain of transformations is returned. To be more precise, a tuple with four elements is returned, where the first element is the root-mean-square error of the translational part, the second element is the root-mean-square error of the rotational part, the third element is the maximum translational error and the fourth element is the maximum rotational error. The returned errors are identical to the errors returned by `calibrate_hand_eye`.

'optimization_method': Optimization method that was set for the hand-eye calibration (see `set_calib_data`).

'camera_calib_error_corrected_tool': The root mean square error (RMSE) of the back projection of the calibration mark centers into camera images, via the pose chain using corrected tool poses. By contrast, *'camera_calib_error'* uses the direct back projection of *'calib_obj_pose'*. This parameter is only available if *'optimization_method'* is set to *'stochastic'*.

'hand_eye_calib_error_corrected_tool': After a successful hand_eye calibration, the pose error of the complete chain of transformations using corrected tool poses is returned. By contrast, *'hand_eye_calib_error'* uses the input tool poses. This parameter is only available if *'optimization_method'* is set to *'stochastic'*.

The parameters *'reference_camera'*, *'common_motion_vector'*, and *'optimization_method'* can be set with `set_calib_data`. The other parameters are set during the model creation or are a result of the calibration process and cannot be modified.

Camera-Related Data

`ItemType`=*'camera'*: `ItemIdx` determines, if data is queried for all cameras in general or for a specific camera. With `ItemIdx`=*'general'*, the default value of a parameter for all cameras is returned. In contrast, if you pass a valid camera index instead, i.e., a number between 0 and `NumCameras`-1 (`NumCameras` is specified during model creation with `create_calib_data`), only the parameter value of the specified camera is returned.

By selecting the following parameters in `DataName`, you can query which camera parameters are (or have been) optimized during the calibration performed by `calibrate_cameras`:

'calib_settings': List of the camera parameters that are marked for calibration.

'excluded_settings': List of camera parameters that are excluded from the calibration.

These parameters can be modified by a corresponding call to `set_calib_data`.

The following parameters can only be queried for a specific camera, i.e., you must pass a valid camera index in `ItemIdx`:

'type': The camera type that was set with `set_calib_data_cam_param`.

'init_params': Initial internal camera parameters (set with `set_calib_data_cam_param`).

'params': Optimized internal camera parameters.

'params_deviations': Standard deviations of the optimized camera parameters, as estimated at the end of the camera calibration. Note that if the tuple returned for *'params'* contains n elements, the tuple returned for *'params_deviations'* contains $(n-1)$ elements since the camera parameter tuple contains the camera type in the first element of the tuple, whereas the tuple returned for *'params_deviations'* does not contain the camera type.

'params_covariances': Covariance matrix of the optimized camera parameters, as estimated at the end of the camera calibration. Note that if the tuple returned for *'params'* contains n elements, the tuple returned for *'params_covariances'* contains $(n-1) \times (n-1)$ elements since the camera parameter tuple contains the camera type in the first element of the tuple, whereas the tuple returned for *'params_covariances'* does not contain the camera type.

'params_labels': A convenience list of labels for the entries returned by *'params'*. This list is camera-type specific. Note that this list contains the label *'camera_type'* in its first position. If the first element of the tuple is removed, the list refers to the labels of *'params_deviations'* and the labels of the rows and columns of *'params_covariances'*.

'init_pose': Initial camera pose, relative to the current reference camera. It is computed internally based on observation poses during the calibration process (see Calibration).

'pose': Optimized camera pose, relative to the current reference camera. If one single telecentric camera is calibrated, the translation along the z-axis is set to the value 0.0. If more than one telecentric camera is calibrated, the camera poses are moved in direction of their z-axis until they all lie on a sphere centered at the first observed calibration plate. The radius of the sphere corresponds to the longest distance of a camera to the first observed calibration plate. If this calculated distance is smaller than 1 m, the radius is set to 1 m.

'pose_labels': A convenience list of labels for the entries returned by *'pose'*.

The calibrated camera parameters (*'params'* and *'pose'*) can be queried only after a successful execution of `calibrate_cameras`. The initial internal camera parameters *'init_params'* can be queried after a successful call to `set_calib_data_cam_param`.

Data Related to Calibration Objects

`ItemType`=*'calib_obj'*: `ItemIdx` must be set to a valid calibration object index (number between 0 and `NumCalibObjects`-1). `NumCalibObjects` is specified during the model creation with `create_calib_data`.

The following parameters can be queried with `DataName` and are returned in `DataValue`:

'num_marks': Number of calibration marks of the calibration object.

'x', *'y'*, *'z'*: Coordinates of the calibration marks relative to the calibration object coordinate system.

These parameters can be modified with `set_calib_data_calib_object`.

Data Related to Calibration Object Poses

`ItemType`=*'calib_obj_pose'*: `ItemIdx` determines, if data is queried for all calibration object poses in general or for a specific calibration object pose. With `ItemIdx`=*'general'*, the default value of a parameter for all calibration object poses is returned. In contrast, if you pass a valid calibration object index instead, i.e., a tuple containing a valid index pair `[CalibObjIdx, CalibObjPoseIdx]`, only the parameter value of the specified calibration object pose is returned.

By selecting the following parameters in `DataName`, you can query which calibration object pose parameters are (or have been) optimized during the calibration performed by `calibrate_cameras`:

'calib_settings': List of calibration object pose parameters marked for calibration.

'excluded_settings': List of calibration object pose parameters excluded from calibration.

These parameters can be set with `set_calib_data`.

The following parameters can only be queried for a specific calibration object pose, i.e., you must pass a valid index pair `[CalibObjIdx, CalibObjPoseIdx]` in `ItemIdx`:

'init_pose': Initial calibration object pose. It is computed internally based on observation poses during the calibration process (see Calibration). This pose is relative to the current reference camera.

'pose': Optimized calibration object pose, relative to current reference camera.

'pose_labels': A convenience list of labels for the entries returned by *'pose'*.

These parameters cannot be explicitly modified and can only be queried after `calibrate_cameras` was executed.

Hand-Eye Calibration Related Data

`ItemType`=*'tool'*: The following parameters can be queried with `DataName` and are returned in `DataValue`:

'tool_in_base_pose': Pose of the robot tool in robot base coordinates with Index `ItemIdx`. These poses were previously set using `set_calib_data` and served as input for the hand-eye calibration algorithm.

'tool_in_base_pose_corrected': Corrected pose of the robot tool in robot base coordinates of the input *'tool_in_base_pose'* with Index `ItemIdx`. This parameter is only available if *'optimization_method'* is set to *'stochastic'* and after `calibrate_hand_eye` was executed.

'tool_translation_deviation', *'tool_rotation_deviation'*: Standard deviations of the input poses of the robot tool in robot base coordinates. `ItemIdx` has to be set to *'general'*. This parameter is only available if *'optimization_method'* is set to *'stochastic'* and after `calibrate_hand_eye` was executed.

After performing a successful hand-eye calibration using `calibrate_hand_eye`, the following poses can be queried for a calibration data model of type:

'hand_eye_moving_cam', *'hand_eye_scara_moving_cam'*: For `ItemType`=*'camera'* and `DataName`=*'tool_in_cam_pose'*, the pose of the robot tool in the camera coordinate system is returned in `DataValue`. For `ItemType`=*'calib_obj'* and `DataName`=*'obj_in_base_pose'*, the pose of the calibration object in the robot base coordinate system is returned in `DataValue`.

Note that when calibrating SCARA robots, it is not possible to determine the Z translation of *'obj_in_base_pose'*. To eliminate this ambiguity the Z translation *'obj_in_base_pose'* is internally set to 0.0 and the *'tool_in_cam_pose'* is calculated accordingly. It is necessary to determine the true translation in Z after the calibration (see `calibrate_hand_eye`).

The standard deviations and the covariance matrices of the 6 pose parameters of both poses can be queried with *'tool_in_cam_pose_deviations'*, *'tool_in_cam_pose_covariances'* (`ItemType`=*'camera'*), *'obj_in_base_pose_deviations'*, and *'obj_in_base_pose_covariances'* (`ItemType`=*'calib_obj'*). Like poses, they are specified in the units [m] and [°].

'hand_eye_stationary_cam', *'hand_eye_scara_stationary_cam'*: For `ItemType`=*'camera'* and `DataName`=*'base_in_cam_pose'*, the pose of the robot base in the camera coordinate system is returned in `DataValue`. For `ItemType`=*'calib_obj'* and `DataName`=*'obj_in_tool_pose'*, the pose of the calibration object in the robot tool coordinate system is returned in `DataValue`.

Note that when calibrating SCARA robots, it is not possible to determine the Z translation of *'obj_in_tool_pose'*. To eliminate this ambiguity the Z translation of *'obj_in_tool_pose'* is internally set to 0.0 and the *'base_in_cam_pose'* is calculated accordingly. It is necessary to determine the true translation in Z after the calibration (see `calibrate_hand_eye`).

The standard deviations and the covariance matrices of the 6 pose parameters of both poses can be queried with *'base_in_cam_pose_deviations'*, *'base_in_cam_pose_covariances'* (`ItemType`=*'camera'*), *'obj_in_tool_pose_deviations'*, and *'obj_in_tool_pose_covariances'* (`ItemType`=*'calib_obj'*). Like poses, they are specified in the units [m] and [°].

Parameters

▷ **`CalibDataID`** (input_control) ..... calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **`ItemType`** (input_control) ..... string ⇝ *string*
Type of calibration data item.
Default: 'camera'
List of values: `ItemType` ∈ {'model', 'camera', 'calib_obj', 'calib_obj_pose', 'tool'}

▷ **`ItemIdx`** (input_control) ..... integer(-array) ⇝ *integer* / string
Index of the affected item (depending on the selected `ItemType`).
Default: 0
Suggested values: `ItemIdx` ∈ {0, 1, 2, 'general'}

▷ **`DataName`** (input_control) ..... attribute.name(-array) ⇝ *string*
The name of the inspected data.
Default: 'params'
List of values: `DataName` ∈ {'type', 'reference_camera', 'num_cameras', 'num_calib_objs', 'camera_setup_model', 'camera_calib_error', 'camera_calib_error_corrected_tool', 'hand_eye_calib_error', 'hand_eye_calib_error_corrected_tool', 'optimization_method', 'num_marks', 'x', 'y', 'z', 'params', 'pose', 'init_params', 'init_pose', 'params_deviations', 'params_covariances', 'params_labels', 'pose_labels', 'calib_settings', 'excluded_settings', 'common_motion_vector', 'tool_in_cam_pose', 'obj_in_base_pose', 'base_in_cam_pose', 'obj_in_tool_pose', 'tool_in_base_pose', 'tool_in_cam_pose_deviations', 'obj_in_base_pose_deviations', 'base_in_cam_pose_deviations', 'obj_in_tool_pose_deviations', 'tool_in_cam_pose_covariances', 'obj_in_base_pose_covariances', 'base_in_cam_pose_covariances', 'obj_in_tool_pose_covariances', 'tool_translation_deviation', 'tool_rotation_deviation', 'tool_in_base_pose_corrected'}

▷ **DataValue** (output_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string
Requested data.

Example

```
* Get the camera type of camera 0.
get_calib_data (CalibDataID, 'camera', 0, 'type', CameraType)

* Get the optimized (calibrated) pose of pose 1 of the
* calibration object 2.
get_calib_data (CalibDataID, 'calib_obj_pose', [2,1], 'pose', CalobjPose)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

calibrate_cameras, calibrate_hand_eye, create_calib_data, read_calib_data

Module

Calibration

get_calib_data_observ_contours (: Contours : CalibDataID, ContourName, CameraIdx, CalibObjIdx, CalibObjPoseIdx :)

Get contour-based observation data from a calibration data model.

The operator get_calib_data_observ_contours reads contour-based observation data from a calibration data model CalibDataID and returns it in Contours. These contours result from a preceding call of find_calib_object. The parameters CameraIdx, CalibObjIdx, and CalibObjPoseIdx are indices of the observing camera, calibration plate, and calibration object pose. Together, they specify an observation from the calibration model. Note that if an observation exists, but it was stored in the calibration model CalibDataID by set_calib_data_observ_points, no contour-based results can be returned.

By setting ContourName to one of the following values, you can select the specific type of the contour results:

'marks': The contours of the calibration plate marks.

'marks_with_hole': The calibration plate marks which contain a hole. In this case, the output returned in Contours are regions instead of contours.

'caltab': The contour of the calibration plate finder pattern.

'last_caltab': The contour of the calibration plate finder pattern, which has been extracted by the last successful preceding call to find_calib_object. Note that the observation of the successful call to find_calib_object is used and consequently the values in CameraIdx, CalibObjIdx, and CalibObjPoseIdx are ignored.

The mentioned finder pattern depends on the calibration plate:

- Calibration plates with hexagonally arranged marks: Special mark hexagon (i.e., a mark and its six neighbors) where either four or six marks contain a hole, see create_caltab.
- Calibration plates with rectangularly arranged marks: The border of the calibration plate with a triangle in one corner.

Parameters

▷ **Contours** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Contour-based result(s).

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **ContourName** (input_control) . . . . . string ⇝ *string*
Name of contour objects to be returned.
Default: 'marks'
List of values: ContourName ∈ {'marks', 'caltab', 'last_caltab', 'marks_with_hole'}

▷ **CameraIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observing camera.
Default: 0

▷ **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration plate.
Default: 0

▷ **CalibObjPoseIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration object pose.
Default: 0

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

get_calib_data_observ_points (: : CalibDataID, CameraIdx, CalibObjIdx, CalibObjPoseIdx : Row, Column, Index, Pose)

Get point-based observation data from a calibration data model.

The operator get_calib_data_observ_points reads point-based observation data from a calibration data model CalibDataID. This operator reads back observation data stored by set_calib_data_observ_points or find_calib_object. See set_calib_data_observ_points for a detailed description of the arguments.

Please note that if set_calib_data_observ_points is used for the calibration, the returned values of Row and Column are the original values that have been set with set_calib_data_observ_points. Similarly, if find_calib_object is used for the extraction, the values of Row and Column returned by get_calib_data_observ_points coincide with the coordinates of the detected points computed by find_calib_object.

Note that get_calib_data_observ_points returns the pose of an uncalibrated model. To get the pose of a calibrated model, use get_calib_data.

Parameters

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **CameraIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observing camera.
Default: 0

▷ **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration object.
Default: 0

▷ **CalibObjPoseIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration object pose.
Default: 0

▷ **Row** (output_control) . . . . . number-array ⇝ *real* / integer
Row coordinates of the detected points.

▷ **Column** (output_control) . . . . . number-array ⇝ *real* / integer
Column coordinates of the detected points.

▷ **Index** (output_control) . . . . . number-array ⇝ *integer* / real
Correspondence of the detected points to the points of the observed calibration object.

▷ **Pose** (output_control) . . . . . number-array ⇝ *real* / integer
Roughly estimated pose of the observed calibration object relative to the observing camera.
Number of elements: 7

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

get_camera_setup_param (: : CameraSetupModelID, CameraIdx, GenParamName : GenParamValue)

Get generic camera setup model parameters.

The operator get_camera_setup_param can be used to inspect diverse generic parameters of the camera setup model CameraSetupModelID. Two types of parameters can be queried with this operator:

General parameters:

By setting CameraIdx to *'general'* and GenParamName to one of the following values, general camera setup parameters are returned in GenParamValue:

'num_cameras': Number of cameras described in the model. The number of cameras is fixed with the creation of the camera setup model and cannot be changed after that (see create_camera_setup_model).

'camera_calib_error': The root mean square error (RMSE) of the back projection of the optimization of the camera system. This error is identical with the error returned by calibrate_cameras.

'reference_camera': Returns the index of the camera that has been defined as reference camera within the system. If no reference camera has been specified using set_camera_setup_param, the index 0 is returned. If the coordinate system has been moved by setting a pose with the parameter *'coord_transf_pose'* in set_camera_setup_param, the origin of the coordinate system is not located in any of the available cameras. Therefore, the index -1 is returned.

'coord_transf_pose': Returns the pose in which the coordinate system of the setup has been moved. Please note that after setting a reference camera with set_camera_setup_param, the pose of this camera is returned. Adjusting this coordinate system subsequently using the parameter *'coord_transf_pose'* in set_camera_setup_param yields a pose that corresponds to the location and orientation of the desired coordinate system relative to the current one.

Camera parameters:

By setting CameraIdx to a valid setup camera index (a value between 0 and NumCameras-1) and GenParamName to one of the following values, camera-specific parameters are returned in GenParamValue:

'type': Camera type (see set_camera_setup_cam_param).

'params': A tuple with internal camera parameters. The length of the tuple depends on the camera type.

'params_deviations': A tuple representing the standard deviations of the internal camera parameters. The length of the tuple depends on the camera type.

'params_covariances': A tuple representing the covariance matrix if the internal camera parameters. The length of the tuple depends on the camera type.

'pose': Camera pose relative to the setup's coordinate system (see `create_camera_setup_model` for more details).

Note that the camera needs to be set first by `set_camera_setup_cam_param`, before any of its parameters can be inspected by `get_camera_setup_param`. If `CameraIdx` is an index of an undefined camera, the operator returns an error.

For more information about the calibration process of your camera setup see the chapter Calibration.

Parameters

▷ **`CameraSetupModelID`** (input_control) . . . . . camera_setup_model ⇝ *handle*
Handle to the camera setup model.

▷ **`CameraIdx`** (input_control) . . . . . integer(-array) ⇝ *integer* / string
Index of the camera in the setup.
Default: 0
Suggested values: `CameraIdx` ∈ {0, 1, 2, 'general'}

▷ **`GenParamName`** (input_control) . . . . . attribute.name ⇝ *string*
Names of the generic parameters to be queried.
List of values: `GenParamName` ∈ {'camera_calib_error', 'type', 'params', 'params_deviations', 'params_covariances', 'pose', 'reference_camera', 'coord_transf_pose', 'num_cameras'}

▷ **`GenParamValue`** (output_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string
Values of the generic parameters to be queried.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

`query_calib_data_observ_indices` (: : `CalibDataID`, `ItemType`, `ItemIdx` : `Index1`, `Index2`)

Query information about the relations between cameras, calibration objects, and calibration object poses.

A calibration data model (`CalibDataID`) contains a collection of observations, which are added to the model by `set_calib_data_observ_points`. Each observation is associated to an observing camera, an observed calibration object, and a calibration object pose. With the operator `query_calib_data_observ_indices`, you can query observation indices associated to a camera or an calibration object, depending on the parameter `ItemType`.

For `ItemType`=*'camera'*, you must pass a valid camera index in `ItemIdx`. Then, `Index1` returns a list of calibration object indices and `Index2` returns a list of pose indices. Each pair `[Index1[I],Index2[I]]` represents calibration object pose that are 'observed' by camera `ItemIdx`.

For `ItemType`=*'calib_obj'*, you must specify a valid calibration object index in `ItemIdx`. Then, `Index1` returns a list of camera indices and `Index2` returns a list of corresponding calibration object pose indices. Each pair `[Index1[I],Index2[I]]` denotes that camera `Index1[I]` is observing the `Index2[I]`th pose of calibration object `ItemIdx`.

This operator is particularly suitable for accessing observation data of a calibration data model whose configuration is unknown at the moment of its usage (e.g., if it was just read from a file). As a special case, this operator can be used to get the precise list of poses of one calibration object (see the example).

Parameters

▷ **`CalibDataID`** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **ItemType** (input_control) . . . . . string ⇝ *string*
Kind of referred object.
Default: 'camera'
List of values: ItemType ∈ {'camera', 'calib_obj'}

▷ **ItemIdx** (input_control) . . . . . number ⇝ *integer*
Camera index or calibration object index (depending on the selected ItemType).
Default: 0
Suggested values: ItemIdx ∈ {0, 1, 2}

▷ **Index1** (output_control) . . . . . number-array ⇝ *integer*
List of calibration object indices or list of camera indices (depending on ItemType).

▷ **Index2** (output_control) . . . . . number-array ⇝ *integer*
Calibration object numbers.

Example

```
* Read a calibration model from a file.
read_calib_data ('calib_data.ccd',CalibDataID)

* Get calibration object indices assigned to calibration object 0.
query_calib_data_observ_indices (CalibDataID, 'calib_obj', 0, _, \
                                 CalibObjPoseIndices)
* CalibObjPoseIndices contains the list of pose indices of calibration
* object 0. In order to be stored in the model, each calibration object
* needs to be observed by at least one camera in the setup (a calibration
* object pose that is not observed by any camera cannot be stored in
* the model). Typically, a calibration object pose can be observed by more
* than one camera. Hence, some calibration object pose indices might appear
* repeatedly in CalibObjPoseIndices. We use tuple_sort and tuple_uniq to
* extract a unique list of calibration object pose indices for calibration
* object 0.
tuple_sort (CalibObjPoseIndices, CalibObjPoseIndices)
tuple_uniq (CalibObjPoseIndices, CalibObjPoseIndices)

* Get poses of calibration objects observed by camera 2.
calibrate_cameras (CalibDataID, Error)
query_calib_data_observ_indices (CalibDataID, 'camera', 2, CalibObjIndices,\
                                 CalibObjPoseIndices)
for I := 0 to |CalibObjIndices|-1 by 1
  get_calib_data (CalibDataID, 'calib_obj_pose', \
                  [CalibObjIndices[I], CalibObjPoseIndices[I]], \
                  'pose', CalibObjPose)
endfor
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Calibration

read_calib_data (: : FileName : CalibDataID)

Restore a calibration data model from a file.

The operator read_calib_data restores a calibration data model from a file specified by its FileName and returns a handle to the restored model in CalibDataID. The model file must have been created by write_calib_data.

Note that write_calib_data does not store any calibration results into the file. Yet, calibrate_cameras can be called for a fully configured calibration model immediately after the reading. All calibration results are accessible afterwards.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
The path and file name of the model file.
File extension: .ccd

▷ **CalibDataID** (output_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Calibration

read_camera_setup_model (: : FileName : CameraSetupModelID)

Restore a camera setup model from a file.

The operator read_camera_setup_model restores a camera setup model from a file specified by its FileName and returns a handle to the restored model in CameraSetupModelID. The model file must have been created by write_camera_setup_model.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
The path and file name of the model file.
File extension: .csm

▷ **CameraSetupModelID** (output_control) . . . . . camera_setup_model ⇝ *handle*
Handle to the camera setup model.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Calibration

remove_calib_data (: : CalibDataID, ItemType, ItemIdx :)

Remove a data set from a calibration data model.

The operator remove_calib_data, removes data from the calibration data model CalibDataID. Currently, only the hand-eye calibration data set can be altered. With ItemType='tool', you can remove the pose of the robot tool (in robot base coordinates), which was used to obtain the observation of the pose of the calibration object with the same index ItemIdx (corresponds to the parameter CalibObjPoseIdx of any of the operators find_calib_object, set_calib_data_observ_pose, or set_calib_data_observ_pose). Note, that the corresponding observation of the calibration object with the same index ItemIdx that was previously set in the model also has to be removed. Otherwise, the operator calibrate_hand_eye will report an error.

Parameters

▷ **CalibDataID** (input_control) ..... calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **ItemType** (input_control) ..... string ⇝ *string*
Type of the calibration data item.
Default: 'tool'
List of values: ItemType ∈ {'tool'}

▷ **ItemIdx** (input_control) ..... number(-array) ⇝ *integer* / string
Index of the affected item.
Default: 0
Suggested values: ItemIdx ∈ {0, 1, 2}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

set_calib_data, remove_calib_data_observ

Possible Successors

calibrate_hand_eye

See also

calibrate_cameras

Module

Calibration

remove_calib_data_observ (: : CalibDataID, CameraIdx, CalibObjIdx, CalibObjPoseIdx :)

Remove observation data from a calibration data model.

The operator remove_calib_data_observ removes observations that were set in a calibration data model CalibDataID using find_calib_object, set_calib_data_observ_points, or set_calib_data_observ_pose. The parameters CameraIdx, CalibObjIdx, and CalibObjPoseIdx should specify a valid observation from the calibration model. Note that if the calibration data model CalibDataID is used in calibrate_hand_eye, the corresponding tool pose also has to be deleted using remove_calib_data.

Parameters

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **CameraIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observing camera.
Default: 0

▷ **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration object.
Default: 0

▷ **CalibObjPoseIdx** (input_control) . . . . . number ⇝ *integer*
Index of the observed calibration object pose.
Default: 0

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`find_calib_object`, `set_calib_data_observ_points`, `set_calib_data_observ_pose`

Possible Successors

`remove_calib_data`, `calibrate_cameras`, `calibrate_hand_eye`

Module

Calibration

serialize_calib_data (: : CalibDataID : SerializedItemHandle)

Serialize a calibration data model.

`serialize_calib_data` serializes the data of a calibration data model (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_calib_data` is converted to a serialized item. The calibration data model is defined by the handle `CalibDataID`. The serialized calibration data model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_calib_data`.

Note that no calibration results are serialized. You can access them with the operator `get_calib_data`, either as individual items or in form of a camera setup model and store them separately.

Parameters

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_calib_data` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_calib_data

Module

Calibration

serialize_camera_setup_model (: : CameraSetupModelID : SerializedItemHandle)

Serialize a camera setup model.

serialize_camera_setup_model serializes the data of a camera setup model (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_camera_setup_model is converted to a serialized item. The camera setup model is defined by the handle CameraSetupModelID. The serialized camera setup model is returned by the handle SerializedItemHandle and can be deserialized by deserialize_camera_setup_model.

Parameters

▷ **CameraSetupModelID** (input_control) ..... camera_setup_model ⇝ *handle*
Handle to the camera setup model.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_camera_setup_model returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_camera_setup_model

Module

Calibration

set_calib_data (: : CalibDataID, ItemType, ItemIdx, DataName, DataValue :)

Set data in a calibration data model.

With the operator set_calib_data, you can set data in the calibration data model CalibDataID.

Note that an overview on how the calibration data model is filled with data during the processes of camera calibration and hand-eye calibration is provided by the description of get_calib_data.

The calibration data model can contain various kinds of data. How to set specific data in the calibration data model is described for different categories of data:

- Model-related data (ItemType *'model'*)
- Camera-related data (ItemType *'camera'*)
- Data related to calibration object poses (ItemType *'calib_obj_pose'*)
- Hand-eye calibration related data (ItemType *'tool'*)

The parameter ItemIdx lets you select whether the new value should be set for all items of a type or only for an individual one. The parameters to set are passed in DataName, their values in DataValue.

To get detailed information about the calibration process of your camera setup see the chapter Calibration.

Model-related data

ItemType=*'model'*: ItemIdx must be set to *'general'*.

Depending on the selection in DataName, you can set the following model-related parameters to the value passed in DataValue:

'reference_camera': Set the reference camera for the calibration model to the passed camera index. All poses stored in the calibration data model are specified in the coordinate system of the reference camera (see get_calib_data).

'common_motion_vector': For stereo setups with telecentric line scan cameras, a string with a Boolean value (i.e., *'true'* or *'false'*) that determines whether the cameras have a common motion vector.

'optimization_method': Set the optimization method to be used in the hand-eye calibration process. If DataValue=*'linear'* is set, a linear method is used for the hand-eye calibration. If DataValue=*'nonlinear'* is set, a nonlinear method is used for the hand-eye calibration. If DataValue=*'stochastic'* is set, a method is used which also takes the uncertainty of measured observations into account (see calibrate_hand_eye for more details).

Camera-related data

ItemType=*'camera'*: ItemIdx determines, if data is set for all cameras in general or for a specific camera. With ItemIdx=*'general'*, the new settings are applied to all cameras in the model. If you pass a valid camera index instead, i.e., a number between 0 and NumCameras-1 (NumCameras is specified during model creation with create_calib_data), only the specified camera is affected by the changes.

By selecting the following parameters in DataName, you can **specify which camera parameters shall be optimized during the calibration** performed by calibrate_cameras:

'calib_settings': The camera parameters listed in DataValue are marked for optimization for the affected camera(s) (additionally to the camera parameters that were already marked for optimization). Note that by default, all parameters are marked for the optimization. That is, *'calib_settings'* is mainly suited to add previously excluded parameters again.

'excluded_settings': The camera parameters listed in DataValue are excluded from the optimization for the affected camera(s).

The following camera parameters can be passed in DataValue. See Calibration for affected camera types and further details about the parameters.

Internal camera parameters

'focus': Focal length of the lens.

'magnification': Magnification of the lens.

'kappa': Divisional distortion coefficient kappa.

'k1',*'k2'*,*'k3'*: Polynomial radial distortion parameters.

'poly_tan_2': An alias parameter for all polynomial tangential distortion parameters, i.e., p1 and p2.

'poly': An alias parameter for all polynomial distortion parameters, i.e., k1, k2, k3, p1, and p2.

'image_plane_dist': The distance of the tilted image plane from the perspective projection center.

'tilt': Tilt and rotation of the tilt lens.

'cx',*'cy'*: Coordinates of the camera's principal point.

'principal_point': An alias parameter for *'cx'* and *'cy'*.

'sx',*'sy'*: Sensor element dimensions.

'params': All internal camera parameters.

External camera parameters

'alpha',*'beta'*,*'gamma'*: Rotation part of the camera pose.

'transx',*'transy'*,*'transz'*: Translation part of the camera pose.

'pose': All external camera parameters.

Further camera parameters

'vx',*'vy'*,*'vz'*: Motion vector parameters. Note that for stereo setups with telecentric line scan cameras with a common motion vector (i.e., *'common_motion_vector'* = *'true'*), the motion vector optimization parameters of the reference camera determine which parameters of the common motion vector are optimized. For this kind of setup, it is recommended not to exclude any motion vector parameters from the optimization.

'all': All camera parameters.

By default, all parameters are marked for calibration. As an exception, the camera pose is excluded from the optimization for calibration setups with only one camera (`NumCameras`=1). This setting makes the calibration process equivalent to the one performed by `camera_calibration`.

Data related to calibration object poses

`ItemType`=*'calib_obj_pose'*: `ItemIdx` determines, if data is set for all calibration object poses in general or for a specific calibration object pose. With `ItemIdx`=*'general'* the new settings are applied to all calibration object poses in the model. If you pass a valid calibration object pose index instead, i.e., a tuple containing a valid index pair `[CalibObjIdx, CalibObjPoseIdx]`, you specify a calibration object pose, which is affected by the changes.

By selecting the following parameters in `DataName`, you can **specify which calibration object pose parameters shall be optimized during the calibration** performed by `calibrate_cameras`:

'calib_settings': The calibration object pose settings listed in `DataValue` are marked for optimization for the affected pose(s). Note that by default, all calibration pose parameters are marked for the optimization. That is, *'calib_settings'* is mainly suited to add previously excluded parameters again.

'excluded_settings': The calibration object pose settings listed in `DataValue` are excluded from the optimization for the affected pose(s).

The following calibration pose parameters can be passed in `DataValue`:

'alpha',*'beta'*,*'gamma'*: Rotation part of the calibration object pose.

'transx',*'transy'*,*'transz'*: Translation part of the calibration object pose.

'pose': All calibration object pose parameters.

'all': All calibration objects optimization parameters, i.e., the same as *'pose'*.

By default all parameters are marked for calibration.

The current settings for any model item can be queried with the operator `get_calib_data`.

Hand-eye calibration related data

`ItemType`=*'tool'*: `ItemIdx` must be set to a valid calibration object pose index.

By selecting the following parameter in `DataName`, you can set the pose of the robot tool:

'tool_in_base_pose': Set the pose of the robot tool (in robot base coordinates), which was used to obtain the observation of the pose of the calibration object with the same index `ItemIdx` (corresponds to the parameter `CalibObjPoseIdx` of any of the operators `find_calib_object`, `set_calib_data_observ_pose`, or `set_calib_data_observ_points`).

Parameters

▷ **`CalibDataID`** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **`ItemType`** (input_control) . . . . . string ⇝ *string*
Type of calibration data item.
Default: 'model'
List of values: `ItemType` ∈ {'model', 'camera', 'calib_obj_pose', 'tool'}

▷ **`ItemIdx`** (input_control) . . . . . number(-array) ⇝ *integer* / string
Index of the affected item (depending on the selected `ItemType`).
Default: 'general'
Suggested values: `ItemIdx` ∈ {0, 1, 2, 'general'}

▷ **DataName** (input_control) . . . . . attribute.name ⇝ *string*
Parameter(s) to set.
Default: 'reference_camera'
List of values: DataName ∈ {'reference_camera', 'calib_settings', 'excluded_settings', 'common_motion_vector', 'optimization_method', 'tool_in_base_pose'}

▷ **DataValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer
New value(s).
Default: 0
Suggested values: DataValue ∈ {0, 1, 2, 'all', 'pose', 'params', 'alpha', 'beta', 'gamma', 'transx', 'transy', 'transz', 'focus', 'magnification', 'kappa', 'poly', 'poly_tan_2', 'k1', 'k2', 'k3', 'image_plane_dist', 'tilt', 'principal_point', 'cx', 'cy', 'sx', 'sy', 'vx', 'vy', 'vz', 'true', 'false', 'linear', 'nonlinear', 'stochastic'}

Example

```
* Here, the cell size is known exactly, thus it is excluded from
* the optimization.
set_calib_data (CalibDataID, 'camera', 'general', 'excluded_settings', \
                ['sx','sy'])
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

set_calib_data_observ_points, find_calib_object

Possible Successors

calibrate_cameras, calibrate_hand_eye

Module

Calibration

set_calib_data_calib_object (: : CalibDataID, CalibObjIdx, CalibObjDescr :)

Define a calibration object in a calibration model.

The operator set_calib_data_calib_object defines the calibration object with the index CalibObjIdx in the camera calibration data model CalibDataID. The index must be between 0 and NumCalibObjects-1 (NumCalibObjects is specified during model creation with create_calib_data and can be queried with get_calib_data).

If a calibration object description with index CalibObjIdx is already defined, then the current object description overwrites it (the description is 'substituted'). Note that all NumCalibObjects calibration objects must be set to perform calibrate_cameras.

The parameter CalibObjDescr can be used in two ways:

as a file name: it specifies a calibration plate description file as created with create_caltab or gen_caltab.

as a numerical tuple: it specifies the 3D coordinates of all points of the calibration object. All X, Y, and Z coordinates, respectively, of all points must be packed sequentially in the tuple in form: [X, Y, Z], i.e., [X1, ..., Xn, Y1, ..., Yn, Z1, ..., Zn], where |X| = |Y| = |Z| and all coordinates are in meters.

To query the calibration objects parameters stored earlier in a calibration data model, use get_calib_data.

To get detailed information about the calibration process of your camera setup see the chapter Calibration.

Parameters

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
Calibration object index.
Default: 0
Suggested values: CalibObjIdx ∈ {0, 1, 2}

▷ **CalibObjDescr** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
3D point coordinates or a description file name.
List of values: CalibObjDescr ∈ {'calplate.cpd', 'calplate_5mm.cpd', 'calplate_10mm.cpd', 'calplate_20mm.cpd', 'calplate_40mm.cpd', 'calplate_80mm.cpd', 'calplate_160mm.cpd', 'calplate_320mm.cpd', 'calplate_640mm.cpd', 'calplate_1200mm.cpd', 'calplate_20mm_dark_on_light.cpd', 'calplate_40mm_dark_on_light.cpd', 'calplate_80mm_dark_on_light.cpd', 'caltab.descr', 'caltab_650um.descr', 'caltab_2500um.descr', 'caltab_6mm.descr', 'caltab_10mm.descr', 'caltab_30mm.descr', 'caltab_100mm.descr', 'caltab_200mm.descr', 'caltab_800mm.descr', 'caltab_small.descr', 'caltab_big.descr'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_calib_data, set_calib_data_cam_param

Possible Successors

set_calib_data_cam_param, set_calib_data_observ_points, find_calib_object

Module

Calibration

set_calib_data_cam_param (: : CalibDataID, CameraIdx, CameraType, CameraParam :)

Set type and initial parameters of a camera in a calibration data model.

The operator set_calib_data_cam_param sets the initial camera parameters CameraParam for the camera with the index CameraIdx in the calibration data model CalibDataID. The parameter CameraIdx must be between 0 and NumCameras-1 (NumCameras is specified during model creation with create_calib_data and can be queried with get_calib_data). If a camera with CameraIdx was already defined, its parameters are overwritten by the current ones (the camera is substituted). In this case, the selection which camera parameters are marked for optimization is reset and maybe has to be set again. Note that all NumCameras cameras must be set to perform calibrate_cameras. The calibration procedure refines these initial parameters. You can find further information about the calibration process of different camera setups in Calibration.

The parameter CameraType is only provided for backwards compatibility. The information about the camera type is contained in the first element of CameraParam. Therefore, CameraType should be set either to its default value *[]* (the recommended option) or to the same value as the first element of CameraParam. In any other case an error is raised.

An overview of all available camera types and their respective parameters is given in CameraParam.

The camera type can be queried later by calling get_calib_data with the arguments ItemType='camera' and DataName='type'. The initial camera parameters can be queried by calling get_calib_data with arguments ItemType='camera' and DataName='init_params'.

Parameters

▷ **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **CameraIdx** (input_control) . . . . . number-array ⇝ *integer* / string
Camera index.
Default: 0
Suggested values: CameraIdx ∈ {'all', 0, 1, 2}

▷ **CameraType** (input_control) . . . . . string(-array) ⇝ *string*
Type of the camera.
Default: []
List of values: CameraType ∈ {[]}

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Initial camera internal parameters.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_calib_data, set_calib_data_calib_object

Possible Successors

set_calib_data_calib_object, set_calib_data_observ_points, find_calib_object

Module

Calibration

set_calib_data_observ_points (: : CalibDataID, CameraIdx, CalibObjIdx, CalibObjPoseIdx, Row, Column, Index, Pose :)

Set point-based observation data in a calibration data model.

For a calibration model of type CalibSetup='calibration_object' (see create_calib_data), cameras are calibrated based on so-called observations of calibration objects. With set_calib_data_observ_points, you store such an observation in the calibration data model CalibDataID. An observation consists of the following data:

CameraIdx: index of the observing camera

CalibObjIdx: index of the observed calibration object

CalibObjPoseIdx: index of the observed pose of the calibration object. You can choose it freely, without following a strict order. If you specify an index that already exists for the calibration object CalibObjIdx, the corresponding observation data is replaced by the new one. Of course, the same index can be assigned to poses of different calibration objects.

Row, **Column**, **Index**: Extracted image coordinates and corresponding index of the calibration marks of the calibration object. Row and Column are tuples containing the same number of elements. Index can either contain a tuple (of the same length) or the value *'all'*, indicating that the points [Row, Column] correspond in a one-to-one relation to the calibration marks of the calibration object. If the number of row or column coordinates does not match the number of calibration marks, a corresponding error message is returned.

Pose: A roughly estimated pose of the observed calibration object relative to observing camera.

If you are using the HALCON calibration plate, it is recommended to use find_calib_object instead of set_calib_data_observ_points, since the contour information, which it stores in the calibration data model, enables a more precise calibration procedure with calibrate_cameras.

The observation data can be accessed later by calling get_calib_data_observ_points using the same values for the arguments CameraIdx, CalibObjIdx, and CalibObjPoseIdx.

Parameters

- **CalibDataID** (input_control) . . . . . calib_data ⇝ *handle*
  Handle of a calibration data model.
- **CameraIdx** (input_control) . . . . . number ⇝ *integer*
  Index of the observing camera.
  Default: 0
  Suggested values: CameraIdx ∈ {0, 1, 2}
- **CalibObjIdx** (input_control) . . . . . number ⇝ *integer*
  Index of the calibration object.
  Default: 0
  Suggested values: CalibObjIdx ∈ {0, 1, 2}
- **CalibObjPoseIdx** (input_control) . . . . . number ⇝ *integer*
  Index of the observed calibration object.
  Default: 0
  Suggested values: CalibObjPoseIdx ∈ {0, 1, 2}
  Restriction: CalibObjPoseIdx >= 0
- **Row** (input_control) . . . . . number-array ⇝ *real* / integer
  Row coordinates of the extracted points.
- **Column** (input_control) . . . . . number-array ⇝ *real* / integer
  Column coordinates of the extracted points.
- **Index** (input_control) . . . . . number-array ⇝ *integer* / string
  Correspondence of the extracted points to the calibration marks of the observed calibration object.
  Default: 'all'
  Suggested values: Index ∈ {'all', 0, 1, 2}
- **Pose** (input_control) . . . . . number-array ⇝ *real* / integer
  Roughly estimated pose of the observed calibration object relative to the observing camera.
  Number of elements: 7

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Alternatives

find_calib_object

Module

Calibration

set_camera_setup_cam_param (: : CameraSetupModelID, CameraIdx, CameraType, CameraParam, CameraPose :)

Define type, parameters, and relative pose of a camera in a camera setup model.

The operator set_camera_setup_cam_param defines the internal parameters and the pose of the camera with CameraIdx in the camera setup model CameraSetupModelID. The parameter CameraIdx must be between 0 and NumCameras-1 (see get_camera_setup_param with argument *'num_cameras'*). If a camera with CameraIdx was already defined, its parameters are overwritten by the current ones (the camera is 'substituted').

The number of values in CameraParam depends on the camera type. See the description of set_calib_data_cam_param for a list of values and Calibration for details on camera types and camera parameters.

The parameter CameraType is only provided for backwards compatibility. The information about the camera type is contained in the first element of CameraParam. Therefore, CameraType should be set either to its default value *[]* (the recommended option) or to the same value as the first element of CameraParam. In any other case an error is raised.

The parameter CameraPose specifies the pose of the camera relative to the setup's coordinate system (see set_camera_setup_param for further explanations on the setup's coordinate system).

All of the parameters set by set_camera_setup_cam_param can be read back by get_camera_setup_param. While the camera type can be changed only with a new call to set_camera_setup_cam_param, all other camera parameters can be modified by set_camera_setup_param. Furthermore, set_camera_setup_param can set additional data to a camera: standard deviations or covariances of the internal camera parameters.

Parameters

▷ **CameraSetupModelID** (input_control) . . . . . camera_setup_model ⇝ *handle*
Handle to the camera setup model.

▷ **CameraIdx** (input_control) . . . . . number-array ⇝ *integer*
Index of the camera in the setup.
Suggested values: CameraIdx ∈ {0, 1, 2}

▷ **CameraType** (input_control) . . . . . string(-array) ⇝ *string*
Type of the camera.
Default: []
List of values: CameraType ∈ {[]}

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **CameraPose** (input_control) . . . . . number-array ⇝ *real* / integer
Pose of the camera relative to the setup's coordinate system.
Number of elements: 7

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

set_camera_setup_param (: : CameraSetupModelID, CameraIdx, GenParamName, GenParamValue :)

Set generic camera setup model parameters.

The operator set_camera_setup_param can be used to set diverse generic parameters or transformations for the camera setup model CameraSetupModelID. Two types of parameters can be set with this operator:

Coordinate system of the setup and transformation of camera poses:

By setting CameraIdx to *'general'* and GenParamName to one of the following values, you can perform the following general pose transformation for all cameras:

'reference_camera': When setting GenParamValue to a valid camera index, all camera poses are recomputed relative to the coordinate system of this camera.

'coord_transf_pose': When passing a tuple in HALCON pose format in GenParamValue, the current coordinate system is moved into this pose. The pose in GenParamValue represents the location and orientation of the desired coordinate system relative to the current one. All camera poses are recomputed relative to the new coordinate system.

The recomputed camera poses can be inspected with the operator get_camera_setup_param.

Camera parameters:

By setting CameraIdx to a valid setup camera index (a value between 0 and NumCameras-1) and GenParamName to one of the following values, camera specific parameters can be set with GenParamValue:

'params': A tuple with internal camera parameters.

'params_deviations': A tuple with the standard deviations of the internal camera parameters except for CameraType, Width, and Height, thus |params_deviations|=|params|-3. The internal camera parameters are camera-type dependent. See the description of set_calib_data_cam_param for a list of values and calibrate_cameras for details on camera types and camera parameters.

'params_covariances': A tuple with the covariance matrix of the internal camera parameters. The tuple must represent a square matrix whose both dimensions are identical to the number of standard deviation values, thus |params_covariances|=|params_deviations|^2=(|params|-3)^2, see *'params_deviations'*.

'pose': A tuple representing the pose of the camera in HALCON pose format, relative to camera setup's coordinate system. See the above section for further details.

Note that the camera must already be defined in the model, before any of its parameters can be changed by set_camera_setup_param. If CameraIdx is an index of a undefined camera, the operator returns an error.

All parameters can be read back by get_camera_setup_param.

Parameters

▷ **CameraSetupModelID** (input_control) . . . . . camera_setup_model ⇝ *handle*
Handle to the camera setup model.

▷ **CameraIdx** (input_control) . . . . . integer(-array) ⇝ *integer* / string
Unique index of the camera in the setup.
Default: 0
Suggested values: CameraIdx ∈ {0, 1, 2, 'general'}

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Names of the generic parameters to be set.
List of values: GenParamName ∈ {'params', 'params_deviations', 'params_covariances', 'pose', 'reference_camera', 'coord_transf_pose'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / integer / string
Values of the generic parameters to be set.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_camera_setup_model, read_camera_setup_model

Module

Calibration

write_calib_data (: : CalibDataID, FileName :)

Store a calibration data model into a file.

The operator write_calib_data stores a calibration data model CalibDataID into a file specified by its file name FileName. The information stored in the file includes:

- initial camera parameters
- calibration object descriptions
- observation data
- model settings: generic and specific optimization parameters for both cameras and calibration object poses.

Note that no calibration results are stored in the file. You can access them with the operator get_calib_data, either as individual items or in form of a camera setup model and store them separately.

The calibration data model can be later read with read_calib_data.

Parameters

▷ **CalibDataID** (input_control) ..... calib_data ⇝ *handle*
Handle of a calibration data model.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
The file name of the model to be saved.
File extension: .ccd

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- CalibDataID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Calibration

write_camera_setup_model (: : CameraSetupModelID, FileName :)

Store a camera setup model into a file.

The operator write_camera_setup_model stores a camera setup model CameraSetupModelID into a file specified by its file name FileName.

The calibration data model can be later read with read_camera_setup_model.

Parameters

▷ **CameraSetupModelID** (input_control) . . . . . camera_setup_model ⇝ *handle*
Handle to the camera setup model.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
The file name of the model to be saved.
File extension: .csm

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

6.8 Projection

cam_par_pose_to_hom_mat3d (: : CameraParam, Pose : HomMat3D)

Convert internal camera parameters and a 3D pose into a 3×4 projection matrix.

cam_par_pose_to_hom_mat3d converts the internal camera parameters CameraParam and the 3D pose Pose, which represent the external camera parameters, into the 3×4 projection matrix HomMat3D, which can be used to project points from 3D to 2D. The conversion can only be performed if the distortion coefficients in CameraParam are 0. If necessary, change_radial_distortion_cam_par must be used to achieve this. The internal camera parameters and the pose are typically obtained with calibrate_cameras.

Parameters

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **Pose** (input_control) . . . . . pose ⇝ *real* / integer
3D pose.
Number of elements: 7

▷ **HomMat3D** (output_control) . . . . . hom_mat3d ⇝ *real*
3×4 projection matrix.

Result

cam_par_pose_to_hom_mat3d returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

calibrate_cameras, change_radial_distortion_cam_par

Possible Successors

project_point_hom_mat3d, project_hom_point_hom_mat3d

See also

Module

Foundation

project_3d_point (: : X, Y, Z, CameraParam : Row, Column)

Project 3D points into (sub-)pixel image coordinates.

project_3d_point projects one or more 3D points (with coordinates X, Y, and Z) into the image plane (in pixels) and returns the result in Row and Column. The coordinates X, Y, and Z are given in the camera coordinate system, i.e., they describe the position of the points relative to the camera.

The internal camera parameters CameraParam describe the projection characteristics of the camera (see Calibration for details).

Parameters

- ▷ **X** (input_control) ..... point3d.x-array ⇝ *real*
  X coordinates of the 3D points to be projected in the camera coordinate system.
- ▷ **Y** (input_control) ..... point3d.y-array ⇝ *real*
  Y coordinates of the 3D points to be projected in the camera coordinate system.
- ▷ **Z** (input_control) ..... point3d.z-array ⇝ *real*
  Z coordinates of the 3D points to be projected in the camera coordinate system.
- ▷ **CameraParam** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **Row** (output_control) ..... point.y-array ⇝ *real*
  Row coordinates of the projected points (in pixels).
- ▷ **Column** (output_control) ..... point.x-array ⇝ *real*
  Column coordinates of the projected points (in pixels).

Example

```
* Set internal camera parameters and pose of the world coordinate
* system in camera coordinates.
* Note that, typically, these values are the result of a prior
* calibration.
gen_cam_par_area_scan_division (0.01, -731, 5.2e-006, 5.2e-006, \
                                654, 519, 1280, 1024, CameraParam)
create_pose (0.1, 0.2, 0.3, 40, 50, 60, \
             'Rp+T', 'gba', 'point', WorldPose)
* Convert pose into transformation matrix.
pose_to_hom_mat3d(WorldPose, HomMat3D)
* Transform 3D points from world into the camera coordinate system.
affine_trans_point_3d(HomMat3D, [3.0, 3.2], [4.5, 4.5], [3.8, 4.2], X, Y, Z)
* Project 3D points into image.
project_3d_point(X, Y, Z, CameraParam, Row, Column)
```

Result

project_3d_point returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

Calibration

project_hom_point_hom_mat3d (: : HomMat3D, Px, Py, Pz, Pw : Qx, Qy, Qw)

Project a homogeneous 3D point using a 3×4 projection matrix.

projective_trans_hom_point_3d applies the 3×4 projection matrix HomMat3D to all homogeneous input points (Px,Py,Pz,Pw) and returns an array of homogeneous output points (Qx,Qy,Qw). The transformation is described by the homogeneous transformation matrix given in HomMat3D. This corresponds to the following equation (input and output points as homogeneous vectors):

$$\begin{pmatrix} Qx \\ Qy \\ Qw \end{pmatrix} = HomMat3D \cdot \begin{pmatrix} Px \\ Py \\ Pz \\ Pw \end{pmatrix}$$

To transform the homogeneous coordinates to Euclidean coordinates, they must be divided by Qw:

$$\begin{pmatrix} Ex \\ Ey \end{pmatrix} = \begin{pmatrix} \frac{Qx}{Qw} \\ \frac{Qy}{Qw} \end{pmatrix}$$

This can be achieved directly by calling project_point_hom_mat3d. Thus, project_hom_point_hom_mat3d is primarily useful for transforming points or point sets for which the resulting points might lie on the line at infinity, i.e., points that potentially have $Qw = 0$, for which the above division cannot be performed.

Note that, consistent with the conventions used by the projection in calibrate_cameras, Qx corresponds to the column coordinate of an image and Qy corresponds to the row coordinate.

Parameters

- ▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
  3×4 projection matrix.
- ▷ **Px** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input point (x coordinate).
- ▷ **Py** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input point (y coordinate).
- ▷ **Pz** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input point (z coordinate).
- ▷ **Pw** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input point (w coordinate).
- ▷ **Qx** (output_control) . . . . . real(-array) ⇝ *real*
  Output point (x coordinate).
- ▷ **Qy** (output_control) . . . . . real(-array) ⇝ *real*
  Output point (y coordinate).
- ▷ **Qw** (output_control) . . . . . real(-array) ⇝ *real*
  Output point (w coordinate).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

cam_par_pose_to_hom_mat3d

Alternatives

project_point_hom_mat3d, project_3d_point

Module

Foundation

project_point_hom_mat3d (: : HomMat3D, Px, Py, Pz : Qx, Qy)

Project a 3D point using a 3×4 projection matrix.

project_point_hom_mat3d applies the 3×4 projection matrix HomMat3D to all input points (Px,Py,Pz) and returns an array of output points (Qx,Qy). The transformation is described by the 3×4 projection matrix given in HomMat3D. This corresponds to the following equations (input and output points as homogeneous vectors):

$$\begin{pmatrix} Tx \\ Ty \\ Tw \end{pmatrix} = \texttt{HomMat3D} \cdot \begin{pmatrix} \texttt{Px} \\ \texttt{Py} \\ \texttt{Pz} \\ 1 \end{pmatrix}$$

project_point_hom_mat3d then transforms the homogeneous coordinates to Euclidean coordinates by dividing them by Tw:

$$\begin{pmatrix} \texttt{Qx} \\ \texttt{Qy} \end{pmatrix} = \begin{pmatrix} \frac{Tx}{Tw} \\ \frac{Ty}{Tw} \end{pmatrix}$$

If a point on the line at infinity ($Tw = 0$) is created by the transformation, an error is returned. If this is undesired, project_hom_point_hom_mat3d can be used.

Note that, consistent with the conventions used by the projection in calibrate_cameras, Qx corresponds to the column coordinate of an image and Qy corresponds to the row coordinate.

Parameters

- ▷ **HomMat3D** (input_control) . . . hom_mat3d ⇝ *real*
  3×4 projection matrix.
- ▷ **Px** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (x coordinate).
- ▷ **Py** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (y coordinate).
- ▷ **Pz** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (z coordinate).
- ▷ **Qx** (output_control) . . . real(-array) ⇝ *real*
  Output point (x coordinate).
- ▷ **Qy** (output_control) . . . real(-array) ⇝ *real*
  Output point (y coordinate).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

6.9 Rectification

change_radial_distortion_cam_par (: : Mode, CamParamIn, DistortionCoeffs : CamParamOut)

Determine new camera parameters in accordance to the specified radial distortion.

change_radial_distortion_cam_par modifies the internal camera parameters in accordance to the specified radial distortion coefficients DistortionCoeffs. The operator can only be used for area scan cameras (with any lens type) and for line scan cameras with telecentric lenses. Line scan cameras with perspective lenses are not supported.

With the parameter Mode, one of the following modes can be selected:

'fixed': Only the distortion coefficients are modified, the other internal camera parameters remain unchanged. In general, this leads to a change of the visible part of the scene.

'fullsize': For area scan cameras, the scale factors S_x andS_y and the image center point $(C_x, C_y)^T$ are modified in order to preserve the visible part of the scene. For line scan cameras with telecentric lenses, the scale factor S_x, the image center point $(C_x, C_y)^T$, and the V_y component of the motion vector are changed to achieve the this effect. Thus, all points visible in the original image are also visible in the modified (rectified) image. In general, this leads to undefined pixels in the modified image.

'adaptive': A trade-off between the other modes: The visible part of the scene is slightly reduced to prevent undefined pixels in the modified image. The same parameters as for *'fullsize'* are modified.

'preserve_resolution': As in the mode *'fullsize'*, all points visible in the original image are also visible in the modified (rectified) image. For area scan cameras, the scale factors S_x and S_y and the image center point $(C_x, C_y)^T$ are modified. For line scan cameras with telecentric lenses, the scale factor S_x, the image center point $(C_x, C_y)^T$, and potentially the V_y component of the motion vector are changed to achieve the this effect. In general, this leads to undefined pixels in the modified image. In contrast to the mode *'fullsize'*, additionally the size of the modified image is increased such that the image resolution does not decrease in any part of the image.

In all modes, the distortion coefficients in CamParamOut are set to DistortionCoeffs. For telecentric line scan cameras, the motion vector also influences the percieved distortion. For example, a nonzero V_x component leads to skewed pixels. Furthermore, if $V_y \neq S_x/\text{Magnification}$, the pixels appear to be non-square. Therefore, for telecentric line scan cameras, up to three more components can be passed in addition to κ or $(K_1, K_2, K_3, P_1, P_2)$, respectively, in DistortionCoeffs. These specify the new V_x, V_y, and V_z components of the motion vector.

The transformation of a pixel in the modified image into the image plane using CamParamOut results in the same point as the transformation of a pixel in the original image via CamParamIn.

Parameters

▷ **Mode** (input_control) ..... string ⇝ *string*
Mode
Default: 'adaptive'
Suggested values: Mode ∈ {'fullsize', 'adaptive', 'fixed', 'preserve_resolution'}

▷ **CamParamIn** (input_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters (original).

▷ **DistortionCoeffs** (input_control) ..... real(-array) ⇝ *real* / integer
Desired radial distortions.
Number of elements: DistortionCoeffs == 1 || DistortionCoeffs == 5
Default: 0.0

▷ **CamParamOut** (output_control) ..... campar ⇝ *real* / integer / string
Internal camera parameters (modified).

Result

change_radial_distortion_cam_par returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

camera_calibration, read_cam_par

Possible Successors

change_radial_distortion_image, change_radial_distortion_contours_xld, gen_radial_distortion_map

camera_calibration, read_cam_par, change_radial_distortion_image, change_radial_distortion_contours_xld, change_radial_distortion_points

Module

Calibration

change_radial_distortion_contours_xld (Contours : ContoursRectified : CamParamIn, CamParamOut :)

Change the radial distortion of contours.

change_radial_distortion_contours_xld changes the radial distortion of the input contours Contours in accordance to the internal camera parameters CamParamIn and CamParamOut. Each subpixel of an input contour is transformed into the image plane using CamParamIn and subsequently projected into a subpixel of the corresponding contour in ContoursRectified using CamParamOut.

If CamParamOut was computed via change_radial_distortion_cam_par, the contours ContoursRectified are equivalent to Contours obtained with a lens with a modified radial distortion κ. If $\kappa = 0$ the contours are rectified. A subsequent pose estimation (determination of the external camera parameters) is not affected by this operation.

Please note that change_radial_distortion_contours_xld does not work for line scan cameras with perspective lenses.

Parameters

- ▷ **Contours** (input_object) ..... xld_cont(-array) ⇝ *object*
  Original contours.
- ▷ **ContoursRectified** (output_object) ..... xld_cont(-array) ⇝ *object*
  Resulting contours with modified radial distortion.
- ▷ **CamParamIn** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameter for Contours.
- ▷ **CamParamOut** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameter for ContoursRectified.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

change_radial_distortion_cam_par, gen_contours_skeleton_xld, edges_sub_pix, smooth_contours_xld

Possible Successors

change_radial_distortion_cam_par, camera_calibration, read_cam_par, change_radial_distortion_image, change_radial_distortion_points

Module

Calibration

change_radial_distortion_image (Image, Region : ImageRectified : CamParamIn, CamParamOut :)

Change the radial distortion of an image.

change_radial_distortion_image changes the radial distortion of the input image Image in accordance to the internal camera parameters CamParamIn and CamParamOut. Each pixel of the output image that lies within the region Region is transformed into the image plane using CamParamOut and subsequently projected into a subpixel of Image using CamParamIn. The resulting gray value is determined by bilinear interpolation. If the subpixel is outside of Image, the corresponding pixel in ImageRectified is set to 'black' and eliminated from the image domain.

If the gray values of all pixels in the output image shall be calculated, it is sufficient to pass an empty object in Region (which must be previously generated by, for example, using gen_empty_obj). This is especially useful if the size of the output image differs from the size of the input image, and hence, it is not possible to simply pass the region of the input image in Region.

If CamParamOut was computed via change_radial_distortion_cam_par, ImageRectified is equivalent to Image obtained with a lens with a modified radial distortion κ. If $\kappa = 0$ the image is rectified. A subsequent pose estimation (determination of the external camera parameters) is not affected by this operation.

Please note that change_radial_distortion_image does not work for line scan cameras with perspective lenses. Instead, you might want to use image_to_world_plane.

Attention

change_radial_distortion_image can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device. As the OpenCL implementation uses single precision arithmetic, the results can differ from the CPU implementation.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Original image.
- ▷ **Region** (input_object) ..... region ⇝ *object*
  Region of interest in ImageRectified.
- ▷ **ImageRectified** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Resulting image with modified radial distortion.
- ▷ **CamParamIn** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameter for Image.
- ▷ **CamParamOut** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameter for Image.

Result

change_radial_distortion_image returns 2 (H_MSG_TRUE) if all parameter values are correct. If the input is empty (no input image is available) the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on channel level.

Possible Predecessors

change_radial_distortion_cam_par, read_image, grab_image

Possible Successors

edges_image, threshold

Module

Calibration

change_radial_distortion_points (: : Row, Col, CamParamIn, CamParamOut : RowChanged, ColChanged)

Change the radial distortion of pixel coordinates.

change_radial_distortion_points changes the radial distortion of input image coordinates (Row, Col) in accordance to the internal camera parameters CamParamIn and CamParamOut. Each input pixel (Row, Col) is transformed into the image plane using CamParamIn and projected into another image using CamParamOut.

Please note that change_radial_distortion_points does not work for line scan cameras with perspective lenses.

Parameters

- ▷ **Row** (input_control) ..... real-array ⇝ *real*
  Original row component of pixel coordinates.
- ▷ **Col** (input_control) ..... real-array ⇝ *real*
  Original column component of pixel coordinates.
- ▷ **CamParamIn** (input_control) ..... campar ⇝ *real* / integer / string
  The inner camera parameters of the camera used to create the input pixel coordinates.
- ▷ **CamParamOut** (input_control) ..... campar ⇝ *real* / integer / string
  The inner camera parameters of a camera.
- ▷ **RowChanged** (output_control) ..... real-array ⇝ *real*
  Row component of pixel coordinates after changing the radial distortion.
- ▷ **ColChanged** (output_control) ..... real-array ⇝ *real*
  Column component of pixel coordinates after changing the radial distortion.

Result

change_radial_distortion_points returns 2 (H_MSG_TRUE) if all parameter values are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

contour_to_world_plane_xld (Contours : ContoursTrans : CameraParam, WorldPose, Scale :)

Transform an XLD contour into the plane z=0 of a world coordinate system.

The operator contour_to_world_plane_xld transforms contour points given in Contours into the plane z=0 in a world coordinate system and returns the 3D contour points in ContoursTrans. The world coordinate system is chosen by passing its 3D pose relative to the camera coordinate system in WorldPose. Hence, latter one is expected in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *ccs* denotes the camera coordinate system and *wcs* the world coordinate system (see Transformations / Poses and "Solution Guide III-C - 3D Vision"). In CameraParam you must pass the internal camera parameters (see Calibration for the sequence of the parameters and the underlying camera model).

In many cases CameraParam and WorldPose are the result of calibrating the camera with the operator calibrate_cameras. See below for an example.

With the parameter Scale you can scale the resulting 3D coordinates. The parameter Scale must be specified as the ratio *desired unit/original unit*. The original unit is determined by the coordinates of the calibration object.

If the original unit is meters (which is the case if you use the standard calibration plate), you can set the desired unit directly by selecting *'m'*, *'cm'*, *'mm'* or *'um'* for the parameter `Scale`.

Internally, the operator first computes the line of sight between the projection center and the image point in the camera coordinate system, taking into account the radial distortions. The line of sight is then transformed into the world coordinate system specified in `WorldPose`. By intersecting the plane z=0 with the line of sight the 3D coordinates of the transformed contour `ContoursTrans` are obtained.

Parameters

- ▷ **`Contours`** (input_object) ..... xld_cont(-array) ⇝ *object*
  Input XLD contours to be transformed in image coordinates.
- ▷ **`ContoursTrans`** (output_object) ..... xld_cont(-array) ⇝ *object*
  Transformed XLD contours in world coordinates.
- ▷ **`CameraParam`** (input_control) ..... number-array ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **`WorldPose`** (input_control) ..... pose ⇝ *real* / integer
  3D pose of the world coordinate system in camera coordinates.
  Number of elements: 7
- ▷ **`Scale`** (input_control) ..... number ⇝ *string* / integer / real
  Scale or dimension
  Default: 'm'
  Suggested values: `Scale` ∈ {'m', 'cm', 'mm', 'microns', 'um', 1.0, 0.01, 0.001, 1.0e-6, 0.0254, 0.3048, 0.9144}
  Restriction: Scale > 0

Example

```
*  Perform camera calibration (with standard calibration plate).
calibrate_cameras (CalibDataID, Error)
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* Get reference pose (pose 2 of calibration object 0).
get_calib_data (CalibDataID, 'calib_obj_pose', [0,2], 'pose', WorldPose)
*  Compensate thickness of plate.
set_origin_pose(ObjInCameraPose, 0, 0, 0.0006, WorldPose)
*  Transform contours into world coordinate system (unit mm).
contour_to_world_plane_xld(Contours, ContoursTrans, CamParam, \
                           WorldPose, 'mm')
```

Result

`contour_to_world_plane_xld` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

gen_image_to_world_plane_map (: Map : CameraParam, WorldPose, WidthIn, HeightIn, WidthMapped, HeightMapped, Scale, MapType :)

Generate a projection map that describes the mapping between the image plane and the plane z=0 of a world coordinate system.

gen_image_to_world_plane_map generates a projection map Map, which describes the mapping between the image plane and the plane z=0 (plane of measurements) in a world coordinate system. This map can be used to rectify an image with the operator map_image. The rectified image shows neither radial nor perspective distortions; it corresponds to an image acquired by a distortion-free camera that looks perpendicularly onto the plane of measurements. The world coordinate system (*wcs*) is chosen by passing its 3D pose relative to the camera coordinate system (*ccs*) in WorldPose. Thus the pose is expected in the form ${}^{ccs}\mathbf{P}_{wcs}$ (see Transformations / Poses and "Solution Guide III-C - 3D Vision"). In CameraParam you must pass the internal camera parameters (see Calibration for the sequence of the parameters and the underlying camera model).

In many cases CameraParam and WorldPose are the result of calibrating the camera with the operator calibrate_cameras. See below for an example.

The size of the images to be mapped can be specified by the parameters WidthIn and HeightIn. The pixel position of the upper left corner of the output image is determined by the origin of the world coordinate system. The size of the output image can be chosen by the parameters WidthMapped, HeightMapped, and Scale. WidthMapped and HeightMapped must be given in pixels.

The parameter Scale can be used to specify the size of a pixel in the transformed image. There are two ways to use this parameter:

Scale pixels to metric units:

Scale the image such that one pixel in the transformed image corresponds to a metric unit, e.g., setting *'mm'* determines that a pixel in the transformed image corresponds to the area 1mm × 1mm in the plane of measurements. For this, the original unit needs to be meters. This is the case if you use a standard calibration plate.

List of values: *'m'*, *'cm'*, *'mm'*, *'microns'*, *'um'*.

Default: *'m'*.

Control scaling manually:

Scale the image by giving a number that determines the ratio of *original unit length / desired number of pixels*. E.g., if your original unit is meters and you want every pixel of your transformed image to represent 3mm × 3mm of the measuring plane, your scale is calculated Scale = $0.003/1 = 0.003$. If you want to perform a task like shape-based matching on your transformed image, it is useful to scale the image such that its content appears in a size similar to the original image.

Restriction: Scale > 0.

The mapping function is stored in the output image Map. Map has the same size as the resulting images after the mapping. MapType is used to specify the type of the output Map. If *'nearest_neighbor'* is chosen, Map consists of one image containing one channel, in which for each pixel of the resulting image the linearized coordinate of the pixel of the input image is stored that is the nearest neighbor to the transformed coordinates. If *'bilinear'* interpolation is chosen, Map consists of one image containing five channels. In the first channel for each pixel in the resulting image the linearized coordinates of the pixel in the input image is stored that is in the upper left position relative to the transformed coordinates. The four other channels contain the weights of the four neighboring pixels of the transformed coordinates which are used for the bilinear interpolation, in the following order:

2	3
4	5

The second channel, for example, contains the weights of the pixels that lie to the upper left relative to the transformed coordinates. If *'coord_map_sub_pix'* is chosen, Map consists of one vector field image of the semantic type 'vector_field_absolute', in which for each pixel of the resulting image the subpixel precise coordinates in the input image are stored.

If several images have to be mapped using the same camera parameters, gen_image_to_world_plane_map in combination with map_image is much more efficient than the operator image_to_world_plane because the mapping function needs to be computed only once.

If you want to re-use the created map in another program, you can save it as a multi-channel image with the operator `write_image`, using the format *'tiff'*.

Parameters

▷ **Map** (output_object) . . . . . (multichannel-)image ⇝ *object :* int4 / int8 / uint2 / vector_field
Image containing the mapping data.

▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

▷ **WorldPose** (input_control) . . . . . pose ⇝ *real* / integer
3D pose of the world coordinate system in camera coordinates.
Number of elements: 7

▷ **WidthIn** (input_control) . . . . . extent.x ⇝ *integer*
Width of the images to be transformed.
Restriction: WidthIn >= 1

▷ **HeightIn** (input_control) . . . . . extent.y ⇝ *integer*
Height of the images to be transformed.
Restriction: HeightIn >= 1

▷ **WidthMapped** (input_control) . . . . . extent.x ⇝ *integer*
Width of the resulting mapped images in pixels.
Restriction: WidthMapped >= 1

▷ **HeightMapped** (input_control) . . . . . extent.y ⇝ *integer*
Height of the resulting mapped images in pixels.
Restriction: HeightMapped >= 1

▷ **Scale** (input_control) . . . . . number ⇝ *string* / integer / real
Scale or unit.
Default: 'm'
Suggested values: `Scale` ∈ {'m', 'cm', 'mm', 'microns', 'um', 1.0, 0.01, 0.001, 1.0e-6, 0.0254, 0.3048, 0.9144}
Restriction: Scale > 0

▷ **MapType** (input_control) . . . . . string ⇝ *string*
Type of the mapping.
Default: 'bilinear'
List of values: `MapType` ∈ {'nearest_neighbor', 'bilinear', 'coord_map_sub_pix'}

Example

```
* Calibrate camera.
calibrate_cameras (CalibDataID, Error)
* Obtain camera parameters.
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* Example values, if no calibration data is available:
CamParam := ['area_scan_division', 0.0087, -1859, 8.65e-006, 8.6e-006, \
             362.5, 291.6, 768, 576]
* Get reference pose (pose 4 of calibration object 0).
get_calib_data (CalibDataID, 'calib_obj_pose',\
                [0,4], 'pose', Pose)
* Example values, if no calibration data is available:
Pose := [-0.11, -0.21, 2.51, 352.73, 346.73, 336.48, 0]
* Compensate thickness of plate.
set_origin_pose (Pose, -1.125, -1.0, 0, PoseNewOrigin)
* Transform the image into the world plane.
read_image (Image, 'calib/calib-3d-coord-04')
gen_image_to_world_plane_map (MapSingle, CamParam, PoseNewOrigin,\
                  CamParam[6], CamParam[7], 900, 800, 0.0025, 'bilinear')
map_image (Image, MapSingle, ImageMapped)
```

Result

`gen_image_to_world_plane_map` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

gen_radial_distortion_map (: Map : CamParamIn, CamParamOut, MapType :)

Generate a projection map that describes the mapping of images corresponding to a changing radial distortion.

gen_radial_distortion_map computes the mapping of images corresponding to a changing radial distortion in accordance to the internal camera parameters CamParamIn and CamParamOut which can be obtained, e.g., using the operator calibrate_cameras. CamParamIn and CamParamOut contain the old and the new camera parameters including the old and the new radial distortion, respectively (also see Calibration for the sequence of the parameters and the underlying camera model). Each pixel of the potential output image is transformed into the image plane using CamParamOut and subsequently projected into a subpixel position of the potential input image using CamParamIn. Note that gen_radial_distortion_map can only be used with area scan cameras.

The mapping function is stored in the output image Map. The size of Map is given by the camera parameters CamParamOut and therefore defines the size of the resulting mapped images using map_image. The size of the images to be mapped with map_image is determined by the camera parameters CamParamIn. MapType is used to specify the type of the output Map. If *'nearest_neighbor'* is chosen, Map consists of one image containing one channel, in which for each pixel of the resulting image the linearized coordinate of the pixel of the input image is stored that is the nearest neighbor to the transformed coordinates. If *'bilinear'* interpolation is chosen, Map consists of one image containing five channels. In the first channel for each pixel in the resulting image the linearized coordinates of the pixel in the input image is stored that is in the upper left position relative to the transformed coordinates. The four other channels contain the weights of the four neighboring pixels of the transformed coordinates which are used for the bilinear interpolation, in the following order:

2	3
4	5

The second channel, for example, contains the weights of the pixels that lie to the upper left relative to the transformed coordinates. If *'coord_map_sub_pix'* is chosen, Map consists of one vector field image of the semantic type 'vector_field_absolute', in which for each pixel of the resulting image the subpixel precise coordinates in the input image are stored.

If CamParamOut was computed via change_radial_distortion_cam_par, the mapping describes the effect of a lens with a modified radial distortion κ. If $\kappa = 0$, the mapping corresponds to a rectification. A subsequent pose estimation (determination of the external camera parameters) is not affected by this operation.

If several images have to be mapped using the same camera parameters, gen_radial_distortion_map in combination with map_image is much more efficient than the operator change_radial_distortion_image because the transformation must be computed only once.

If you want to re-use the created map in another program, you can save it as a multi-channel image with the operator write_image, using the format *'tiff'*.

Parameters

▷ **Map** (output_object) . . . . . (multichannel-)image ⇝ *object :* int4 / int8 / uint2 / vector_field
Image containing the mapping data.

▷ **CamParamIn** (input_control) . . . . . campar ⇝ *real* / integer / string
Old camera parameters.

▷ **CamParamOut** (input_control) . . . . . campar ⇝ *real* / integer / string
New camera parameters.

▷ **MapType** (input_control) . . . . . string ⇝ *string*
Type of the mapping.
Default: 'bilinear'
List of values: MapType ∈ {'nearest_neighbor', 'bilinear', 'coord_map_sub_pix'}

Result

gen_radial_distortion_map returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

image_points_to_world_plane (: : CameraParam, WorldPose, Rows, Cols, Scale : X, Y)

Transform image points into the plane z=0 of a world coordinate system.

The operator image_points_to_world_plane transforms image points which are given in Rows and Cols into the plane z=0 in a world coordinate system and returns their 3D coordinates in X and Y. The world coordinate system is chosen by passing its pose relative to the camera coordinate system in WorldPose. Hence, latter one is expected in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *ccs* denotes the camera coordinate system and *wcs* the world coordinate system (see Transformations / Poses and "Solution Guide III-C - 3D Vision"). In CameraParam you must pass the internal camera parameters (see Calibration for the sequence of the parameters and the underlying camera model).

In many cases CameraParam and WorldPose are the result of calibrating the camera with the operator calibrate_cameras. See below for an example.

With the parameter Scale you can scale the resulting 3D coordinates. The parameter Scale must be specified as the ratio *desired unit/original unit*. The original unit is determined by the coordinates of the calibration object. If the original unit is meters (which is the case if you use the standard calibration plate), you can set the desired unit directly by selecting *'m'*, *'cm'*, *'mm'* or *'um'* for the parameter Scale.

Internally, the operator first computes the line of sight between the projection center and the image contour points in the camera coordinate system, taking into account the radial distortions. The line of sight is then transformed

into the world coordinate system specified in WorldPose. By intersecting the plane z=0 with the line of sight the 3D coordinates X and Y are obtained.

It is recommended to use only those image points Rows and Cols, that lie within the calibrated image size. The mathematical model does only work well for image points, that lie within the calibration range.

Parameters

- ▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **WorldPose** (input_control) . . . . . pose ⇝ *real* / integer
  3D pose of the world coordinate system in camera coordinates.
  Number of elements: 7
- ▷ **Rows** (input_control) . . . . . coordinates.y-array ⇝ *real* / integer
  Row coordinates of the points to be transformed.
  Default: 100.0
- ▷ **Cols** (input_control) . . . . . coordinates.x-array ⇝ *real* / integer
  Column coordinates of the points to be transformed.
  Default: 100.0
- ▷ **Scale** (input_control) . . . . . number ⇝ *string* / integer / real
  Scale or dimension
  Default: 'm'
  Suggested values: Scale ∈ {'m', 'cm', 'mm', 'microns', 'um', 1.0, 0.01, 0.001, 1.0e-6, 0.0254, 0.3048, 0.9144}
  Restriction: Scale > 0
- ▷ **X** (output_control) . . . . . coordinates.x-array ⇝ *real*
  X coordinates of the points in the world coordinate system.
- ▷ **Y** (output_control) . . . . . coordinates.y-array ⇝ *real*
  Y coordinates of the points in the world coordinate system.

Example

```
*  Perform camera calibration (with standard calibration plate).
calibrate_cameras (CalibDataID, Error)
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* Get reference pose (pose 2 of calibration object 0).
get_calib_data (CalibDataID, 'calib_obj_pose',\
                [0,2], 'pose', WorldPose)
*  Compensate thickness of plate.
set_origin_pose(ObjInCameraPose, 0, 0, 0.0006, WorldPose)
*  Transform image points into world coordinate system (unit mm).
image_points_to_world_plane(CamParam, WorldPose, PointRows, PointColumns, \
                            'mm', PointXCoord, PointYCoord)
```

Result

image_points_to_world_plane returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

image_to_world_plane (Image : ImageWorld : CameraParam, WorldPose, Width, Height, Scale, Interpolation :)

Rectify an image by transforming it into the plane z=0 of a world coordinate system.

image_to_world_plane rectifies an image Image by transforming it into the plane z=0 (plane of measurements) in a world coordinate system. The resulting rectified image ImageWorld shows neither radial nor perspective distortions; it corresponds to an image acquired by a distortion-free camera that looks perpendicularly onto the plane of measurements. The world coordinate system is chosen by passing its 3D pose relative to the camera coordinate system in WorldPose. Hence, latter one is expected in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *ccs* denotes the camera coordinate system and *wcs* the world coordinate system (see Transformations / Poses and "Solution Guide III-C - 3D Vision"). In CameraParam you must pass the internal camera parameters (see Calibration for the sequence of the parameters and the underlying camera model).

In many cases CameraParam and WorldPose are the result of calibrating the camera with the operator calibrate_cameras. See below for an example.

The pixel position of the upper left corner of the output image ImageWorld is determined by the origin of the world coordinate system. The size of the output image ImageWorld can be chosen by the parameters Width, Height, and Scale. Width and Height must be given in pixels.

The parameter Scale can be used to specify the size of a pixel in the transformed image. There are two ways to use this parameter:

Scale pixels to metric units:

Scale the image such that one pixel in the transformed image corresponds to a metric unit, e.g., setting *'mm'* determines that a pixel in the transformed image corresponds to the area 1mm $\times$ 1mm in the plane of measurements. For this, the original unit needs to be meters. This is the case if you use a standard calibration plate.

List of values: *'m'*, *'cm'*, *'mm'*, *'microns'*, *'um'*.

Default: *'m'*.

Control scaling manually:

Scale the image by giving a number that determines the ratio of *original unit length / desired number of pixels*. E.g., if your original unit is meters and you want every pixel of your transformed image to represent 3mm $\times$ 3mm of the measuring plane, your scale is calculated Scale $= 0.003/1 = 0.003$. If you want to perform a task like shape-based matching on your transformed image, it is useful to scale the image such that its content appears in a size similar to the original image.

Restriction: Scale > *0*.

The parameter Interpolation specifies, whether bilinear interpolation (*'bilinear'*) should be applied between the pixels in the input image or whether the gray value of the nearest neighboring pixel (*'nearest_neighbor'*) should be used.

If several images have to be rectified using the same parameters, gen_image_to_world_plane_map in combination with map_image is much more efficient than the operator image_to_world_plane because the mapping function needs to be computed only once.

Attention

image_to_world_plane can be executed on OpenCL devices if the input image does not exceed the maximum size of image objects of the selected device. There can be slight differences in the output compared to the execution on the CPU.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **ImageWorld** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
  Transformed image.
- ▷ **CameraParam** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **WorldPose** (input_control) ..... pose ⇝ *real* / integer
  3D pose of the world coordinate system in camera coordinates.
  Number of elements: 7

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the resulting image in pixels.
Restriction: Width >= 1

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the resulting image in pixels.
Restriction: Height >= 1

▷ **Scale** (input_control) . . . . . number ⇝ *string* / integer / real
Scale or unit.
Default: 'm'
Suggested values: Scale ∈ {'m', 'cm', 'mm', 'microns', 'um', 1.0, 0.01, 0.001, 1.0e-6, 0.0254, 0.3048, 0.9144}
Restriction: Scale > 0

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Type of interpolation.
Default: 'bilinear'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear'}

Example

```
* Calibrate camera.
calibrate_cameras (CalibDataID, Error)
* Obtain camera parameters.
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* Example values, if no calibration data is available:
CamParam := ['area_scan_division', 0.0087, -1859, 8.65e-006, 8.6e-006, \
             362.5, 291.6, 768, 576]
* Get reference pose (pose 4 of calibration object 0).
get_calib_data (CalibDataID, 'calib_obj_pose',\
                [0,4], 'pose', Pose)
* Example values, if no calibration data is available:
Pose := [-0.11, -0.21, 2.51, 352.73, 346.73, 336.48, 0]
* Compensate thickness of plate.
set_origin_pose (Pose, -1.125, -1.0, 0, PoseNewOrigin)
* Transform the image into the world plane.
read_image (Image, 'calib/calib-3d-coord-04')
image_to_world_plane (Image, ImageWorld, CamParam, PoseNewOrigin,\
                      900, 800, 0.0025, 'bilinear')
```

Result

image_to_world_plane returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Calibration

6.10 Self-Calibration

```
radial_distortion_self_calibration (
    Contours : SelectedContours : Width, Height, InlierThreshold,
    RandSeed, DistortionModel, DistortionCenter,
    PrincipalPointVar : CameraParam )
```

Calibrate the radial distortion.

radial_distortion_self_calibration estimates the distortion parameters and the distortion center of a lens from a set of XLD Contours.

The distortion parameters are returned in CameraParam. Because no other parameters are estimated - particularly not the focal length or the magnification - a telecentric camera model is returned with Magnification 1 and scale factor 1 for S_x and S_y. See Calibration for more information on the different camera models.

Application

Based on the result of radial_distortion_self_calibration, you can remove lens distortions from images by passing the parameter CameraParam, which contains the distortion parameters, to the operators change_radial_distortion_cam_par and change_radial_distortion_image.

Basic principle

The estimation of the distortions is based on the assumption that a significant number of straight lines are visible in the image. Because of lens distortions, these lines will be projected to curved contours. The operator now determines suitable parameters by which the curved contours can be straightened again, thus compensating the lens distortions.

Extract input contours

To get suitable input contours Contours, you can, e.g., use edges_sub_pix or lines_gauss. The contours should be equally distributed and should lie near the image border because there the degree of distortion is at its maximum and therefore the calibration is most stable. To improve speed and robustness, you can try to to obtain long linear or circular segments, e.g., with segment_contours_xld, union_collinear_contours_xld, union_cocircular_contours_xld, or select_shape_xld. If a single image does not contain enough straight contours in the scene, you can use the contours of multiple images (concat_obj).

Set parameters for contour selection

The operator automatically estimates those contours from Contours that are images of straight lines in the scene using the robust RANSAC method. The contours that do not fulfill this condition and hence are not suited for the calibration process are called outliers. The operator can cope with a maximum outlier percentage of 50 percent. A contour is classified as an outlier if the mean deviation of the contour from its associated straight line is, after the distortion correction, higher than a given threshold T.

$$\frac{1}{m}\sum_{j=1}^{m}|d_j| > \texttt{InlierThreshold} \cdot \frac{m}{100} = T$$

The value InlierThreshold describes the mean deviation of a contour from its associated line in pixels for a contour that contains 100 points. The actual threshold T is derived from InlierThreshold by scaling it with the reference length (100) and the number of contour points m. Therefore, similar contours are classified alike. Typical values of InlierThreshold range from 0.05 to 0.5. The higher the value, the more deviation is tolerated. By choosing the value 0, all the contours of Contours are used for the calibration process. The RANSAC contour selection will then be suppressed to enable a manual contour selection. This can be helpful if the outlier percentage is higher than 50 percent.

With the parameter RandSeed, you can control the randomized behavior of the RANSAC algorithm and force it to return reproducible results. The parameter is passed as initial value to the internally used random number generator. If it is set to a positive value, the operator returns identical results for each call with identical parameter values. The value set for the HALCON system variable *'seed_rand'* (see set_system) does not affect the results of radial_distortion_self_calibration.

radial_distortion_self_calibration returns the contours that were chosen for the calibration process in SelectedContours.

Select distortion model

The distortion model used in the calibration can be selected with the parameter DistortionModel. By choosing the division model (DistortionModel = *'division'*), the distortions are modeled by the distortion parameter κ. By choosing the polynomial model (DistortionModel = *'polynomial'*), the distortions are modeled by the radial distortion parameters K_1, K_2, K_3 and the decentering distortion parameters P_1, P_2. See Calibration for details on the different camera models.

Set parameters for the distortion center estimation

The starting value for the estimation of the distortion center $c = (c_x, c_y)$ is the center of the image; the image size is defined by Width and Height.

The distortion parameters (κ, c_x, c_y) or $(K_1, K_2, K_3, P_1, P_2, c_x, c_y)$, respectively, are estimated via the methods *'variable'*, *'adaptive'*, or *'fixed'*, which are specified via the parameter DistortionCenter:

'variable' In the default mode *'variable'*, the distortion center c is estimated with all the other calibration parameters at the same time. Here, many contours should lie equally distributed near the image borders or the distortion should be high. Otherwise, the search for the distortion center could be ill-posed, which results in instability.

'adaptive' With the method *'adaptive'*, the distortion center c is at first fixed in the image center. Then, the outliers are eliminated by using the InlierThreshold. Finally, the calibration process is rerun by estimating (κ, c_x, c_y) or $(K_1, K_2, K_3, P_1, P_2, c_x, c_y)$, respectively, which will be accepted if $c = (c_x, c_y)$ results from a stable calibration and lies near the image center. Otherwise, c will be assumed to lie in the image center. This method should be used if the distortion center can be assumed to lie near the image center and if very few contours are available or the position of other contours is bad (e.g., the contours have the same direction or lie in the same image region).

'fixed' By choosing the method *'fixed'*, the distortion center will be assumed fixed in the image center and only κ or $(K_1, K_2, K_3, P_1, P_2)$, respectively, will be estimated. This method should be used in case of very weak distortions or few contours in bad position.

In order to control the deviation of c from the image center, the parameter PrincipalPointVar can be used in the methods *'adaptive'* and *'variable'*. If the deviation from the image center should be controlled, PrincipalPointVar must lie between 1 and 100. The higher the value, the more the distortion center can deviate from the image center. By choosing the value 0, the principal point is not controlled, i.e., the principal point is determined solely based on the contours. The parameter PrincipalPointVar should be used in cases of weak distortions or similarly oriented contours. Otherwise, a stable solution cannot be guaranteed.

Runtime

The runtime of radial_distortion_self_calibration is shortest for DistortionCenter = *'variable'* and PrincipalPointVar = *0*. The runtime for DistortionCenter = *'variable'* and PrincipalPointVar > *0* increases significantly for smaller values of PrincipalPointVar. The runtimes for DistortionCenter = *'adaptive'* and DistortionCenter = *'fixed'* are also significantly higher than for DistortionCenter = *'variable'* and PrincipalPointVar = *0*.

Attention

Since the polynomial model (DistortionModel = *'polynomial'*) uses more parameters than the division model (DistortionModel = *'division'*) the calibration using the polynomial model can be slightly less stable than the calibration using the division model, which becomes noticeable in the accuracy of the decentering distortion parameters P_1, P_2. To improve the stability, contours of multiple images can be used. Additional stability can be achieved by setting DistortionCenter = *'fixed'*, DistortionCenter = *'adaptive'*, or PrincipalPointVar > *0*, which was already mentioned above.

Parameters

▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
Contours that are available for the calibration.

▷ **SelectedContours** (output_object) ..... xld_cont-array ⇝ *object*
Contours that were used for the calibration

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the images from which the contours were extracted.
Default: 640
Suggested values: Width ∈ {640, 768}
Restriction: Width > 0

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the images from which the contours were extracted.
Default: 480
Suggested values: Height ∈ {480, 576}
Restriction: Height > 0

▷ **InlierThreshold** (input_control) . . . . . real ⇝ *real*
Threshold for the classification of outliers.
Default: 0.05
Suggested values: InlierThreshold ∈ {0.01, 0.02, 0.03, 0.04, 0.05, 0.06, 0.07, 0.08, 0.09, 0.1}
Restriction: InlierThreshold >= 0

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed value for the random number generator.
Default: 42

▷ **DistortionModel** (input_control) . . . . . string ⇝ *string*
Determines the distortion model.
Default: 'division'
List of values: DistortionModel ∈ {'division', 'polynomial'}

▷ **DistortionCenter** (input_control) . . . . . string ⇝ *string*
Determines how the distortion center will be estimated.
Default: 'variable'
List of values: DistortionCenter ∈ {'fixed', 'adaptive', 'variable'}

▷ **PrincipalPointVar** (input_control) . . . . . real ⇝ *real*
Controls the deviation of the distortion center from the image center; larger values allow larger deviations from the image center; 0 switches the penalty term off.
Default: 0.0
Suggested values: PrincipalPointVar ∈ {0.0, 5.0, 10.0, 20.0, 50.0, 100.0}
Restriction: PrincipalPointVar >= 0.0 && PrincipalPointVar <= 100.0

▷ **CameraParam** (output_control) . . . . . campar ⇝ *real* / integer / string
Internal camera parameters.

Example

```
* Assume that GrayImage is one image in gray values with a
* resolution of 640 x 480 and a suitable number of contours.  Then
* the following example performs the calibration using these
* contours and corrects the image with the estimated distortion
* parameters.
edges_sub_pix (GrayImage, Edges, 'canny', 1.0, 20, 40)
segment_contours_xld (Edges, ContoursSplit, 'lines_circles', 5, 8, 4)
radial_distortion_self_calibration (ContoursSplit, SelectedContours, \
                                    640, 480, 0.08, 42, 'division', \
                                    'variable', 0, CameraParam)
get_domain (GrayImage, Domain)
change_radial_distortion_cam_par ('fullsize', CameraParam, 0, CamParamOut)
change_radial_distortion_image (GrayImage, Domain, ImageRectified, \
                                CameraParam, CamParamOut)
```

Result

If the parameters are valid, the operator radial_distortion_self_calibration returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Calibration

radiometric_self_calibration (Images : : ExposureRatios, Features, FunctionType, Smoothness, PolynomialDegree : InverseResponse)

Perform a radiometric self-calibration of a camera.

radiometric_self_calibration performs a radiometric self-calibration of a camera. For this, at least two images that show the same image contents (scene) must be passed in Images. All images passed in Images must be acquired with different exposures. Typically, the different exposures are obtained by changing the shutter times at the camera. It is not recommended to change the exposure by changing the aperture of the lens since in this case the exposures cannot be determined accurately enough. The ratio of the exposures of consecutive images is passed in ExposureRatios. For example, a value of *0.5* specifies that the second image of an image pair has been acquired with half the exposure of the first image of the pair. The exposure ratio can easily be determined from the shutter times since the exposure is proportional to the shutter time. The exposure ratio must be greater than 0 and smaller than 1. This means that the images must be sorted according to descending exposure. ExposureRatios must contain one element less than the number of images passed in Images. If all exposure ratios are identical, as a simplification a single value can be passed in ExposureRatios.

As described above, the images passed in Images must show identical image contents. Hence, it is typically necessary that neither the camera nor the objects in the scene move. If the camera has rotated around the optical center, the images should be aligned to a reference image (one of the images) using proj_match_points_ransac and projective_trans_image. If the features used for the radiometric calibration are determined from the 2D gray value histogram of consecutive image pairs (Features $= '2d\_histogram'$), it is essential that the images are aligned and that the objects in the scene do not move. For Features $= '1d\_histograms'$, the features used for the radiometric calibration are determined from the 1D gray value histograms of the image pairs. In this mode, the calibration can theoretically be performed if the 1D histograms of the images do not change by the movement of the objects in the images. This can, for example, be the case if an object moves in front of a uniformly textured background. However, it is preferable to use Features $= '2d\_histogram'$ because this mode is more accurate. The mode Features $= '1d\_histograms'$ should only be used if it is impossible to construct the camera set-up such that neither the camera nor the objects in the scene move.

Furthermore, care should be taken to cover the range of gray values without gaps by choosing appropriate image contents. Whether there are gaps in the range of gray values can easily be checked based on the 1D gray value histograms of the images or the 2D gray value histograms of consecutive images. In the 1D gray value histograms (see gray_histo_abs), there should be no areas between the minimum and maximum gray value that have a frequency of 0 or a very small frequency. In the 2D gray value histograms (see histo_2dim), a single connected region having the shape of a "strip" should result from a threshold operation with a lower threshold of 1. If more than one connected component results, a more suitable image content should be chosen. If the image content can be chosen such that the gray value range of the image (e.g., 0-255 for byte images) can be covered with two images with different exposures, and if there are no gaps in the histograms, the two images suffice for the calibration. This, however, is typically not the case, and hence multiple images must be used to cover the entire gray value range. As described above, for this multiple images with different exposures must be taken to cover the entire gray value range as well as possible. For this, normally the first image should be exposed such that the maximum gray value is slightly below the saturation limit of the camera, or such that the image is significantly overexposed. If the first image is overexposed, a significant overexposure is necessary to enable radiometric_self_calibration to detect the overexposed areas reliably. If the camera exhibits an unusual saturation behavior (e.g., a saturation

limit that lies significantly below the maximum gray value) the overexposed areas should be masked out by hand with reduce_domain in the overexposed image.

radiometric_self_calibration returns the inverse gray value response function of the camera in InverseResponse. The inverse response function can be used to create an image with a linear response by using InverseResponse as the LUT in lut_trans. The parameter FunctionType determines which function model is used to model the response function. For FunctionType $= 'discrete'$, the response function is described by a discrete function with the relevant number of gray values (256 for byte images). For FunctionType $= 'polynomial'$, the response is described by a polynomial of degree PolynomialDegree. The computation of the response function is slower for FunctionType $= 'discrete'$. However, since a polynomial tends to oscillate in the areas in which no gray value information can be derived, even if smoothness constraints are imposed as described below, the discrete model should usually be preferred over the polynomial model.

The inverse response function is returned as a tuple of integer values for FunctionType $= 'discrete'$ and FunctionType $= 'polynomial'$. In some applications, it might be desirable to return the inverse response function as floating point values to avoid the numerical error that is introduced by rounding. For example, if the inverse response function must be inverted to obtain the response function of the camera, there is some loss of information if the values are returned as integers. For these applications, FunctionType can be set to *'discrete_real'* or *'polynomial_real'*, in which case the inverse response function will be returned as a tuple of floating point numbers.

The parameter Smoothness defines (in addition to the constraints on the response function that can be derived from the images) constraints on the smoothness of the response function. If, as described above, the gray value range can be covered completely and without gaps, the default value of *1* should not be changed. Otherwise, values > 1 can be used to obtain a stronger smoothing of the response function, while values < 1 lead to a weaker smoothing. The smoothing is particularly important in areas for which no gray value information can be derived from the images, i.e., in gaps in the histograms and for gray values smaller than the minimum gray value of all images or larger than the maximum gray value of all images. In these areas, the smoothness constraints lead to an interpolation or extrapolation of the response function. Because of the nature of the internally derived constraints, FunctionType $= 'discrete'$ favors an exponential function in the undefined areas, whereas FunctionType $= 'polynomial'$ favors a straight line. Please note that the interpolation and extrapolation is always less reliable than to cover the gray value range completely and without gaps. Therefore, in any case it should be attempted first to acquire the images optimally, before the smoothness constraints are used to fill in the remaining gaps. In all cases, the response function should be checked for plausibility after the call to radiometric_self_calibration. In particular, it should be checked whether InverseResponse is monotonic. If this is not the case, a more suitable scene should be used to avoid interpolation, or Smoothness should be set to a larger value. For FunctionType $= 'polynomial'$, it may also be necessary to change PolynomialDegree. If, despite these changes, an implausible response is returned, the saturation behavior of the camera should be checked, e.g., based on the 2D gray value histogram, and the saturated areas should be masked out by hand, as described above.

When the inverse gray value response function of the camera is determined, the absolute energy falling on the camera cannot be determined. This means that InverseResponse can only be determined up to a scale factor. Therefore, an additional constraint is used to fix the unknown scale factor: the maximum gray value that can occur should occur for the maximum input gray value, e.g., InverseResponse$[255] = 255$ for byte images. This constraint usually leads to the most intuitive results. If, however, a multichannel image (typically an RGB image) should be radiometrically calibrated (for this, each channel must be calibrated separately), the above constraint may lead to the result that a different scaling factor is determined for each channel. This may lead to the result that gray tones no longer appear gray after the correction. In this case, a manual white balancing step must be carried out by identifying a homogeneous gray area in the original image, and by deriving appropriate scaling factors from the corrected gray values for two of the three response curves (or, in general, for $n - 1$ of the n channels). Here, the response curve that remains invariant should be chosen such that all scaling factors are < 1. With the scaling factors thus determined, new response functions should be calculated by multiplying each value of a response function with the scaling factor corresponding to that response function.

Parameters

▷ **Images** (input_object) . . . . . singlechannelimage-array ⇝ *object :* byte / uint2
Input images.

▷ **ExposureRatios** (input_control) ..... real(-array) ⇝ *real*
Ratio of the exposure energies of successive image pairs.
Default: 0.5
Suggested values: ExposureRatios ∈ {0.25, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8}
Restriction: ExposureRatios > 0 && ExposureRatios < 1

▷ **Features** (input_control) ..... string ⇝ *string*
Features that are used to compute the inverse response function of the camera.
Default: '2d_histogram'
List of values: Features ∈ {'2d_histogram', '1d_histograms'}

▷ **FunctionType** (input_control) ..... string ⇝ *string*
Type of the inverse response function of the camera.
Default: 'discrete'
List of values: FunctionType ∈ {'discrete', 'polynomial', 'discrete_real', 'polynomial_real'}

▷ **Smoothness** (input_control) ..... real ⇝ *real*
Smoothness of the inverse response function of the camera.
Default: 1.0
Suggested values: Smoothness ∈ {0.3, 0.5, 0.7, 0.8, 1.0, 1.2, 1.5, 2.0, 3.0}
Restriction: Smoothness > 0

▷ **PolynomialDegree** (input_control) ..... integer ⇝ *integer*
Degree of the polynomial if FunctionType = *'polynomial'*.
Default: 5
Suggested values: PolynomialDegree ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: PolynomialDegree >= 1 && PolynomialDegree <= 20

▷ **InverseResponse** (output_control) ..... number-array ⇝ *integer* / real
Inverse response function of the camera.

Example

```
open_framegrabber ('1394IIDC', 1, 1, 0, 0, 0, 0, 'default', -1, \
                   'default', -1, 'default', 'default', 'default', \
                   -1, -1, AcqHandle)
* Define appropriate shutter times.
Shutters := [1000,750,500,250,125]
Num := |Shutters|
* Grab and accumulate images with the different exposures.  In this
* loop, it must be ensured that the scene remains static.
gen_empty_obj (Images)
for I := 0 to Num-1 by 1
    set_framegrabber_param (AcqHandle, 'shutter', Shutters[I])
    grab_image (Image, AcqHandle)
    concat_obj (Images, Image, Images)
endfor
* Compute the exposure ratios from the shutter times.
ExposureRatios := real(Shutters[1:Num-1])/real(Shutters[0:Num-2])
radiometric_self_calibration (Images, ExposureRatios, '2d_histogram', \
                              'discrete', 1, 5, InverseResponse)
* Note that if the frame grabber supports hardware LUTs, we could
* also call set_framegrabber_lut here instead of lut_trans below.
* This would be more efficient.
while (1)
    grab_image_async (Image, AcqHandle, -1)
    lut_trans (Image, ImageLinear, InverseResponse)
    * Process radiometrically correct image.
    * [...]
endwhile
close_framegrabber (AcqHandle)
```

Result

If the parameters are valid, the operator radiometric_self_calibration returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Calibration

stationary_camera_self_calibration (: : NumImages, ImageWidth, ImageHeight, ReferenceImage, MappingSource, MappingDest, HomMatrices2D, Rows1, Cols1, Rows2, Cols2, NumCorrespondences, EstimationMethod, CameraModel, FixedCameraParams : CameraMatrices, Kappa, RotationMatrices, X, Y, Z, Error)

Perform a self-calibration of a stationary projective camera.

stationary_camera_self_calibration performs a self-calibration of a stationary projective camera. Here, stationary means that the camera may only rotate around the optical center and may zoom. Hence, the optical center may not move. Projective means that the camera model is a pinhole camera that can be described by a projective 3D-2D transformation. In particular, radial distortions can only be modeled for cameras with constant parameters. If the lens exhibits significant radial distortions they should be removed, at least approximately, with change_radial_distortion_image.

The camera model being used can be described as follows:

$$\mathbf{x} = \mathtt{P}\mathbf{X} \ .$$

Here, $\mathbf{x}$ is a homogeneous 2D vector, $\mathbf{X}$ a homogeneous 3D vector, and P a homogeneous 3×4 projection matrix. The projection matrix P can be decomposed as follows:

$$\mathtt{P} = \mathtt{K}(\mathtt{R}|\mathbf{t}) \ .$$

Here, R is a 3×3 rotation matrix and $\mathbf{t}$ is an inhomogeneous 3D vector. These two entities describe the position (pose) of the camera in 3D space. This convention is analogous to the convention used in camera_calibration, i.e., for R = I and $\mathbf{t} = 0$ the x axis points to the right, the y axis downwards, and the z axis points forward. K is the calibration matrix of the camera (the camera matrix) which can be described as follows:

$$\mathtt{K} = \begin{pmatrix} af & sf & u \\ 0 & f & v \\ 0 & 0 & 1 \end{pmatrix} \ .$$

Here, f is the focal length of the camera in pixels, a the aspect ratio of the pixels, s is a factor that models the skew of the image axes, and (u, v) is the principal point of the camera in pixels. In this convention, the x axis corresponds to the column axis and the y axis to the row axis.

Since the camera is stationary, it can be assumed that $\mathbf{t} = 0$. With this convention, it is easy to see that the fourth coordinate of the homogeneous 3D vector $\mathbf{X}$ has no influence on the position of the projected 3D point.

Consequently, the fourth coordinate can be set to 0, and it can be seen that $\mathbf{X}$ can be regarded as a point at infinity, and hence represents a direction in 3D. With this convention, the fourth coordinate of $\mathbf{X}$ can be omitted, and hence $\mathbf{X}$ can be regarded as inhomogeneous 3D vector which can only be determined up to scale since it represents a direction. With this, the above projection equation can be written as follows:

$$\mathbf{x} = \mathtt{K}\mathtt{R}\mathbf{X} \ .$$

If two images of the same point are taken with a stationary camera, the following equations hold:

$$\begin{aligned} \mathbf{x}_1 &= \mathtt{K}_1\mathtt{R}_1\mathbf{X} \\ \mathbf{x}_2 &= \mathtt{K}_2\mathtt{R}_2\mathbf{X} \end{aligned}$$

and consequently

$$\mathbf{x}_2 = \mathtt{K}_2\mathtt{R}_2\mathtt{R}_1^{-1}\mathtt{K}_1^{-1}\mathbf{x}_1 = \mathtt{K}_2\mathtt{R}_{12}\mathtt{K}_1^{-1}\mathbf{x}_1 = \mathtt{H}_{12}\mathbf{x}_1 \ .$$

If the camera parameters do not change when taking the two images, $K_1 = K_2$ holds. Because of the above, the two images of the same 3D point are related by a projective 2D transformation. This transformation can be determined with `proj_match_points_ransac`. It needs to be taken into account that the order of the coordinates of the projective 2D transformations in HALCON is the opposite of the above convention. Furthermore, it needs to be taken into account that `proj_match_points_ransac` uses a coordinate system in which the origin of a pixel lies in the upper left corner of the pixel, whereas `stationary_camera_self_calibration` uses a coordinate system that corresponds to the definition used in `camera_calibration`, in which the origin of a pixel lies in the center of the pixel. For projective 2D transformations that are determined with `proj_match_points_ransac` the rows and columns must be exchanged and a translation of $(0.5, 0.5)$ must be applied. Hence, instead of $\mathtt{H}_{12} = \mathtt{K}_2\mathtt{R}_{12}\mathtt{K}_1^{-1}$ the following equations hold in HALCON:

$$\mathtt{H}_{12} = \begin{pmatrix} 0 & 1 & 0.5 \\ 1 & 0 & 0.5 \\ 0 & 0 & 1 \end{pmatrix} \mathtt{K}_2\mathtt{R}_{12}\mathtt{K}_1^{-1} \begin{pmatrix} 0 & 1 & -0.5 \\ 1 & 0 & -0.5 \\ 0 & 0 & 1 \end{pmatrix}$$

and

$$\mathtt{K}_2\mathtt{R}_{12}\mathtt{K}_1^{-1} = \begin{pmatrix} 0 & 1 & -0.5 \\ 1 & 0 & -0.5 \\ 0 & 0 & 1 \end{pmatrix} \mathtt{H}_{12} \begin{pmatrix} 0 & 1 & 0.5 \\ 1 & 0 & 0.5 \\ 0 & 0 & 1 \end{pmatrix} \ .$$

From the above equation, constraints on the camera parameters can be derived in two ways. First, the rotation can be eliminated from the above equation, leading to equations that relate the camera matrices with the projective 2D transformation between the two images. Let $\mathtt{H}_{ij}$ be the projective transformation from image i to image j. Then,

$$\begin{aligned} \mathtt{K}_j\mathtt{K}_j^\top &= \mathtt{H}_{ij}\mathtt{K}_i\mathtt{K}_i^\top\mathtt{H}_{ij}^\top \\ \mathtt{K}_j^{-\top}\mathtt{K}_j^{-1} &= \mathtt{H}_{ij}^{-\top}\mathtt{K}_i^{-\top}\mathtt{K}_i^{-1}\mathtt{H}_{ij}^{-1} \end{aligned}$$

From the second equation, linear constraints on the camera parameters can be derived. This method is used for `EstimationMethod` = *'linear'*. Here, all source images i given by `MappingSource` and all destination images j given by `MappingDest` are used to compute constraints on the camera parameters. After the camera parameters have been determined from these constraints, the rotation of the camera in the respective images can be determined based on the equation $\mathtt{R}_{ij} = \mathtt{K}_j^{-1}\mathtt{H}_{ij}\mathtt{K}_i$ and by constructing a chain of transformations from the reference image `ReferenceImage` to the respective image. From the first equation above, a nonlinear method to determine the camera parameters can be derived by minimizing the following error:

$$E = \sum_{(i,j)\in\{(s,d)\}} \left\| \mathtt{K}_j\mathtt{K}_j^\top - \mathtt{H}_{ij}\mathtt{K}_i\mathtt{K}_i^\top\mathtt{H}_{ij}^\top \right\|_F^2$$

Here, analogously to the linear method, $\{(s,d)\}$ is the set of overlapping images specified by MappingSource and MappingDest. This method is used for EstimationMethod = *'nonlinear'*. To start the minimization, the camera parameters are initialized with the results of the linear method. These two methods are very fast and return acceptable results if the projective 2D transformations H_{ij} are sufficiently accurate. For this, it is essential that the images do not have radial distortions. It can also be seen that in the above two methods the camera parameters are determined independently from the rotation parameters, and consequently the possible constraints are not fully exploited. In particular, it can be seen that it is not enforced that the projections of the same 3D point lie close to each other in all images. Therefore, stationary_camera_self_calibration offers a complete bundle adjustment as a third method (EstimationMethod = *'gold_standard'*). Here, the camera parameters and rotations as well as the directions in 3D corresponding to the image points (denoted by the vectors **X** above), are determined in a single optimization by minimizing the following error:

$$E = \sum_{i=1}^{n} \left(\sum_{j=1}^{m} \| \mathbf{x}_{ij} - \mathrm{K}_i \mathrm{R}_i \mathbf{X}_j \|^2 + \frac{1}{\sigma^2}(u_i^2 + v_i^2) \right)$$

In this equation, only the terms for which the reconstructed direction $\mathbf{X}_j$ is visible in image i are taken into account. The starting values for the parameters in the bundle adjustment are derived from the results of the nonlinear method. Because of the high complexity of the minimization the bundle adjustment requires a significantly longer execution time than the two simpler methods. Nevertheless, because the bundle adjustment results in significantly better results, it should be preferred.

In each of the three methods the camera parameters that should be computed can be specified. The remaining parameters are set to a constant value. Which parameters should be computed is determined with the parameter CameraModel which contains a tuple of values. CameraModel must always contain the value *'focus'* that specifies that the focal length f is computed. If CameraModel contains the value *'principal_point'* the principal point (u, v) of the camera is computed. If not, the principal point is set to (ImageWidth/2, ImageHeight/2). If CameraModel contains the value *'aspect'* the aspect ratio a of the pixels is determined, otherwise it is set to 1. If CameraModel contains the value *'skew'* the skew of the image axes is determined, otherwise it is set to 0. Only the following combinations of the parameters are allowed: *'focus'*, *['focus', 'principal_point']*, *['focus', 'aspect']*, *['focus', 'principal_point', 'aspect']*, and *['focus', 'principal_point', 'aspect', 'skew']*.

Additionally, it is possible to determine the parameter Kappa, which models radial lens distortions, if EstimationMethod = *'gold_standard'* has been selected. In this case, *'kappa'* can also be included in the parameter CameraModel. Kappa corresponds to the radial distortion parameter κ of the division model for lens distortions (see camera_calibration).

When using EstimationMethod = *'gold_standard'* to determine the principal point, it is possible to penalize estimations far away from the image center. This can be done by adding a sigma to the parameter *'principal_point: 0.5'*. If no sigma is given the penalty term in the above equation for calculating the error is omitted.

The parameter FixedCameraParams determines whether the camera parameters can change in each image or whether they should be assumed constant for all images. To calibrate a camera so that it can later be used for measuring with the calibrated camera, only FixedCameraParams = *'true'* is useful. The mode FixedCameraParams = *'false'* is mainly useful to compute spherical mosaics with gen_spherical_mosaic if the camera zoomed or if the focus changed significantly when the mosaic images were taken. If a mosaic with constant camera parameters should be computed, of course FixedCameraParams = *'true'* should be used. It should be noted that for FixedCameraParams = *'false'* the camera calibration problem is determined very badly, especially for long focal lengths. In these cases, often only the focal length can be determined. Therefore, it may be necessary to use CameraModel = *'focus'* or to constrain the position of the principal point by using a small Sigma for the penalty term for the principal point.

The number of images that are used for the calibration is passed in NumImages. Based on the number of images, several constraints for the camera model must be observed. If only two images are used, even under the assumption of constant parameters not all camera parameters can be determined. In this case, the skew of the image axes should be set to 0 by *not* adding *'skew'* to CameraModel. If FixedCameraParams = *'false'* is used, the full set of camera parameters can never be determined, no matter how many images are used. In this case, the skew should be set to 0 as well. Furthermore, it should be noted that the aspect ratio can only be determined accurately if at least one image is rotated around the optical axis (the z axis of the camera coordinate system) with respect to the other images. If this is not the case the computation of the aspect ratio should be suppressed by *not* adding *'aspect'* to CameraModel.

As described above, to calibrate the camera it is necessary that the projective transformation for each overlapping image pair is determined with proj_match_points_ransac. For example, for a 2×2 block of images in the following layout

1	2
3	4

the following projective transformations should be determined, assuming that all images overlap each other: 1↦2, 1↦3, 1↦4, 2↦3, 2↦4 and 3↦4. The indices of the images that determine the respective transformation are given by MappingSource and MappingDest. The indices are start at 1. Consequently, in the above example MappingSource = *[1,1,1,2,2,3]* and MappingDest = *[2,3,4,3,4,4]* must be used. The number of images in the mosaic is given by NumImages. It is used to check whether each image can be reached by a chain of transformations. The index of the reference image is given by ReferenceImage. On output, this image has the identity matrix as its transformation matrix.

The 3×3 projective transformation matrices that correspond to the image pairs are passed in HomMatrices2D. Additionally, the coordinates of the matched point pairs in the image pairs must be passed in Rows1, Cols1, Rows2, and Cols2. They can be determined from the output of proj_match_points_ransac with tuple_select or with the HDevelop function subset. To enable stationary_camera_self_calibration to determine which point pair belongs to which image pair, NumCorrespondences must contain the number of found point matches for each image pair.

The computed camera matrices K_i are returned in CameraMatrices as 3×3 matrices. For FixedCameraParams = *'false'*, NumImages matrices are returned. Since for FixedCameraParams = *'true'* all camera matrices are identical, a single camera matrix is returned in this case. The computed rotations R_i are returned in RotationMatrices as 3×3 matrices. RotationMatrices always contains NumImages matrices.

If EstimationMethod = *'gold_standard'* is used, (X, Y, Z) contains the reconstructed directions $\mathbf{X}_j$. In addition, Error contains the average projection error of the reconstructed directions. This can be used to check whether the optimization has converged to useful values.

If the computed camera parameters are used to project 3D points or 3D directions into the image i the respective camera matrix should be multiplied with the corresponding rotation matrix (with hom_mat2d_compose).

Parameters

- ▷ **NumImages** (input_control) . . . integer ⇝ *integer*
  Number of different images that are used for the calibration.
  Restriction: NumImages >= 2
- ▷ **ImageWidth** (input_control) . . . extent.x ⇝ *integer*
  Width of the images from which the points were extracted.
  Restriction: ImageWidth > 0
- ▷ **ImageHeight** (input_control) . . . extent.y ⇝ *integer*
  Height of the images from which the points were extracted.
  Restriction: ImageHeight > 0
- ▷ **ReferenceImage** (input_control) . . . integer ⇝ *integer*
  Index of the reference image.
- ▷ **MappingSource** (input_control) . . . integer-array ⇝ *integer*
  Indices of the source images of the transformations.
- ▷ **MappingDest** (input_control) . . . integer-array ⇝ *integer*
  Indices of the target images of the transformations.
- ▷ **HomMatrices2D** (input_control) . . . hom_mat2d-array ⇝ *real*
  Array of 3×3 projective transformation matrices.
- ▷ **Rows1** (input_control) . . . point.y-array ⇝ *real* / integer
  Row coordinates of corresponding points in the respective source images.
- ▷ **Cols1** (input_control) . . . point.x-array ⇝ *real* / integer
  Column coordinates of corresponding points in the respective source images.
- ▷ **Rows2** (input_control) . . . point.y-array ⇝ *real* / integer
  Row coordinates of corresponding points in the respective destination images.
- ▷ **Cols2** (input_control) . . . point.x-array ⇝ *real* / integer
  Column coordinates of corresponding points in the respective destination images.
- ▷ **NumCorrespondences** (input_control) . . . integer-array ⇝ *integer*
  Number of point correspondences in the respective image pair.

▷ **EstimationMethod** (input_control) . . . . . string ⇝ *string*
Estimation algorithm for the calibration.
Default: 'gold_standard'
List of values: EstimationMethod ∈ {'linear', 'nonlinear', 'gold_standard'}

▷ **CameraModel** (input_control) . . . . . string-array ⇝ *string*
Camera model to be used.
Default: ['focus','principal_point']
List of values: CameraModel ∈ {'focus', 'aspect', 'skew', 'principal_point', 'kappa'}

▷ **FixedCameraParams** (input_control) . . . . . string ⇝ *string*
Are the camera parameters identical for all images?
Default: 'true'
List of values: FixedCameraParams ∈ {'true', 'false'}

▷ **CameraMatrices** (output_control) . . . . . hom_mat2d-array ⇝ *real*
(Array of) 3×3 projective camera matrices that determine the internal camera parameters.

▷ **Kappa** (output_control) . . . . . real(-array) ⇝ *real*
Radial distortion of the camera.

▷ **RotationMatrices** (output_control) . . . . . hom_mat2d-array ⇝ *real*
Array of 3×3 transformation matrices that determine rotation of the camera in the respective image.

▷ **X** (output_control) . . . . . point3d.x-array ⇝ *real*
X-Component of the direction vector of each point if EstimationMethod = *'gold_standard'* is used.

▷ **Y** (output_control) . . . . . point3d.y-array ⇝ *real*
Y-Component of the direction vector of each point if EstimationMethod = *'gold_standard'* is used.

▷ **Z** (output_control) . . . . . point3d.z-array ⇝ *real*
Z-Component of the direction vector of each point if EstimationMethod = *'gold_standard'* is used.

▷ **Error** (output_control) . . . . . real(-array) ⇝ *real*
Average error per reconstructed point if EstimationMethod = *'gold_standard'* is used.

Example

```
* Assume that Images contains four images in the layout given in the
* above description.  Then the following example performs the camera
* self-calibration using these four images.
From := [1,1,1,2,2,3]
To := [2,3,4,3,4,4]
HomMatrices2D := []
Rows1 := []
Cols1 := []
Rows2 := []
Cols2 := []
NumMatches := []
for J := 0 to |From|-1 by 1
    select_obj (Images, ImageF, From[J])
    select_obj (Images, ImageT, To[J])
    points_foerstner (ImageF, 1, 2, 3, 100, 0.1, 'gauss', 'true', \
                      RowsF, ColsF, _, _, _, _, _, _, _, _)
    points_foerstner (ImageT, 1, 2, 3, 100, 0.1, 'gauss', 'true', \
                      RowsT, ColsT, _, _, _, _, _, _, _, _)
    proj_match_points_ransac (ImageF, ImageT, RowsF, ColsF, RowsT, ColsT, \
                              'ncc', 10, 0, 0, 480, 640, 0, 0.5, \
                              'gold_standard', 2, 42, HomMat2D, \
                              Points1, Points2)
    HomMatrices2D := [HomMatrices2D,HomMat2D]
    Rows1 := [Rows1,subset(RowsF,Points1)]
    Cols1 := [Cols1,subset(ColsF,Points1)]
    Rows2 := [Rows2,subset(RowsT,Points2)]
    Cols2 := [Cols2,subset(ColsT,Points2)]
    NumMatches := [NumMatches,|Points1|]
endfor
```

```
stationary_camera_self_calibration (4, 640, 480, 1, From, To, \
                                    HomMatrices2D, Rows1, Cols1, \
                                    Rows2, Cols2, NumMatches, \
                                    'gold_standard', \
                                    ['focus','principal_point'], \
                                    'true', CameraMatrix, Kappa, \
                                    RotationMatrices, X, Y, Z, Error)
```

Result

If the parameters are valid, the operator `stationary_camera_self_calibration` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Classification

7.1 Gaussian Mixture Models

add_class_train_data_gmm (: : GMMHandle, ClassTrainDataHandle :)

Add training data to a Gaussian Mixture Model (GMM).

add_class_train_data_gmm adds the training data specified by ClassTrainDataHandle to a Gaussian Mixture Model (GMM) specified by GMMHandle.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
Handle of a GMM which receives the training data.

▷ **ClassTrainDataHandle** (input_control) ..... class_train_data ⇝ *handle*
Handle of training data for a classifier.

Result

If the parameters are valid, the operator add_class_train_data_gmm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- GMMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

add_sample_class_gmm (: : GMMHandle, Features, ClassID, Randomize :)

Add a training sample to the training data of a Gaussian Mixture Model.

add_sample_class_gmm adds a training sample to the Gaussian Mixture Model (GMM) given by GMMHandle. The training sample is given by Features and ClassID. Features is the feature vector of the sample, and consequently must be a real vector of length NumDim, as specified in create_class_gmm. ClassID is the class of the sample, an integer between 0 and NumClasses-1 (set in create_class_gmm).

In the special case where the feature vectors are of **integer** type, they are lying in the feature space in a grid with step width 1.0. For example, the RGB feature vectors typically used for color classification are triples having integer values between 0 and 255 for each of their components. In fact, there might be even several feature vectors representing the same point. When training a GMM with such data, the training algorithm may tend to align the modeled Gaussians along linearly dependent lines or planes of data that are parallel to the grid dimensions. If the number of Centers returned by train_class_gmm is unusually high, this indicates such a behavior of the algorithm. The parameter Randomize can be used to handle such undesired effects. If Randomize $>$ 0.0, random Gaussian noise with mean 0 and standard deviation Randomize is added to each component of the training data vectors, and the transformed training data is stored in the GMM. For values of Randomize $\leq$ 1.0, the randomized data will look like small clouds around the grid points, which does not improve the properties of the data cloud. For values of Randomize $\gg$ 2.0, the randomization might have a too strong influence on the resulting GMM. For integer feature vectors, a value of Randomize between 1.5 and 2.0 is recommended, which transforms the integer data into homogeneous clouds, without modifying its general form in the feature space. If the data has been created from integer data by scaling, the same problem may occur. Here, Randomize must be scaled with the same scale factor that was used to scale the original data.

Before the GMM can be trained with train_class_gmm, *all* training samples must be added to the GMM with add_sample_class_gmm.

The number of currently stored training samples can be queried with get_sample_num_class_gmm. Stored training samples can be read out again with get_sample_class_gmm.

Normally, it is useful to save the training samples in a file with write_samples_class_gmm to facilitate reusing the samples, and to facilitate that, if necessary, new training samples can be added to the data set, and hence to facilitate that a *newly created* GMM can be trained *anew* with the extended data set.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **Features** (input_control) ..... real-array ⇝ *real*
Feature vector of the training sample to be stored.

▷ **ClassID** (input_control) ..... number ⇝ *integer*
Class of the training sample to be stored.

▷ **Randomize** (input_control) ..... real ⇝ *real*
Standard deviation of the Gaussian noise added to the training data.
Default: 0.0
Suggested values: Randomize ∈ {0.0, 1.5, 2.0}
Restriction: Randomize >= 0.0

Result

If the parameters are valid, the operator add_sample_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- GMMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

classify_class_gmm (: : GMMHandle, Features, Num : ClassID, ClassProb, Density, KSigmaProb)

Calculate the class of a feature vector by a Gaussian Mixture Model.

classify_class_gmm computes the best Num classes of the feature vector Features with the Gaussian Mixture Model (GMM) GMMHandle and returns the classes in ClassID and the corresponding probabilities of the classes in ClassProb. Before calling classify_class_gmm, the GMM must be trained with train_class_gmm.

classify_class_gmm corresponds to a call to evaluate_class_gmm and an additional step that extracts the best Num classes. As described with evaluate_class_gmm, the output values of the GMM can be interpreted as probabilities of the occurrence of the respective classes. However, here the posterior probability ClassProb is further normalized as ClassProb $= p(i|x)/p(x)$, where $p(i|x)$ and $p(x)$ are specified with evaluate_class_gmm. In most cases it should be sufficient to use Num $= 1$ in order to decide whether the probability of the best class is high enough. In some applications it may be interesting to also take the second best class into account (Num $= 2$), particularly if it can be expected that the classes show a significant degree of overlap.

Density and KSigmaProb are explained with evaluate_class_gmm.

Parameters

- ▷ **GMMHandle** (input_control) . . . class_gmm ⇝ *handle*
  GMM handle.
- ▷ **Features** (input_control) . . . real-array ⇝ *real*
  Feature vector.
- ▷ **Num** (input_control) . . . integer ⇝ *integer*
  Number of best classes to determine.
  Default: 1
  Suggested values: Num ∈ {1, 2, 3, 4, 5}
- ▷ **ClassID** (output_control) . . . integer(-array) ⇝ *integer*
  Result of classifying the feature vector with the GMM.
- ▷ **ClassProb** (output_control) . . . real-array ⇝ *real*
  A-posteriori probability of the classes.
- ▷ **Density** (output_control) . . . real-array ⇝ *real*
  Probability density of the feature vector.
- ▷ **KSigmaProb** (output_control) . . . real-array ⇝ *real*
  Normalized k-sigma-probability for the feature vector.

Result

If the parameters are valid, the operator classify_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

clear_class_gmm (: : GMMHandle :)

Clear a Gaussian Mixture Model.

clear_class_gmm clears the Gaussian Mixture Model (GMM) given by GMMHandle and frees all memory required for the GMM. After calling clear_class_gmm, the GMM can no longer be used. The handle GMMHandle becomes invalid.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm(-array) ⇝ *handle*
GMM handle.

Result

If the parameters are valid, the operator clear_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- GMMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

clear_samples_class_gmm (: : GMMHandle :)

Clear the training data of a Gaussian Mixture Model.

clear_samples_class_gmm clears all training samples that have been stored in the Gaussian Mixture Model (GMM) GMMHandle. clear_samples_class_gmm should only be used if the GMM is trained in the same process that uses the GMM for evaluation with evaluate_class_gmm or for classification with classify_class_gmm. In this case, the memory required for the training samples can be freed with clear_samples_class_gmm, and hence memory can be saved. In the normal usage, in which the GMM is trained offline and written to a file with write_class_gmm, it is typically unnecessary to call clear_samples_class_gmm because write_class_gmm does not save the training samples, and hence the online process, which reads the GMM with read_class_gmm, requires no memory for the training samples.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm(-array) ⇝ *handle*
GMM handle.

Result

If the parameters are valid, the operator clear_samples_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- GMMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

create_class_gmm (: : NumDim, NumClasses, NumCenters, CovarType, Preprocessing, NumComponents, RandSeed : GMMHandle)

Create a Gaussian Mixture Model for classification

create_class_gmm creates a Gaussian Mixture Model (GMM) for classification. NumDim specifies the number of dimensions of the feature space, NumClasses specifies the number of classes. A GMM consists of NumCenters *Gaussian centers* per class. NumCenters can not only be the exact number of centers to be used, but, depending on the number of parameters, can specify upper and lower bounds for the number of centers:

exactly one parameter: The parameter determines the exact number of centers to be used for all classes.

exactly two parameters: The first parameter determines the minimum number of centers, the second determines the maximum number of centers for all classes.

exactly $2 \cdot NumClasses$ **parameters:** Alternatingly every first parameter determines the minimum number of centers per class and every second parameters determines the maximum number of centers per class.

When upper and lower bounds are specified, the optimum number of centers will be determined with the help of the Minimum Message Length Criterion (MML). In general, we recommend to start the training with (too) many centers as maximum and the expected number of centers as minimum.

Each center is described by the parameters center $\mathbf{m}_j$, covariance matrix $\mathbf{C}_j$, and mixing coefficient P_j. These parameters are calculated from the training data by means of the Expectation Maximization (EM) algorithm. A GMM

can approximate an arbitrary probability density, provided that enough centers are being used. The covariance matrices $\mathbf{C}_j$ have the dimensions NumDim · NumDim (NumComponents · NumComponents if preprocessing is used) and are symmetric. Further constraints can be given by CovarType:

For CovarType = *'spherical'*, $\mathbf{C}_j$ is a scalar multiple of the identity matrix $\mathbf{C}_j = s_j^2\mathbf{I}$. The center density function $p(\mathbf{x}|j)$ is

$$p(\mathbf{x}|j) = \frac{1}{(2\pi s_j^2)^{d/2}} \exp(-\frac{\|\mathbf{x}-\mathbf{m}_j\|^2}{2s_j^2})$$

For CovarType = *'diag'*, $\mathbf{C}_j$ is a diagonal matrix

$\mathbf{C}_j = diag(s_{j,1}^2, ..., s_{j,d}^2)$. The center density function $p(\mathbf{x}|j)$ is

$$p(\mathbf{x}|j) = \frac{1}{(2\pi \prod_{i=1}^{d} s_{j,i}^2)^{d/2}} \exp(-\sum_{i=1}^{d} \frac{(x_i - m_{j,i})^2}{2s_{j,i}^2})$$

For CovarType = *'full'*, $\mathbf{C}_j$ is a positive definite matrix. The center density function $p(\mathbf{x}|j)$ is

$$p(\mathbf{x}|j) = \frac{1}{(2\pi)^{d/2}|\mathbf{C}_j|^{\frac{1}{2}}} \exp(-\frac{1}{2}(\mathbf{x}-\mathbf{m}_j)^T\mathbf{C}^{-1}(\mathbf{x}-\mathbf{m}_j))$$

The complexity of the calculations increases from CovarType = *'spherical'* over CovarType = *'diag'* to CovarType = *'full'*. At the same time the flexibility of the centers increases. In general, *'spherical'* therefore needs higher values for NumCenters than *'full'*.

The procedure to use GMM is as follows: First, a GMM is created by create_class_gmm. Then, training vectors are added by add_sample_class_gmm, afterwards they can be written to disk with write_samples_class_gmm. With train_class_gmm the classifier center parameters (defined above) are determined. Furthermore, they can be saved with write_class_gmm for later classifications.

From the mixing probabilities P_j and the center density function $p(\mathbf{x}|j)$, the probability density function $p(\mathbf{x})$ can be calculated by:

$$p(x) = \sum_{j=1}^{n_{comp}} P(j)p(\mathbf{x}|j)$$

The probability density function $p(\mathbf{x})$ can be evaluated with evaluate_class_gmm for a feature vector $\mathbf{x}$. classify_class_gmm sorts the $p(\mathbf{x})$ and therefore discovers the most probable class of the feature vector.

The parameters Preprocessing and NumComponents can be used to preprocess the training data and reduce its dimensions. These parameters are explained in the description of the operator create_class_mlp.

create_class_gmm initializes the coordinates of the centers with random numbers. To ensure that the results of training the classifier with train_class_gmm are reproducible, the seed value of the random number generator is passed in RandSeed.

Parameters

▷ **NumDim** (input_control) ..... integer ⇝ *integer*
Number of dimensions of the feature space.
Default: 3
Suggested values: NumDim ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumDim >= 1

▷ **NumClasses** (input_control) ..... integer ⇝ *integer*
Number of classes of the GMM.
Default: 5
Suggested values: NumClasses ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: NumClasses >= 1

▷ **NumCenters** (input_control) . . . . . integer(-array) ⇝ *integer*
Number of centers per class.
Default: 1
Suggested values: NumCenters ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30}
Restriction: NumClasses >= 1

▷ **CovarType** (input_control) . . . . . string ⇝ *string*
Type of the covariance matrices.
Default: 'spherical'
List of values: CovarType ∈ {'spherical', 'diag', 'full'}

▷ **Preprocessing** (input_control) . . . . . string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'normalization'
List of values: Preprocessing ∈ {'none', 'normalization', 'principal_components', 'canonical_variates'}

▷ **NumComponents** (input_control) . . . . . integer ⇝ *integer*
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = *'none'* and Preprocessing = *'normalization'*).
Default: 10
Suggested values: NumComponents ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumComponents >= 1

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed value of the random number generator that is used to initialize the GMM with random values.
Default: 42

▷ **GMMHandle** (output_control) . . . . . class_gmm ⇝ *handle*
GMM handle.

Example

```
* Classification with Gaussian Mixture Models
create_class_gmm (NumDim , NumClasses, [1,5], 'full', 'none',\
                  NumComponents, 42, GMMHandle)
* Add the training data
for J := 0 to NumData-1 by 1
    * Features := [...]
    * ClassID := [...]
    add_sample_class_gmm (GMMHandle, Features, ClassID, Randomize)
endfor
* Train the GMM
train_class_gmm (GMMHandle, 100, 0.001, 'training', 0.0001, Centers, Iter)
* Classify unknown data in 'Features'
classify_class_gmm (GMMHandle, Features, 1, ID, Prob, Density, KSigmaProb)
```

Result

If the parameters are valid, the operator create_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

deserialize_class_gmm (: : SerializedItemHandle : GMMHandle)

Deserialize a serialized Gaussian Mixture Model.

deserialize_class_gmm deserializes a Gaussian Mixture Model (GMM) (including its training samples), that was serialized by serialize_class_gmm (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized Gaussian Mixture Model is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created Gaussian Mixture Model with the handle GMMHandle.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **GMMHandle** (output_control) ..... class_gmm ⇝ *handle*
GMM handle.

Result

If the parameters are valid, the operator deserialize_class_gmm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

evaluate_class_gmm (: : GMMHandle, Features : ClassProb, Density, KSigmaProb)

Evaluate a feature vector by a Gaussian Mixture Model.

evaluate_class_gmm computes three different probability values for a feature vector Features with the Gaussian Mixture Model (GMM) GMMHandle.

The a-posteriori probability of class i for the sample Features(x) is computed as

$$p(i|\mathbf{x}) = \sum_{j=1}^{n_{comp}} P(j)p(\mathbf{x}|j)$$

and returned for each class in ClassProb. The formulas for the calculation of the center density function $p(\mathbf{x}|j)$ are described with create_class_gmm.

The probability density of the feature vector is computed as a sum of the posterior class probabilities

$$p(\mathbf{x}) = \sum_{i=1}^{n_{classes}} Pr(i)p(i|\mathbf{x})$$

and is returned in Density. Here, $Pr(i)$ are the prior classes probabilities as computed by train_class_gmm. Density can be used for novelty detection, i.e., to reject feature vectors that do not belong to any of the trained classes. However, since Density depends on the scaling of the feature vectors and since Density is a probability density, and consequently does not need to lie between 0 and 1, the novelty detection can typically be performed more easily with KSigmaProb (see below).

A *k-sigma error ellipsoid* is defined as a locus of points for which

$$(\mathbf{x} - \mu)^T C^{-1} (\mathbf{x} - \mu) = k^2$$

In the one dimensional case this is the interval $[\mu - k\sigma, \mu + k\sigma]$. For any 1D Gaussian distribution, it is true that approximately 68% of the occurrences of the random variable are within this range for $k = 1$, approximately 95% for $k = 2$, approximately 99% for $k = 3$, etc. This probability is called k-sigma probability and is denoted by $P[k]$. $P[k]$ can be computed numerically for univariate as well as for multivariate Gaussian distributions, where it should be noted that for the same values of k, $P^{(N)}[k] > P^{(N+1)}[k]$ (here N and (N+1) denote dimensions). For Gaussian mixture models the k-sigma probability is computed as:

$$P_{GMM}[\mathbf{x}] = \sum_{j=1}^{n_{comp}} P(j) P_j[k_j]$$

where

$$k_j^2 = (\mathbf{x} - \mu_j)^T C_j^{-1} (\mathbf{x} - \mu_j)$$

. $P_{GMM}[k]$ are weighted with the class priors and then normalized. The maximum value of all classes is returned in KSigmaProb, such that

$$\text{KSigmaProb} = \frac{1}{\Pr_{max}} \max\left(Pr(i) P_{GMM}[\mathbf{x}]\right)$$

KSigmaProb can be used for novelty detection, as it indicates how well a feature vector fits into the distribution of the class it is assigned to. Typically, feature vectors having values below 0.0001 should be rejected. Note that the rejection threshold defined by the parameter RejectionThreshold in classify_image_class_gmm refers to the KSigmaProb values.

Before calling evaluate_class_gmm, the GMM must be trained with train_class_gmm.

The position of the maximum value of ClassProb is usually interpreted as the class of the feature vector and the corresponding value as the probability of the class. In this case, classify_class_gmm should be used instead of evaluate_class_gmm, because classify_class_gmm directly returns the class and corresponding probability.

Parameters

- ▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
  GMM handle.
- ▷ **Features** (input_control) ..... real-array ⇝ *real*
  Feature vector.
- ▷ **ClassProb** (output_control) ..... real-array ⇝ *real*
  A-posteriori probability of the classes.
- ▷ **Density** (output_control) ..... real ⇝ *real*
  Probability density of the feature vector.

▷ **KSigmaProb** (output_control) . . . . . real ⇝ *real*
Normalized k-sigma-probability for the feature vector.

Result

If the parameters are valid, the operator `evaluate_class_gmm` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_class_train_data_gmm (: : GMMHandle : ClassTrainDataHandle)

Get the training data of a Gaussian Mixture Model (GMM).

`get_class_train_data_gmm` gets the training data of a Gaussian Mixture Model (GMM) and returns it in `ClassTrainDataHandle`.

Parameters

▷ **GMMHandle** (input_control) . . . . . class_gmm ⇝ *handle*
Handle of a GMM that contains training data.

▷ **ClassTrainDataHandle** (output_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data of the classifier.

Result

If the parameters are valid, the operator `get_class_train_data_gmm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

get_params_class_gmm (: : GMMHandle : NumDim, NumClasses, MinCenters, MaxCenters, CovarType)

Return the parameters of a Gaussian Mixture Model.

get_params_class_gmm returns the parameters of a Gaussian Mixture Model (GMM) that were specified when the GMM was created with create_class_gmm. This is particularly useful if the GMM was read with read_class_gmm. The output of get_params_class_gmm can, for example, be used to check whether the feature vectors and/or the target data to be used have appropriate dimensions to be used with GMM. For a description of the parameters, see create_class_gmm.

Parameters

- ▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
  GMM handle.
- ▷ **NumDim** (output_control) ..... integer ⇝ *integer*
  Number of dimensions of the feature space.
- ▷ **NumClasses** (output_control) ..... integer ⇝ *integer*
  Number of classes of the GMM.
- ▷ **MinCenters** (output_control) ..... integer-array ⇝ *integer*
  Minimum number of centers per GMM class.
- ▷ **MaxCenters** (output_control) ..... integer-array ⇝ *integer*
  Maximum number of centers per GMM class.
- ▷ **CovarType** (output_control) ..... string ⇝ *string*
  Type of the covariance matrices.

Result

If the parameters are valid, the operator get_params_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_prep_info_class_gmm (: : GMMHandle, Preprocessing : InformationCont, CumInformationCont)

Compute the information content of the preprocessed feature vectors of a GMM.

get_prep_info_class_gmm computes the information content of the training vectors that have been transformed with the preprocessing given by Preprocessing. Preprocessing can be set to *'principal_components'* or *'canonical_variates'*. The preprocessing methods are described with create_class_mlp. The information content is derived from the variations of the transformed components of the feature vector, i.e., it

is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (NumComponents for *'principal_components'* and *'canonical_variates'*, see create_class_gmm), and is returned in InformationCont as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the n-th component of CumInformationCont, i.e., CumInformationCont contains the sums of the first n elements of InformationCont. To use get_prep_info_class_gmm, a sufficient number of samples must be added to the GMM given by GMMHandle by using add_sample_class_gmm or read_samples_class_gmm.

InformationCont and CumInformationCont can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent x% (e.g., 90%) of the data. This can be decided easily from the first value of CumInformationCont that lies above x%. The number thus obtained can be used as the value for NumComponents in a new call to create_class_gmm. The call to get_prep_info_class_gmm already requires the creation of a GMM, and hence the setting of NumComponents in create_class_gmm to an initial value. However, if get_prep_info_class_gmm is called, it is typically not known how many components are relevant, and hence how to set NumComponents in this call. Therefore, the following two-step approach should typically be used to select NumComponents: In a first step, a GMM with the maximum number for NumComponents is created (NumComponents for *'principal_components'* and *'canonical_variates'*). Then, the training samples are added to the GMM and are saved in a file using write_samples_class_gmm. Subsequently, get_prep_info_class_gmm is used to determine the information content of the components, and with this NumComponents. After this, a new GMM with the desired number of components is created, and the training samples are read with read_samples_class_gmm. Finally, the GMM is trained with train_class_gmm.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **Preprocessing** (input_control) ..... string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'principal_components'
List of values: Preprocessing ∈ {'principal_components', 'canonical_variates'}

▷ **InformationCont** (output_control) ..... real-array ⇝ *real*
Relative information content of the transformed feature vectors.

▷ **CumInformationCont** (output_control) ..... real-array ⇝ *real*
Cumulative information content of the transformed feature vectors.

Example

```
* Create the initial GMM
create_class_gmm (NumDim, NumClasses, NumCenters, 'full',\
                  'principal_components', NumComponents, 42, GMMHandle)
* Generate and add the training data
for J := 0 to NumData-1 by 1
    * Generate training features and classes
    * Data = [...]
    * ClassID = [...]
    add_sample_class_gmm (GMMHandle, Data, ClassID, Randomize)
endfor
write_samples_class_gmm (GMMHandle, 'samples.gtf')
* Compute the information content of the transformed features
get_prep_info_class_gmm (GMMHandle, 'principal_components',\
                         InformationCont, CumInformationCont)
* Determine Comp by inspecting InformationCont and CumInformationCont
* NumComponents = [...]
* Create the actual GMM
create_class_gmm (NumDim, NumClasses, NumCenters, 'full',\
                  'principal_components', NumComponents, 42, GMMHandle)
* Train the GMM
read_samples_class_gmm (GMMHandle, 'samples.gtf')
```

```
train_class_gmm (GMMHandle, 200, 0.0001, 0.0001, Regularize, Centers, Iter)
write_class_gmm (GMMHandle, 'classifier.gmm')
```

Result

If the parameters are valid, the operator `get_prep_info_class_gmm` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

`get_prep_info_class_gmm` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`add_sample_class_gmm`, `read_samples_class_gmm`

Possible Successors

`clear_class_gmm`, `create_class_gmm`

Module

Foundation

get_sample_class_gmm (: : GMMHandle, NumSample : Features, ClassID)

Return a training sample from the training data of a Gaussian Mixture Models (GMM).

`get_sample_class_gmm` reads out a training sample from the Gaussian Mixture Model (GMM) given by `GMMHandle` that was stored with `add_sample_class_gmm` or `add_samples_image_class_gmm`. The index of the sample is specified with `NumSample`. The index is counted from 0, i.e., `NumSample` must be a number between 0 and `NumSamples` − 1, where `NumSamples` can be determined with `get_sample_num_class_gmm`. The training sample is returned in `Features` and `ClassID`. `Features` is a feature vector of length `NumDim`, while `ClassID` is its class (see `add_sample_class_gmm` and `create_class_gmm`).

`get_sample_class_gmm` can, for example, be used to reclassify the training data with `classify_class_gmm` in order to determine which training samples, if any, are classified incorrectly.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **NumSample** (input_control) ..... integer ⇝ *integer*
Index of the stored training sample.

▷ **Features** (output_control) ..... real-array ⇝ *real*
Feature vector of the training sample.

▷ **ClassID** (output_control) ..... number ⇝ *integer*
Class of the training sample.

Example

```
create_class_gmm (2, 2, [1,10], 'spherical', 'none', 2, 42, GMMHandle)
read_samples_class_gmm (GMMHandle, 'samples.gsf')
train_class_gmm (GMMHandle, 100, 1e-4, 'training', 1e-4, Centers, Iter)
```

```
* Reclassify the training samples
get_sample_num_class_gmm (GMMHandle, NumSamples)
for I := 0 to NumSamples-1 by 1
  get_sample_class_gmm (GMMHandle, I, Features, Class)
  classify_class_gmm (GMMHandle, Features, 2, ClassID, ClassProb,\
                      Density, KSigmaProb)
  if (not (Class == ClassProb[0]))
    * classified incorrectly
  endif
endfor
```

Result

If the parameters are valid, the operator `get_sample_class_gmm` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`create_class_gmm`

Module

Foundation

`get_sample_num_class_gmm` (: : GMMHandle : NumSamples)

Return the number of training samples stored in the training data of a Gaussian Mixture Model (GMM).

`get_sample_num_class_gmm` returns in `NumSamples` the number of training samples that are stored in the Gaussian Mixture Model (GMM) given by `GMMHandle`. `get_sample_num_class_gmm` should be called before the individual training samples are read out with `get_sample_class_gmm`, e.g., for the purpose of reclassifying the training data (see `get_sample_class_gmm`).

Parameters

▷ **`GMMHandle`** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **`NumSamples`** (output_control) ..... integer ⇝ *integer*
Number of stored training samples.

Result

If the parameters are valid, the operator `get_sample_num_class_gmm` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_class_gmm

Module

Foundation

read_class_gmm (: : FileName : GMMHandle)

Read a Gaussian Mixture Model from a file.

read_class_gmm reads a Gaussian Mixture Model (GMM) that has been stored with write_class_gmm. Since the training of an GMM can consume a relatively long time, the GMM is typically trained in an offline process and written to a file with write_class_gmm. In the online process the GMM is read with read_class_gmm and subsequently used for evaluation with evaluate_class_gmm or for classification with classify_class_gmm. The default HALCON file extension for the GMM classifier is 'ggc'.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
File extension: .ggc

▷ **GMMHandle** (output_control) . . . . . class_gmm ⇝ *handle*
GMM handle.

Result

If the parameters are valid, the operator read_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

create_class_gmm, write_class_gmm

Module

Foundation

read_samples_class_gmm (: : GMMHandle, FileName :)

Read the training data of a Gaussian Mixture Model from a file.

read_samples_class_gmm reads training samples from the file given by FileName and adds them to the training samples that have already been stored in the Gaussian Mixture Model (GMM) given by GMMHandle. The GMM must be created with create_class_gmm before calling read_samples_class_gmm. As described with train_class_gmm and write_samples_class_gmm, read_samples_class_gmm, add_sample_class_gmm, and write_samples_class_gmm can be used to build up a database of training samples, and hence to improve the performance of the GMM by retraining the GMM with extended data sets.

It should be noted that the training samples must have the correct dimensionality. The feature vectors stored in FileName must have the lengths NumDim that was specified with create_class_gmm, and enough classes must have been created in create_class_gmm. If this is not the case, an error message is returned.

It is possible to read files of samples that were written with write_samples_class_svm or write_samples_class_mlp.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
File name.

Result

If the parameters are valid, the operator read_samples_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- GMMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

select_feature_set_gmm (: : ClassTrainDataHandle, SelectionMethod, GenParamName, GenParamValue : GMMHandle, SelectedFeatureIndices, Score)

Selects an optimal combination from a set of features to classify the provided data.

select_feature_set_gmm selects an optimal subset from a set of features to solve a given classification problem. The classification problem has to be specified with annotated training data in ClassTrainDataHandle and will be classified by a Gaussian Mixture Model. Details of the properties of this classifier can be found in create_class_gmm.

The result of the operator is a trained classifier that is returned in GMMHandle. Additionally, the list of indices or names of the selected features is returned in SelectedFeatureIndices. To use this classifier, calculate for new input data all features mentioned in SelectedFeatureIndices and pass them to the classifier.

A possible application of this operator can be a comparison of different parameter sets for certain feature extraction techniques. Another application is to search for a feature that is discriminating between different classes.

To define the features that should be selected from ClassTrainDataHandle, the dimensions of the feature vectors in ClassTrainDataHandle can be grouped into subfeatures by calling

set_feature_lengths_class_train_data. A subfeature can contain several subsequent elements of a feature vector. select_feature_set_gmm decides for each of these subfeatures, if it is better to use it for the classification or leave it out.

The indices of the selected subfeatures are returned in SelectedFeatureIndices. If names were set in set_feature_lengths_class_train_data, these names are returned instead of the indices. If set_feature_lengths_class_train_data was not called for ClassTrainDataHandle before, each element of the feature vector is considered as a subfeature.

The selection method SelectionMethod is either a greedy search *'greedy'* (iteratively add the feature with highest gain) or the dynamically oscillating search *'greedy_oscillating'* (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method *'greedy'* is generally preferable, since it is faster. Only in cases when the subfeatures are low-dimensional or redundant, the method *'greedy_oscillating'* should be chosen.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in Score.

The following generic parameters can be set in GenParamName and GenParamValue:

'min_centers': Minimal number of clusters to represent a class in the training data.
Suggested values: *'1'*, *'2'*
Default: *'1'*

'max_center': Maximal number of clusters to represent a class in the training data.
Suggested values: *'1'*, *'5'*, *'10'*
Default: *'1'*

'covar_type': Type of the covariance to represent the size of a cluster.
List of values: *'spherical'*, *'diag'*, *'full'*
Default: *'spherical'*

'random_seed': Random seed.
Default: *'42'*

'threshold': Training threshold.
Default: *'0.001'*

'regularize': Regularization value.
Default: *'0.0001'*

'randomize': Randomize the input vector.
Default: *'0'*

'class_priors': Mode to determine the a-priori probabilities of the classes.
List of values: *'training'*, *'uniform'*
Default: *'training'*

A more exact description of those parameters can be found in create_class_gmm and train_class_gmm.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_gmm may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

▷ **SelectionMethod** (input_control) . . . . . string ⇝ *string*
Method to perform the selection.
Default: 'greedy'
List of values: SelectionMethod ∈ {'greedy', 'greedy_oscillating'}

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Names of generic parameters to configure the classifier.
Default: []
List of values: GenParamName ∈ {'min_centers', 'max_center', 'covar_type', 'random_seed', 'threshold', 'regularize', 'randomize', 'class_priors'}

▷ **GenParamValue** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Values of generic parameters to configure the classifier.
Default: []
Suggested values: GenParamValue ∈ {1, 2, 3, 'spherical', 'diag', 'full', 42, 0.001, 0.0001, 0}

▷ **GMMHandle** (output_control) . . . . . class_gmm ⇝ *handle*
A trained GMM classifier using only the selected features.

▷ **SelectedFeatureIndices** (output_control) . . . . . string-array ⇝ *string*
The selected feature set, contains indices or names.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
The achieved score using two-fold cross-validation.

Example

```
* Find out which of the two features distinguishes two Classes
NameFeature1 := 'Good Feature'
NameFeature2 := 'Bad Feature'
LengthFeature1 := 3
LengthFeature2 := 2
* Create training data
create_class_train_data (LengthFeature1+LengthFeature2,\
  ClassTrainDataHandle)
* Define the features which are in the training data
set_feature_lengths_class_train_data (ClassTrainDataHandle, [LengthFeature1,\
  LengthFeature2], [NameFeature1, NameFeature2])
* Add training data
*                                                          |Feat1|  |Feat2|
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  2,1  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  2,1  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  3,4  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  3,4  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [0,0,1,  5,6  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,3,2,  5,6  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [0,0,1,  5,6  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,3,2,  5,6  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [0,0,1,  5,6  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,3,2,  5,6  ], 1)
* Add more data
* ...
* Select the better feature with a GMM
select_feature_set_gmm (ClassTrainDataHandle, 'greedy', [], [], GMMHandle,\
  SelectedFeatureGMM, Score)
* Use the classifier
* ...
```

Result

If the parameters are valid, the operator select_feature_set_gmm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

`serialize_class_gmm` (: : GMMHandle : SerializedItemHandle)

Serialize a Gaussian Mixture Model (GMM).

`serialize_class_gmm` serializes a Gaussian Mixture Model (GMM) and its stored training samples (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_class_gmm` and `write_samples_class_gmm` is converted to a serialized item. The Gaussian Mixture Model is defined by the handle `GMMHandle`. The serialized Gaussian Mixture Model is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_class_gmm`.

Parameters

▷ **`GMMHandle`** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **`SerializedItemHandle`** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_class_gmm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`train_class_gmm` (: : GMMHandle, MaxIter, Threshold, ClassPriors, Regularize : Centers, Iter)

Train a Gaussian Mixture Model.

train_class_gmm trains the Gaussian Mixture Model (GMM) referenced by GMMHandle. Before the GMM can be trained, all training samples to be used for the training must be stored in the GMM using add_sample_class_gmm, add_samples_image_class_gmm, or read_samples_class_gmm. After the training, new training samples can be added to the GMM and the GMM can be trained again.

During the training, the error that results from the GMM applied to the training vectors will be minimized with the expectation maximization (EM) algorithm.

MaxIter specifies the maximum number of iterations per class for the EM algorithm. In practice, values between *20* and *200* should be sufficient for most problems. Threshold specifies a threshold for the relative changes of the error. If the relative change in error exceeds the threshold after MaxIter iterations, the algorithm will be canceled for this class. Because the algorithm starts with the maximum specified number of centers (parameter NumCenters in create_class_gmm), in case of a premature termination the number of centers and the error for this class will not be optimal. In this case, a new training with different parameters (e.g., another value for RandSeed in create_class_gmm) can be tried.

ClassPriors specifies the method of calculation of the class priors in GMM. If *'training'* is specified, the priors of the classes are taken from the proportion of the corresponding sample data during training. If *'uniform'* is specified, the priors are set equal to 1/NumClasses for all classes.

Regularize is used to regularize (nearly) *singular* covariance matrices during the training. A covariance matrix might *collapse* to singularity if it is trained with linearly dependent data. To avoid this, a small value specified by Regularize is added to each main diagonal element of the covariance matrix, which prevents this element from becoming smaller than Regularize. A recommended value for Regularize is *0.0001*. If Regularize is set to *0.0*, no regularization is performed.

The centers are initially randomly distributed. In individual cases, relatively high errors will result from the algorithm because the initial random values determined by RandSeed in create_class_gmm lead to local minima. In this case, a new GMM with a different value for RandSeed should be generated to test whether a significantly smaller error can be obtained.

It should be noted that, depending on the number of centers, the type of covariance matrix, and the number of training samples, the training can take from a few seconds to several hours.

On output, train_class_gmm returns in Centers the number of centers per class that have been found to be optimal by the EM algorithm. These values can be used as a reference in NumCenters (in create_class_gmm) for future GMMs. If the number of centers found by training a new GMM on integer training data is unexpectedly high, this might be corrected by adding a Randomize noise to the training data in add_sample_class_gmm. Iter contains the number of performed iterations per class. If a value in Iter equals MaxIter, the training algorithm has been terminated prematurely (see above).

Parameters

▷ **GMMHandle** (input_control) . . . . . class_gmm ⇝ *handle*
GMM handle.

▷ **MaxIter** (input_control) . . . . . integer ⇝ *integer*
Maximum number of iterations of the expectation maximization algorithm
Default: 100
Suggested values: MaxIter ∈ {10, 20, 30, 50, 100, 200}

▷ **Threshold** (input_control) . . . . . real ⇝ *real*
Threshold for relative change of the error for the expectation maximization algorithm to terminate.
Default: 0.001
Suggested values: Threshold ∈ {0.001, 0.0001}
Restriction: Threshold >= 0.0 && Threshold <= 1.0

▷ **ClassPriors** (input_control) . . . . . string ⇝ *string*
Mode to determine the a-priori probabilities of the classes
Default: 'training'
List of values: ClassPriors ∈ {'training', 'uniform'}

▷ **Regularize** (input_control) . . . . . real ⇝ *real*
Regularization value for preventing covariance matrix singularity.
Default: 0.0001
Restriction: Regularize >= 0.0 && Regularize < 1.0

▷ **Centers** (output_control) . . . . . integer-array ⇝ *integer*
Number of found centers per class

▷ **Iter** (output_control) . . . . . integer-array ⇝ *integer*
Number of executed iterations per class

Example

```
create_class_gmm (NumDim, NumClasses, [1,5], 'full', 'none', 0, 42,\
                  GMMHandle)
* Add the training data
read_samples_class_gmm (GMMHandle, 'samples.gsf')
* Train the GMM
train_class_gmm (GMMHandle, 100, 1e-4, 'training', 1e-4, Centers, Iter)
* Write the Gaussian Mixture Model to file
write_class_gmm (GMMHandle, 'gmmclassifier.gmm')
```

Result

If the parameters are valid, the operator `train_class_gmm` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- GMMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

write_class_gmm (: : GMMHandle, FileName :)

Write a Gaussian Mixture Model to a file.

`write_class_gmm` writes the Gaussian Mixture Model (GMM) `GMMHandle` to the file given by `FileName`. The default HALCON file extension for the GMM classifier is ’ggc’. `write_class_gmm` is typically called after the GMM has been trained with `train_class_gmm`. The GMM can be read with `read_class_gmm`. `write_class_gmm` does *not* write any training samples that possibly have been stored in the GMM. For this purpose, `write_samples_class_gmm` should be used.

Parameters

▷ **GMMHandle** (input_control) . . . . . class_gmm ⇝ *handle*
GMM handle.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name.
File extension: .ggc

Result

If the parameters are valid, the operator write_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_samples_class_gmm (: : GMMHandle, FileName :)

Write the training data of a Gaussian Mixture Model to a file.

write_samples_class_gmm writes the training samples stored in the Gaussian Mixture Model (GMM) GMMHandle to the file given by FileName. write_samples_class_gmm can be used to build up a database of training samples, and hence to improve the performance of the GMM by training it with an extended data set (see train_class_gmm).

The file FileName is overwritten by write_samples_class_gmm. Nevertheless, extending the database of training samples is easy because read_samples_class_gmm and add_sample_class_gmm add the training samples to the training samples that are already stored in memory with the GMM.

The created file can be read with read_samples_class_mlp if the classifier of a multilayer perceptron (MLP) should be used. The class of a training sample in the GMM corresponds to a component of the target vector in the MLP being 1.0.

Parameters

▷ **GMMHandle** (input_control) . . . . . class_gmm ⇝ *handle*
GMM handle.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name.

Result

If the parameters are valid, the operator write_samples_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

7.2 K-Nearest Neighbors

add_class_train_data_knn (: : KNNHandle, ClassTrainDataHandle :)

Add training data to a k-nearest neighbors (k-NN) classifier.

add_class_train_data_knn adds the training data specified by ClassTrainDataHandle to a k-nearest neighbors (k-NN) classifier specified by KNNHandle.

Parameters

- ▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
  Handle of a k-NN which receives the training data.
- ▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
  Training data for a classifier.

Result

If the parameters are valid, the operator add_class_train_data_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- KNNHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

create_class_knn

Module

Foundation

add_sample_class_knn (: : KNNHandle, Features, ClassID :)

Add a sample to a k-nearest neighbors (k-NN) classifier.

add_sample_class_knn adds a feature vector to a k-nearest neighbors (k-NN) data structure. The length of a feature vector was specified in create_class_knn by NumDim. A handle to a k-NN data structure has to be specified in KNNHandle.

The feature vectors are collected in Features. The length of the input vector must be a multiple of NumDim. Each feature vector needs a class which can be given by ClassID, if only one was specified, the class is used for all vectors. The class is a natural number greater or equal to 0. If only one class is used, the class has to be 0. In case the operator classify_image_class_knn will be used, all numbers starting from 0 to the number of classes-1 should be used, since otherwise an empty region will be generated for each unused number.

It is allowed to add samples to an already trained k-NN classificator. The new data is only integrated after another call to train_class_knn.

If the k-NN classifier has been trained with automatic feature normalization enabled, the supplied features Features are interpreted as unnormalized and are normalized as it was defined by the last call to train_class_knn. Please see train_class_knn for more information on normalization.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **Features** (input_control) . . . . . number(-array) ⇝ *real*
List of features to add.

▷ **ClassID** (input_control) . . . . . integer(-array) ⇝ *integer*
Class IDs of the features.

Result

If the parameters are valid, the operator add_sample_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- KNNHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

classify_class_knn (: : KNNHandle, Features : Result, Rating)

Search for the next neighbors for a given feature vector.

classify_class_knn searches for the next *'k'* neighbors of the feature vector given in Features. The distance which is used to determine the next neighbor is the L2-norm of the given vector and the training samples.

The value of *'k'* can be set via set_params_class_knn. The results can either be the determined class of the feature vector or the indices of the nearest neighbors. The selection of the result behavior can be made by set_params_class_knn via the generic parameters *'method'* and *'max_num_classes'*:

'classes_distance': returns the nearest samples for each of maximally *'max_num_classes'* different classes, if they have a representative in the nearest *'k'* neighbors. The results in `Result` are classes sorted by their minimal distance in `Rating`. There is no efficient way to determine in a k-NN-tree the nearest neighbor for exactly *'max_num_classes'* classes.

'classes_frequency': counts the occurrences of certain classes among the nearest *'k'* neighbors and returns the occurring classes in `Result` sorted by their relative frequency that is returned in `Rating`. Again, maximally *'max_num_classes'* values are returned.

'classes_weighted_frequencies': counts the occurrences of certain classes among the nearest *'k'* neighbors and returns the occurring classes in `Result` sorted by their relative frequency weighted with the average distance that is returned in `Rating`. Again, maximally *'max_num_classes'* values are returned.

'neighbors_distance': returns the indices of the nearest *'k'* neighbors in `Result` and the distances in `Rating`.

The default behavior is *'classes_distance'* and returns the classes and distances.

Parameters

▷ **`KNNHandle`** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **`Features`** (input_control) . . . . . number-array ⇝ *real*
Features that should be classified.

▷ **`Result`** (output_control) . . . . . number-array ⇝ *integer*
The classification result, either class IDs or sample indices.

▷ **`Rating`** (output_control) . . . . . number-array ⇝ *real*
A rating for the results. This value contains either a distance, a frequency or a weighted frequency.

Result

If the parameters are valid, the operator `classify_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

`clear_class_knn` (: : KNNHandle :)

Clear a k-NN classifier.

`clear_class_knn` clears the k-NN classifiers given in `KNNHandle`. After calling `clear_class_knn`, `KNNHandle` becomes invalid.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

Result

If the parameters are valid, the operator `clear_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

Module

Foundation

create_class_knn (: : NumDim : KNNHandle)

Create a k-nearest neighbors (k-NN) classifier.

`create_class_knn` creates a k-nearest neighbors (k-NN) data structure. This can be either used to classify data or to approximately locate nearest neighbors in a `NumDim`-dimensional space.

Most of the operators described in Classification/K-Nearest-Neighbor use the resulting handle `KNNHandle`.

The k-NN classifies by searching approximately the nearest neighbors and returning their classes as result. With the used approximation, the search time is logarithmically to the number of samples and dimensions.

The dimension of the feature vectors is the only parameter that necessarily has to be set in `NumDim`.

Parameters

▷ **NumDim** (input_control) . . . . . number-array ⇝ *integer*
Number of dimensions of the feature.
Default: 10

▷ **KNNHandle** (output_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

Result

If the parameters are valid, the operator `create_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

deserialize_class_knn (: : SerializedItemHandle : KNNHandle)

Deserialize a serialized k-NN classifier.

deserialize_class_knn deserializes a k-NN classifier (k-NN) (including its training samples), that was serialized by serialize_class_knn (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized k-NN classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created k-NN classifier with the handle KNNHandle.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **KNNHandle** (output_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

Result

If the parameters are valid, the operator deserialize_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_class_train_data_knn (: : KNNHandle : ClassTrainDataHandle)

Get the training data of a k-nearest neighbors (k-NN) classifier.

get_class_train_data_knn gets the training data of a k-nearest neighbors (k-NN) classifier and returns it in ClassTrainDataHandle.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier that contains training data.

▷ **ClassTrainDataHandle** (output_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data of the classifier.

Result

If the parameters are valid, the operator get_class_train_data_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

get_params_class_knn (: : KNNHandle,
GenParamName : GenParamValue)

Get parameters of a k-NN classification.

get_params_class_knn gets parameters of the k-NN referred by KNNHandle. The possible entries in GenParamName are:

'method': Retrieve the currently selected method for determining the result of classify_class_knn. The result can be *'classes_distance'*, *'classes_frequency'*, *'classes_weighted_frequencies'* or *'neighbors_distance'*.

'k': The number of nearest neighbors that is considered to determine the results.

'max_num_classes': The maximum number of classes that are returned. This parameter is ignored in case the method *'neighbors_distance'* is selected.

'num_checks': Defines the maximum number of runs through the trees.

'epsilon': A parameter to lower the accuracy in the tree to gain speed.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of the parameters that can be read from the k-NN classifier.
Default: ['method','k']
List of values: GenParamName ∈ {'method', 'num_checks', 'epsilon', 'k'}

▷ **GenParamValue** (output_control) . . . . . number-array ⇝ *integer / real / string*
Values of the selected parameters.

Result

If the parameters are valid, the operator `get_params_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_sample_class_knn (: : KNNHandle, IndexSample : Features, ClassID)

Return a training sample from the training data of a k-nearest neighbors (k-NN) classifier.

`get_sample_class_knn` reads a training sample from the k-nearest neighbors (k-NN) classifier given by `KNNHandle` that was added with `add_sample_class_knn` or `read_class_knn`. The index of the sample is specified with `IndexSample`. The index is counted from 0, i.e., `IndexSample` must be a number between 0 and `NumSamples` −1, where `NumSamples` can be determined with `get_sample_num_class_knn`. The training sample is returned in `Features` and `ClassID`. `Features` is a feature vector of length `NumDim` (see `create_class_knn`), while `ClassID` is the class label, which is a number between 0 and the number of classes.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **IndexSample** (input_control) . . . . . integer ⇝ *integer*
Index of the training sample.

▷ **Features** (output_control) . . . . . real-array ⇝ *real*
Feature vector of the training sample.

▷ **ClassID** (output_control) . . . . . integer-array ⇝ *integer*
Class of the training sample.

Result

If the parameters are valid the operator `get_sample_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_sample_num_class_knn (: : KNNHandle : NumSamples)

Return the number of training samples stored in the training data of a k-nearest neighbors (k-NN) classifier.

get_sample_num_class_knn returns in NumSamples the number of training samples that are stored in the k-nearest neighbors (k-NN) classifier given by KNNHandle. get_sample_num_class_knn should be called before the individual training samples are accessed with get_sample_class_knn.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **NumSamples** (output_control) . . . . . integer ⇝ *integer*
Number of stored training samples.

Result

If KNNHandle is valid, the operator get_sample_num_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_class_knn (: : FileName : KNNHandle)

Read the k-NN classifier from a file.

read_class_knn reads the saved classifier from the file FileName (see write_class_knn). The values of the current classifier are overwritten. The default HALCON file extension for the k-NN classifier is 'gnc'.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name of the classifier.
File extension: .gnc

▷ **KNNHandle** (output_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

Result

read_class_knn returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open the file FileName or the file has the wrong format.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

select_feature_set_knn (: : ClassTrainDataHandle, SelectionMethod, GenParamName, GenParamValue : KNNHandle, SelectedFeatureIndices, Score)

Selects an optimal subset from a set of features to solve a certain classification problem.

select_feature_set_knn selects an optimal subset from a set of features to solve a certain classification problem. The classification problem has to be specified with annotated training data in ClassTrainDataHandle and will be classified by a a k-nearest neighbors classifier. Details of the properties of this classifier can be found in create_class_knn.

The result of the operator is a trained classifier that is returned in KNNHandle. Additionally, the list of indices or names of the selected features is returned in SelectedFeatureIndices. To use this classifier, calculate for new input data all features mentioned in SelectedFeatureIndices and pass them to the classifier.

A possible application of this operator can be a comparison of different parameter sets for certain feature extraction techniques. Another application is to search for a property that is discriminating between different classes of parts or classes of errors.

To define the features that should be selected from ClassTrainDataHandle, the dimensions of the feature vectors in ClassTrainDataHandle can be grouped into subfeatures by calling set_feature_lengths_class_train_data. A subfeature can contain several subsequent elements of a feature vector. The operator decides for each of these subfeatures, if it is better to use it for the classification or leave it out.

The indices of the selected subfeatures are returned in SelectedFeatureIndices. If names were set in set_feature_lengths_class_train_data, these names are returned instead of the indices. If set_feature_lengths_class_train_data was not called for ClassTrainDataHandle before, each element of the feature vector is considered as a subfeature.

The selection method SelectionMethod is either a greedy search *'greedy'* (iteratively add the feature with highest gain) or the dynamically oscillating search *'greedy_oscillating'* (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method *'greedy'* is generally preferable, since it is faster. Only in cases when the subfeatures are low-dimensional or redundant, the method *'greedy_oscillating'* should be chosen.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in Score.

The k-NN classifier can be parameterized using the following values in GenParamName and GenParamValue:

'num_neighbors': The number of minimally evaluated nodes, increase this value for high dimensional data.
Suggested values: *'1'*, *'2'*, *'5'*, *'10'*
Default: *'1'*

'num_trees': Number of search trees in the k-NN classifier
Suggested values: *'1'*, *'4'*, *'10'*
Default: *'4'*

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator `select_feature_set_knn` may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

- ▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
  Handle of the training data.
- ▷ **SelectionMethod** (input_control) . . . . . string ⇝ *string*
  Method to perform the selection.
  Default: 'greedy'
  List of values: `SelectionMethod` ∈ {'greedy', 'greedy_oscillating'}
- ▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
  Names of generic parameters to configure the selection process and the classifier.
  Default: []
  List of values: `GenParamName` ∈ {'num_neighbors', 'num_trees'}
- ▷ **GenParamValue** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
  Values of generic parameters to configure the selection process and the classifier.
  Default: []
  Suggested values: `GenParamValue` ∈ {1, 2, 3}
- ▷ **KNNHandle** (output_control) . . . . . class_knn ⇝ *handle*
  A trained k-NN classifier using only the selected features.
- ▷ **SelectedFeatureIndices** (output_control) . . . . . string-array ⇝ *string*
  The selected feature set, contains indices or names.
- ▷ **Score** (output_control) . . . . . real-array ⇝ *real*
  The achieved score using two-fold cross-validation.

Example

```
* Find out which of the two features distinguishes two Classes
NameFeature1 := 'Good Feature'
NameFeature2 := 'Bad Feature'
LengthFeature1 := 3
LengthFeature2 := 2
* Create training data
create_class_train_data (LengthFeature1+LengthFeature2,\
  ClassTrainDataHandle)
* Define the features which are in the training data
set_feature_lengths_class_train_data (ClassTrainDataHandle, [LengthFeature1,\
  LengthFeature2], [NameFeature1, NameFeature2])
* Add training data
*                                                        |Feat1| |Feat2|
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  2,1  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  2,1  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  3,4  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  3,4  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [0,0,1,  5,6  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,3,2,  5,6  ], 1)
* Add more data
```

```
* ...
* Select the better feature with the k-NN classifier
select_feature_set_knn (ClassTrainDataHandle, 'greedy', [], [], KNNHandle,\
  SelectedFeatureKNN, Score)
* Use the classifier
* ...
```

Result

If the parameters are valid, the operator `select_feature_set_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

serialize_class_knn (: : KNNHandle : SerializedItemHandle)

Serialize a k-NN classifier.

`serialize_class_knn` serializes a k-NN classifier (k-NN) and its stored training samples (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_class_knn` is converted to a serialized item. The k-NN classifier is defined by the handle `KNNHandle`. The serialized k-NN classifier is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_class_knn`.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_params_class_knn (: : KNNHandle, GenParamName, GenParamValue :)

Set parameters for k-NN classification.

set_params_class_knn sets parameters for the classification of the k-nearest neighbors (k-NN) classifier KNNHandle. It controls the behavior of classify_class_knn.

The value of *'k'* can be set via GenParamName and GenParamValue. Increasing *'k'* also increases the accuracy of the resulting neighbors and increases the run time.

The results can either be the determined class of the feature vector or the indices of the nearest neighbors. The result behavior can be selected with set_params_class_knn via the generic parameters *'method'* and *'max_num_classes'*:

'classes_distance': returns the nearest samples for each of maximally *'max_num_classes'* different classes, if they have a representative in the nearest *'k'* neighbors. The results are classes sorted by their minimal distance. There is no efficient way to determine in a k-NN-tree the nearest neighbor for exactly *'max_num_classes'* classes.

'classes_frequency': counts the occurrences of certain classes among the nearest *'k'* neighbors and returns the occurrent classes sorted by their relative frequency that is returned, too. Again, maximally *'max_num_classes'* values are returned.

'classes_weighted_frequencies': counts the occurrences of certain classes among the nearest *'k'* neighbors and returns the occurrent classes sorted by their relative frequency weighted with the average distance that is returned, too. Again, maximally *'max_num_classes'* values are returned.

'neighbors_distance': returns the indices of the nearest *'k'* neighbors and the distances.

The default behavior is *'classes_distance'*.

The option *'num_checks'* allows to set the number of maximal runs through the trees. The parameter has to be positive and the default value is *32*. The higher this value is, the more accurate the results will be. As a trade-off, the running time will also be higher. Setting this parameter to *0* triggers an exact search.

The option *'epsilon'* allows to set a stop criteria if the value is increased from the default value 0.0. The higher the value is set, the less accurate results of the estimated neighbors can be expected, while it might speed up the search.

Parameters

▷ **KNNHandle** (input_control) ..... class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **GenParamName** (input_control) ..... string-array ⇝ *string*
Names of the generic parameters that can be adjusted for the k-NN classifier.
Default: ['method','k','max_num_classes']
List of values: GenParamName ∈ {'method', 'num_checks', 'epsilon', 'k', 'max_num_classes'}

▷ **GenParamValue** (input_control) ..... number-array ⇝ *integer* / real / string
Values of the generic parameters that can be adjusted for the k-NN classifier.
Default: ['classes_distance',5,1]
Suggested values: GenParamValue ∈ {'classes_distance', 'classes_frequency', 'classes_weighted_frequencies', 'neighbors_distance', 32, 0.0, 0.02, 0, 1, 2, 3, 4, 5, 6}

Result

If the parameters are valid, the operator `set_params_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- KNNHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

train_class_knn (: : KNNHandle, GenParamName, GenParamValue :)

Creates the search trees for a k-NN classifier.

`train_class_knn` creates the search trees for a k-NN classifier.

It is possible to set the number of trees via the parameters `GenParamName` and `GenParamValue` by *'num_trees'*. The default value for the number of search trees is *4*. A higher number of trees improves the accuracy of the search, but increases the run time.

It is possible to add more samples after training using the operator `add_sample_class_knn`. The added data affects the classification only, if `train_class_knn` is called again.

Automatic feature normalization can be activated by setting *'normalization'* in `GenParamName` and *'true'* in `GenParamValue`. The feature vectors are normalized by normalizing each dimension separately. For each dimension, the mean and standard deviation is calculated over the training samples. Every feature vector is normalized by subtracting the mean and dividing by the standard deviation of the individual dimension. This results in a normalization, where each dimension has zero mean and unit variance. If the standard deviation happens to be zero, only the mean is subtracted. Please note however, that a feature dimension with no standard deviation does not change the classification result and should be removed. Automatic feature normalization will change the stored training data, but the original data can be restored at any time by calling `train_class_knn` with *'normalization'* set to *'false'*. If normalization is used, the operator `classify_class_knn` interprets the input data as unnormalized and performs normalization internally as it has been defined in the last call to `train_class_knn`.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of the generic parameters that can be adjusted for the k-NN classifier creation.
Default: []
List of values: `GenParamName` ∈ {'num_trees', 'normalization'}

▷ **GenParamValue** (input_control) . . . . . number-array ⇝ *integer / string / real*
Values of the generic parameters that can be adjusted for the k-NN classifier creation.
Default: []
Suggested values: GenParamValue ∈ {4, 'false', 'true'}

Result

If the parameters are valid, the operator train_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- KNNHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

write_class_knn (: : KNNHandle, FileName :)

Save the k-NN classifier in a file.

write_class_knn writes the k-NN classifier KNNHandle to the file given by FileName. The classifier can be read again with read_class_knn. Since the samples are an intrinsic component of a k-NN-classifier, the operator write_class_knn saves them within the class file. In contrast to other classifiers like SVM, there is no operator for saving the samples separately. The samples can be retrieved from a k-NN-classifier using get_sample_class_knn. The default HALCON file extension for the k-NN classifier is 'gnc'.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of the file in which the classifier will be written.
File extension: .gnc

Result

write_class_knn returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open file FileName.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

7.3 Look-Up Table

clear_class_lut (: : ClassLUTHandle :)

Clear a look-up table classifier.

clear_class_lut clears the look-up table (LUT) given by ClassLUTHandle and frees all memory required for the LUT. After calling clear_class_lut, the LUT classifier can no longer be used. The handle ClassLUTHandle becomes invalid.

Parameters

▷ **ClassLUTHandle** (input_control) ..... class_lut(-array) ⇝ *handle*
Handle of the LUT classifier.

Result

If ClassLUTHandle is valid, the operator clear_class_lut returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

classify_image_class_lut

create_class_lut_mlp, create_class_lut_svm, create_class_lut_gmm

Module

Foundation

create_class_lut_gmm (: : GMMHandle, GenParamName,
GenParamValue : ClassLUTHandle)

Create a look-up table using a gaussian mixture model to classify byte images.

create_class_lut_gmm generates a look-up table (LUT) ClassLUTHandle using the data of a trained gaussian mixture model (GMM) GMMHandle to classify multi-channel byte images. By using this GMM-based LUT classifier the operator classify_image_class_gmm of the subsequent classification can be replaced by the operator classify_image_class_lut. The classification gets a major speed-up, because the estimation of the class in every image point is no longer necessary since every possible response of the GMM is stored in the LUT. For the generation of the LUT, the parameters NumDim, Preprocessing, and NumComponents defined in the earlier called operator create_class_gmm are important. In NumDim, the number of image channels the images must have to be classified is defined. By using the Preprocessing (see create_class_gmm)

the number of image channels can be transformed to NumComponents. NumComponents defines the length of the feature vector, which the classifier classify_class_gmm handles internally. Because of performance and disk space, the LUT is restricted to be maximal *3*-dimensional. Since it replaces the operator classify_class_gmm, NumComponents $\leq$ *3* must hold. If there is no preprocessing that reduces the number of image channels (NumDim = NumComponents), all possible pixel values, which can occur in a byte image, are classified with classify_class_gmm. The returned classes are stored in the LUT. If there is a preprocessing that reduces the number of image channels (NumDim > NumComponents), the preprocessing parameters of the GMM are stored in a separate structure of the LUT. To create the LUT, all transformed pixel values are classified with classify_class_gmm. The returned classes are stored in the LUT. Because of the discretization of the LUT, the accuracy of the LUT classifier could become lower than the accuracy of classify_image_class_gmm. With *'bit_depth'* and *'class_selection'* the accuracy of the classification, the required storage, and the runtime needed to create the LUT can be controlled.

The following parameters of the GMM-based LUT classifier can be set with GenParamName and GenParamValue:

'bit_depth': Number of bits used from the pixels. It controls the storage requirement of the LUT classifier and is bounded by the bit depth of the image (*'bit_depth'* $\leq$ *8*). If the bit depth of the LUT is smaller (*'bit_depth'* $<$ *8*), the classes of multiple pixel combinations will be mapped to the same LUT entry, which can result in a lower accuracy for the classification. One of these clusters contains $2^{NumComponents \cdot (8-bit\_depth)}$ pixel combinations, where NumComponents denotes the dimension of the LUT, which is specified in create_class_gmm. For example, for *'bit_depth'* = *7*, NumComponents = *3*, the classes of 8 pixel combinations are mapped in the same LUT entry. The LUT requires at most $2^{NumComponents \cdot bit\_depth+2}$ bytes of storage. For example, for NumComponents = *3*, *'bit_depth'* = *8* and NumClasses $<$ *16* (specified in create_class_gmm), the LUT requires 8 MB of storage with internal storage optimization. If NumClasses = *1*, the LUT requires only 2 MB of storage by using the full bit depth of the LUT. The runtime for the classification in classify_image_class_lut becomes minimal if the LUT fits into the cache. **Suggested values:** *6*,*7*,*8*

Default: *8*

Restriction: *'bit_depth'* $\geq$ *1*, *'bit_depth'* $\leq$ *8*.

'class_selection': Method for the class selection for the LUT. Can be modified to control the accuracy and the runtime needed to create the LUT classifier. The value in *'class_selection'* is ignored if the bit depth of the LUT is maximal, thus *'bit_depth'* = *8* holds. If the bit depth of the LUT is smaller (*'bit_depth'* $<$ *8*), the classes of multiple pixel combinations will be mapped to the same LUT entry. One of these clusters contains $2^{NumComponents \cdot (8-bit\_depth)}$ pixel combinations, where NumComponents denotes the dimension of the LUT, which is specified in create_class_gmm. By choosing *'class_selection'* = *'best'*, the class that appears most often in the cluster is stored in the LUT. For *'class_selection'* = *'fast'*, only one pixel of the cluster, i.e., the pixel with the smallest value (component-wise), is classified. The returned class is stored in the LUT. In this case, the accuracy of the subsequent classification could become lower. On the other hand, the runtime needed to create the LUT can be reduced, which is proportional to the maximal needed storage of the LUT, which is defined with $2^{NumComponents \cdot bit\_depth+2}$.

List of values: *'fast'*, *'best'*

Default: *'fast'*

'rejection_threshold': Threshold for the rejection of uncertain classified points of the GMM. The parameter represents a threshold on the K-sigma probability measure returned by the classification (see classify_class_gmm and evaluate_class_gmm). All pixels having a probability below *'rejection_threshold'* are not assigned to any class.

Default: *0.0001*

Restriction: *'rejection_threshold'* $\geq$ *0*, *'rejection_threshold'* $\leq$ *1*.

Parameters

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **GenParamName** (input_control) ..... attribute.name-array ⇝ *string*
Names of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamName ∈ {'bit_depth', 'class_selection', 'rejection_threshold'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / integer / real
Values of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamValue ∈ {8, 7, 6, 'fast', 'best'}

▷ **ClassLUTHandle** (output_control) . . . . . class_lut ⇝ *handle*
Handle of the LUT classifier.

Result

If the parameters are valid, the operator create_class_lut_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

create_class_lut_knn (: : KNNHandle, GenParamName, GenParamValue : ClassLUTHandle)

Create a look-up table using a k-nearest neighbors classifier (k-NN) to classify byte images.

create_class_lut_knn generates a look-up table (LUT) ClassLUTHandle using the data of a trained k-nearest neighbors classifier (k-NN) KNNHandle to classify multi-channel byte images. By using this k-NN-based LUT classifier, the operator classify_image_class_knn of the subsequent classification can be replaced by the operator classify_image_class_lut. The classification is speed up considerably, because the estimation of the class in every image point is no longer necessary since every possible response of the k-NN is stored in the LUT. For the generation of the LUT, the parameter NumDim of called operator create_class_knn is important. The number of image channels the images must have to be classified is defined in NumDim.

To create the LUT, all pixel values are classified with classify_class_knn. The returned classes are stored in the LUT. Because of the discretization of the LUT, the accuracy of the LUT classifier could become lower than the accuracy of classify_image_class_knn.

With *'bit_depth'* the accuracy of the classification, the required storage, and the runtime needed to create the LUT can be controlled.

The following parameters of the k-NN-based LUT classifier can be set with GenParamName and GenParamValue:

'bit_depth': Number of bits used from the pixels. It controls the storage requirement of the LUT classifier and is bounded by the bit depth of the image (*'bit_depth'* $\leq$ *8*). If the bit depth of the LUT is smaller (*'bit_depth'* $<$ *8*), the classes of multiple pixel combinations will be mapped to the same LUT entry, which can result in a lower accuracy for the classification. One of these clusters contains $2^{NumDim \cdot (8-bit\_depth)}$ pixel combinations, where NumDim denotes the dimension of the LUT, which is specified in create_class_knn. For example, for *'bit_depth'* $=$ *7*, NumDim $=$ *3*, the classes of 8 pixel combinations are mapped in the same LUT entry. The LUT requires at most

$2^{NumDim \cdot bit\_depth+2}$ bytes of storage. For example, for NumDim = *3*, *'bit_depth'* = *8* and number of classes is smaller than *16*, the LUT requires 8 MB of storage with internal storage optimization. The runtime for the classification in classify_image_class_lut becomes minimal if the LUT fits into the cache.

Suggested values: *6*,*7*,*8*

Default: *8*

Restriction: *'bit_depth'* $\geq$ *1*, *'bit_depth'* $\leq$ *8*.

'rejection_threshold': Threshold for the rejection of uncertain classified points of the k-NN. The parameter represents a threshold on the distance returned by the classification (see classify_class_knn). All pixels having a distance over *'rejection_threshold'* are not assigned to any class.

Default: *5*

Restriction: *'rejection_threshold'* $\geq$ *0*.

Parameters

▷ **KNNHandle** (input_control) . . . . . class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamName ∈ {'bit_depth', 'rejection_threshold'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / integer / real
Values of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamValue ∈ {8, 7, 6, 0.5, 5, 10, 50}

▷ **ClassLUTHandle** (output_control) . . . . . class_lut ⇝ *handle*
Handle of the LUT classifier.

Result

If the parameters are valid, the operator create_class_lut_knn returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

create_class_lut_mlp (: : MLPHandle, GenParamName, GenParamValue : ClassLUTHandle)

Create a look-up table using a multi-layer perceptron to classify byte images.

create_class_lut_mlp generates a look-up table (LUT) ClassLUTHandle using the data of a trained multi-layer perceptron (MLP) MLPHandle to classify multi-channel byte images. By using this MLP-based LUT

classifier the operator classify_image_class_mlp of the subsequent classification can be replaced by the operator classify_image_class_lut. The classification gets a major speed-up, because the estimation of the class in every image point is no longer necessary since every possible response of the MLP is stored in the LUT. For the generation of the LUT, the parameters NumInput, Preprocessing, and NumComponents defined in the earlier called operator create_class_mlp are important. In NumInput, the number of image channels the images must have to be classified is defined. By using the Preprocessing (see create_class_mlp) the number of image channels can be transformed to NumComponents. NumComponents defines the length of the feature vector, which the classifier classify_class_mlp handles internally. Because of performance and disk space, the LUT is restricted to be maximal *3*-dimensional. Since it replaces the operator classify_class_mlp, NumComponents $\leq$ *3* must hold. If there is no preprocessing that reduces the number of image channels (NumInput = NumComponents), all possible pixel values, which can occur in a byte image, are classified with classify_class_mlp. The returned classes are stored in the LUT. If there is a preprocessing that reduces the number of image channels (NumInput > NumComponents), the preprocessing parameters of the MLP are stored in a separate structure of the LUT. To create the LUT, all transformed pixel values are classified with classify_class_mlp. The returned classes are stored in the LUT. Because of the discretization of the LUT, the accuracy of the LUT classifier could become lower than the accuracy of classify_image_class_mlp. With *'bit_depth'* and *'class_selection'* the accuracy of the classification, the required storage, and the runtime needed to create the LUT can be controlled.

The following parameters of the MLP-based LUT classifier can be set with GenParamName and GenParamValue:

'bit_depth': Number of bits used from the pixels. It controls the storage requirement of the LUT classifier and is bounded by the bit depth of the image (*'bit_depth'* $\leq$ *8*). If the bit depth of the LUT is smaller (*'bit_depth'* $<$ *8*), the classes of multiple pixel combinations will be mapped to the same LUT entry, which can result in a lower accuracy for the classification. One of these clusters contains $2^{NumComponents \cdot (8-bit\_depth)}$ pixel combinations, where NumComponents denotes the dimension of the LUT, which is specified in create_class_mlp. For example, for *'bit_depth'* = *7*, NumComponents = *3*, the classes of *8* pixel combinations are mapped in the same LUT entry. The LUT requires at most $2^{NumComponents \cdot bit\_depth+2}$ bytes of storage. For example, for NumComponents = *3*, *'bit_depth'* = *8* and NumOutput $<$ *16* (specified in create_class_mlp), the LUT requires 8 MB of storage with internal storage optimization. If NumOutput = *1*, the LUT requires only 2 MB of storage by using the full bit depth of the LUT. The runtime for the classification in classify_image_class_lut becomes minimal if the LUT fits into the cache.

Suggested values: *6*,*7*,*8* **Default:** *8*

Restriction: *'bit_depth'* $\geq$ *1*, *'bit_depth'* $\leq$ *8*.

'class_selection': Method for the class selection for the LUT. Can be modified to control the accuracy and the runtime needed to create the LUT classifier. The value in *'class_selection'* is ignored if the bit depth of the LUT is maximal, thus *'bit_depth'* = *8* holds. If the bit depth of the LUT is smaller (*'bit_depth'* $<$ *8*), the classes of multiple pixel combinations will be mapped to the same LUT entry. One of these clusters contains $2^{NumComponents \cdot (8-bit\_depth)}$ pixel combinations, where NumComponents denotes the dimension of the LUT, which is specified in create_class_mlp. By choosing *'class_selection'* = *'best'*, the class that appears most often in the cluster is stored in the LUT. For *'class_selection'* = *'fast'*, only one pixel of the cluster, i.e., the pixel with the smallest value (component-wise), is classified. The returned class is stored in the LUT. In this case, the accuracy of the subsequent classification could become lower. On the other hand, the runtime needed to create the LUT can be reduced, which is proportional to the maximal needed storage of the LUT, which is defined with $2^{NumComponents \cdot bit\_depth+2}$.

List of values: *'fast'*, *'best'*

Default: *'fast'*,

'rejection_threshold': Threshold for the rejection of uncertain classified points of the MLP. The parameter represents a threshold on the probability measure returned by the classification (see classify_class_mlp and evaluate_class_mlp). All pixels having a probability below *'rejection_threshold'* are not assigned to any class.

Default: *0.5*

Restriction: *'rejection_threshold'* $\geq$ *0*, *'rejection_threshold'* $\leq$ *1*.

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamName ∈ {'bit_depth', 'class_selection', 'rejection_threshold'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / integer / real
Values of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamValue ∈ {8, 7, 6, 'fast', 'best'}

▷ **ClassLUTHandle** (output_control) . . . . . class_lut ⇝ *handle*
Handle of the LUT classifier.

Result

If the parameters are valid, the operator create_class_lut_mlp returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

create_class_lut_svm (: : SVMHandle, GenParamName, GenParamValue : ClassLUTHandle)

Create a look-up table using a Support-Vector-Machine to classify byte images.

create_class_lut_svm generates a look-up table (LUT) ClassLUTHandle using the data of a trained Support-Vector-Machine (SVM) SVMHandle to classify multi-channel byte images. By using this SVM-based LUT classifier the operator classify_image_class_svm of the subsequent classification can be replaced by the operator classify_image_class_lut. The classification gets a major speed-up, because the estimation of the class in every image point is no longer necessary since every possible response of the SVM is stored in the LUT. For the generation of the LUT, the parameters NumFeatures, Preprocessing, and NumComponents defined in the earlier called operator create_class_svm are important. In NumFeatures, the number of image channels the images must have to be classified is defined. By using the Preprocessing (see create_class_svm) the number of image channels can be transformed to NumComponents. NumComponents defines the length of the feature vector, which the classifier classify_class_svm handles internally. Because of performance and disk space, the LUT is restricted to be maximal *3*-dimensional. Since it replaces the operator classify_class_svm, NumComponents $\leq$ *3* must hold. If there is no preprocessing that reduces the number of image channels (NumFeatures = NumComponents), all possible pixel values, which can occur in a byte image, are classified with

classify_class_svm. The returned classes are stored in the LUT. If there is a preprocessing that reduces the number of image channels (NumFeatures > NumComponents), the preprocessing parameters of the SVM are stored in a separate structure of the LUT. To create the LUT, all transformed pixel values are classified with classify_class_svm. The returned classes are stored in the LUT. Because of the discretization of the LUT, the accuracy of the LUT classifier could become lower than the accuracy of classify_image_class_svm. With *'bit_depth'* and *'class_selection'* the accuracy of the classification, the required storage, and the runtime needed to create the LUT can be controlled.

The following parameters of the SVM-based LUT classifier can be set with GenParamName and GenParamValue:

'bit_depth': Number of bits used from the pixels. It controls the storage requirement of the LUT classifier and is bounded by the bit depth of the image (*'bit_depth'* $\leq$ *8*). If the bit depth of the LUT is smaller (*'bit_depth'* $<$ *8*), the classes of multiple pixel combinations will be mapped to the same LUT entry, which can result in a lower accuracy for the classification. One of these clusters contains $2^{NumComponents \cdot (8-bit\_depth)}$ pixel combinations, where NumComponents denotes the dimension of the LUT, which is specified in create_class_svm. For example, for *'bit_depth'* = *7*, NumComponents = *3*, the classes of 8 pixel combinations are mapped in the same LUT entry. The LUT requires at most $2^{NumComponents \cdot bit\_depth+2}$ bytes of storage. For example, for NumComponents = *3*, *'bit_depth'* = *8* and NumClasses $<$ *16* (specified in create_class_svm), the LUT requires 8 MB of storage with internal storage optimization. If NumClasses = *1*, the LUT requires only 2 MB of storage by using the full bit depth of the LUT. The runtime for the classification in classify_image_class_lut becomes minimal if the LUT fits into the cache.

Suggested values: *6*,*7*,*8*

Default: *8*

Restriction: *'bit_depth'* $\geq$ *1*, *'bit_depth'* $\leq$ *8*.

'class_selection': Method for the class selection for the LUT. Can be modified to control the accuracy and the runtime needed to create the LUT classifier. The value in *'class_selection'* is ignored if the bit depth of the LUT is maximal, thus *'bit_depth'* = *8* holds. If the bit depth of the LUT is smaller (*'bit_depth'* $<$ *8*), the classes of multiple pixel combinations will be mapped to the same LUT entry. One of these clusters contains $2^{NumComponents \cdot (8-bit\_depth)}$ pixel combinations, where NumComponents denotes the dimension of the LUT, which is specified in create_class_svm. By choosing *'class_selection'* = *'best'*, the class that appears most often in the cluster is stored in the LUT. For *'class_selection'* = *'fast'*, only one pixel of the cluster, i.e., the pixel with the smallest value (component-wise), is classified. The returned class is stored in the LUT. In this case, the accuracy of the subsequent classification could become lower. On the other hand, the runtime needed to create the LUT can be reduced, which is proportional to the maximal needed storage of the LUT, which is defined with $2^{NumComponents \cdot bit\_depth+2}$.

List of values: *'fast'*, *'best'*

Default: *'fast'*

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **GenParamName** (input_control) ..... attribute.name-array ⇝ *string*
Names of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamName ∈ {'bit_depth', 'class_selection'}

▷ **GenParamValue** (input_control) ..... attribute.value-array ⇝ *string* / integer
Values of the generic parameters that can be adjusted for the LUT classifier creation.
Default: []
Suggested values: GenParamValue ∈ {8, 7, 6, 'fast', 'best'}

▷ **ClassLUTHandle** (output_control) ..... class_lut ⇝ *handle*
Handle of the LUT classifier.

Result

If the parameters are valid, the operator create_class_lut_svm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

7.4 Misc

add_sample_class_train_data (: : ClassTrainDataHandle, Order, Features, ClassID :)

Add a training sample to training data.

add_sample_class_train_data adds a training sample to the training data given by ClassTrainDataHandle. The training sample is given by Features and ClassID. Features is the feature vector of the sample, and consequently must be a real vector of length NumDim, as specified in create_class_train_data. ClassID is the class of the sample. More than one training sample can be added at once. In this case the parameter Order defines in which order the elements of the feature vectors are passed in Features. If it is set to *'row'*, the first training sample comes first, the second comes second, and so on. If it is set to *'column'*, the first dimension of all feature vectors comes first, and then the second dimension of all feature vectors, and so on. The third possible mode for Order is *'feature_column'*. This mode expects features which were grouped before with set_feature_lengths_class_train_data to come completely and row-wise before the second feature, and so on.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

▷ **Order** (input_control) . . . . . string ⇝ *string*
The order of the feature vector.
Default: 'row'
List of values: Order ∈ {'row', 'column', 'feature_column'}

▷ **Features** (input_control) . . . . . number-array ⇝ *real*
Feature vector of the training sample.

▷ **ClassID** (input_control) . . . . . integer-array ⇝ *integer*
Class of the training sample.

Result

If the parameters are valid, the operator add_sample_class_train_data returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassTrainDataHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

clear_class_train_data (: : ClassTrainDataHandle :)

Clears training data for classifiers.

`clear_class_train_data` clears the training data given in `ClassTrainDataHandle`. After calling `clear_class_train_data`, `ClassTrainDataHandle` becomes invalid.

Parameters

▷ **ClassTrainDataHandle** (input_control) ..... class_train_data ⇝ *handle*
Handle of training data for a classifier.

Result

If the parameters are valid, the operator `clear_class_train_data` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassTrainDataHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_class_train_data`

`create_class_train_data`

Module

Foundation

create_class_train_data (: : NumDim : ClassTrainDataHandle)

Create a handle for training data for classifiers.

`create_class_train_data` creates a handle for training data for classifiers. The handle is returned in `ClassTrainDataHandle`. The dimension of the feature vectors is specified with `NumDim`. Only feature vectors of this length can be added to the handle.

Parameters

▷ **NumDim** (input_control) . . . . . number ⇝ *integer*
Number of dimensions of the feature vector.
Default: 10

▷ **ClassTrainDataHandle** (output_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

Example

```
* Find out which of the two features distinguishes two Classes
NameFeature1 := 'Good Feature'
NameFeature2 := 'Bad Feature'
LengthFeature1 := 3
LengthFeature2 := 2
* Create training data
create_class_train_data (LengthFeature1+LengthFeature2,\
  ClassTrainDataHandle)
* Define the features which are in the training data
set_feature_lengths_class_train_data (ClassTrainDataHandle, [LengthFeature1,\
  LengthFeature2], [NameFeature1, NameFeature2])
* Add training data
*                                                        |Feat1| |Feat2|
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  2,1  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  2,1  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  3,4  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  3,4  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [0,0,1,  5,6  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,3,2,  5,6  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [0,0,1,  5,6  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,3,2,  5,6  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [0,0,1,  5,6  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,3,2,  5,6  ], 1)
* Add more data
* ...
* Select the better feature with the classifier of your choice
select_feature_set_knn (ClassTrainDataHandle, 'greedy', [], [], KNNHandle,\
  SelectedFeature, Score)
select_feature_set_svm (ClassTrainDataHandle, 'greedy', [], [], SVMHandle,\
  SelectedFeature, Score)
select_feature_set_mlp (ClassTrainDataHandle, 'greedy', [], [], MLPHandle,\
  SelectedFeature, Score)
select_feature_set_gmm (ClassTrainDataHandle, 'greedy', [], [], GMMHandle,\
  SelectedFeature, Score)
* Use the classifier
* ...
```

Result

If the parameters are valid, the operator `create_class_train_data` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

select_feature_set_knn, read_class_knn

Module

Foundation

deserialize_class_train_data (: : SerializedItemHandle : ClassTrainDataHandle)

Deserialize serialized training data for classifiers.

deserialize_class_train_data deserializes training data for classifiers, that were serialized by serialize_class_train_data (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized training data is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created training data block with the handle ClassTrainDataHandle.

Parameters

- ▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
  Handle of the serialized item.
- ▷ **ClassTrainDataHandle** (output_control) ..... class_train_data ⇝ *handle*
  Handle of the training data.

Result

If the parameters are valid, the operator deserialize_class_train_data returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_sample_class_train_data (: : ClassTrainDataHandle, IndexSample : Features, ClassID)

Return a training sample from training data.

get_sample_class_train_data reads a training sample from the training data given by ClassTrainDataHandle that was added, e.g., with add_sample_class_train_data. The index of the sample is specified with IndexSample. The index is counted from 0. That means that IndexSample must be a number between 0 and NumSamples − 1, where NumSamples can be determined with get_sample_num_class_train_data. The training sample is returned in Features

and ClassID. Features is a feature vector of length NumDim (see create_class_train_data) and ClassID is the class of the feature vector.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of training data for a classifier.

▷ **IndexSample** (input_control) . . . . . integer ⇝ *integer*
Number of stored training sample.

▷ **Features** (output_control) . . . . . real-array ⇝ *real*
Feature vector of the training sample.

▷ **ClassID** (output_control) . . . . . integer ⇝ *integer*
Class of the training sample.

Result

If the parameters are valid, the operator get_sample_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_sample_num_class_train_data (: : ClassTrainDataHandle : NumSamples)

Return the number of training samples stored in the training data.

get_sample_num_class_train_data returns in NumSamples the number of training samples which are stored in the training data specified by ClassTrainDataHandle.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of training data.

▷ **NumSamples** (output_control) . . . . . integer ⇝ *integer*
Number of stored training samples.

Result

If ClassTrainDataHandle is valid, the operator get_sample_num_class_train_data returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_class_train_data

Module

Foundation

read_class_train_data (: : FileName : ClassTrainDataHandle)

Read the training data for classifiers from a file.

read_class_train_data reads the saved training data for classifiers from the file FileName (see write_class_train_data). The default HALCON file extension for training data for a classifier is 'ctd'.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name of the training data.
File extension: .ctd

▷ **ClassTrainDataHandle** (output_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

Result

read_class_train_data returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open the file FileName or the file has the wrong format.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

create_class_train_data, write_class_train_data

Module

Foundation

select_sub_feature_class_train_data (: : ClassTrainDataHandle, SubFeatureIndices : SelectedClassTrainDataHandle)

Select certain features from training data to create training data containing less features.

select_sub_feature_class_train_data selects certain features from the training data in ClassTrainDataHandle and returns the subset in SelectedClassTrainDataHandle. The features that should be selected can be chosen by SubFeatureIndices. If set_feature_lengths_class_train_data was not called before, the indices refer to the columns. If set_feature_lengths_class_train_data was called before, the grouping defined there is relevant for the meaning of the indices. The entry n in the list selects then the n-th feature group. If set_feature_lengths_class_train_data was called with names for the feature groups, those names can be used instead of the indices.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

▷ **SubFeatureIndices** (input_control) . . . . . number-array ⇝ *integer* / string
Indices or names to select the subfeatures or columns.

▷ **SelectedClassTrainDataHandle** (output_control) . . . . . class_train_data ⇝ *handle*
Handle of the reduced training data.

Example

```
* Find out which of the two features distinguishes two Classes
NameFeature1 := 'Good Feature'
NameFeature2 := 'Bad Feature'
LengthFeature1 := 3
LengthFeature2 := 2
* Create training data
create_class_train_data (LengthFeature1+LengthFeature2,\
                         ClassTrainDataHandle)
* Define the features which are in the training data
set_feature_lengths_class_train_data (ClassTrainDataHandle, [LengthFeature1,\
                           LengthFeature2], [NameFeature1, NameFeature2])
* Add training data
*                                                          |Feat1| |Feat2|
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  2,1  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  2,1  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  3,4  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  3,4  ], 1)
* Add more data
* ...
* Select one of the features
select_sub_feature_class_train_data (ClassTrainDataHandle, NameFeature1, \
                                     SelectedClassTrainDataHandle)
* Add training data to a classifier
create_class_knn (LengthFeature1, KNNHandle)
add_class_train_data_knn (KNNHandle, SelectedClassTrainDataHandle)
train_class_knn (KNNHandle, [], [])
* Use the classifier
* ...
```

Result

If the parameters are valid, the operator `select_sub_feature_class_train_data` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

serialize_class_train_data (: : ClassTrainDataHandle : SerializedItemHandle)

Serialize training data for classifiers.

`serialize_class_train_data` serializes training data for classifiers and its stored training samples (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that

is written in a file by write_class_train_data is converted to a serialized item. The training data is defined by the handle ClassTrainDataHandle. The serialized training data is returned by the handle SerializedItemHandle and can be deserialized by deserialize_class_train_data.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_class_train_data returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_class_train_data, read_class_train_data

Module

Foundation

set_feature_lengths_class_train_data (: : ClassTrainDataHandle, SubFeatureLength, Names :)

Define subfeatures in training data.

set_feature_lengths_class_train_data defines subfeatures in the training data in ClassTrainDataHandle. The subfeatures are defined in SubFeatureLength by a set of lengths that groups the previously added columns subsequently into subfeatures. It is not possible to group columns which are not subsequent. The sum over all entries in SubFeatureLength must be equal to the number of dimensions set in create_class_train_data with the parameter NumDim. Optionally, names for all subsets can be defined in Names.

An exemplary situation in which this operator is helpful is described here: Two different data sources are available. Both data sources provide a vector of a certain length. The first data source provides data of length n and the second of length m. In order to automatically decide which of the data sources is more valuable for a certain classification problem, training data can be created that contains both data sources. E.g., if create_class_train_data was called with NumDim $= n + m = w$, then set_feature_lengths_class_train_data can be called with *[n,m]* in SubFeatureLength and *[Name1, Name2]* in Names to describe this situation for a later usage of operators like select_feature_set_knn or select_feature_set_svm. Then the classification problem has to be specified via calls of add_sample_class_train_data, by giving a vector of the first data source and a vector of the second data source as the combined feature vector of length w. The result of the call of select_feature_set_knn would then be either *[Name1]* if the first is more relevant, *[Name2]* if the second is more relevant or *[Name1, Name2]* if both are necessary.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data that should be partitioned into subfeatures.

▷ **SubFeatureLength** (input_control) . . . . . number-array ⇝ *integer*
Length of the subfeatures.

▷ **Names** (input_control) . . . . . string-array ⇝ *string*
Names of the subfeatures.

Example

```
* Find out which of the two features distinguishes two Classes
NameFeature1 := 'Good Feature'
NameFeature2 := 'Bad Feature'
LengthFeature1 := 3
LengthFeature2 := 2
* Create training data
create_class_train_data (LengthFeature1+LengthFeature2,\
  ClassTrainDataHandle)
* Define the features which are in the training data
set_feature_lengths_class_train_data (ClassTrainDataHandle, [LengthFeature1,\
  LengthFeature2], [NameFeature1, NameFeature2])
* Add training data
*                                                          |Feat1| |Feat2|
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  2,1  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  2,1  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  3,4  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  3,4  ], 1)
* Add more data
* ...
* Select the better feature
select_feature_set_knn (ClassTrainDataHandle, 'greedy', [], [], KNNHandle,\
  SelectedFeature, Score)
classify_class_knn (KNNHandle, [1,1,1], Result, Rating)
classify_class_knn (KNNHandle, [2,2,2], Result, Rating)
* Use the classifier
* ...
```

Result

If the parameters are valid, the operator `set_feature_lengths_class_train_data` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ClassTrainDataHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

`write_class_train_data` (: : `ClassTrainDataHandle`, `FileName` :)

Save the training data for classifiers in a file.

write_class_train_data writes the training data for classifiers ClassTrainDataHandle to the file given by FileName. The classifier can be read again with read_class_train_data. The default HALCON file extension for the training data is 'ctd'.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of the file in which the training data will be written.
File extension: .ctd

Result

write_class_train_data returns 2 (H_MSG_TRUE). An exception is raised if it was not possible to open file FileName.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

7.5 Neural Nets

```
add_class_train_data_mlp ( : : MLPHandle,
    ClassTrainDataHandle : )
```

Add training data to a multilayer perceptron (MLP).

add_class_train_data_mlp adds the training data specified by ClassTrainDataHandle to a multilayer perceptron (MLP) specified by MLPHandle.

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle which receives the training data.

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Training data for a classifier.

Result

If the parameters are valid, the operator add_class_train_data_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

add_sample_class_mlp (: : MLPHandle, Features, Target :)

Add a training sample to the training data of a multilayer perceptron.

add_sample_class_mlp adds a training sample to the multilayer perceptron (MLP) given by MLPHandle. The training sample is given by Features and Target. Features is the feature vector of the sample, and consequently must be a real vector of length NumInput, as specified in create_class_mlp. Target is the target vector of the sample, which must have the length NumOutput (see create_class_mlp) for all three types of activation functions of the MLP (exception: see below). If the MLP is used for regression (function approximation), i.e., if OutputFunction = *'linear'*, Target is the value of the function at the coordinate Features. In this case, Target can contain arbitrary real numbers. For OutputFunction = *'logistic'*, Target can only contain the values *0.0* and *1.0*. A value of *1.0* specifies that the attribute in question is present, while a value of *0.0* specifies that the attribute is absent. Because in this case the attributes are independent, arbitrary combinations of *0.0* and *1.0* can be passed. For OutputFunction = *'softmax'*, Target also can only contain the values *0.0* and *1.0*. In contrast to OutputFunction = *'logistic'*, the value *1.0* must be present for exactly one element of the tuple Target. The location in the tuple designates the class of the sample. For ease of use, a single integer value may be passed if OutputFunction = *'softmax'*. This value directly designates the class of the sample, which is counted from 0, i.e., the class must be an integer between 0 and NumOutput − 1. The class is converted to a target vector of length NumOutput internally.

Before the MLP can be trained with train_class_mlp, *all* training samples must be added to the MLP with add_sample_class_mlp.

The number of currently stored training samples can be queried with get_sample_num_class_mlp. Stored training samples can be read out again with get_sample_class_mlp.

Normally, it is useful to save the training samples in a file with write_samples_class_mlp to facilitate reusing the samples, and to facilitate that, if necessary, new training samples can be added to the data set, and hence to facilitate that a *newly created* MLP can be trained *anew* with the extended data set.

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

▷ **Features** (input_control) . . . . . real-array ⇝ *real*
Feature vector of the training sample to be stored.

▷ **Target** (input_control) . . . . . number(-array) ⇝ *integer* / real
Class or target vector of the training sample to be stored.

Result

If the parameters are valid, the operator add_sample_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MLPHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

classify_class_mlp (: : MLPHandle, Features, Num : Class, Confidence)

Calculate the class of a feature vector by a multilayer perceptron.

classify_class_mlp computes the best Num classes of the feature vector Features with the multilayer perceptron (MLP) MLPHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. Before calling classify_class_mlp, the MLP must be trained with train_class_mlp.

classify_class_mlp can only be called if the MLP is used as a classifier with OutputFunction = *'softmax'* (see create_class_mlp). Otherwise, an error message is returned. classify_class_mlp corresponds to a call to evaluate_class_mlp and an additional step that extracts the best Num classes. As described with evaluate_class_mlp, the output values of the MLP can be interpreted as probabilities of the occurrence of the respective classes. In most cases it should be sufficient to use Num = *1* in order to decide whether the probability of the best class is high enough. In some applications it may be interesting to also take the second best class into account (Num = *2*), particularly if it can be expected that the classes show a significant degree of overlap.

Parameters

- ▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
  MLP handle.
- ▷ **Features** (input_control) . . . . . real-array ⇝ *real*
  Feature vector.
- ▷ **Num** (input_control) . . . . . integer-array ⇝ *integer*
  Number of best classes to determine.
  Default: 1
  Suggested values: Num ∈ {1, 2, 3, 4, 5}
- ▷ **Class** (output_control) . . . . . integer(-array) ⇝ *integer*
  Result of classifying the feature vector with the MLP.
- ▷ **Confidence** (output_control) . . . . . real(-array) ⇝ *real*
  Confidence(s) of the class(es) of the feature vector.

Result

If the parameters are valid, the operator classify_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

clear_class_mlp (: : MLPHandle :)

Clear a multilayer perceptron.

clear_class_mlp clears the multilayer perceptron (MLP) given by MLPHandle and frees all memory required for the MLP. After calling clear_class_mlp, the MLP can no longer be used. The handle MLPHandle becomes invalid.

Parameters

▷ **MLPHandle** (input_control) ..... class_mlp(-array) ⇝ *handle*
MLP handle.

Result

If MLPHandle is valid, the operator clear_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

Module

Foundation

clear_samples_class_mlp (: : MLPHandle :)

Clear the training data of a multilayer perceptron.

clear_samples_class_mlp clears all training samples that have been added to the multilayer perceptron (MLP) MLPHandle with add_sample_class_mlp or read_samples_class_mlp. clear_samples_class_mlp should only be used if the MLP is trained in the same process that uses the MLP for evaluation with evaluate_class_mlp or for classification with classify_class_mlp. In

this case, the memory required for the training samples can be freed with clear_samples_class_mlp, and hence memory can be saved. In the normal usage, in which the MLP is trained offline and written to a file with write_class_mlp, it is typically unnecessary to call clear_samples_class_mlp because write_class_mlp does not save the training samples, and hence the online process, which reads the MLP with read_class_mlp, requires no memory for the training samples.

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp(-array) ⇝ *handle*
MLP handle.

Result

If the parameters are valid, the operator clear_samples_class_mlp returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

create_class_mlp (: : NumInput, NumHidden, NumOutput,
OutputFunction, Preprocessing, NumComponents,
RandSeed : MLPHandle)

Create a multilayer perceptron for classification or regression.

create_class_mlp creates a neural net in the form of a multilayer perceptron (MLP), which can be used for classification or regression (function approximation), depending on how OutputFunction is set. The MLP consists of three layers: an input layer with NumInput input variables (units, neurons), a hidden layer with NumHidden units, and an output layer with NumOutput output variables. The MLP performs the following steps to calculate the activations z_j of the hidden units from the input data x_i (the so-called feature vector):

$$\begin{aligned} a_j^{(1)} &= \sum_{i=1}^{n_i} w_{ji}^{(1)} x_i + b_j^{(1)}, \qquad j = 1, \ldots, n_h \\ z_j &= \tanh\left(a_j^{(1)}\right), \qquad j = 1, \ldots, n_h \end{aligned}$$

Here, the matrix $w_{ji}^{(1)}$ and the vector $b_j^{(1)}$ are the weights of the input layer (first layer) of the MLP. In the hidden layer (second layer), the activations z_j are transformed in a first step by using linear combinations of the variables in an analogous manner as above:

$$a_k^{(2)} = \sum_{j=1}^{n_h} w_{kj}^{(2)} z_j + b_k^{(2)}, \qquad k = 1, \ldots, n_o$$

Here, the matrix $w_{kj}^{(2)}$ and the vector $b_k^{(2)}$ are the weights of the second layer of the MLP.

The activation function used in the output layer can be determined by setting OutputFunction. For OutputFunction = *'linear'*, the data are simply copied:

$$y_k = a_k^{(2)}, \qquad k = 1, \ldots, n_o$$

This type of activation function should be used for regression problems (function approximation). This activation function is not suited for classification problems.

For OutputFunction = *'logistic'*, the activations are computed as follows:

$$y_k = \frac{1}{1 + \exp\left(-a_k^{(2)}\right)}, \qquad k = 1, \ldots, n_o$$

This type of activation function should be used for classification problems with multiple (NumOutput) independent logical attributes as output. This kind of classification problem is relatively rare in practice.

For OutputFunction = *'softmax'*, the activations are computed as follows:

$$y_k = \frac{\exp\left(a_k^{(2)}\right)}{\sum_{l=1}^{n_o} \exp\left(a_l^{(2)}\right)}, \qquad k = 1, \ldots, n_o$$

This type of activation function should be used for common classification problems with multiple (NumOutput) mutually exclusive classes as output. In particular, OutputFunction = *'softmax'* must be used for the classification of pixel data with classify_image_class_mlp.

The parameters Preprocessing and NumComponents can be used to specify a preprocessing of the feature vectors. For Preprocessing = *'none'*, the feature vectors are passed unaltered to the MLP. NumComponents is ignored in this case.

For all other values of Preprocessing, the training data set is used to compute a transformation of the feature vectors during the training as well as later in the classification or evaluation.

For Preprocessing = *'normalization'*, the feature vectors are normalized by subtracting the mean of the training vectors and dividing the result by the standard deviation of the individual components of the training vectors. Hence, the transformed feature vectors have a mean of 0 and a standard deviation of 1. The normalization does not change the length of the feature vector. NumComponents is ignored in this case. This transformation can be used if the mean and standard deviation of the feature vectors differs substantially from 0 and 1, respectively, or for data in which the components of the feature vectors are measured in different units (e.g., if some of the data are gray value features and some are region features, or if region features are mixed, e.g., 'circularity' (unit: scalar) and 'area' (unit: pixel squared)). In these cases, the training of the net will typically require fewer iterations than without normalization.

For Preprocessing = *'principal_components'*, a principal component analysis is performed. First, the feature vectors are normalized (see above). Then, an orthogonal transformation (a rotation in the feature space) that decorrelates the training vectors is computed. After the transformation, the mean of the training vectors is 0 and the covariance matrix of the training vectors is a diagonal matrix. The transformation is chosen such that the transformed features that contain the most variation is contained in the first components of the transformed feature vector. With this, it is possible to omit the transformed features in the last components of the feature vector, which typically are mainly influenced by noise, without losing a large amount of information. The parameter NumComponents can be used to determine how many of the transformed feature vector components should be used. Up to NumInput components can be selected. The operator get_prep_info_class_mlp can be used to determine how much information each transformed component contains. Hence, it aids the selection of NumComponents. Like data normalization, this transformation can be used if the mean and standard deviation of the feature vectors differs substantially from 0 and 1, respectively, or for feature vectors in which the components of the data are measured in different units. In addition, this transformation is useful if it can be expected that the features are highly correlated.

In contrast to the above three transformations, which can be used for all MLP types, the transformation specified by Preprocessing = *'canonical_variates'* can only be used if the MLP is used as a classifier with

OutputFunction = *'softmax'*). The computation of the canonical variates is also called linear discriminant analysis. In this case, a transformation that first normalizes the training vectors and then decorrelates the training vectors on average over all classes is computed. At the same time, the transformation maximally separates the mean values of the individual classes. As for Preprocessing = *'principal_components'*, the transformed components are sorted by information content, and hence transformed components with little information content can be omitted. For canonical variates, up to $\min(\text{NumOutput} - 1, \text{NumInput})$ components can be selected. Also in this case, the information content of the transformed components can be determined with get_prep_info_class_mlp. Like principal component analysis, canonical variates can be used to reduce the amount of data without losing a large amount of information, while additionally optimizing the separability of the classes after the data reduction.

For the last two types of transformations (*'principal_components'* and *'canonical_variates'*), the actual number of input units of the MLP is determined by NumComponents, whereas NumInput determines the dimensionality of the input data (i.e., the length of the untransformed feature vector). Hence, by using one of these two transformations, the number of input variables, and thus usually also the number of hidden units can be reduced. With this, the time needed to train the MLP and to evaluate and classify a feature vector is typically reduced.

Usually, NumHidden should be selected in the order of magnitude of NumInput and NumOutput. In many cases, much smaller values of NumHidden already lead to very good classification results. If NumHidden is chosen too large, the MLP may overfit the training data, which typically leads to bad generalization properties, i.e., the MLP learns the training data very well, but does not return very good results on unknown data.

create_class_mlp initializes the above described weights with random numbers. To ensure that the results of training the classifier with train_class_mlp are reproducible, the seed value of the random number generator is passed in RandSeed. If the training results in a relatively large error, it sometimes may be possible to achieve a smaller error by selecting a different value for RandSeed and retraining an MLP.

After the MLP has been created, typically training samples are added to the MLP by repeatedly calling add_sample_class_mlp or read_samples_class_mlp. After this, the MLP is typically trained using train_class_mlp. Hereafter, the MLP can be saved using write_class_mlp. Alternatively, the MLP can be used immediately after training to evaluate data using evaluate_class_mlp or, if the MLP is used as a classifier (i.e., for OutputFunction = *'softmax'*), to classify data using classify_class_mlp.

The training of the MLP will usually result in very sharp boundaries between the different classes, i.e., the confidence for one class will drop from close to 1 (within the region of the class) to close to 0 (within the region of a different class) within a very narrow "band" in the feature space. If the classes do not overlap, this transition happens at a suitable location between the classes; if the classes overlap, the transition happens at a suitable location within the overlapping area. While this sharp transition is desirable in many applications, in some applications a smoother transition between different classes (i.e., a transition within a wider "band" in the feature space) is desirable to reflect a level of uncertainty within the region in the feature space between the classes. Furthermore, as described above, it may be desirable to prevent overfitting of the MLP to the training data. For these purposes, the MLP can be regularized by using set_regularization_params_class_mlp.

An MLP, as defined above, has no inherent capability for novelty detection, i.e., it will classify a random feature vector into one of the classes with a confidence close to 1 (unless the random feature vector happens to lie in a region of the feature space in which the training samples of different classes overlap). In some applications, however, it is desirable to reject feature vectors that do not lie close to any class, where "closesness" defined by the proximity of the feature vector to the collection of feature vectors in the training set. To provide an MLP with the ability for novelty detection, i.e., to reject feature vectors that do not belong to any class, an explicit rejection class can be created by setting NumOutput to the number of actual classes plus 1. Then, set_rejection_params_class_mlp can be used to configure train_class_mlp to automatically generate samples for this rejection class.

The combination of regularization and an automatic generation of a rejection class is useful in many applications since it provides a smooth transition between the actual classes and from the actual classes to the rejection class. This reflects the requirement of these applications that only feature vectors within the area of the feature space that corresponds to the training samples of each class should have a confidence close to 1, whereas random feature vectors not belonging to any class should have a confidence close to 0, and that transitions between the classes should be smooth, reflecting a growing degree of uncertainty the farther a feature vector lies from the respective class. In particular, OCR applications sometimes have this requirement (see create_ocr_class_mlp).

A comparison of the MLP and the support vector machine (SVM) (see create_class_svm) typically shows that SVMs are generally faster at training, especially for huge training sets, and achieve slightly better recognition rates than MLPs. The MLP is faster at classification and should therefore be preferred in time critical applications. Please note that this guideline assumes optimal tuning of the parameters.

Parameters

▷ **NumInput** (input_control) . . . . . integer ⇝ *integer*
Number of input variables (features) of the MLP.
Default: 20
Suggested values: NumInput ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumInput >= 1

▷ **NumHidden** (input_control) . . . . . integer ⇝ *integer*
Number of hidden units of the MLP.
Default: 10
Suggested values: NumHidden ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 120, 150}
Restriction: NumHidden >= 1

▷ **NumOutput** (input_control) . . . . . integer ⇝ *integer*
Number of output variables (classes) of the MLP.
Default: 5
Suggested values: NumOutput ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 120, 150}
Restriction: NumOutput >= 1

▷ **OutputFunction** (input_control) . . . . . string ⇝ *string*
Type of the activation function in the output layer of the MLP.
Default: 'softmax'
List of values: OutputFunction ∈ {'linear', 'logistic', 'softmax'}

▷ **Preprocessing** (input_control) . . . . . string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'normalization'
List of values: Preprocessing ∈ {'none', 'normalization', 'principal_components', 'canonical_variates'}

▷ **NumComponents** (input_control) . . . . . integer ⇝ *integer*
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = *'none'* and Preprocessing = *'normalization'*).
Default: 10
Suggested values: NumComponents ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumComponents >= 1

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed value of the random number generator that is used to initialize the MLP with random values.
Default: 42

▷ **MLPHandle** (output_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

Example

```
* Use the MLP for regression (function approximation)
create_class_mlp (1, NumHidden, 1, 'linear', 'none', 1, 42, MLPHandle)
* Generate the training data
* D = [...]
* T = [...]
* Add the training data
for J := 0 to NumData-1 by 1
    add_sample_class_mlp (MLPHandle, D[J], T[J])
endfor
* Train the MLP
train_class_mlp (MLPHandle, 200, 0.001, 0.001, Error, ErrorLog)
* Generate test data
* X = [...]
* Compute the output of the MLP on the test data
for J := 0 to N-1 by 1
    evaluate_class_mlp (MLPHandle, X[J], Y)
endfor

* Use the MLP for classification
create_class_mlp (NumIn, NumHidden, NumOut, 'softmax', \
```

```
                  'normalization', NumIn, 42, MLPHandle)
* Generate and add the training data
for J := 0 to NumData-1 by 1
    * Generate training features and classes
    * Data = [...]
    * Class = [...]
    add_sample_class_mlp (MLPHandle, Data, Class)
endfor
* Train the MLP
train_class_mlp (MLPHandle, 100, 1, 0.01, Error, ErrorLog)
* Use the MLP to classify unknown data
for J := 0 to N-1 by 1
    * Extract features
    * Features = [...]
    classify_class_mlp (MLPHandle, Features, 1, Class, Confidence)
endfor
```

Result

If the parameters are valid, the operator `create_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

deserialize_class_mlp (: : SerializedItemHandle : MLPHandle)

Deserialize a serialized multilayer perceptron.

`deserialize_class_mlp` deserializes a multilayer perceptron (MLP) (including its training samples), that was serialized by `serialize_class_mlp` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized multilayer perceptron is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created multilayer perceptron with the handle `MLPHandle`.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **MLPHandle** (output_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

Result

If the parameters are valid, the operator `deserialize_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

evaluate_class_mlp (: : MLPHandle, Features : Result)

Calculate the evaluation of a feature vector by a multilayer perceptron.

`evaluate_class_mlp` computes the result `Result` of evaluating the feature vector `Features` with the multilayer perceptron (MLP) `MLPHandle`. The formulas used for the evaluation are described with `create_class_mlp`. Before calling `evaluate_class_mlp`, the MLP must be trained with `train_class_mlp`.

If the MLP is used for regression (function approximation), i.e., if (`OutputFunction` = *'linear'*), `Result` is the value of the function at the coordinate `Features`. For `OutputFunction` = *'logistic'* and *'softmax'*, the values in `Result` can be interpreted as probabilities. Hence, for `OutputFunction` = *'logistic'* the elements of `Result` represent the probabilities of the presence of the respective independent attributes. Typically, a threshold of 0.5 is used to decide whether the attribute is present or not. Depending on the application, other thresholds may be used as well. For `OutputFunction` = *'softmax'* usually the position of the maximum value of `Result` is interpreted as the class of the feature vector, and the corresponding value as the probability of the class. In this case, `classify_class_mlp` should be used instead of `evaluate_class_mlp` because `classify_class_mlp` directly returns the class and corresponding probability.

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

▷ **Features** (input_control) . . . . . real-array ⇝ *real*
Feature vector.

▷ **Result** (output_control) . . . . . real-array ⇝ *real*
Result of evaluating the feature vector with the MLP.

Result

If the parameters are valid, the operator `evaluate_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_class_train_data_mlp (: : MLPHandle : ClassTrainDataHandle)

Get the training data of a multilayer perceptron (MLP).

get_class_train_data_mlp gets the training data of a multilayer perceptron (MLP) and returns it in ClassTrainDataHandle.

Parameters

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
Handle of a MLP that contains training data.

▷ **ClassTrainDataHandle** (output_control) ..... class_train_data ⇝ *handle*
Handle of the training data of the classifier.

Result

If the parameters are valid, the operator get_class_train_data_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

get_params_class_mlp (: : MLPHandle : NumInput, NumHidden, NumOutput, OutputFunction, Preprocessing, NumComponents)

Return the parameters of a multilayer perceptron.

get_params_class_mlp returns the parameters of a multilayer perceptron (MLP) that were specified when the MLP was created with create_class_mlp. This is particularly useful if the MLP was read from a file with read_class_mlp. The output of get_params_class_mlp can, for example, be used to check whether the feature vectors and, if necessary, the target data to be used with the MLP have the correct lengths. For a description of the parameters, see create_class_mlp.

Parameters

- ▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
  MLP handle.
- ▷ **NumInput** (output_control) ..... integer ⇝ *integer*
  Number of input variables (features) of the MLP.
- ▷ **NumHidden** (output_control) ..... integer ⇝ *integer*
  Number of hidden units of the MLP.
- ▷ **NumOutput** (output_control) ..... integer ⇝ *integer*
  Number of output variables (classes) of the MLP.
- ▷ **OutputFunction** (output_control) ..... string ⇝ *string*
  Type of the activation function in the output layer of the MLP.
- ▷ **Preprocessing** (output_control) ..... string ⇝ *string*
  Type of preprocessing used to transform the feature vectors.
- ▷ **NumComponents** (output_control) ..... integer ⇝ *integer*
  Preprocessing parameter: Number of transformed features.

Result

If the parameters are valid, the operator get_params_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_prep_info_class_mlp (: : MLPHandle, Preprocessing : InformationCont, CumInformationCont)

Compute the information content of the preprocessed feature vectors of a multilayer perceptron.

get_prep_info_class_mlp computes the information content of the training vectors that have been transformed with the preprocessing given by Preprocessing. Preprocessing can be set to *'principal_components'* or *'canonical_variates'*. The preprocessing methods are described with create_class_mlp. The information content is derived from the variations of the transformed components of the feature vector, i.e., it is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (NumInput for *'principal_components'* and $\min(\text{NumOutput}-1, \text{NumInput})$ for *'canonical_variates'*, see create_class_mlp), and is returned in InformationCont as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the n-th component of CumInformationCont, i.e., CumInformationCont contains

the sums of the first n elements of InformationCont. To use get_prep_info_class_mlp, a sufficient number of samples must be added to the multilayer perceptron (MLP) given by MLPHandle by using add_sample_class_mlp or read_samples_class_mlp.

InformationCont and CumInformationCont can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent x% (e.g., 90%) of the data. This can be decided easily from the first value of CumInformationCont that lies above x%. The number thus obtained can be used as the value for NumComponents in a new call to create_class_mlp. The call to get_prep_info_class_mlp already requires the creation of an MLP, and hence the setting of NumComponents in create_class_mlp to an initial value. However, if get_prep_info_class_mlp is called it is typically not known how many components are relevant, and hence how to set NumComponents in this call. Therefore, the following two-step approach should typically be used to select NumComponents: In a first step, an MLP with the maximum number for NumComponents is created (NumInput for *'principal_components'* and min(NumOutput − 1NumInput) for *'canonical_variates'*). Then, the training samples are added to the MLP and are saved in a file using write_samples_class_mlp. Subsequently, get_prep_info_class_mlp is used to determine the information content of the components, and with this NumComponents. After this, a new MLP with the desired number of components is created, and the training samples are read with read_samples_class_mlp. Finally, the MLP is trained with train_class_mlp.

Parameters

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

▷ **Preprocessing** (input_control) ..... string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'principal_components'
List of values: Preprocessing ∈ {'principal_components', 'canonical_variates'}

▷ **InformationCont** (output_control) ..... real-array ⇝ *real*
Relative information content of the transformed feature vectors.

▷ **CumInformationCont** (output_control) ..... real-array ⇝ *real*
Cumulative information content of the transformed feature vectors.

Example

```
* Create the initial MLP
create_class_mlp (NumIn, NumHidden, NumOut, 'softmax', \
                  'principal_components', NumIn, 42, MLPHandle)
* Generate and add the training data
for J := 0 to NumData-1 by 1
    * Generate training features and classes
    * Data = [...]
    * Class = [...]
    add_sample_class_mlp (MLPHandle, Data, Class)
endfor
write_samples_class_mlp (MLPHandle, 'samples.mtf')
* Compute the information content of the transformed features
get_prep_info_class_mlp (MLPHandle, 'principal_components',\
                         InformationCont, CumInformationCont)
* Determine NumComp by inspecting InformationCont and CumInformationCont
* NumComp = [...]
* Create the actual MLP
create_class_mlp (NumIn, NumHidden, NumOut, 'softmax', \
                  'principal_components', NumComp, 42, MLPHandle)
* Train the MLP
read_samples_class_mlp (MLPHandle, 'samples.mtf')
train_class_mlp (MLPHandle, 100, 1, 0.01, Error, ErrorLog)
write_class_mlp (MLPHandle, 'classifier.mlp')
```

Result

If the parameters are valid, the operator get_prep_info_class_mlp returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

get_prep_info_class_mlp may return the error 9211 (Matrix is not positive definite) if Preprocessing = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_regularization_params_class_mlp (: : MLPHandle, GenParamName : GenParamValue)

Return the regularization parameters of a multilayer perceptron.

get_regularization_params_class_mlp returns the regularization parameters of a multilayer perceptron (MLP) that were specified with set_regularization_params_class_mlp. Furthermore, get_regularization_params_class_mlp returns the parameters that were determined by an automatic determination of the regularization parameters. For a description of the parameters, see set_regularization_params_class_mlp.

Parameters

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

▷ **GenParamName** (input_control) ..... string ⇝ *string*
Name of the regularization parameter to return.
Default: 'weight_prior'
List of values: GenParamName ∈ {'weight_prior', 'noise_prior', 'num_well_determined_params', 'fraction_well_determined_params', 'num_outer_iterations', 'num_inner_iterations'}

▷ **GenParamValue** (output_control) ..... number(-array) ⇝ *real* / integer
Value of the regularization parameter.

Result

If the parameters are valid, the operator get_regularization_params_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_rejection_params_class_mlp (: : MLPHandle, GenParamName : GenParamValue)

Get the parameters of a rejection class.

get_rejection_params_class_mlp returns the rejection class parameters of a multilayer perceptron (MLP) that were specified with set_rejection_params_class_mlp. For a description of the parameters, see set_rejection_params_class_mlp.

Parameters

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

▷ **GenParamName** (input_control) ..... string(-array) ⇝ *string*
Names of the generic parameters to return.
Default: 'sampling_strategy'
List of values: GenParamName ∈ {'sampling_strategy', 'hyperbox_tolerance', 'rejection_sample_factor', 'random_seed', 'rejection_class_index'}

▷ **GenParamValue** (output_control) ..... string(-array) ⇝ *string* / real / integer
Values of the generic parameters.

Result

If the parameters are valid, the operator get_rejection_params_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_class_mlp

Possible Successors

train_class_mlp

Module

Foundation

get_sample_class_mlp (: : MLPHandle, IndexSample : Features, Target)

Return a training sample from the training data of a multilayer perceptron.

get_sample_class_mlp reads out a training sample from the multilayer perceptron (MLP) given by MLPHandle that was added with add_sample_class_mlp or read_samples_class_mlp. The index of the sample is specified with IndexSample. The index is counted from 0, i.e., IndexSample must be a number between 0 and NumSamples − 1, where NumSamples can be determined with get_sample_num_class_mlp. The training sample is returned in Features and Target. Features is a feature vector of length NumInput, while Target is a target vector of length NumOutput (see add_sample_class_mlp and create_class_mlp).

get_sample_class_mlp can, for example, be used to reclassify the training data with classify_class_mlp in order to determine which training samples, if any, are classified incorrectly.

Parameters

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

▷ **IndexSample** (input_control) ..... integer ⇝ *integer*
Number of stored training sample.

▷ **Features** (output_control) . . . . . real-array ⇝ *real*
Feature vector of the training sample.

▷ **Target** (output_control) . . . . . real-array ⇝ *real*
Target vector of the training sample.

Example

```
* Train an MLP
create_class_mlp (NumIn, NumHidden, NumOut, 'softmax', \
                  'canonical_variates', NumComp, 42, MLPHandle)
read_samples_class_mlp (MLPHandle, 'samples.mtf')
train_class_mlp (MLPHandle, 100, 1, 0.01, Error, ErrorLog)
* Reclassify the training samples
get_sample_num_class_mlp (MLPHandle, NumSamples)
for I := 0 to NumSamples-1 by 1
    get_sample_class_mlp (MLPHandle, I, Data, Target)
    classify_class_mlp (MLPHandle, Data, 1, Class, Confidence)
    Result := gen_tuple_const(NumOut,0)
    Result[Class] := 1
    Diffs := Target-Result
    if (sum(fabs(Diffs)) > 0)
        * Sample has been classified incorrectly
    endif
endfor
```

Result

If the parameters are valid, the operator `get_sample_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_sample_num_class_mlp (: : MLPHandle : NumSamples)

Return the number of training samples stored in the training data of a multilayer perceptron.

`get_sample_num_class_mlp` returns in `NumSamples` the number of training samples that are stored in the multilayer perceptron (MLP) given by `MLPHandle`. `get_sample_num_class_mlp` should be called before the individual training samples are accessed with `get_sample_class_mlp`, e.g., for the purpose of reclassifying the training data (see `get_sample_class_mlp`).

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

▷ **NumSamples** (output_control) . . . . . integer ⇝ *integer*
Number of stored training samples.

Result

If MLPHandle is valid, the operator get_sample_num_class_mlp returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

read_class_mlp (: : FileName : MLPHandle)

Read a multilayer perceptron from a file.

read_class_mlp reads a multilayer perceptron (MLP) that has been stored with write_class_mlp. Since the training of an MLP can consume a relatively long time, the MLP is typically trained in an offline process and written to a file with write_class_mlp. In the online process the MLP is read with read_class_mlp and subsequently used for evaluation with evaluate_class_mlp or for classification with classify_class_mlp. The default HALCON file extension for the MLP classifier is 'gmc'.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
File extension: .gmc

▷ **MLPHandle** (output_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

Result

If the parameters are valid, the operator read_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_class_mlp, write_class_mlp

Module

Foundation

read_samples_class_mlp (: : MLPHandle, FileName :)

Read the training data of a multilayer perceptron from a file.

read_samples_class_mlp reads training samples from the file given by FileName and adds them to the training samples that have already been added to the multilayer perceptron (MLP) given by MLPHandle. The MLP must be created with create_class_mlp before calling read_samples_class_mlp. As described with train_class_mlp and write_samples_class_mlp, the operators read_samples_class_mlp, add_sample_class_mlp, and write_samples_class_mlp can be used to build up a extensive set of training samples, and hence to improve the performance of the MLP by retraining the MLP with extended data sets.

It should be noted that the training samples must have the correct dimensionality. The feature vectors and target vectors stored in FileName must have the lengths NumInput and NumOutput that were specified with create_class_mlp. If this is not the case an error message is returned.

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.

Result

If the parameters are valid, the operator read_samples_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MLPHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

select_feature_set_mlp (: : ClassTrainDataHandle, SelectionMethod, GenParamName, GenParamValue : MLPHandle, SelectedFeatureIndices, Score)

Selects an optimal combination of features to classify the provided data.

select_feature_set_mlp selects an optimal subset from a set of features to solve a given classification problem. The classification problem has to be specified with annotated training data in ClassTrainDataHandle and will be classified by a Multilayer Perceptron. Details of the properties of this classifier can be found in create_class_mlp.

The result of the operator is a trained classifier that is returned in MLPHandle. Additionally, the list of indices or names of the selected features is returned in SelectedFeatureIndices. To use this classifier, calculate for new input data all features mentioned in SelectedFeatureIndices and pass them to the classifier.

A possible application of this operator can be a comparison of different parameter sets for certain feature extraction techniques. Another application is to search for a feature that is discriminating between different classes.

To define the features that should be selected from ClassTrainDataHandle, the dimensions of the feature vectors in ClassTrainDataHandle can be grouped into subfeatures by calling set_feature_lengths_class_train_data. A subfeature can contain several subsequent elements of a feature vector. select_feature_set_mlp decides for each of these subfeatures, if it is better to use it for the classification or leave it out.

The indices of the selected subfeatures are returned in SelectedFeatureIndices. If names were set in set_feature_lengths_class_train_data, these names are returned instead of the indices. If set_feature_lengths_class_train_data was not called for ClassTrainDataHandle before, each element of the feature vector is considered as a subfeature.

The selection method SelectionMethod is either a greedy search *'greedy'* (iteratively add the feature with highest gain) or the dynamically oscillating search *'greedy_oscillating'* (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method *'greedy'* is generally preferable, since it is faster. Only in cases when the subfeatures are low-dimensional or redundant, the method *'greedy_oscillating'* should be chosen.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in Score.

With GenParamName and GenParamValue the number of hidden layer can be set by *'num_hidden'*. The default value is *80*. Larger values for this parameter lead to longer classification times, while it allows a more expressive classifier.

Attention

This operator may take considerable time, depending on the size of the data and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_mlp may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data.

▷ **SelectionMethod** (input_control) . . . . . string ⇝ *string*
Method to perform the selection.
Default: 'greedy'
List of values: SelectionMethod ∈ {'greedy', 'greedy_oscillating'}

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Names of generic parameters to configure the selection process and the classifier.
Default: []
List of values: GenParamName ∈ {'num_hidden'}

▷ **GenParamValue** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Values of generic parameters to configure the selection process and the classifier.
Default: []
Suggested values: GenParamValue ∈ {50, 80, 100}

▷ **MLPHandle** (output_control) . . . . . class_mlp ⇝ *handle*
A trained MLP classifier using only the selected features.

▷ **SelectedFeatureIndices** (output_control) . . . . . string-array ⇝ *string*
The selected feature set, contains indices referring.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
The achieved score using two-fold cross-validation.

Example

```
* Find out which of the two features distinguishes two Classes
NameFeature1 := 'Good Feature'
NameFeature2 := 'Bad Feature'
LengthFeature1 := 3
LengthFeature2 := 2
* Create training data
create_class_train_data (LengthFeature1+LengthFeature2,\
  ClassTrainDataHandle)
* Define the features which are in the training data
set_feature_lengths_class_train_data (ClassTrainDataHandle, [LengthFeature1,\
  LengthFeature2], [NameFeature1, NameFeature2])
* Add training data
*                                                        |Feat1| |Feat2|
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  2,1  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  2,1  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  3,4  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  3,4  ], 1)
* Add more data
* ...
* Select the better feature with a MLP
select_feature_set_mlp (ClassTrainDataHandle, 'greedy', [], [], MLPHandle,\
  SelectedFeatureMLP, Score)
* Use the classifier
* ...
```

Result

If the parameters are valid, the operator `select_feature_set_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

serialize_class_mlp (: : MLPHandle : SerializedItemHandle)

Serialize a multilayer perceptron (MLP).

serialize_class_mlp serializes a multilayer perceptron (MLP) and its stored training samples (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_class_mlp and write_samples_class_mlp is converted to a serialized item. The multilayer perceptron is defined by the handle MLPHandle. The serialized multilayer perceptron is returned by the handle SerializedItemHandle and can be deserialized by deserialize_class_mlp.

Parameters

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_regularization_params_class_mlp (: : MLPHandle, GenParamName, GenParamValue :)

Set the regularization parameters of a multilayer perceptron.

set_regularization_params_class_mlp sets the regularization parameters of the multilayer perceptron (MLP) passed in MLPHandle. The regularization parameter to be set is specified with GenParamName. Its value is specified with GenParamValue.

GenParamName can assume the following values:

'num_outer_iterations': This parameter determines whether the regularization parameters should be determined automatically (GenParamValue >= 1) or manually (GenParamValue = 0, default), as described below in the sections "Technical Background" and "Automatic Determination of the Regularization Parameters". As described in detail in the section "Automatic Determination of the Regularization Parameters", *'num_outer_iterations'* should not be set too large (in the range of 1 to 5) to enable manual checking of the convergence of the automatic determination of the regularization parameters.

'num_inner_iterations': This parameter potentially enables somewhat faster convergence of the automatic determination of the regularization parameters, as described below in the section "Automatic Determination of the Regularization Parameters". It should typically be left at its default value of 1.

'weight_prior': On the one hand, this selects the regularization model to be used, as described below in the section "Technical Background". On the other hand, if manual determination of the regularization parameters has been selected (i.e., *'num_outer_iterations'* = 0), the regularization parameters are set with GenParamName, whereas the initial values of the regularization parameters are set if automatic determination of the regularization parameters has been selected (i.e., *'num_outer_iterations'* >= 1), as described below in the section "Automatic Determination of the Regularization Parameters". Manual determination of the regularization parameters (see the section "Regularization Parameters" below) is only realistic if a single regularization parameter is used. In all other cases, the regularization parameters should be determined automatically.

'noise_prior': This allows to specify a noise prior for MLPs that have been configured for regression, as described below in the section "Application Areas". If manual determination of the regularization parameters has been selected, the noise prior is set with GenParamName, whereas the initial value of the noise prior is set if automatic determination of the regularization parameters has been selected. Typically, it is only useful to use this parameter if the regularization parameters are determined automatically.

Please note that the automatic determination of the regularization parameters requires a very large amount of memory and runtime, as described in detail in the section "Complexity" below. Therefore, NumHidden should not be selected too large when the MLP is created with create_class_mlp. For example, normal OCR applications seldom require NumHidden to be larger than 30-60.

Application Areas

As described at create_class_mlp, it may be desirable to regularize the MLP to enforce a smoother transition of the confidences between the different classes and to prevent overfitting of the MLP to the training data. To achieve this, a penalty for large MLP weights (which are the main reason for very sharp transitions between classes) can be added to the training of the MLP in train_class_mlp by setting GenParamName to *'weight_prior'* and setting GenParamValue to a value > 0.

If the MLP has been configured for regression (i.e., if OutputFunction was set to *'linear'* in create_class_mlp), an inverse variance of the expected noise in the data can be specified by setting GenParamName to *'noise_prior'* and setting GenParamValue to a value > 0. Setting the noise prior only has an effect if a weight prior has been specified. In this case, it can be used to weight the data error term (the output error of the MLP) against the weight error term.

As described in more detail below, the regularization parameters of the MLP may be determined automatically (at the expense of significantly increased training times) by setting GenParamName to *'num_outer_iterations'* and setting GenParamValue to a value > 0.

Technical Background

There are three different kinds of penalty terms that can be set with *'weight_prior'*. Note that in the following the parameters $w_{ji}^{(l)}$ and $b_k^{(l)}$ refer to the weights of the different layers of the MLP, as described in create_class_mlp.

If a single value α is specified, all MLP weights are penalized equally by adding the following term to the optimization in train_class_mlp:

$$E_W = \frac{\alpha}{2}\left(\sum_{i=1}^{n_i}\sum_{j=1}^{n_h}\left(w_{ji}^{(1)}\right)^2 + \sum_{j=1}^{n_h}\left(b_j^{(1)}\right)^2 + \sum_{j=1}^{n_h}\sum_{k=1}^{n_o}\left(w_{kj}^{(2)}\right)^2 + \sum_{k=1}^{n_o}\left(b_k^{(2)}\right)^2\right)$$

Alternatively, four values $[\alpha_{w1}, \alpha_{b1}, \alpha_{w2}, \alpha_{b2}]$ can be specified. These four parameters enable the individual regularization of the four groups of weights:

$$E_W = \frac{\alpha_{w1}}{2}\sum_{i=1}^{n_i}\sum_{j=1}^{n_h}\left(w_{ji}^{(1)}\right)^2 + \frac{\alpha_{b1}}{2}\sum_{j=1}^{n_h}\left(b_j^{(1)}\right)^2 + \frac{\alpha_{w2}}{2}\sum_{j=1}^{n_h}\sum_{k=1}^{n_o}\left(w_{kj}^{(2)}\right)^2 + \frac{\alpha_{b2}}{2}\sum_{k=1}^{n_o}\left(b_k^{(2)}\right)^2$$

Finally, $n_i + 3$ values $[\alpha_1, \ldots, \alpha_{n_i}, \alpha_{b1}, \alpha_{w2}, \alpha_{b2}]$ can be specified. These $n_i + 3$ parameters enable the individual regularization of each input variable $x_1, \ldots, x_{n_i}$ and the regularization of the remaining three groups of weights:

$$E_W = \sum_{i=1}^{n_i}\frac{\alpha_i}{2}\sum_{j=1}^{n_h}\left(w_{ji}^{(1)}\right)^2 + \frac{\alpha_{b1}}{2}\sum_{j=1}^{n_h}\left(b_j^{(1)}\right)^2 + \frac{\alpha_{w2}}{2}\sum_{j=1}^{n_h}\sum_{k=1}^{n_o}\left(w_{kj}^{(2)}\right)^2 + \frac{\alpha_{b2}}{2}\sum_{k=1}^{n_o}\left(b_k^{(2)}\right)^2$$

This kind of regularization is only useful in conjunction with the automatic determination of the regularization parameters described below. If the automatic determination of the regularization parameters returns a very large value of α_j (compared to the smallest value of the n_i values α_i), the corresponding input variable has little relevance for the MLP output. If this is the case, it should be tested whether the input variable can be omitted from the input of the MLP without negatively affecting the MLP's performance. The advantage of omitting irrelevant input variables is an increased speed of the MLP for classification.

The parameters α can be regarded as the inverse variance of a Gaussian prior distribution on the MLP weights, i.e., they express an expectation about the size of the MLP weights. The larger the α are chosen, the smaller the MLP weights will be.

Regularization Parameters

The larger the regularization parameter(s) *'weight_prior'* are chosen, the smoother the transition of the confidences between the different classes will be. The required values for the regularization parameter(s) depend on the MLP, especially the number of hidden units, the training data, and the scale of the training data (if no normalization is used). Typically, a higher value for the regularization parameter(s) is necessary if the MLP has more hidden units and if the training data consists of more points. For typical applications, the regularization parameters are determined by verifying the MLP performance on a test data set that is independent from the training data set. If an independent test data set is unavailable, cross validation can be used. Cross validation works by splitting the data set into separate parts (for example, 80% of the data set for training and 20% for testing), training the MLP with the training data set (the 80% of the data in the above example), and testing the MLP performance on the test set (the 20% of the data in the above example). The procedure can be repeated for the other possible splits of the data (in the 80%–20% example, there are five possible splits). This procedure can, for example, start with relatively large values of the weight regularization parameters (which will typically result in misclassifications on the test data set). The weight regularization parameters can then be decreased until an acceptable performance on the test data sets is reached.

Automatic Determination of the Regularization Parameters

The regularization parameters, i.e., the weight priors and the noise prior, can also be determined automatically by `train_class_mlp` using the so-called evidence procedure (for details about the evidence procedure, please refer to the articles in the section "References" below). This training mode can be selected by setting `GenParamName` to *'num_outer_iterations'* and setting `GenParamValue` to a value > 0. Note that this typically results in training times that are one to three orders of magnitude larger than simply training the MLP with fixed regularization parameters.

The evidence procedure is an iterative algorithm that performs the following two steps for a number of outer iterations: first, the network is trained using the current values of the regularization parameters; next, the regularization parameters are re-estimated using the weights of the optimized MLP. In the first iteration, the weight priors and noise priors specified with *'weight_prior'* and *'noise_prior'* are used. Thus, for the automatic determination of the regularization parameters, the values specified by the user serve as the starting parameters for the evidence procedure. The starting parameters for the weight priors should not be set too large because this might over-regularize the training and may result in badly determined regularization parameters. The initial values for the weight priors should typically be in the range 0.01-0.1.

The number of outer iterations can be set by setting `GenParamName` to *'num_outer_iterations'* and setting `GenParamValue` to a value > 0. If `GenParamValue` is set to 0 (this is the default value), the evidence procedure is not executed and the MLP is simply trained using the user-specified regularization parameters.

The number of outer iterations should be set high enough to ensure the convergence of the regularization parameters. In contrast to the training of the MLP's weights, a numerical convergence criterion is typically very difficult to specify and some human judgment is typically required to decide whether the regularization parameters have converged sufficiently. Therefore, it might not be possible to set the number of outer iterations a-priori to ensure convergence of the regularization parameters. In these cases, the outer loop over the steps of the evidence procedure can be implemented manually by setting *'num_outer_iterations'* to 1 and calling `train_class_mlp` repeatedly. This has the advantage that the weight priors and noise prior can be queried after each iteration and can be checked manually for convergence. In this approach, the performance of the MLP can even be checked after each iteration on an independent test set to check the generalization performance of the classifier.

If the number of outer iterations has been determined (approximately) for a class of applications, it may be possible to reduce the run time of the training (if MLPs should be trained in the future with similar data sets) by setting `GenParamName` to *'num_inner_iterations'* and setting `GenParamValue` to a value > 1 (the default value is 1) and by reducing the number of outer iterations. The number of outer iterations can typically not be reduced by the same factor by which the number of inner iterations is increased. Using this approach, the run time of the training

can be optimized. However, this approach is only useful if many MLPs are trained with similar data sets. If this is not the case, *'num_inner_iterations'* should be left at its default value of 1.

The automatically determined weight priors and noise prior can be queried after the training using `get_regularization_params_class_mlp` by setting `GenParamName` to *'weight_prior'* or *'noise_prior'*, respectively.

In addition to the weight prior and noise prior, the evidence procedure determines an estimate of the number of parameters of the MLP that can be determined well using the training data. This result can be queried using `get_regularization_params_class_mlp` by setting `GenParamName` to *'num_well_determined_params'*. Alternatively, the fraction of well-determined parameters can be queried by setting `GenParamName` to *'fraction_well_determined_params'*. If the number of well-determined parameters is significantly smaller than n_w (where n_w is the number of weights in the MLP, as described in the section "Complexity" below) or the fraction of well-determined parameters is significantly smaller than 1, consider reducing the number of hidden units or, if the number of hidden units cannot be decreased without increasing the error rate of the MLP significantly, consider performing a preprocessing that reduces the number of input variables to the net, i.e., canonical variates or principal components.

Please note that the number of well-determined parameters can only be determined after the weight priors and noise prior have been determined. This is the reason why the evidence procedure ends with the determination of the regularization parameters and not with the training of the MLP weights. Hence, after the evidence procedure the MLP will not have been trained with the latest regularization parameters. This should make no difference if they have converged. If you want the training to end with an optimization of the weights using the latest values of the regularization parameters, you can set *'num_outer_iterations'* to 0 and can call `train_class_mlp` again. If you do so, please note, however, that the number of well-determined parameters may change and, therefore, the value returned by `get_regularization_params_class_mlp` is technically inconsistent.

Saved Parameters

Note that the parameters *'num_outer_iterations'* and *'num_inner_iterations'* only affect the training of the MLP. Therefore, they are not saved when the MLP is stored using `write_class_mlp` or `serialize_class_mlp`. Thus, they must be set anew if the MLP is loaded again using `read_class_mlp` or `deserialize_class_mlp` and if training using the automatic determination of the regularization parameters should be continued. All other parameters described above (*'weight_prior'*, *'noise_prior'*, *'num_well_determined_params'*, and *'fraction_well_determined_params'*) are saved.

Parameters

▷ **`MLPHandle`** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

▷ **`GenParamName`** (input_control) ..... string ⇝ *string*
Name of the regularization parameter to set.
Default: 'weight_prior'
List of values: `GenParamName` ∈ {'weight_prior', 'noise_prior', 'num_outer_iterations', 'num_inner_iterations'}

▷ **`GenParamValue`** (input_control) ..... number(-array) ⇝ *real* / integer
Value of the regularization parameter.
Default: 1.0
Suggested values: `GenParamValue` ∈ {0.01, 0.1, 1.0, 10.0, 100.0, 0, 1, 2, 3, 5, 10, 15, 20}

Complexity

Let n_i denote the number of input units of the MLP (i.e., n_i = `NumHidden` or n_i = `NumComponents`, depending on the value of `Preprocessing`, as described at `create_class_mlp`), n_h the number of hidden units, and n_o the number of output units. Then, the number of weights of the MLP is $n_w = (n_i+1)n_h+(n_h+1)n_o$. Let n_d denote the number of training samples. Let n_M denote the number of iterations set with `MaxIterations` in `train_class_mlp`. Let n_O and n_I denote the number of outer and inner iterations, respectively.

The run time of the training without regularization or with regularization with fixed regularization parameters is of complexity $O(n_M n_w n_d)$. In contrast, the runtime of the training with automatic determination of the regularization parameters is of complexity

$O(n_O n_M n_w n_d) + O(n_O n_w^2 n_d) + O(n_O n_w^3) + O(n_O n_I n_w^3)$.

The training without regularization or with regularization with fixed regularization parameters requires at least $48n_w + 24n_h n_d + 16n_o n_d$ bytes of memory. The training with automatic determination of the regularization parameters requires at least $24n_w^2 + 48n_w + 72n_h n_d + 56n_o n_d$ bytes of memory. Under special circumstances, another $24n_w^2 + 8n_w$ bytes of memory are required.

Result

If the parameters are valid, the operator `set_regularization_params_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MLPHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_class_mlp`

Possible Successors

`get_regularization_params_class_mlp`, `train_class_mlp`

set_rejection_params_class_mlp (: : MLPHandle, GenParamName, GenParamValue :)

Set the parameters of a rejection class.

set_rejection_params_class_mlp sets the parameters of an automatically generated rejection class inside of a multilayer perceptron (MLP) given by MLPHandle. In some applications, it is desirable to know whether a feature vector is similar to one of the training set. If a feature vector lies outside of the provided training set, it should be classified as a special rejection class. This means that the feature vector is different to the confidence area of the classifier. If a rejection class should be created automatically, an additional class must be specified while creating the classifier in create_class_mlp. Here, the parameter NumOutput must be increased by one.

The parameters of the rejection class are selected with GenParamName and the respective values with GenParamValue.

'rejection_class_index': By default, the last class serves as the rejection class. If another class should be used, GenParamName must be set to *'rejection_class_index'* and GenParamValue to the class index.

'sampling_strategy': Currently, three strategies exist to generate samples for the rejection class during the training of the MLP. These strategies can be selected by setting GenParamName to *'sampling_strategy'* and GenParamValue to *'hyperbox_around_all_classes'*, *'hyperbox_around_each_class'*, or *'hyperbox_ring_around_each_class'*. The sampling strategy *'hyperbox_around_all_classes'* takes the bounding box of all training samples that have been provided so far. The sampling strategy *'hyperbox_around_each_class'* is similar with the only difference that the bounding box around each class is taken as the area where the rejection samples are generated. The sampling strategy *'hyperbox_ring_around_each_class'* generates samples only in the enlarged areas around the bounding box of each class, thus generating a hyperbox ring around the original samples. Please note that with increasing dimensionality the sampling strategies *'hyperbox_around_each_class'* and *'hyperbox_ring_around_each_class'* provide the same result. If no rejection class sampling strategy should be used, which is the default, GenParamValue must be set to *'no_rejection_class'*.

'hyperbox_tolerance': The factor *'hyperbox_tolerance'* describes by what amount the bounding box should be enlarged in all dimensions. Then, inside this box samples are randomly generated from a uniform distribution. The default value is 0.2.

'rejection_sample_factor': The number of rejection samples is the number of provided samples multiplied by *'rejection_sample_factor'*. If not enough samples are generated, the rejection class may not be classified correctly. If the rejection class has too many samples, the normal classes are classified as rejection class. The default value is 1.0. Note that the training time will increase by a factor of $1 + f$, where f is the value of *'rejection_sample_factor'*.

'random_seed': To ensure reproducible results, a random seed can be set with *'random_seed'*. The default value is 42.

Because this operator only parametrizes the training of the MLP, the values are not saved by write_class_mlp.

Parameters

train_class_mlp

Module

Foundation

train_class_mlp (: : MLPHandle, MaxIterations, WeightTolerance, ErrorTolerance : Error, ErrorLog)

Train a multilayer perceptron.

train_class_mlp trains the multilayer perceptron (MLP) given in MLPHandle. Before the MLP can be trained, *all* training samples to be used for the training must be stored in the MLP using add_sample_class_mlp or read_samples_class_mlp. If after the training new additional training samples should be used a new MLP must be created with create_class_mlp, in which again *all* training samples to be used (i.e., the original ones and the additional ones) must be stored. In these cases, it is useful to save and read the training data with write_samples_class_mlp and read_samples_class_mlp, respectively. A second training with additional training samples is not explicitly forbidden by train_class_mlp. However, this typically does not lead to good results because the training of an MLP is a complex nonlinear optimization problem, and consequently the second training with new data will very likely lead to the fact that the optimization gets stuck in a local minimum.

If a rejection class has been specified using set_rejection_params_class_mlp, before the actual training the samples for the rejection class are generated.

During the training, the error the MLP achieves on the stored training samples is minimized by using a nonlinear optimization algorithm. If the MLP has been regularized with set_regularization_params_class_mlp, an additional weight penalty term is taken into account. With this, the MLP weights described in create_class_mlp are determined. Furthermore, if an automatic determination of the regularization parameters has been specified with set_regularization_params_class_mlp, these parameters are optimized as well. As described at set_regularization_params_class_mlp, training the MLP with automatic determination of the regularization parameters requires significantly more time than training an unregularized MLP or an MLP with fixed regularization parameters.

create_class_mlp initializes the MLP weights with random values to make it very likely that the optimization converges to the global minimum of the error function. Nevertheless, in rare cases it may happen that the random values determined with RandSeed in create_class_mlp result in a relatively large optimum error, i.e., that the optimization gets stuck in a local minimum. If it can be conjectured that this has happened the MLP should be created anew with a different value for RandSeed in order to check whether a significantly smaller error can be achieved.

The parameters MaxIterations, WeightTolerance, and ErrorTolerance control the nonlinear optimization algorithm. Note that if an automatic determination of the regularization parameters has been specified with set_regularization_params_class_mlp, these parameters refer to one training within one step of the evidence procedure. MaxIterations specifies the maximum number of iterations of the optimization algorithm. In practice, values between *100* and *200* should be sufficient for most problems. WeightTolerance specifies a threshold for the change of the weights per iteration. Here, the absolute value of the change of the weights between two iterations is summed. Hence, this value depends on the number of weights as well as the size of the weights, which in turn depend on the scaling of the training data. Typically, values between *0.00001* and *1* should be used. ErrorTolerance specifies a threshold for the change of the error value per iteration. This

value depends on the number of training samples as well as the number of output variables of the MLP. Also here, values between *0.00001* and *1* should typically be used. The optimization is terminated if the weight change is smaller than `WeightTolerance` and the change of the error value is smaller than `ErrorTolerance`. In any case, the optimization is terminated after at most `MaxIterations` iterations. It should be noted that, depending on the size of the MLP and the number of training samples, the training can take from a few seconds to several hours.

On output, `train_class_mlp` returns the error of the MLP with the optimal weights on the training samples in `Error`. Furthermore, `ErrorLog` contains the error value as a function of the number of iterations. With this, it is possible to decide whether a second training of the MLP with the same training data without creating the MLP anew makes sense. If `ErrorLog` is regarded as a function, it should drop off steeply initially, while leveling out very flatly at the end. If `ErrorLog` is still relatively steep at the end, it usually makes sense to call `train_class_mlp` again. It should be noted, however, that this mechanism should *not* be used to train the MLP successively with `MaxIterations` = *1* (or other small values for `MaxIterations`) because this will substantially increase the number of iterations required to train the MLP. Note that if an automatic determination of the regularization parameters has been specified with `set_regularization_params_class_mlp`, `Error` and `ErrorLog` refer to the last training that was executed in the evidence procedure. If the error log should be monitored within the individual iterations of the evidence procedure, the outer iteration of the evidence procedure must be implemented explicitly, as described at `set_regularization_params_class_mlp`.

Parameters

- ▷ **`MLPHandle`** (input_control) ..... class_mlp ⇝ *handle*
  MLP handle.
- ▷ **`MaxIterations`** (input_control) ..... integer ⇝ *integer*
  Maximum number of iterations of the optimization algorithm.
  Default: 200
  Suggested values: `MaxIterations` ∈ {20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300}
- ▷ **`WeightTolerance`** (input_control) ..... real ⇝ *real*
  Threshold for the difference of the weights of the MLP between two iterations of the optimization algorithm.
  Default: 1.0
  Suggested values: `WeightTolerance` ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
  Restriction: WeightTolerance >= 1.0e-8
- ▷ **`ErrorTolerance`** (input_control) ..... real ⇝ *real*
  Threshold for the difference of the mean error of the MLP on the training data between two iterations of the optimization algorithm.
  Default: 0.01
  Suggested values: `ErrorTolerance` ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
  Restriction: ErrorTolerance >= 1.0e-8
- ▷ **`Error`** (output_control) ..... real ⇝ *real*
  Mean error of the MLP on the training data.
- ▷ **`ErrorLog`** (output_control) ..... real-array ⇝ *real*
  Mean error of the MLP on the training data as a function of the number of iterations of the optimization algorithm.

Example

```
* Train an MLP
create_class_mlp (NumIn, NumHidden, NumOut, 'softmax', \
                  'normalization', 1, 42, MLPHandle)
read_samples_class_mlp (MLPHandle, 'samples.mtf')
train_class_mlp (MLPHandle, 100, 1, 0.01, Error, ErrorLog)
write_class_mlp (MLPHandle, 'classifier.mlp')
```

Result

If the parameters are valid, the operator `train_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

`train_class_mlp` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- MLPHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

`write_class_mlp` (: : MLPHandle, FileName :)

Write a multilayer perceptron to a file.

`write_class_mlp` writes the multilayer perceptron (MLP) `MLPHandle` to the file given by `FileName`. The default HALCON file extension for the MLP classifier is 'gmc'. `write_class_mlp` is typically called after the MLP has been trained with `train_class_mlp`. The MLP can be read with `read_class_mlp`. `write_class_mlp` does *not* write any training samples that possibly have been stored in the MLP. For this purpose, `write_samples_class_mlp` should be used.

Parameters

▷ **`MLPHandle`** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

▷ **`FileName`** (input_control) . . . . . filename.write ⇝ *string*
File name.
File extension: `.gmc`

Result

If the parameters are valid, the operator `write_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

write_samples_class_mlp (: : MLPHandle, FileName :)

Write the training data of a multilayer perceptron to a file.

write_samples_class_mlp writes the training samples stored in the multilayer perceptron (MLP) MLPHandle to the file given by FileName. write_samples_class_mlp can be used to build up a database of training samples, and hence to improve the performance of the MLP by training it with an extended data set (see train_class_mlp). For other possible uses of write_samples_class_mlp see get_prep_info_class_mlp.

The file FileName is overwritten by write_samples_class_mlp. Nevertheless, extending the database of training samples is easy to do because read_samples_class_mlp and add_sample_class_mlp add the training samples to the training samples that are already stored in memory with the MLP.

Parameters

▷ **MLPHandle** (input_control) . . . . . class_mlp ⇝ *handle*
MLP handle.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name.

Result

If the parameters are valid, the operator write_samples_class_mlp returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

7.6 Support Vector Machines

add_class_train_data_svm (: : SVMHandle,
ClassTrainDataHandle :)

Add training data to a support vector machine (SVM).

add_class_train_data_svm adds the training data specified by ClassTrainDataHandle to a support vector machine (SVM) specified by SVMHandle.

Parameters

▷ **SVMHandle** (input_control) . . . . . class_svm ⇝ *handle*
Handle of a SVM which receives the training data.

▷ **ClassTrainDataHandle** (input_control) . . . . . class_train_data ⇝ *handle*
Training data for a classifier.

Result

If the parameters are valid, the operator add_class_train_data_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SVMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

add_sample_class_svm (: : SVMHandle, Features, Class :)

Add a training sample to the training data of a support vector machine.

add_sample_class_svm adds a training sample to the support vector machine (SVM) given by SVMHandle. The training sample is given by Features and Class. Features is the feature vector of the sample, and consequently must be a real vector of length NumFeatures, as specified in create_class_svm. Class is the target of the sample, which must be in the range of 0 to NumClasses-1 (see create_class_svm). In the special case of *'novelty-detection'* the class is to be set to *0* as only one class is assumed. Before the SVM can be trained with train_class_svm, training samples must be added to the SVM with add_sample_class_svm. The usage of support vectors of an already trained SVM as training samples is described in train_class_svm.

The number of currently stored training samples can be queried with get_sample_num_class_svm. Stored training samples can be read out again with get_sample_class_svm.

Normally, it is useful to save the training samples in a file with write_samples_class_svm to facilitate reusing the samples and to facilitate that, if necessary, new training samples can be added to the data set, and hence to facilitate that a *newly created* SVM can be trained with the extended data set.

Parameters

▷ **SVMHandle** (input_control) . . . . . class_svm ⇝ *handle*
SVM handle.

▷ **Features** (input_control) . . . . . real-array ⇝ *real*
Feature vector of the training sample to be stored.

▷ **Class** (input_control) . . . . . number ⇝ *integer* / real
Class of the training sample to be stored.

Result

If the parameters are valid the operator `add_sample_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SVMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

`clear_samples_class_svm`, `get_support_vector_class_svm`

Module

Foundation

classify_class_svm (: : SVMHandle, Features, Num : Class)

Classify a feature vector by a support vector machine.

`classify_class_svm` computes the best `Num` classes of the feature vector `Features` with the SVM `SVMHandle` and returns them in `Class`. If the classifier was created in the `Mode` = *'one-versus-one'*, the classes are ordered by the number of votes of the sub-classifiers. If `Mode` = *'one-versus-all'* was used, the classes are ordered by the value of each sub-classifier (see `create_class_svm` for more details). If the classifier was created in the `Mode` = *'novelty-detection'*, it determines whether the feature vector belongs to the same class as the training data (`Class` = 1) or is regarded as outlier (`Class` = 0). In this case `Num` must be set to 1 as the classifier only determines membership.

Before calling `classify_class_svm`, the SVM must be trained with `train_class_svm`.

Parameters

▷ **SVMHandle** (input_control) . . . . . class_svm ⇝ *handle*
SVM handle.

▷ **Features** (input_control) . . . . . real-array ⇝ *real*
Feature vector.

▷ **Num** (input_control) . . . . . integer-array ⇝ *integer*
Number of best classes to determine.
Default: 1
Suggested values: Num ∈ {1, 2, 3, 4, 5}

▷ **Class** (output_control) . . . . . integer(-array) ⇝ *integer*
Result of classifying the feature vector with the SVM.

Result

If the parameters are valid the operator classify_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

clear_class_svm (: : SVMHandle :)

Clear a support vector machine.

clear_class_svm clears the support vector machine (SVM) given by SVMHandle and frees all memory required for the SVM. After calling clear_class_svm, the SVM can no longer be used. The handle SVMHandle becomes invalid.

Parameters

▷ **SVMHandle** (input_control) . . . . . class_svm(-array) ⇝ *handle*
SVM handle.

Result

If SVMHandle is valid the operator clear_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SVMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

clear_samples_class_svm (: : SVMHandle :)

Clear the training data of a support vector machine.

clear_samples_class_svm clears all training samples that have been added to the support vector machine (SVM) SVMHandle with add_sample_class_svm or read_samples_class_svm. clear_samples_class_svm should only be used if the SVM is trained in the same process that uses the SVM for classification with classify_class_svm. In this case, the memory required for the training samples can be freed with clear_samples_class_svm, and hence memory can be saved. In the normal usage, in which the SVM is trained offline and written to a file with write_class_svm, it is typically unnecessary to call clear_samples_class_svm because write_class_svm does not save the training samples, and hence the online process, which reads the SVM with read_class_svm, requires no memory for the training samples.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm(-array) ⇝ *handle*
SVM handle.

Result

If the parameters are valid the operator clear_samples_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SVMHandle

Module

Foundation

create_class_svm (: : NumFeatures, KernelType, KernelParam, Nu, NumClasses, Mode, Preprocessing, NumComponents : SVMHandle)

Create a support vector machine for pattern classification.

create_class_svm creates a support vector machine that can be used for pattern classification. The dimension of the patterns to be classified is specified in NumFeatures, the number of different classes in NumClasses.

For a binary classification problem in which the classes are linearly separable the SVM algorithm selects data vectors from the training set that are utilized to construct the optimal separating hyperplane between different classes. This hyperplane is optimal in the sense that the margin between the convex hulls of the different classes is maximized. The training patterns that are located at the margin define the hyperplane and are called *support vectors* (SV).

Classification of a feature vector z is performed with the following formula:

$$f(z) \quad = \quad sign\left(\sum_{i=1}^{n_{sv}} \alpha_i y_i < x_i, z > +b\right)$$

Here, x_i are the support vectors, y_i encodes their class membership (± 1) and α_i the weight coefficients. The distance of the hyperplane to the origin is b. The α and b are determined during training with `train_class_svm`. Note that only a subset of the original training set (n_{sv}: number of support vectors) is necessary for the definition of the decision boundary and therefore data vectors that are not support vectors are discarded. The classification speed depends on the evaluation of the dot product between support vectors and the feature vector to be classified, and hence depends on the length of the feature vector and the number n_{sv} of support vectors.

For classification problems in which the classes are not linearly separable the algorithm is extended in two ways. First, during training a certain amount of errors (overlaps) is compensated with the use of slack variables. This means that the α are upper bounded by a regularization constant. To enable an intuitive control of the amount of training errors, the *Nu*-SVM version of the training algorithm is used. Here, the regularization parameter `Nu` is an asymptotic upper bound on the number of training errors and an asymptotic lower bound on the number of support vectors. As a rule of thumb, the parameter `Nu` should be set to the prior expectation of the application's specific error ratio, e.g., *0.01* (corresponding to a maximum training error of 1%). Please note that a too big value for `Nu` might lead to an infeasible training problem, i.e., the SVM cannot be trained correctly (see `train_class_svm` for more details). Since this can only be determined during training, an exception can only be raised there. In this case, a new SVM with `Nu` chosen smaller must be created.

Second, because the above SVM exclusively calculates dot products between the feature vectors, it is possible to incorporate a kernel function into the training and testing algorithm. This means that the dot products are substituted by a kernel function, which implicitly performs the dot product in a higher dimensional feature space. Given the appropriate kernel transformation, an originally not linearly separable classification task becomes linearly separable in the higher dimensional feature space.

Different kernel functions can be selected with the parameter `KernelType`. For `KernelType` = *'linear'* the dot product, as specified in the above formula is calculated. This kernel should solely be used for linearly or nearly linearly separable classification tasks. The parameter `KernelParam` is ignored here.

The radial basis function (RBF) `KernelType` = *'rbf'* is the best choice for a kernel function because it achieves good results for many classification tasks. It is defined as:

$$K(x,z) \quad = \quad e^{-\gamma \cdot \left\|x-z\right\|^2}$$

Here, the parameter `KernelParam` is used to select γ. The intuitive meaning of γ is the amount of influence of a support vector upon its surroundings. A big value of γ (small influence on the surroundings) means that each training vector becomes a support vector. The training algorithm learns the training data "by heart", but lacks any generalization ability (over-fitting). Additionally, the training/classification times grow significantly. A too small value for γ (big influence on the surroundings) leads to few support vectors defining the separating hyperplane (under-fitting). One typical strategy is to select a small γ-`Nu` pair and consecutively increase the values as long as the recognition rate increases.

With `KernelType` = *'polynomial_homogeneous'* or *'polynomial_inhomogeneous'*, polynomial kernels can be selected. They are defined in the following way:

$$\begin{aligned} K(x,z) &= (< x,z >)^d \\ K(x,z) &= (< x,z > +1)^d \end{aligned}$$

The degree of the polynomial kernel must be set with `KernelParam`. Please note that a too high degree polynomial ($d > 10$) might result in numerical problems.

As a rule of thumb, the RBF kernel provides a good choice for most of the classification problems and should therefore be used in almost all cases. Nevertheless, the linear and polynomial kernels might be better suited for certain applications and can be tested for comparison. Please note that the novelty-detection Mode and the operator reduce_class_svm are provided only for the RBF kernel.

Mode specifies the general classification task, which is either how to break down a multi-class decision problem to binary sub-cases or whether to use a special classifier mode called *'novelty-detection'*. Mode = *'one-versus-all'* creates a classifier where each class is compared to the rest of the training data. During testing the class with the largest output (see the classification formula without sign) is chosen. Mode = *'one-versus-one'* creates a binary classifier between each single class. During testing a vote is cast and the class with the majority of the votes is selected. The optimal Mode for multi-class classification depends on the number of classes. Given n classes *'one-versus-all'* creates n classifiers, whereas *'one-versus-one'* creates $n(n-1)/2$. Note that for a binary decision task *'one-versus-one'* would create exactly one, whereas *'one-versus-all'* unnecessarily creates two symmetric classifiers. For few classes (approximately up to 10) *'one-versus-one'* is faster for training and testing, because the sub-classifier all consist of fewer training data and result in overall fewer support vectors. In case of many classes *'one-versus-all'* is preferable, because *'one-versus-one'* generates a prohibitively large amount of sub-classifiers, as their number increases to the square of the number of classes.

A special case of classification is Mode = *'novelty-detection'*, where the test data is classified only with regard to membership to the training data, i.e., NumClasses must be set to 1. The separating hyperplane lies around the training data and thereby implicitly divides the training data from the rejection class. The advantage is that the rejection class is not defined explicitly, which is difficult to do in certain applications like texture classification. The resulting support vectors are all lying at the border. With the parameter Nu, the ratio of outliers in the training data set is specified. Note, that when classifying in the *'novelty-detection'* mode, the class of the training data is returned with index 1 and the rejection class is returned with index 0. Thus, the first class serves as rejection class. In contrast, when using the MLP classifier, the last class serves as rejection class by default.

The parameters Preprocessing and NumComponents can be used to specify a preprocessing of the feature vectors. For Preprocessing = *'none'*, the feature vectors are passed unaltered to the SVM. NumComponents is ignored in this case.

For all other values of Preprocessing, the training data set is used to compute a transformation of the feature vectors during the training as well as later in the classification.

For Preprocessing = *'normalization'*, the feature vectors are normalized. In case of a polynomial kernel, the minimum and maximum value of the training data set is transformed to -1 and +1. In case of the RBF kernel, the data is normalized by subtracting the mean of the training vectors and dividing the result by the standard deviation of the individual components of the training vectors. Hence, the transformed feature vectors have a mean of 0 and a standard deviation of 1. The normalization does not change the length of the feature vector. NumComponents is ignored in this case. This transformation can be used if the mean and standard deviation of the feature vectors differs substantially from 0 and 1, respectively, or for data in which the components of the feature vectors are measured in different units (e.g., if some of the data are gray value features and some are region features, or if region features are mixed, e.g., 'circularity' (unit: scalar) and 'area' (unit: pixel squared)). The normalization transformation should be performed in general, because it increases the numerical stability during training/testing.

For Preprocessing = *'principal_components'*, a principal component analysis (PCA) is performed. First, the feature vectors are normalized (see above). Then, an orthogonal transformation (a rotation in the feature space) that decorrelates the training vectors is computed. After the transformation, the mean of the training vectors is 0 and the covariance matrix of the training vectors is a diagonal matrix. The transformation is chosen such that the transformed features that contain the most variation is contained in the first components of the transformed feature vector. With this, it is possible to omit the transformed features in the last components of the feature vector, which typically are mainly influenced by noise, without losing a large amount of information. The parameter NumComponents can be used to determine how many of the transformed feature vector components should be used. Up to NumFeatures components can be selected. The operator get_prep_info_class_svm can be used to determine how much information each transformed component contains. Hence, it aids the selection of NumComponents. Like data normalization, this transformation can be used if the mean and standard deviation of the feature vectors differs substantially from 0 and 1, respectively, or for feature vectors in which the components of the data are measured in different units. In addition, this transformation is useful if it can be expected that the features are highly correlated. Please note that the RBF kernel is very robust against the dimensionality reduction performed by PCA and should therefore be the first choice when speeding up the classification time.

The transformation specified by Preprocessing = *'canonical_variates'* first normalizes the training vectors and then decorrelates the training vectors on average over all classes. At the same time, the transformation maxi-

mally separates the mean values of the individual classes. As for Preprocessing = *'principal_components'*, the transformed components are sorted by information content, and hence transformed components with little information content can be omitted. For canonical variates, up to min(NumClasses−1, NumFeatures) components can be selected. Also in this case, the information content of the transformed components can be determined with get_prep_info_class_svm. Like principal component analysis, canonical variates can be used to reduce the amount of data without losing a large amount of information, while additionally optimizing the separability of the classes after the data reduction. The computation of the canonical variates is also called linear discriminant analysis.

For the last two types of transformations (*'principal_components'* and *'canonical_variates'*), the length of input data of the SVM is determined by NumComponents, whereas NumFeatures determines the dimensionality of the input data (i.e., the length of the untransformed feature vector). Hence, by using one of these two transformations, the size of the SVM with respect to data length is reduced, leading to shorter training/classification times by the SVM.

After the SVM has been created with create_class_svm, typically training samples are added to the SVM by repeatedly calling add_sample_class_svm or read_samples_class_svm. After this, the SVM is typically trained using train_class_svm. Hereafter, the SVM can be saved using write_class_svm. Alternatively, the SVM can be used immediately after training to classify data using classify_class_svm.

A comparison of the SVM and the multi-layer perceptron (MLP) (see create_class_mlp) typically shows that SVMs are generally faster at training, especially for huge training sets, and achieve slightly better recognition rates than MLPs. The MLP is faster at classification and should therefore be preferred in time critical applications. Please note that this guideline assumes optimal tuning of the parameters.

Parameters

▷ **NumFeatures** (input_control) . . . integer ⇝ *integer*
Number of input variables (features) of the SVM.
Default: 10
Suggested values: NumFeatures ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumFeatures >= 1

▷ **KernelType** (input_control) . . . string ⇝ *string*
The kernel type.
Default: 'rbf'
List of values: KernelType ∈ {'linear', 'rbf', 'polynomial_inhomogeneous', 'polynomial_homogeneous'}

▷ **KernelParam** (input_control) . . . real ⇝ *real*
Additional parameter for the kernel function. In case of RBF kernel the value for γ. For polynomial kernel the degree
Default: 0.02
Suggested values: KernelParam ∈ {0.01, 0.02, 0.05, 0.1, 0.5}

▷ **Nu** (input_control) . . . real ⇝ *real*
Regularization constant of the SVM.
Default: 0.05
Suggested values: Nu ∈ {0.0001, 0.001, 0.01, 0.05, 0.1, 0.2, 0.3}
Restriction: Nu > 0.0 && Nu < 1.0

▷ **NumClasses** (input_control) . . . integer ⇝ *integer*
Number of classes.
Default: 5
Suggested values: NumClasses ∈ {2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: NumClasses >= 1

▷ **Mode** (input_control) . . . string ⇝ *string*
The mode of the SVM.
Default: 'one-versus-one'
List of values: Mode ∈ {'novelty-detection', 'one-versus-all', 'one-versus-one'}

▷ **Preprocessing** (input_control) . . . string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'normalization'
List of values: Preprocessing ∈ {'none', 'normalization', 'principal_components', 'canonical_variates'}

▷ **NumComponents** (input_control) . . . integer ⇝ *integer*
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = *'none'* and

Preprocessing = *'normalization'*).
Default: 10
Suggested values: NumComponents ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumComponents >= 1

▷ **SVMHandle** (output_control) ..... class_svm ⇝ *handle*
SVM handle.

Example

```
create_class_svm (NumFeatures, 'rbf', 0.01, 0.01, NumClasses,\
                  'one-versus-all', 'normalization', NumFeatures,\
                  SVMHandle)
* Generate and add the training data
for J := 0 to NumData-1 by 1
    * Generate training features and classes
    * Data = [...]
    * Class = ...
    add_sample_class_svm (SVMHandle, Data, Class)
endfor
* Train the SVM
train_class_svm (SVMHandle, 0.001, 'default')
* Use the SVM to classify unknown data
for J := 0 to N-1 by 1
    * Extract features
    * Features = [...]
    classify_class_svm (SVMHandle, Features, 1, Class)
endfor
```

Result

If the parameters are valid the operator create_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

add_sample_class_svm

Alternatives

read_dl_classifier, create_class_mlp, create_class_gmm

deserialize_class_svm (: : SerializedItemHandle : SVMHandle)

Deserialize a serialized support vector machine (SVM).

deserialize_class_svm deserializes a support vector machine (SVM) (including its training samples), that was serialized by serialize_class_svm (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized support vector machine is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created support vector machine with the handle SVMHandle.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **SVMHandle** (output_control) ..... class_svm ⇝ *handle*
SVM handle.

Result

If the parameters are valid, the operator deserialize_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

evaluate_class_svm (: : SVMHandle, Features : Result)

Evaluate a feature vector by a support vector machine.

evaluate_class_svm calculates for a feature vector provided in Features the Result given a SVM in SVMHandle. The operator evaluate_class_svm can only be used if the SVM was created in the Mode = *'novelty-detection'*. If the feature vector lies in the class, a Result value bigger *1.0* is returned. If the feature vector lies outside the class boundary, e.g., is an outlier, a value smaller *1.0* is returned.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **Features** (input_control) ..... real-array ⇝ *real*
Feature vector.

▷ **Result** (output_control) ..... real(-array) ⇝ *real*
Result of evaluating the feature vector with the SVM.

Result

If the parameters are valid the operator evaluate_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_class_train_data_svm (: : SVMHandle : ClassTrainDataHandle)

Get the training data of a support vector machine (SVM).

get_class_train_data_svm gets the training data of a support vector machine (SVM) and returns it in ClassTrainDataHandle.

Parameters

▷ **SVMHandle** (input_control) . . . . . class_svm ⇝ *handle*
Handle of a SVM that contains training data.

▷ **ClassTrainDataHandle** (output_control) . . . . . class_train_data ⇝ *handle*
Handle of the training data of the classifier.

Result

If the parameters are valid, the operator get_class_train_data_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

get_params_class_svm (: : SVMHandle : NumFeatures, KernelType, KernelParam, Nu, NumClasses, Mode, Preprocessing, NumComponents)

Return the parameters of a support vector machine.

get_params_class_svm returns the parameters of a support vector machine (SVM) that were specified when the SVM was created with create_class_svm. This is particularly useful if the SVM was read from a file with read_class_svm. The output of get_params_class_svm can, for example, be used to check whether the feature vectors and, if necessary, the target data to be used with the SVM have the correct lengths. For a description of the parameters, see create_class_svm.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **NumFeatures** (output_control) ..... integer ⇝ *integer*
Number of input variables (features) of the SVM.

▷ **KernelType** (output_control) ..... string ⇝ *string*
The kernel type.

▷ **KernelParam** (output_control) ..... real ⇝ *real*
Additional parameter for the kernel.

▷ **Nu** (output_control) ..... real ⇝ *real*
Regularization constant of the SVM.

▷ **NumClasses** (output_control) ..... integer ⇝ *integer*
Number of classes of the test data.

▷ **Mode** (output_control) ..... string ⇝ *string*
The mode of the SVM.

▷ **Preprocessing** (output_control) ..... string ⇝ *string*
Type of preprocessing used to transform the feature vectors.

▷ **NumComponents** (output_control) ..... integer ⇝ *integer*
Preprocessing parameter: Number of transformed features (ignored for `Preprocessing` = *'none'* and `Preprocessing` = *'normalization'*).

Result

If the parameters are valid the operator `get_params_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_prep_info_class_svm (: : SVMHandle, Preprocessing : InformationCont, CumInformationCont)

Compute the information content of the preprocessed feature vectors of a support vector machine

`get_prep_info_class_svm` computes the information content of the training vectors that have been transformed with the preprocessing given by `Preprocessing`. `Preprocessing` can be set to *'principal_components'* or *'canonical_variates'*. The preprocessing methods are described with `create_class_svm`. The information content is derived from the variations of the transformed components of the feature vector, i.e., it is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (`NumFeatures` for *'principal_components'* and $\min(\texttt{NumClasses} - 1, \texttt{NumFeatures})$ for *'canonical_variates'*, see `create_class_svm`), and is returned in `InformationCont` as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the n-th component of `CumInformationCont`, i.e., `CumInformationCont` contains the sums of the first n elements of `InformationCont`. To use

get_prep_info_class_svm, a sufficient number of samples must be added to the support vector machine (SVM) given by SVMHandle by using add_sample_class_svm or read_samples_class_svm.

InformationCont and CumInformationCont can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent x% (e.g., 90%) of the data. This can be decided easily from the first value of CumInformationCont that lies above x%. The number thus obtained can be used as the value for NumComponents in a new call to create_class_svm. The call to get_prep_info_class_svm already requires the creation of an SVM, and hence the setting of NumComponents in create_class_svm to an initial value. However, when get_prep_info_class_svm is called, it is typically not known how many components are relevant, and hence how to set NumComponents in this call. Therefore, the following two-step approach should typically be used to select NumComponents: In a first step, an SVM with the maximum number for NumComponents is created (NumFeatures for *'principal_components'* and $\min(\texttt{NumClasses}-1, \texttt{NumFeatures})$ for *'canonical_variates'*). Then, the training samples are added to the SVM and are saved in a file using write_samples_class_svm. Subsequently, get_prep_info_class_svm is used to determine the information content of the components, and with this NumComponents. After this, a new SVM with the desired number of components is created, and the training samples are read with read_samples_class_svm. Finally, the SVM is trained with train_class_svm.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **Preprocessing** (input_control) ..... string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'principal_components'
List of values: Preprocessing ∈ {'principal_components', 'canonical_variates'}

▷ **InformationCont** (output_control) ..... real-array ⇝ *real*
Relative information content of the transformed feature vectors.

▷ **CumInformationCont** (output_control) ..... real-array ⇝ *real*
Cumulative information content of the transformed feature vectors.

Example

```
* Create the initial SVM
create_class_svm (NumFeatures, 'rbf', 0.01, 0.01, NumClasses,\
                  'one-versus-all', 'normalization', NumFeatures,\
                  SVMHandle)
* Generate and add the training data
for J := 0 to NumData-1 by 1
    * Generate training features and classes
    * Data = [...]
    * Class = ...
    add_sample_class_svm (SVMHandle, Data, Class)
endfor
write_samples_class_svm (SVMHandle, 'samples.mtf')
* Compute the information content of the transformed features
get_prep_info_class_svm (SVMHandle, 'principal_components',\
                         InformationCont, CumInformationCont)
* Determine NumComp by inspecting InformationCont and CumInformationCont
* NumComp = [...]
* Create the actual SVM
create_class_svm (NumFeatures, 'rbf', 0.01, 0.01, NumClasses, \
                  'one-versus-all', 'principal_components', \
                  NumComp, SVMHandle)
* Train the SVM
read_samples_class_svm (SVMHandle, 'samples.mtf')
train_class_svm (SVMHandle, 0.001, 'default')
write_class_svm (SVMHandle, 'classifier.svm')
```

Result

If the parameters are valid the operator get_prep_info_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

get_prep_info_class_svm may return the error 9211 (Matrix is not positive definite) if Preprocessing = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_sample_class_svm (: : SVMHandle, IndexSample : Features, Target)

Return a training sample from the training data of a support vector machine.

get_sample_class_svm reads out a training sample from the support vector machine (SVM) given by SVMHandle that was added with add_sample_class_svm or read_samples_class_svm. The index of the sample is specified with IndexSample. The index is counted from 0, i.e., IndexSample must be a number between 0 and NumSamples − 1, where NumSamples can be determined with get_sample_num_class_svm. The training sample is returned in Features and Target. Features is a feature vector of length NumFeatures (see create_class_svm), while Target is the index of the class, ranging between 0 and NumClasses-1 (see add_sample_class_svm).

get_sample_class_svm can, for example, be used to reclassify the training data with classify_class_svm in order to determine which training samples, if any, are classified incorrectly.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **IndexSample** (input_control) ..... integer ⇝ *integer*
Number of the stored training sample.

▷ **Features** (output_control) ..... real-array ⇝ *real*
Feature vector of the training sample.

▷ **Target** (output_control) ..... integer ⇝ *integer*
Target vector of the training sample.

Example

```
* Train an SVM
create_class_svm (NumFeatures, 'rbf', 0.01, 0.01, NumClasses,\
                  'one-versus-all', 'normalization', NumFeatures,\
                  SVMHandle)
read_samples_class_svm (SVMHandle, 'samples.mtf')
train_class_svm (SVMHandle, 0.001, 'default')
* Reclassify the training samples
```

```
get_sample_num_class_svm (SVMHandle, NumSamples)
for I := 0 to NumSamples-1 by 1
    get_sample_class_svm (SVMHandle, I, Data, Target)
    classify_class_svm (SVMHandle, Data, 1, Class)
    if (Class != Target)
        * Sample has been classified incorrectly
    endif
endfor
```

Result

If the parameters are valid the operator `get_sample_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

get_sample_num_class_svm (: : SVMHandle : NumSamples)

Return the number of training samples stored in the training data of a support vector machine.

`get_sample_num_class_svm` returns in `NumSamples` the number of training samples that are stored in the support vector machine (SVM) given by `SVMHandle`. `get_sample_num_class_svm` should be called before the individual training samples are accessed with `get_sample_class_svm`, e.g., for the purpose of reclassifying the training data (see `get_sample_class_svm`).

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **NumSamples** (output_control) ..... integer ⇝ *integer*
Number of stored training samples.

Result

If `SVMHandle` is valid the operator `get_sample_num_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

get_support_vector_class_svm (: : SVMHandle, IndexSupportVector : Index)

Return the index of a support vector from a trained support vector machine.

The operator get_support_vector_class_svm maps a support vector of a trained SVM (given in SVMHandle) to the original training data set. The index of the SV is specified with IndexSupportVector. The index is counted from 0, i.e., IndexSupportVector must be a number between 0 and NumSupportVectors − 1, where NumSupportVectors can be determined with get_support_vector_num_class_svm. The index of this SV in the training data is returned in Index. This Index can be used for a query with get_sample_class_svm to obtain the feature vectors that become support vectors. get_sample_class_svm can, for example, be used to visualize the support vectors.

Note that when using train_class_svm with a mode different from *'default'* or reducing the SVM with reduce_class_svm, the returned Index will always be *-1*, i.e., it will be invalid. The reason for this is that a consistent mapping between SV and training data becomes impossible.

Parameters

- ▷ **SVMHandle** (input_control) . . . . . class_svm ⇝ *handle*
  SVM handle.
- ▷ **IndexSupportVector** (input_control) . . . . . integer ⇝ *integer*
  Index of the stored support vector.
- ▷ **Index** (output_control) . . . . . real ⇝ *real*
  Index of the support vector in the training set.

Result

If the parameters are valid the operator get_sample_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_class_svm

Module

Foundation

get_support_vector_num_class_svm (: : SVMHandle : NumSupportVectors, NumSVPerSVM)

Return the number of support vectors of a support vector machine.

get_support_vector_num_class_svm returns in NumSupportVectors the number of support vectors that are stored in the support vector machine (SVM) given by SVMHandle. get_support_vector_num_class_svm should be called before the labels of individual support vectors are read out with get_support_vector_class_svm, e.g., for visualizing which the training data become a SV (see get_support_vector_class_svm). The number of SVs in each classifier is listed in NumSVPerSVM. The reason that its sum differs from the Number obtained in NumSupportVectors is that SV evaluations are reused throughout different sub-classifiers. NumSVPerSVM provides the possibility for controlling the process of speeding up SVM classification time with the operator reduce_class_svm.

Parameters

- ▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
  SVM handle.
- ▷ **NumSupportVectors** (output_control) ..... integer ⇝ *integer*
  Total number of support vectors.
- ▷ **NumSVPerSVM** (output_control) ..... integer-array ⇝ *integer*
  Number of SV of each sub-SVM.

Result

If SVMHandle is valid the operator get_sample_num_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_class_svm

Module

Foundation

read_class_svm (: : FileName : SVMHandle)

Read a support vector machine from a file.

read_class_svm reads a support vector machine (SVM) that has been stored with write_class_svm. Since the training of an SVM can consume a relatively long time, the SVM is typically trained in an offline process and written to a file with write_class_svm. In the online process the SVM is read with read_class_svm and subsequently used for classification with classify_class_svm. The default HALCON file extension for the SVM classifier is 'gsc'.

Parameters

- ▷ **FileName** (input_control) ..... filename.read ⇝ *string*
  File name.
  File extension: .gsc
- ▷ **SVMHandle** (output_control) ..... class_svm ⇝ *handle*
  SVM handle.

Result

If the parameters are valid the operator read_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

classify_class_svm, create_class_lut_svm

Alternatives

read_dl_classifier

create_class_svm, write_class_svm

Module

Foundation

read_samples_class_svm (: : SVMHandle, FileName :)

Read the training data of a support vector machine from a file.

read_samples_class_svm reads training samples from the file given by FileName and adds them to the training samples that have already been added to the support vector machine (SVM) given by SVMHandle. The SVM must be created with create_class_svm before calling read_samples_class_svm. As described with train_class_svm and write_samples_class_svm, the operators read_samples_class_svm, add_sample_class_svm, and write_samples_class_svm can be used to build up a extensive set of training samples, and hence to improve the performance of the SVM by retraining the SVM with extended data sets.

It should be noted that the training samples must have the correct dimensionality. The feature vectors and target vectors stored in FileName must have the lengths NumFeatures and NumClasses that were specified with create_class_svm. The target is stored in vector form for compatibility reason with the MLP (see read_samples_class_mlp). If the dimensions are incorrect an error message is returned.

Parameters

▷ **SVMHandle** (input_control) . . . . . class_svm ⇝ *handle*
SVM handle.

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.

Result

If the parameters are valid the operator read_samples_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SVMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

reduce_class_svm (: : SVMHandle, Method, MinRemainingSV, MaxError : SVMHandleReduced)

Approximate a trained support vector machine by a reduced support vector machine for faster classification.

As described in create_class_svm, the classification time of a SVM depends on the number of kernel evaluations between the support vectors and the feature vectors. While the length of the data vectors can be reduced in a preprocessing step like *'principal_components'* or *'canonical_variates'* (see create_class_svm for details), the number of resulting SV depends on the complexity of the classification problem. The number of SVs is determined during training. To further reduce classification time, the number of SVs can be reduced by approximating the original separating hyperplane with fewer SVs than originally required. For this purpose, a copy of the original SVM provided by SVMHandle is created and returned in SVMHandleReduced. This new SVM has the same parametrization as the original SVM, but a different SV expansion. The training samples that are included in SVMHandle are not copied. The original SVM is not modified by reduce_class_svm.

The reduction method is selected with Method. Currently, only a bottom up approach is supported, which iteratively merges SVs. The algorithm stops if either the minimum number of SVs is reached (MinRemainingSV) or if the accumulated maximum error exceeds the threshold MaxError. Note that the approximation reduces the complexity of the hyperplane and thereby leads to a deteriorated classification rate. A common approach is therefore to start from a small MaxError e.g., *0.001*, and to increase its value step by step. To control the reduction ratio, at each step the number of remaining SVs is determined with get_support_vector_num_class_svm and the classification rate is checked on a separate test data set with classify_class_svm.

Parameters

- ▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
  Original SVM handle.
- ▷ **Method** (input_control) ..... string ⇝ *string*
  Type of postprocessing to reduce number of SV.
  Default: 'bottom_up'
  List of values: Method ∈ {'bottom_up'}
- ▷ **MinRemainingSV** (input_control) ..... integer ⇝ *integer*
  Minimum number of remaining SVs.
  Default: 2
  Suggested values: MinRemainingSV ∈ {2, 3, 4, 5, 7, 10, 15, 20, 30, 50}
  Restriction: MinRemainingSV >= 2
- ▷ **MaxError** (input_control) ..... real ⇝ *real*
  Maximum allowed error of reduction.
  Default: 0.001
  Suggested values: MaxError ∈ {0.0001, 0.0002, 0.0005, 0.001, 0.002, 0.005, 0.01, 0.02, 0.05}
  Restriction: MaxError > 0.0
- ▷ **SVMHandleReduced** (output_control) ..... class_svm ⇝ *handle*
  SVMHandle of reduced SVM.

Example

```
* Train an SVM
create_class_svm (NumFeatures, 'rbf', 0.01, 0.01, NumClasses,\
                  'one-versus-all', 'normalization', NumFeatures,\
                  SVMHandle)
read_samples_class_svm (SVMHandle, 'samples.mtf')
train_class_svm (SVMHandle, 0.001, 'default')
```

```
* Create a reduced SVM
reduce_class_svm (SVMHandle, 'bottom_up', 2, 0.01, SVMHandleReduced)
write_class_svm (SVMHandleReduced, 'classifier.svm')
```

Result

If the parameters are valid the operator `train_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`train_class_svm`

Module

Foundation

select_feature_set_svm (: : ClassTrainDataHandle, SelectionMethod, GenParamName, GenParamValue : SVMHandle, SelectedFeatureIndices, Score)

Selects an optimal combination of features to classify the provided data.

`select_feature_set_svm` selects an optimal subset from a set of features to solve a given classification problem. The classification problem has to be specified with annotated training data in `ClassTrainDataHandle` and will be classified by a support vector machine (SVM). Details of the properties of this classifier can be found in `create_class_svm`.

The result of the operator is a trained classifier that is returned in `SVMHandle`. Additionally, the list of indices or names of the selected features is returned in `SelectedFeatureIndices`. To use this classifier, calculate for new input data all features mentioned in `SelectedFeatureIndices` and pass them to the classifier.

A possible application of this operator can be a comparison of different parameter sets for certain feature extraction techniques. Another application is to search for a feature that is discriminating between different classes.

Additionally, the values for *'nu'* and *'gamma'* can be estimated for the SVM. To only estimate these two parameters without altering the feature set, the feature vector has to be specified as one large subfeature.

To define the features that should be selected from `ClassTrainDataHandle`, the dimensions of the feature vectors in `ClassTrainDataHandle` can be grouped into subfeatures by calling `set_feature_lengths_class_train_data`. A subfeature can contain several subsequent elements of a feature vector. The operator decides for each of these subfeatures, if it is better to use it for the classification or leave it out.

The indices of the selected subfeatures are returned in `SelectedFeatureIndices`. If names were set in `set_feature_lengths_class_train_data`, these names are returned instead of the indices. If `set_feature_lengths_class_train_data` was not called for `ClassTrainDataHandle` before, each element of the feature vector is considered as a subfeature.

The selection method `SelectionMethod` is either a greedy search *'greedy'* (iteratively add the feature with highest gain) or the dynamically oscillating search *'greedy_oscillating'* (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method *'greedy'* is generally preferable, since it is faster. Only in cases when the subfeatures are low-dimensional or redundant, the method *'greedy_oscillating'* should be chosen.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in `Score`.

The parameters *'nu'* and *'gamma'* for the SVM that is used to classify can be set to *'auto'* by using the parameters `GenParamName` and `GenParamValue`. If they are set to *'auto'*, the estimated optimal *'nu'* and/or *'gamma'* is estimated. The automatic estimation of *'nu'* and *'gamma'* can take a substantial amount of time (up to days, depending on the data set and the number of features).

Additionally, there is the parameter *'mode'* which can be either set to *'one-versus-all'* or *'one-versus-one'*. An explanation of the two modes as well as of the parameters *'nu'* and *'gamma'* as the kernel parameter of the radial basis function (RBF) kernel can be found in `create_class_svm`.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator `select_feature_set_svm` may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

- ▷ **`ClassTrainDataHandle`** (input_control) . . . . . class_train_data ⇝ *handle*
  Handle of the training data.
- ▷ **`SelectionMethod`** (input_control) . . . . . string ⇝ *string*
  Method to perform the selection.
  Default: 'greedy'
  List of values: `SelectionMethod` ∈ {'greedy', 'greedy_oscillating'}
- ▷ **`GenParamName`** (input_control) . . . . . string(-array) ⇝ *string*
  Names of generic parameters to configure the selection process and the classifier.
  Default: []
  List of values: `GenParamName` ∈ {'nu', 'gamma', 'mode'}
- ▷ **`GenParamValue`** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
  Values of generic parameters to configure the selection process and the classifier.
  Default: []
  Suggested values: `GenParamValue` ∈ {0.02, 0.05, 'auto', 'one-versus-one', 'one-versus-all'}
- ▷ **`SVMHandle`** (output_control) . . . . . class_svm ⇝ *handle*
  A trained SVM classifier using only the selected features.
- ▷ **`SelectedFeatureIndices`** (output_control) . . . . . string-array ⇝ *string*
  The selected feature set, contains indices.
- ▷ **`Score`** (output_control) . . . . . real-array ⇝ *real*
  The achieved score using two-fold cross-validation.

Example

```
* Find out which of the two features distinguishes two Classes
NameFeature1 := 'Good Feature'
NameFeature2 := 'Bad Feature'
LengthFeature1 := 3
LengthFeature2 := 2
* Create training data
create_class_train_data (LengthFeature1+LengthFeature2,\
  ClassTrainDataHandle)
* Define the features which are in the training data
set_feature_lengths_class_train_data (ClassTrainDataHandle, [LengthFeature1,\
  LengthFeature2], [NameFeature1, NameFeature2])
* Add training data
*                                                    |Feat1| |Feat2|
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  2,1  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  2,1  ], 1)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [1,1,1,  3,4  ], 0)
add_sample_class_train_data (ClassTrainDataHandle, 'row', [2,2,2,  3,4  ], 1)
```

```
* Add more data
* ...
* Select the better feature with a SVM
select_feature_set_svm (ClassTrainDataHandle, 'greedy', [], [], SVMHandle,\
  SelectedFeatureSVM, Score)
* Use the classifier
* ...
```

Result

If the parameters are valid, the operator `select_feature_set_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

serialize_class_svm (: : SVMHandle : SerializedItemHandle)

Serialize a support vector machine (SVM).

`serialize_class_svm` serializes a support vector machine (SVM) and its stored training samples (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The same data that is written in a file by `write_class_svm` and `write_samples_class_svm` is converted to a serialized item. The support vector machine is defined by the handle `SVMHandle`. The serialized support vector machine is returned by the handle `SerializedItemHandle` and can be deserialized by `deserialize_class_svm`.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Predecessors

train_class_svm (: : SVMHandle, Epsilon, TrainMode :)

Train a support vector machine.

train_class_svm trains the support vector machine (SVM) given in SVMHandle. Before the SVM can be trained, the training samples to be used for the training must be added to the SVM using add_sample_class_svm or read_samples_class_svm.

Technically, training an SVM means solving a convex quadratic optimization problem. This implies that it can be assured that training terminates after finite steps at the global optimum. In order to recognize termination, the gradient of the function that is optimized internally must fall below a threshold, which is set in Epsilon. By default, a value of *0.001* should be used for Epsilon since this yields the best results in practice. A too big value leads to a too early termination and might result in suboptimal solutions. With a too small value the optimization requires a longer time, often without changing the recognition rate significantly. Nevertheless, if longer training times are possible, a smaller value than *0.001* might be chosen. There are two common reasons for changing Epsilon: First, if you specified a very small value for Nu when calling (create_class_svm), e.g., Nu = *0.001*, a smaller Epsilon might significantly improve the recognition rate. A second case is the determination of the optimal kernel function and its parametrization (e.g., the KernelParam-Nu pair for the RBF kernel) with the computationally intensive n-fold cross validation. Here, choosing a bigger Epsilon reduces the computational time without changing the parameters of the optimal kernel that would be obtained when using the default Epsilon. After the optimal KernelParam-Nu pair is obtained, the final training is conducted with a small Epsilon.

The duration of the training depends on the training data, in particular on the number of resulting support vectors (SVs), and Epsilon. It can lie between seconds and several hours. It is therefore recommended to choose the SVM parameter Nu in create_class_svm so that as few SVs as possible are generated without decreasing the recognition rate. Special care must be taken with the parameter Nu in create_class_svm so that the optimization starts from a feasible region. If too many training errors are chosen with a too big Nu, an exception is raised. In this case, an SVM with the same training data, but with smaller Nu must be trained.

With the parameter TrainMode you can choose between different training modes. Normally, you train an SVM without additional information and TrainMode is set to *'default'*. If multiple SVMs for the same data set but with different kernels are trained, subsequent training runs can reuse optimization results and thus speedup the overall training time of all runs. For this mode, in TrainMode a SVM handle of a previously trained SVM is passed. Note that the SVM handle passed in SVMHandle and the SVMHandle passed in TrainMode must have the same training data, the same mode and the same number of classes (see create_class_svm). The application for this training mode is the evaluation of different kernel functions given the same training set. In the literature this is referred to as alpha seeding.

With TrainMode = *'add_sv_to_train_set'* it is possible to append the support vectors that were generated by a previous call of train_class_svm to the currently saved training set. This mode has two typical application areas: First, it is possible to gradually train a SVM. For this, the complete training set is divided into disjunctive chunks. The first chunk is trained normally using TrainMode = *'default'*. Afterwards, the previous training set is removed with clear_samples_class_svm, the next chunk is added with add_sample_class_svm and trained with TrainMode = *'add_sv_to_train_set'*. This is repeated until all chunks are trained. This approach has the advantage that even huge training data sets can be trained efficiently with respect to memory consumption. A second application area for this mode is that a general purpose classifier can be specialized by adding characteristic

training samples and then retraining it. Please note that the preprocessing (as described in create_class_svm) is not changed when training with TrainMode = *'add_sv_to_train_set'*.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **Epsilon** (input_control) ..... real ⇝ *real*
Stop parameter for training.
Default: 0.001
Suggested values: Epsilon ∈ {0.00001, 0.0001, 0.001, 0.01, 0.1}

▷ **TrainMode** (input_control) ..... number ⇝ *string* / integer
Mode of training. For normal operation: 'default'. If SVs already included in the SVM should be used for training: 'add_sv_to_train_set'. For alpha seeding: the respective SVM handle.
Default: 'default'
List of values: TrainMode ∈ {'default', 'add_sv_to_train_set'}

Example

```
* Train an SVM
create_class_svm (NumFeatures, 'rbf', 0.01, 0.01, NumClasses,\
                  'one-versus-all', 'normalization', NumFeatures,\
                  SVMHandle)
read_samples_class_svm (SVMHandle, 'samples.mtf')
train_class_svm (SVMHandle, 0.001, 'default')
write_class_svm (SVMHandle, 'classifier.svm')
```

Result

If the parameters are valid the operator train_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SVMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Foundation

write_class_svm (: : SVMHandle, FileName :)

Write a support vector machine to a file.

write_class_svm writes the support vector machine (SVM) SVMHandle to the file given by FileName. The default HALCON file extension for the SVM classifier is 'gsc'. write_class_svm is typically called after the SVM has been trained with train_class_svm. The SVM can be read with read_class_svm. write_class_svm does *not* write any training samples that possibly have been stored in the SVM. For this purpose, write_samples_class_svm should be used.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
File name.
File extension: .gsc

Result

If the parameters are valid the operator write_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_samples_class_svm (: : SVMHandle, FileName :)

Write the training data of a support vector machine to a file.

write_samples_class_svm writes the training samples currently stored in the support vector machine (SVM) SVMHandle to the file given by FileName. write_samples_class_svm can be used to build up a database of training samples, and hence to improve the performance of the SVM by training it with an extended data set (see train_class_svm). The file FileName is overwritten by write_samples_class_svm. Nevertheless, extending the database of training samples is easy to do because read_samples_class_svm and add_sample_class_svm add the training samples to the training samples that are already stored in memory with the SVM.

Parameters

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
File name.

Result

If the parameters are valid the operator write_samples_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 8

Control

assign (: : Input : Result)

Assign a new value to a variable.

assign assigns a new value to a variable.

In the full text editor, an assignment is simply entered with the help of the assignment operator ':=', e.g.:

```
u := sin(x) + cos(y)
```

This is equivalent to the C syntax assignment:

```
u = sin(x) + cos(y);
```

If the operator window is used for entering an assignment, assign must be entered into the operator combo box as an operator name. This opens the parameter area, where the parameter Input represents the expression that has to be evaluated to one value and assigned to the variable, i.e., this is the right side of the assignment. The parameter Result gets the name of the variable, i.e., this is the left side of assignment.

Attention

In addition to the parameter type control, which is indicated in the parameter description, assign also supports iconic variables and vector variables. For an assignment, the parameter types of the two parameters Input and Result must be identical. For the assignment of iconic objects, the operator copy_obj is used internally.

Parameters

▷ **Input** (input_control) ..... real(-array) ⇝ *real* / integer / string
New value.
Default: 1

▷ **Result** (output_control) ..... real(-array) ⇝ *real* / integer / string
Variable that has to be changed.

Example

```
Tuple1 := [1,0,3,4,5,6,7,8,9]
Val := sin(1.2) + cos(1.2)
Tuple2 := []
```

Result

If the expression is correct assign returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Alternatives

insert

Module

Foundation

assign_at (: : Index, Value : Result)

Assignment of one or several values to one or several tuple elements.

assign_at assigns a single value to one or several elements of a tuple, or it assigns a number of values elementwise to the specified elements of the output tuple. All other elements of the output tuple keep their values. If the passed indices are out of the current range of the output tuple, the tuple is increased and the new values are initialized to a default value.

In the full text editor an assign_at operation is simply entered with the help of the assignment operator symbol ':=' and the index access operator symbol '[ ]' following the output variable. The Index parameter can be any expression that evaluates to any number of positive integer values. The Value parameter must evaluate to exactly one value or to the same number of indices that are provided via the Index parameter, e.g.:

```
Areas[Radius-1]     := Area
Areas[0,4,|Rad|-1] := 0
FileNames[0,2,4]    := ['f1','f2','f3']
```

The operator assign_at replaces and extends the modifying version of the old insert operator.

Parameters

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *integer*
Indices of the elements that have to be replaced by the new value(s).
Default: 0
Suggested values: Index ∈ {0, 1, 2, 3, 4, 5, 6}
Minimum increment: 1

▷ **Value** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Value(s) that is to be assigned.
Default: 1

▷ **Result** (output_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Result tuple containing the assigned values.

Result

If the expression is correct assign_at returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Alternatives

assign, tuple_replace

Module

Foundation

break (: : :)

Terminate loop execution or leave a switch block.

break terminates the smallest enclosing for, while, or repeat..until loop. In addition, the break statement is used to leave a switch block, in particular at the end of a case branch. The program execution is continued at the program line following the corresponding block.

break statements that are not enclosed by a loop or switch block are invalid.

Example

```
read_image (Image, 'monkey')
threshold (Image, Region, 160, 180)
connection (Region, Regions)
Number := |Regions|
AllRegionsValid := 1
* check if for all regions area <=30
for i := 1 to Number by 1
```

```
  select_obj (Regions, ObjectSelected, i)
  area_center (ObjectSelected, Area, Row, Column)
  if (Area > 30)
    AllRegionsValid := 0
    break
  endif
endfor
```

Result

`break` (as an operator) always returns `2` (`H_MSG_TRUE`).

Alternatives

`continue`

See also

`for`, `while`, `repeat`, `until`, `switch`, `case`

Module

Foundation

`case` (: : Constant :)

Jump label that starts a branch within a `switch` block.

`case` defines a jump label within a `switch` block. It starts a branch that is executed if the value of the control expression of the `switch` statement matches the constant integer expression that is defined in `Constant`. For this parameter only constant integer expressions are accepted. Variable expressions and other data types are not allowed.

As in the programming languages C, C++, and C# the `case` statement does not open a block that is automatically left at the next `case` or `default` statement. In contrast, it works just like a goto label that is accessed if the label matches. In order to leave a `case` branch and continue execution after the end of the `switch` block, the `break` statement can be used anywhere within the `switch` block.

Parameters

▷ **`Constant`** (input_control) . . . . . integer ⇝ *integer*
Constant integer expressions that determines for which value of the switch control expression the branch is accessed.
Default: 1

Result

`case` (as an operator) always returns `2` (`H_MSG_TRUE`).

Alternatives

`elseif`

See also

`switch`, `default`, `endswitch`, `if`

Module

Foundation

`catch` (: : : Exception)

Catches exceptions that were thrown in the preceding `try` block.

With the help of the operators `try`, `catch`, `endtry`, and `throw` it is possible to implement a dynamic exception handling in HDevelop, which is comparable to the exception handling in C++ and C#. The basic concepts of the exception handling in HDevelop are described at the operators `try`, `throw`, and `dev_set_check` as well as in the "`HDevelop User's Guide`".

The operator `catch` ends a block of watched program lines and starts a block of program lines that have to be executed in an error case. If the `try`-`catch` block is executed without an exception, the `catch`-`endtry` block

is ignored and program execution continues after the corresponding endtry operator. In contrast, in an error case the program execution jumps directly from the operator where the error occurred (or from the throw operator) to the catch operator of the surrounding try-catch block. The output control parameter Exception returns a tuple that contains a predefined set of data describing the error in case an operator error occurred. If the exception was thrown by the throw operator, an arbitrary user-defined tuple can be returned.

The most important data within the Exception tuple is the error code. Therefore, this is passed as the first item of the Exception tuple and can be accessed directly with Exception[0]. However, all other data has to be accessed through the operator dev_get_exception_data, because the order and the extent of the provided data may change in future versions and may vary for different programming language exports. Especially, it has to be taken into account that in the exported code there are some items of the error tuple that are not available and others that might not be determined until they are requested (like error messages).

If the exception was thrown by an operator error, a HALCON error code (< 10000) or if the aborted operator belongs to an extension package, a user-defined error code (> 10000) is returned as the error code. A list of all HALCON error codes can be found in the appendix of the "Extension Package Programmer's Manual". The first element of a user-defined Exception tuple thrown by the operator throw should be an error code $\geq$ 30000. Additional tuple elements can be chosen without any restrictions.

If an operator error occurred within HDevelop or HDevEngine, the following information about the error is provided by the Exception tuple:

- The HALCON error code.
- An additional HDevelop specific error code that specifies whether an error was caught within the HALCON operator (code = 21000) or outside the operator, e.g., during the evaluation and assignment of the parameter expressions. In the latter case the error code specifies the kind of error more precisely.
- The HALCON error message.
- An appropriate HDevelop-specific error message.
- The number of the program line, where the error occurred.
- The name of the operator that threw the exception (if the exception was thrown in a protected procedure, '--protected--' is returned instead of the operator name).
- The depth of the call stack (if the error occurred in 'main' a depth of 1 is returned).
- The name of the procedure, where the error occurred.

In most cases, for an automatic exception handling it is sufficient to use the HALCON error code. Additional data is primarily passed in order to provide some information about the error condition to the developer of the HDevelop program for debugging reasons. Attention: in the exported code, in general, information about the error location will not be available.

Attention

The export of the operators try, catch, endtry, and throw is not supported for the language C, but only for the languages C++, C# and VisualBasic/.NET. Only the latter support throwing exceptions across procedures.

Parameters

▷ **Exception** (output_control) ..... exception-array ⇝ *integer* / string
Tuple returning the exception data.

Result

catch always returns 2 (H_MSG_TRUE).

Possible Successors

dev_get_exception_data

See also

try, endtry, throw, dev_get_exception_data, dev_set_check

Module

Foundation

comment (: : Comment :)

Add a comment of one line to the program.

comment allows to add a comment of one line to the program. As parameter value, i.e., as comment, all characters are allowed. If the operator window is used to enter a comment and if there are newlines in the comment line parameter, one comment statement for every text line is inserted.

In the full text editor a comment is marked by entering an asterisk ('*') as first non-whitespace character.

This operator has no effect on the program execution.

Parameters

▷ **Comment** (input_control) . . . . . string ⇝ *string*
Arbitrary sequence of characters.

Example

```
* This is a program with comments
* 'this is a string as comment'
* here are numbers: 4711, 0.815
stop ()
```

Result

comment is never executed.

Module

Foundation

continue (: : :)

Skip the current loop execution.

continue skips the smallest enclosing for, while or repeat..until loop execution. Program execution is continued at the condition line of the loop or at the next line after the continue statement in case no enclosing loop exists.

Result

continue (as operators) always returns 2 (H_MSG_TRUE).

Alternatives

break

See also

for, while, repeat, until

Module

Foundation

convert_tuple_to_vector_1d (: : InputTuple,
SubTupleLength : ResultVector)

Distribute the elements of a tuple to a vector.

convert_tuple_to_vector_1d transforms a tuple into a vector variable. The input tuple InputTuple is split into sub-tuples each comprising of SubTupleLength elements. The sub-tuples are stored in the output vector ResultVector.

Parameters

▷ **InputTuple** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Input tuple.

▷ **SubTupleLength** (input_control) . . . . . number ⇝ *integer*
Desired length of the resulting tuples in the output vector.
Default: 1

▷ **ResultVector** (output_control) . . . . . number-vector1 ⇝ *real* / integer / string
Output vector.

Result

If the values of the specified parameters are correct, `convert_tuple_to_vector_1d` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

See also

`convert_vector_to_tuple`

Module

Foundation

convert_vector_to_tuple (: : InputVector : ResultTuple)

Concatenate the elements of a vector to a single tuple.

`convert_vector_to_tuple` transforms a vector into a tuple. The elements of the input vector `InputVector` get concatenated and stored in the output tuple `ResultTuple`. If `InputVector` has a dimension of 2 or greater its elements are collected in a depth-first search. E.g., the input vector *'1,2,3,4'* will be turned into the result tuple *[1,2,3,4]*.

Parameters

- ▷ **InputVector** (input_control) ..... number-vector ⇝ *real* / integer / string
  Input vector.
- ▷ **ResultTuple** (output_control) ..... real(-array) ⇝ *real* / integer / string
  Output tuple.

Result

If the values of the specified parameters are correct, `convert_vector_to_tuple` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

See also

`convert_tuple_to_vector_1d`

Module

Foundation

default (: : :)

Alternative branch in a `switch` block.

`default` opens an alternative branch in a `switch` block. This branch is accessed if the calculated control expression of the `switch` statement does not match any of the integer constants of the previous `case` statements.

Result

`default` (as an operator) always returns `2` (`H_MSG_TRUE`).

Alternatives

`case`, `elseif`, `else`

See also

`switch`, `case`, `endswitch`, `if`

Module

Foundation

else (: : :)

Alternative of conditional statement.

`else` continues after an `if` or `elseif` block with an alternative block. If the conditions of all corresponding `if` or `elseif` blocks evaluated to *'false'* (*0*), i.e., none of the corresponding `if` or `elseif` blocks has been executed, the following `else` block is executed.

Result

`else` (as operator) always returns `2` (`H_MSG_TRUE`).

Alternatives

`if`, `elseif`

See also

`until`, `for`, `while`

Module

Foundation

elseif (: : Condition :)

Conditional statement with alternative.

`elseif` is a conditional statement that continues after an `if` or another `elseif` block with an alternative block. The `Condition` parameter must evaluate to a Boolean or integer expression.

If `Condition` evaluates to *'true'* (not *0*), the following block body up to the next corresponding block statement `elseif`, `else`, or `endif` is executed. Reaching the end of the block the execution continues after the corresponding `endif` statement.

If `Condition` evaluates to *'false'* (*0*), the execution is continued at the next corresponding block statement `elseif`, `else`, or `endif`.

Parameters

▷ **Condition** (input_control) ..... integer ⇝ *integer*
Condition for the if statement.
Default: 1

Result

If the condition is correct `elseif` (as operator) returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Alternatives

`if`

See also

`else`, `for`, `while`, `until`

Module

Foundation

endfor (: : :)

End statement of a for loop.

`endfor` is the last statement of a `for` loop.

Result

`endfor` always returns `2` (`H_MSG_TRUE`).

See also

`for`

Module

Foundation

endif (: : :)

End of if command.

endif is the last statement of an if, elseif, or else block.

Result

endif always returns 2 (H_MSG_TRUE).

See also

if

Module

Foundation

endswitch (: : :)

Ends a multiway branch block.

endswitch ends a multiway branch block that has been opened by switch.

Result

endswitch always returns 2 (H_MSG_TRUE).

See also

switch

Module

Foundation

endtry (: : :)

Ends a block where exceptions are handled.

With the help of the operators try, catch, endtry, and throw it is possible to implement a dynamic exception handling in HDevelop, which is comparable to the exception handling in C++ and C#. The basic concepts of the exception handling in HDevelop are described at the operators try, throw, and dev_set_check as well as in the "HDevelop User's Guide".

The operator endtry closes the exception handling block that was opened with the operators try and catch.

Attention

The export of the operators try, catch, endtry, and throw is not supported for the language C, but only for the languages C++, C# and VisualBasic/.NET. Only the latter support throwing exceptions across procedure.

Result

endtry always returns 2 (H_MSG_TRUE).

See also

try, catch, throw, dev_get_exception_data, dev_set_check

Module

Foundation

endwhile (: : :)

End statement of a while loop.

endwhile is the last statement of a while loop.

Result

endwhile always returns 2 (H_MSG_TRUE).

See also

while

Module

Foundation

executable_expression (: : Expression :)

Execute a stand-alone operation.

The HDevelop language contains a few operations that are executed stand-alone, i.e., not as an expression within another operator call. The operator `executable_expression` allows to enter such stand-alone operations into the operator window of HDevelop. In the full text editor however, those operations are entered verbatim.

Currently, the following modifying vector operations are stand-alone and can only be used in an executable expression:

- `.clear()`
- `.insert()`
- `.remove()`

For further details about these operations please refer to the HDevelop User's Guide.

Even though `Expression` formally is presented as a control parameter, nonetheless it is also possible to execute stand-alone operations with iconic vectors.

Parameters

▷ **Expression** (input_control) . . . . . number-vector ⇝ *real* / integer / string
Operation to be executed.

Example

```
read_image (Image1, 'fin1')
read_image (Image2, 'fin2')
ImageVector.insert(1, Image1).insert(2, Image2)
* process vector
ImageVector.clear()
```

Result

If the values of the specified parameters are correct, `executable_expression` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Module

Foundation

exit (: : :)

Terminate HDevelop.

`exit` terminates HDevelop. The operator is equivalent to the menu entry `File` ▷ `Quit`. Internally and for exported C++ code the C-function call `exit(0)` is used.

Example

```
read_image (Image, 'fabrik')
intensity (Image, Image, Mean, Deviation)
open_file ('intensity.txt', 'output', FileHandle)
fwrite_string (FileHandle, Mean + ' ' + Deviation)
close_file (FileHandle)
exit ()
```

Result

`exit` returns 0 (o.k.) to the calling environment of HDevelop = operating system.

`stop`

Module

Foundation

export_def (: : Position, Declaration :)

Insert arbitrary text into the export code of a procedure.

export_def allows to define code lines or text blocks that are written verbatim into the output file of a procedure or program that is exported.

The parameter Position controls the placement of the text given in Declaration. The following options are supported:

'in_place' **- #** The text is inserted in the procedure at the actual place, i.e., in between the neighboring program lines.

'at_file_begin' **- #^^** The text is exported at the very beginning of the exported file.

'before_procedure' **- #^** The text is exported immediately before the procedure it is defined in.

'after_procedure' **- #$** The text is exported immediately after the procedure it is defined in.

'at_file_end' **- #$$** The text is exported at the very end of the exported file.

In the program listing, export_def is not represented in normal operator syntax but marked by a special character sequence. The first character within the line is the export marker # that can be followed by a position marker as listed above. If entering an export definition in the full text editor, please note that there must not be any spaces before #.

For better readability, the export character sequence may be followed by one space character that is not interpreted as part of the export text. All additional spaces are added to the export.

For lines that are exported within the current procedure, the export gets the same indentation as the current program lines get. There is one exception: if the export text starts with # immediately after the export markers or the optional space, the export text will not be indented at all, e.g.:

```
for Index := 1 to 5 by 1
\# \#ifdef MY\_SWITCH
\# int cnt = 100;
  * an optional code block
\# \#endif
endfor
```

is exported to:

```
proc (...)
{
  ...
  for (...)
  {
\#ifdef MY\_SWITCH
    int cnt = 100;
    // an optional block
\#endif
  }
  ...
}
```

An export definition can be activated and deactivated as any normal operator. Deactivated export definitions are not exported.

Parameters

▷ **Position** (input_control) . . . . . string ⇝ *string*
Place where the export text is written.
List of values: Position ∈ {'in_place', 'at_file_begin', 'before_procedure', 'after_procedure', 'at_file_end'}

▷ **Declaration** (input_control) . . . . . string ⇝ *string*
Text that is exported.

Result

`export_def` is never executed.

`comment`

Module

Foundation

for (: : Start, End, Step : Index)

Starts a loop block that is usually executed for a fixed number of iterations.

Syntax in HDevelop: `for Index := Start to End by Step`

The `for` statement starts a loop block that is usually executed for a fixed number of iterations. The `for` block ends at the corresponding `endfor` statement.

The number of iterations is defined by the `Start` value, the `End` value, and the increment value `Step`. All of these parameters can be initialized with expressions or variables instead of constant values. Please note that these loop parameters are evaluated only once, namely, immediately before the `for` loop is entered. They are not re-evaluated after the loop cycles, i.e., any modifications of these variables within the loop body will have no influence on the number of iterations.

The passed loop parameters must be either of type `integer` or `real`. If all input parameters are of type `integer`, the `Index` variable will also be of type `integer`. In all other cases the `Index` variable will be of type `real`.

At the beginning of each iteration the loop variable `Index` is compared to the `End` parameter. If the increment value `Step` is positive, the `for` loop is executed as long as the `Index` variable is less than or equal to the `End` parameter. If the increment value `Step` is negative, the `for` loop is executed as long as the `Index` variable is greater than or equal to the `End` parameter.

Attention: If the increment value `Step` is set to a value of type `real`, it may happen that the last loop cycle is omitted owing to rounding errors in case the `Index` variable is expected to match the `End` value exactly in the last cycle. Hence, on some systems the following loop is not executed—as expected—for four times (with the `Index` variable set to 1.3, 1.4, 1.5, and 1.6), but only three times because after three additions the index variable is slightly greater than 1.6 due to rounding errors.

```
I:=[]
for Index := 1.3 to 1.6 by 0.1
  I := [I,Index]
endfor
```

After the execution of the loop body, i.e., upon reaching the corresponding `endfor` statement or a `continue` statement, the increment value (as initialized at the beginning of the `for` loop) is added to the current value of the loop counter `Index`. Then, the loop condition is re-evaluated as described above. Depending on the result the loop is either executed again or finished in which case execution continues with the first statement after the corresponding `endfor` statement.

A `break` statement within the loop—that is not covered by a more internal block—leaves the loop immediately and execution continues after the corresponding `endfor` statement. In contrast, the `continue` statement is used to ignore the rest of the loop body in the current cycle and continue execution with adapting the `Index` variable and re-evaluating the loop condition.

Attention: It is recommended to avoid modifying the `Index` variable of the `for` loop within its body.

If the `for` loop is stopped, e.g., by a `stop` statement or by pressing the `Stop` button, and if the PC is placed manually by the user, the `for` loop is continued at the current iteration as long as the PC remains within the `for` body or is set to the `endfor` statement. If the PC is set on the `for` statement (or before it) and executed again, the loop is reinitialized and restarts at the beginning.

Parameters

▷ **Start** (input_control) ..... number ⇝ *integer* / real
Start value of the loop variable.
Default: 1

▷ **End** (input_control) ..... number ⇝ *integer* / real
End value of the loop variable.
Default: 5

▷ **Step** (input_control) ..... number ⇝ *integer* / real
Increment value of the loop variable.
Default: 1

▷ **Index** (output_control) ..... number ⇝ *integer* / real
Loop variable.

Example

```
read_image (Image, 'fabrik')
threshold (Image, Region, 128, 255)
connection (Region, ConnectedRegions)
select_shape (ConnectedRegions, SelectedRegions, 'area', 'and', 150, 99999)
area_center (SelectedRegions, Area, Row, Column)
dev_close_window ()
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
dev_display (Image)
dev_display (SelectedRegions)
dev_set_color ('white')
for Index := 0 to |Area| - 1 by 1
  set_tposition (WindowHandle, Row[Index], Column[Index])
  write_string (WindowHandle, 'Area=' + Area[Index])
endfor
```

Result

If the values of the specified parameters are correct, `for` (as an operator) returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code is returned.

Alternatives

`while`, `until`

See also

`repeat`, `break`, `continue`, `endfor`

Module

Foundation

global (: : Declaration :)

Declare a global variable.

The `global` statement can be used to declare a global variable. By declaring a variable as global the variable becomes visible to all other procedures that also declare the same variable explicitly as global.

If a variable is not explicitly declared as global inside a procedure, the variable is local within that procedure even if there is a global variable with the same name.

The parameter `Declaration` contains the variable declaration that consists of the optional keyword *'def'*, the type *'object'* or *'tuple'*, the optional keyword *'vector'* (followed by the desired dimension in round brackets), and the variable name.

Setting the type to *'object'* an iconic variable is declared, by setting it to *'tuple'* a control variable is declared.

The keyword *'def'* allows to mark one declaration explicitly as the place where the variable is defined. In most cases this will not be necessary because in HDevelop the variable instance is created as soon as it is declared somewhere. However, if several procedures are exported to a programming language and if the procedures are

not exported into one output file that contains all procedures together but into separate output files it will become necessary to mark one of the global variable declarations as the place where the variable is defined. A set of procedure export files that are linked to one library or application must contain exactly one definition of each global variable in order to avoid both undefined symbols and multiple definitions.

In the program listing, global variable declarations are displayed and must be entered without parenthesis in order to emphasize that the line is a declaration and not an executable operator. The syntax is as follows:

```
global [def] {object|tuple} [vector(<Dimension>)] <Variable Name>
```

Parameters

▷ **Declaration** (input_control) . . . . . string ⇝ *string*
Global variable declaration: optional keyword *'def'*, type, and variable name
Suggested values: Declaration ∈ {'object', 'tuple', 'def object', 'def tuple', 'object vector(1)', 'tuple vector(1)', 'def object vector(1)', 'def tuple vector(1)'}

Result

global is never executed.

Module

Foundation

if (: : Condition :)

Conditional statement.

if is a conditional statement that starts an if block. The Condition parameter must evaluate to a Boolean or integer expression.

If Condition evaluates to *'true'* (not *0*), the following block body up to the next corresponding block statement elseif, else, or endif is executed. Reaching the end of the block the execution continues after the corresponding endif statement.

If Condition evaluates to *'false'* (*0*), the execution is continued at the next corresponding block statement elseif, else, or endif.

Parameters

▷ **Condition** (input_control) . . . . . integer ⇝ *integer*
Condition for the if statement.
Default: 1

Result

If the condition is correct if (as operator) returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Alternatives

elseif, else

See also

for, while, until

Module

Foundation

import (: : ProcedureSource :)

Import one or more external procedures.

The import statement can be used to import additional external procedures from within a HDevelop program. The imported procedures become only available for the procedure that contains the import statement but not for other procedures.

import statements may occur in any line of a procedure. The imported procedures become only available below the import statement and may be overruled by later import statements.

```
proc()
* unresolved procedure call

import ./the\_one\_dir
proc()
* resolves to ./the\_one\_dir/proc.hdvp

import ./the\_other\_dir
proc()
* resolves to ./the\_other\_dir/proc.hdvp
```

The parameter `ProcedureSource` points to the source of the external procedures. It can either be the path of a directory that contains the procedures and/or the procedure libraries to be used or directly the file name of a procedure library. In both cases, the path may either be absolute or relative. In the latter case, HDevelop interprets the path as being relative to the file location of the procedure that contains the `import` statement. Thus, the location of this procedure can be included with '.'. The path has to be in quotes if it contains one or more spaces, otherwise the program line will become invalid.

Contrary to system, user-defined, and session directories HDevelop looks only in the directory specified by an `import` statement for external procedures but not recursively in its subdirectories.

Note, that an `import` statement is never executed and, therefore, `ProcedureSource` has to be evaluated already at the procedure's loading time. Therefore, `ProcedureSource` has to be a constant expression, and, in particular, it is not possible to pass a string variable to `ProcedureSource`.

However, `ProcedureSource` may also contain environment variables, which HDevelop resolves accordingly. Environment variables, regardless of the platform actually used, must always be denoted in Windows syntax, i.e., %VARIABLE%.

`import` neither tests whether the path `ProcedureSource` exists nor whether it points to a procedure library or a directory that contains procedures at all. Therefore, `import` statements with nonexistent or pointless paths nonetheless stay valid program lines, in any case.

Import paths are listed separately in HDevelop's procedure settings. Of course, these paths can't be modified or deactivated from within the procedure settings. Furthermore, procedures that are available only via an `import` statement are marked with a special icon.

In the program listing, import statements are displayed and must be entered without parenthesis in order to emphasize that the line is a declaration and not an executable operator.

Parameters

▷ **ProcedureSource** (input_control) ..... string ⇝ *string*
File location of the external procedures to be loaded: either a directory or a procedure library

Result

`import` is never executed.

Module

Foundation

insert (: : Input, Value, Index : Result)

Assignment of a value to a tuple element.

`insert` is obsolete and is only provided for reasons of backward compatibility. The modifying version of the `insert` operator was replaced by the operator `assign_at`. This operator uses the same notation in the full text editor, so that it is used automatically. The non-modifying version of the `insert` operator is replaced by the new operator `tuple_replace`.

`insert` assigns a single value to a specific element of a tuple.

In the full text editor an insert operation is simply entered with the help of the assignment operator sign ':=' and the index access operator sign '`[ ]`' for the result variable, e.g.:

```
Areas[Radius-1] := Area
```

If the operator window is used for entering the insert operator, `insert` must be entered into the operator combo box as the operator name. This opens the parameter area, where the parameter `Value` represents the expression that has to be evaluated to one value and assigned to the element at position `Index` within the tuple `Input`. The parameter `Result` gets the name of the variable where the result has to be stored.

If the input tuple that is passed via the parameter `Input` and the output tuple that is passed in `Result` are identical (and only in that case), the `insert` operator is listed and can be written in the full text editor in the above assignment notation. In this case, the input tuple is modified and the correct operator notation for above assignment would be:

```
insert (Areas, Area, Radius-1, Areas)
```

If the `Input` tuple and the `Result` tuple differ, the input tuple will not be modified. In this case, within the program listing only the operator notation can be used:

```
insert (Areas, Area, Radius-1, Result)
```

This is the same as:

```
Result := Areas
Result[Radius-1] := Area
```

Please note that the operator `insert` will not increase the tuple if the tuple already stores a value at the passed index. Instead of that the element at the position `Index` will be replaced. Hence, for the `Value` parameter exactly one single value (or an expression that evaluates to one single value) must be passed.

If the passed `Index` parameter is beyond the current tuple size, the tuple will be increased to the required size. The tuple elements that were inserted between the hitherto last element and the new element are undefined.

Parameters

▷ **`Input`** (input_control) . . . . . real(-array) ⇝ *real* / integer / string
Tuple, where the new value has to be inserted.
Default: []

▷ **`Value`** (input_control) . . . . . real ⇝ *real* / integer / string
Value that has to be inserted.
Default: 1
Value range: $0 \leq$ `Value` ≤ 1000000

▷ **`Index`** (input_control) . . . . . integer ⇝ *integer*
Index position for new value.
Default: 0
Suggested values: `Index` $\in \{0, 1, 2, 3, 4, 5, 6\}$
Minimum increment: 1

▷ **`Result`** (output_control) . . . . . real(-array) ⇝ *real* / integer / string
Result tuple with inserted values.

Result

If the expression is correct `insert` returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code returned.

Alternatives

`assign`

Module

Foundation

`par_join` (: : ThreadID :)

Wait for subthreads that were started with the `par_start` qualifier.

The `par_join` operator is used to wait in the calling procedure for all procedures or operators that have been started in separate subthreads by adding the `par_start` qualifier to the according program line. The subthreads to wait for are identified by their thread ids that are passed to the parameter `ThreadID`.

Attention: par_start is not an operator but a qualifier that is added at the begin of the program line that has to be executed in parallel to the calling procedure. The syntax is par_start <ThreadID> : followed by the actual procedure or operator call.

Parameters

▷ **ThreadID** (input_control) ..... thread_id(-array) ⇝ *integer*
Ids of all subthreads to wait for.

Example

```
* start two procedures in separate sub threads
par_start <ThreadID1> : producer_proc()
par_start <ThreadID2> : consumer_proc()
* wait until both procedures have finished
par_join ([ThreadID1, ThreadID2])
```

Result

If the values of the specified parameters are correct, par_join returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Module

Foundation

repeat (: : :)

Start statement of a repeat..until loop.

repeat is the first statement of an repeat..until loop.

Result

repeat always returns 2 (H_MSG_TRUE).

Alternatives

for, while

See also

until, break, continue

Module

Foundation

return (: : :)

Terminate procedure call.

return terminates the current procedure call and returns to the calling procedure. Program execution is continued at the next active program line after the procedure call in the calling procedure. If the current procedure is the main procedure, program execution is finished and the program counter jumps to the end of the program. Note that every procedure except the main procedure has to contain at least one reachable return operator line in order to be able to return from a call to the procedure.

Result

return always returns 2 (H_MSG_TRUE).

Module

Foundation

stop (: : :)

Stop program execution.

The stop operator stops the continuous program execution of the HDevelop program. If this happens, the PC remains on the stop statement (instead of being placed at the next executable program line) to show the reason for the program interruption directly even if numerous comments or other non-executable program lines follow.

The operator is equivalent to the Stop action (F9) in the menu bar. Unless parallel execution is used (via the par_start qualifier), the program can easily be continued with the Run action (F5). See also "Parallel Execution" in the HDevelop User's Guide.

It is possible to redefine the behavior by setting a time parameter in the preferences dialog. In this case, the execution will not stop but continue after waiting for the specified period of time. Within this period of time, the program can be interrupted with F9 or continued with one of the run commands. This is marked by an icon in the first column of the program window.

Attention

This operator is not supported for code export.

Trying to continue a program that uses parallel execution after calling stop may cause non-deterministic thread behavior or errors.

Example

```
read_image (Image, 'fabrik')
regiongrowing (Image, Regions, 3, 3, 6, 100)
count_obj (Regions, Number)
dev_update_window ('off')
for i := 1 to Number by 1
  select_obj (Regions, RegionSelected, i)
  dev_clear_window ()
  dev_display (RegionSelected)
  stop ()
endfor
```

Result

If the program stops at a stop statement, the return state of the previous operator is kept. If the program is continued with the stop operator, stop always returns 2 (H_MSG_TRUE).

See also

exit

Module

Foundation

switch (: : ControlExpression :)

Starts a multiway branch block.

switch starts a block that allows to control the program flow via a multiway branch. The parameter ControlExpression must result in an integer value. This value determines to what case label the execution jumps. Every case statement includes one integer constant. If the integer constant of a case statement is equal to the calculated value of the parameter ControlExpression, the program execution continues there. In addition, an optional default statement can be defined as the last jump label within a switch block. The program execution jumps to this default label, if no case constant matches the calculated ControlExpression value.

As in the programming languages C, C++, and C#, the case statement is a jump label and—in contrast to elseif—not the begin of an enclosed block that is automatically left at the next case or default statement.

In order to leave the switch block after the execution of the code lines of a case branch, as in C or C++ a break statement must be inserted at the end of the case branch. break statements can be used anywhere within a switch block. This causes the program execution to continue after the closing endswitch statement. Without a break statement at the end of a branch the program execution "falls through" to the statements of the following case or default branch.

If the same statements have to be executed in different cases, i.e., for multiple control values, several case statements with different constant expressions can be listed one below the other.

Parameters

▷ **ControlExpression** (input_control) ..... integer ⇝ *integer*
Integer expression that determines at which case label the program execution is continued.

Example

```
TestStr := ''
for Index := 1 to 8 by 1
  TestStr := TestStr + '<'
  switch (Index)
  case 1:
    TestStr := TestStr + '1'
    break
  case 2:
    TestStr := TestStr + '2'
    * intentionally fall through to 3
  case 3:
    TestStr := TestStr + '3'
    * intentionally fall through to 4
  case 4:
    TestStr := TestStr + '4'
    break
  case 5:
  case 6:
    * common case branch for 5 and 5
    TestStr := TestStr + '56'
    break
  case 7:
    * continue for loop
    TestStr := TestStr + '7'
    continue
  default:
    TestStr := TestStr + 'd'
    break
  endswitch
  TestStr := TestStr + '>'
endfor
```

Result

If the condition is correct, `switch` (as an operator) returns `2` (`H_MSG_TRUE`). Otherwise, an exception is raised and an error code is returned.

Alternatives

`if`, `elseif`, `else`

See also

`case`, `default`, `endswitch`, `if`

Module

Foundation

throw (: : Exception :)

Throws a user-defined exception or rethrows a caught exception.

With the help of the operators `try`, `catch`, `endtry`, and `throw` it is possible to implement a dynamic exception handling in HDevelop, which is comparable to the exception handling in C++ and C#. The basic concepts of the exception handling in HDevelop are also described at the operators `try`, and `dev_set_check` as well as in the "HDevelop User's Guide".

The operator throw provides an opportunity to throw an exception from an arbitrary place in the program. This exception can be caught by the catch operator of a surrounding try-catch block. By this means the developer is able to define his own specific error or exception states, for which the normal program execution is aborted in order to continue with a specific cross-procedure exception handling, e.g., for freeing resources or restarting from a defined state.

In such a user-defined exception a nearly arbitrary tuple can be thrown as the Exception parameter, merely the first element of the tuple should be set to a user-defined error code $\geq$ 30000. If different user-defined exception states are possible, they can be distinguished using different error codes ($\geq$ 30000) in the first element or by using additional elements.

In addition, with the help of the operator throw it is possible to rethrow an exception that was caught with the operator catch. This may be sensible, for instance, if within an inner try-catch-endtry block (e.g., within an external procedure) only specific exceptions can be handled in an adequate way and all other exceptions must be passed to the caller, where they can be caught and handled by an outer try-catch-endtry block.

For rethrowing a caught exception, it is possible to pass the Exception tuple that was caught by the catch operator directly to the Exception parameter of the throw operator. Furthermore, it is possible to append arbitrary (but no iconic) user data to the Exception tuple, that can be accessed after catching the exception as *'user_data'* with the operator dev_get_exception_data:

```
try
    ...
catch(Exception)
    ...
    UserData := ...
    throw([Exception, UserData])
endtry
```

Attention

The export of the operators try, catch, endtry, and throw is not supported for the language C, but only for the languages C++, C# and VisualBasic/.NET. Only the latter support throwing exceptions across procedures.

Parameters

▷ **Exception** (input_control) ..... exception-array ⇝ *integer* / string
Tuple returning the exception data or user defined error codes.

Result

If the values of the specified parameters are correct, throw (as operator) returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

See also

try, catch, endtry, dev_get_exception_data, dev_set_check

Module

Foundation

try (: : :)

Starts a program block where exceptions are detected and caught.

With the help of the operators try, catch, endtry, and throw it is possible to implement a dynamic exception handling in HDevelop, which is comparable to the exception handling in C++ and C#. By the operators try, catch, and endtry two code blocks are formed: the first one (try .. catch) contains the watched program lines that perform the normal program logic. The second block (catch .. endtry) contains the code that has is executed if an exception occurs.

The operator try enables the exception handling for the following program lines, i.e., the following code block up to the corresponding catch operator is watched for exceptions. If during the execution of the subsequent program lines an error or another exceptional state occurs, or if an exception is thrown explicitly by the operator throw, the try block is left immediately (or—depending on a user preference—after displaying an error message box) and the program execution continues at the corresponding catch operator. If the exception is thrown within

a procedure that was called from the try block (directly or via other procedure calls), the procedure call and all intermediate procedure calls that are on the call stack above the try block are immediately aborted (or, if applicable, also after displaying an error message box).

Whether an error message box is displayed before the exception is thrown or not, is controlled by the HDevelop preference 'Suppress error message dialogs within try-catch blocks' that can be reached via Edit->Preferences->General Options->Experienced User. This message box also offers the opportunity to stop the program execution before the exception is thrown in order to edit the possibly erroneous operator call.

The program block that is watched for exceptions ends with the corresponding catch operator. If within the watched try block no exception occurred, the following catch block is ignored and the program execution continues after the corresponding endtry operator.

try-catch-endtry blocks can be nested arbitrarily into each other, within a procedure or over different procedure calls, as long as any inner try-catch-endtry block lies completely *either* within an outer try-catch *or* a catch-endtry block. If an exception is thrown within an inner try-catch block, the exception handling is caught in the corresponding catch-endtry block. Hence, the exception is not visible for the outer try-catch blocks unless the exception is rethrown explicitly by calling a throw operator from the catch block.

If within a HALCON operator an error occurs, an exception tuple is created and passed to the catch operator that is responsible for catching the exception. The tuple collects information about the error such as the error code and the error text. After catching an exception, this information can be accessed with the help of the operator dev_get_exception_data. For more information about the passed exception data, how to access them, and considerations about the code export, see the description of that operator. The reference of the operator throw describes how to throw user-defined exception tuples.

HDevelop offers the opportunity to disable the handling of HALCON errors. This can be achieved by calling the operator dev_set_check('~give_error') or by unchecking the check box *Give Error* on the dialog Edit->Preferences->Runtime Settings. If the error handling is switched off, in case of an HALCON error no exception is thrown but the program execution is continued as normal at the next operator. In contrast to that, the operator throw will always throw an exception independently of the *'give_error'* setting. The same applies if an error occurred during the evaluation of an parameter expression.

Attention

The export of the operators try, catch, endtry, and throw is not supported for the language C, but only for the languages C++, C# and VisualBasic/.NET. Only the latter support throwing exceptions across procedures.

Example

```
try
  read_image (Image, 'may_be_not_available')
catch (Exception)
  if (Exception[0] == 5200)
    dev_get_exception_data (Exception, 'error_message', ErrMsg)
    set_tposition (3600, 24, 12)
    write_string (3600, ErrMsg)
    return ()
  else
    * rethrow the exception
    throw ([Exception,'unknown exception in myproc'])
  endif
endtry
```

Result

try always returns 2 (H_MSG_TRUE).

Alternatives

dev_set_check

See also

catch, endtry, throw, dev_get_exception_data, dev_set_check

Module

Foundation

until (: : Condition :)

Continue to execute the body as long as the condition is not true.

until ends a repeat..until loop. The repeat..until loop is executed as long as the Condition parameter evaluates to *'false'* (*0*). The body of the loop is executed at least once, because the condition will be checked at the end of the body.

Parameters

▷ **Condition** (input_control) ..... integer ⇝ *integer*
Condition for loop.

Result

If the values of the specified parameters are correct, until (as operator) returns 2 (H_MSG_TRUE). Otherwise, an exception is raised and an error code returned.

Alternatives

for, while

See also

repeat, if, elseif, else, break, continue

Module

Foundation

while (: : Condition :)

Starts a loop block that is executed as long as the condition is true.

while executes the loop body up to the corresponding endwhile statement as long as the Condition parameter evaluates to *'true'* (or a number not equal *0*).

If the condition evaluates to *'false'* (*0*) the program is continued after the corresponding endwhile statement.

Parameters

▷ **Condition** (input_control) ..... integer ⇝ *integer*
Condition for loop.

Example

```
dev_update_window ('off')

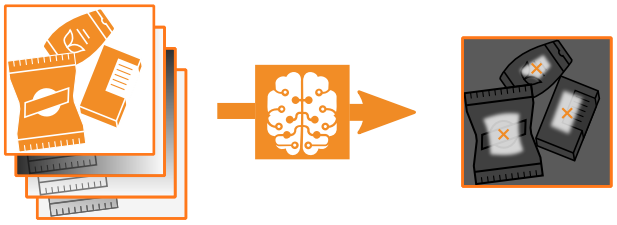
Chapter 9

Deep Learning

Introduction

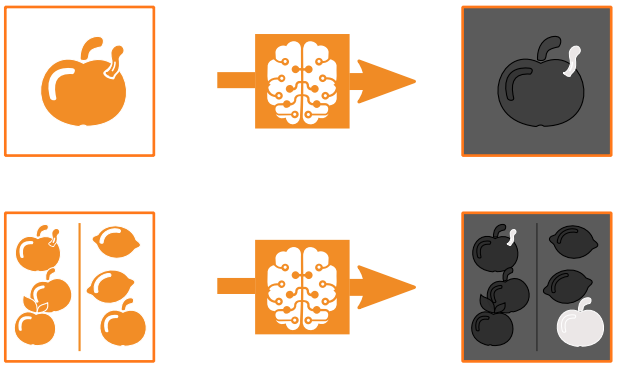
The term deep learning (DL) refers to a family of machine learning methods. In HALCON, the following methods are implemented:

3D Gripping Point Detection: Detect gripping points on objects in a 3D scene. For further information please see the chapter 3D Matching / 3D Gripping Point Detection.



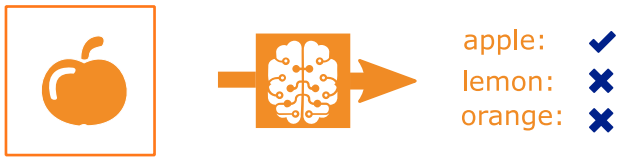
A possible example for a 3D Gripping Point Detection application: A 3D scene (e.g., an RGB image and XYZ-images) is analyzed and possible gripping points are suggested.

Anomaly Detection and Global Context Anomaly Detection Assign to each pixel the likelihood that it shows an unknown feature. For further information please see the chapter Deep Learning / Anomaly Detection and Global Context Anomaly Detection.

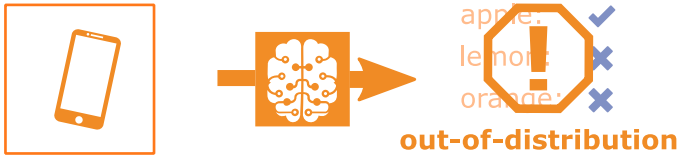


Top: A possible example for anomaly detection: A score is assigned to every pixel of the input image, indicating how likely it shows an unknown feature, i.e., an anomaly. Bottom: A possible example for Global Context Anomaly Detection: A score is assigned to every pixel of the input image, indicating how likely it shows a structural or logical anomaly.

Classification: Classify an image into one class out of a given set of classes. For further information please see the chapter Deep Learning / Classification.

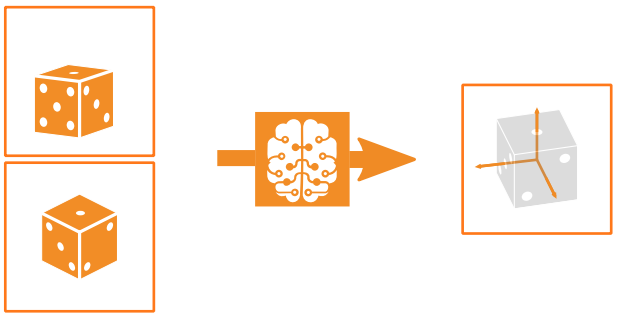


A possible example for classification: The image gets assigned to a class.



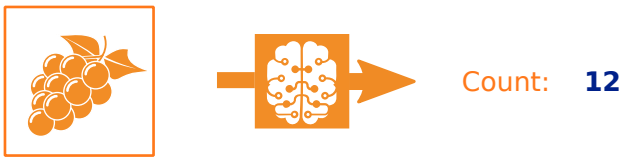
A possible example for Out-of-Distribution Detection for classification: The image is assigned to a class and identified as Out-of-Distribution if applicable.

Deep 3D Matching: Detect objects in a scene and compute their 3D pose. For further information please see the chapter 3D Matching / Deep 3D Matching.



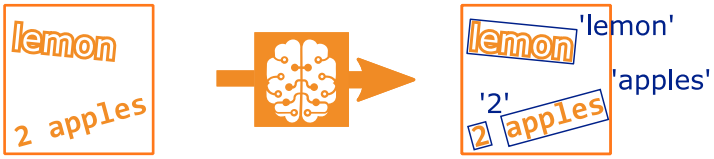
A possible example for a Deep 3D Matching application: Images from different angles are used to detect an object. As a result the 3D pose of the object is computed.

Deep Counting: Detect and count objects in images. For further information please see the chapter Matching / Deep Counting.



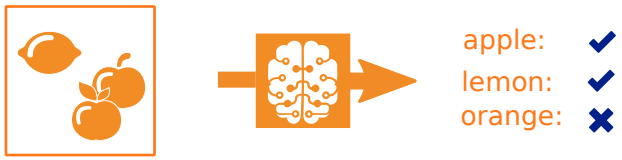
A possible example for a Deep Counting application: Objects in an image are counted and the object quantity is returned.

Deep OCR: Detect and recognize words (not just characters) in an image. For further information please see the chapter OCR / Deep OCR.



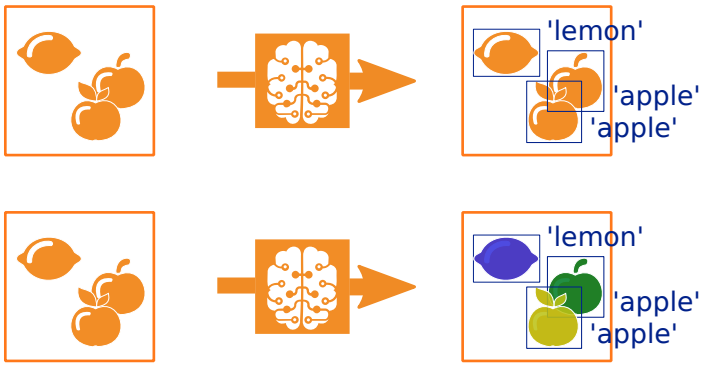
A possible example for deep-learning-based optical character recognition: Words in an image are detected and recognized.

Multi-label Classification: An image is assigned all contained classes from a given set of classes. For further information please see the chapter Deep Learning / Multi-Label Classification.



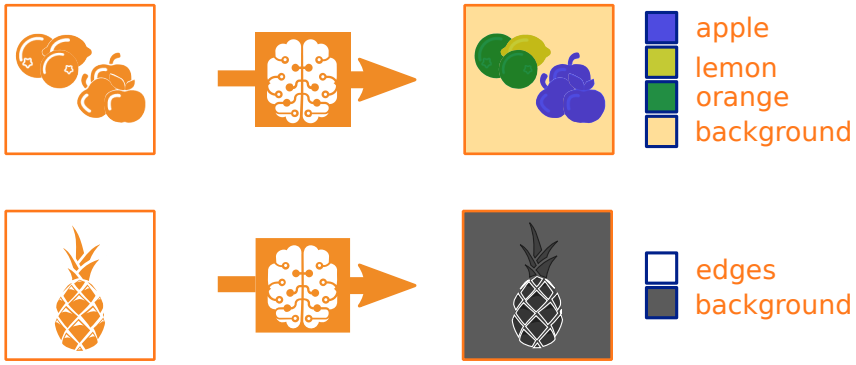
A possible example for multi-label classification: All contained classes are assigned to the image.

Object Detection and Instance Segmentation: Detect objects of the given classes and localize them within the image. Instance segmentation is a special case of object detection, where the model also predicts distinguished object instances and additionally assigns for the found instances their region within the image. For further information please see the chapter Deep Learning / Object Detection and Instance Segmentation.



Top: A possible example for object detection: Within the input image three instances are found and assigned to a class.
Bottom: A possible example for instance segmentation: Every instance gets its individual region marked.

Semantic Segmentation and Edge Extraction: Assign a class to each pixel of an image, but different instances of a class are not distinguished. A special case of semantic segmentation, where every pixel of the input image is assigned to one of the two classes 'edge' and 'background'. For further information please see the chapter Deep Learning / Semantic Segmentation and Edge Extraction.



Top: A possible example for semantic segmentation: Every pixel of the input image is assigned to a class.
Bottom: A possible example for edge extraction: Pixels belonging to specific edges are assigned to the class 'edge'.

All of the deep learning methods listed above use a network for the assignment task. In HALCON they are implemented within the general DL model, see Deep Learning / Model. The model is trained by only considering the input and output, which is also called end-to-end learning. Basically, using images and the information, what is visible in them, the training algorithm adjusts the model in a way to distinguish the different classes and eventually also how to find the corresponding objects. For you, it has the nice outcome of no need for manual feature specification. Instead you have to select and collect appropriate data.

System Requirements and License Information

For Deep learning additional prerequisites apply. Please see the requirements listed in the HALCON "`Installation Guide`", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Note that the required module license depends on the model type used in your application. For a detailed description please refer to the "Installation Guide", paragraph "Dynamic Modules for Deep-Learning-Based Applications".

General Workflow

As the DL methods mentioned above differ in what they do and how they need the data, you need to know which method is most appropriate for your specific task. Once this is clear, you need to collect a suitable amount of data, meaning images and the information needed by the method. After that, there is a common general workflow for all these DL methods:

Prepare the Network and the Data The network needs to be prepared for your task and your data adapted to the specific network.

- Get a network: Read in a pretrained network or create one.
- The network needs to know which problem it shall solve, i.e., which classes are to be distinguished and what such samples look like. This is represented by your dataset, i.e., your images with the corresponding ground truth information.
- The network will impose several requirements on the images (as e.g., the image dimension, gray value range, ...). Therefore the images have to be preprocessed so that the network can process them.
- We recommend to split the dataset into three distinct datasets which are used for training, validation, and testing.

Train the Network and Evaluate the Training Progress Once your network is set up and your data prepared it is time to train the network for your specific task.

- Set the hyperparameters appropriate to your task and system.
- Optionally specify your data augmentation.
- Start the training and evaluate your network.

Apply and Evaluate the Final Network Your network is trained for your task and ready to be applied. But before deploying it in the real world you should evaluate how well the network performs on basis of your test dataset.

Inference Phase When your network is trained and you are satisfied with its performance, you can use it for inference on new images. Thereby the images need to be preprocessed according to the requirements of the network (thus, in the same way as for training).

Data

The term 'data' is used in the context of deep learning as the images and the information, what is in them. This last information has to be provided in a way the network can understand. Not surprisingly, the different DL methods have their own requirements concerning what information has to be provided and how. Please see the corresponding chapters for the specific requirements.

The network further poses requirements on the images regarding the image dimensions, the gray value range, and the type. The specific values depend on the network itself and can be queried with `get_dl_model_param`. Additionally, depending on the method there are also requirements regarding the information as e.g., the bounding boxes. To fulfill all these requirements, the data may have to be preprocessed, which can be done most conveniently with the corresponding procedure `preprocess_dl_samples`.

When you train your network, the network gets adapted to its task. But at one point you will want to evaluate what the network learned and at an even later point you will want to test the network. Therefore the dataset will be split into three subsets which should be independent and identically distributed. In simple words, the subsets should not be connected to each other in any way and each set contains for every class the same distribution of images. This splitting is conveniently done by the procedure `split_dl_dataset`. The clearly largest subset will be used for the retraining. We refer to this dataset as the training dataset. At a certain point the performance of the network is evaluated to check whether it is beneficial to continue the network optimization. For this validation the second set of data is used, the validation dataset. Even if the validation dataset is disjoint from the first one, it has an influence on the network optimization. Therefore to test the possible predictions when the model is deployed in

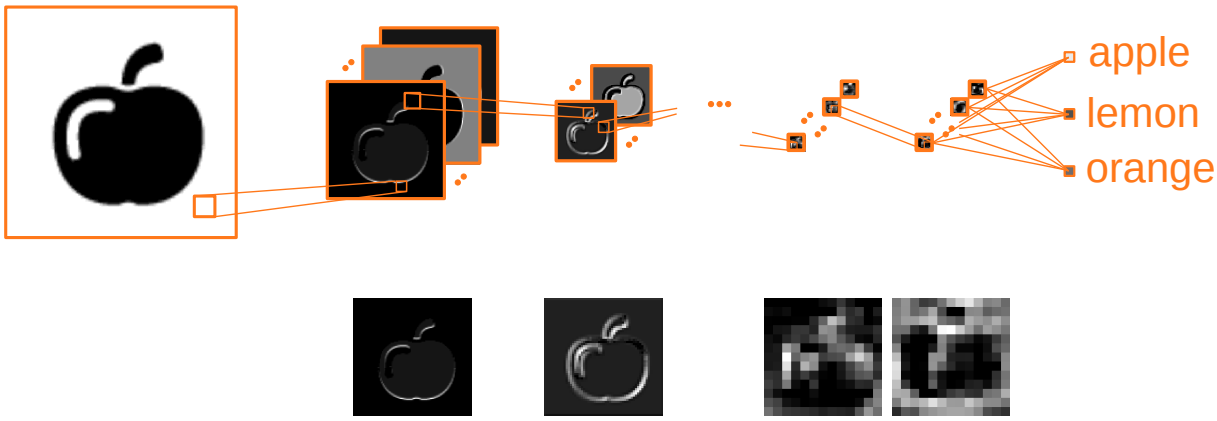
the real world, the third dataset is used, the test dataset. For a representative network validation or evaluation, the validation and test dataset should have statistically relevant data, which gives a lower bound on the amount of data needed.

Note also, that for training the network, you best use representative images, i.e., images like the ones you want to process later and not only 'perfect' images, as otherwise the network may have difficulties with non-'perfect' images.

The Network and the Training Process

In the context of deep learning, the assignments are performed by sending the input image through a network. The output of the total network consists of a number of predictions. Such predictions are e.g., for a classification task the confidence for each class, expressing how likely the image shows an instance of this class.

The specific network will vary, especially from one method to another. Some methods like e.g., object detection, use a subnetwork to generate feature maps (see the explanations given below and in Deep Learning / Object Detection and Instance Segmentation). Here, we will explain a basic Convolutional Neural Network (CNN). Such a network consists of a certain number of layers or filters, which are arranged and connected in a specific way. In general, any layer is a building block performing specific tasks. It can be seen as a container, which receives input, transforms it according to a function, and returns the output to the next layer. Thereby different functions are possible for different types of layers. Several possible examples are given in the "`Solution Guide on Classification`". Many layers or filters have weights, parameters which are also called filter weights. These are the parameters modified during the training of a network. The output of most layers are feature maps. Thereby the number of feature maps (the depth of the layer output) and their size (width and height) depends on the specific layer.



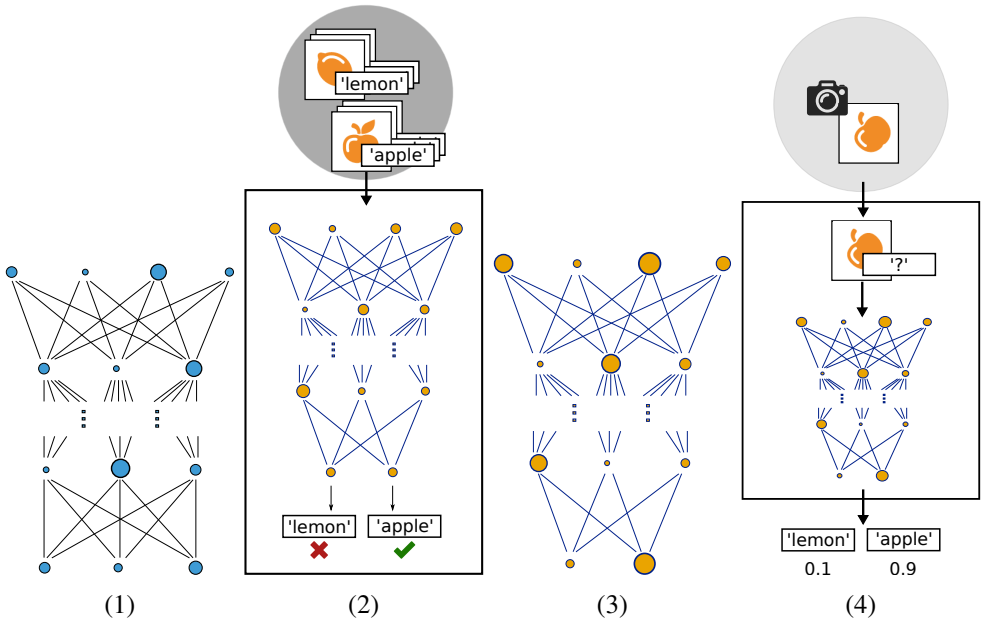
Schema of an extract of a possible classification network. Below we show feature maps corresponding to the layers, zoomed to a uniform size.

To train a network for a specific task, a loss function is added. There are different loss functions depending on the task, but they all work according to the following principle. A loss function compares the prediction from the network with the given information, what it should find in the image (and, if applicable, also where), and penalizes deviations. Now the filter weights are updated in such a way that the loss function is minimized. Thus, training the network for the specific tasks, one strives to minimize the loss (an error function) of the network, in the hope of doing so will also improve the performance measure. In practice, this optimization is done by calculating the gradient and updating the parameters of the different layers (filter weights) accordingly. This is repeated by iterating multiple times over the training data.

There are additional parameters that influence the training, but which are not directly learned during the regular training. These parameters have values set before starting the training. We refer to this last type of parameters as hyperparameters in order to distinguish them from the network parameters that are optimized during training. See the section "Setting the Training Parameters: The Hyperparameters".

To train all filter weights from scratch a lot of resources are needed. Therefore one can take advantage from the following observation. The first layers detect low level features like edges and curves. The feature map of the following layers are smaller, but they represent more complex features. For a large network, the low level features are general enough so the weights of the corresponding layers will not change much among different tasks. This leads to a technique called transfer learning: One takes an already trained network and retrains it for a specific task,

benefiting from already quite suitable filter weights for the lower layers. As a result, considerably less resources are needed. While in general the network should be more reliable when trained on a larger dataset, the amount of data needed for retraining also depends on the complexity of the task. A basic schema for the workflow of transfer learning is shown with the aid of classification in the figure below.



Basic schema of transfer learning with the aid of classification. (1) A pretrained network is read. (2) Training phase, the network gets trained with the training data. (3) The trained model with new capabilities. (4) Inference phase, the trained network infers on new images.

Setting the Training Parameters: The Hyperparameters

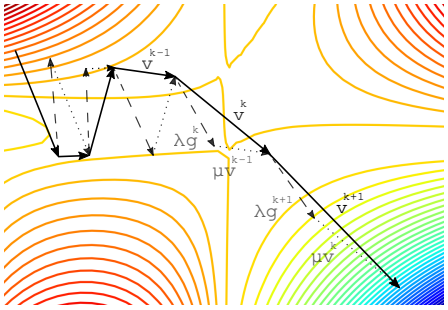
The different DL methods are designed for different tasks and will vary in the way they are built up. They all have in common that during the training of the model one faces a minimization problem. Training the network or subnetwork, one strives to minimize an appropriate loss function, see the section "The Network and the Training Process". For doing so, there is a set of further parameters which is set before starting the training and not optimized during the training. We refer to these parameters as hyperparameters. For a DL model, you can set a change strategy, specifying when and how you want these hyperparameters changed during the training. In this section, we explain the idea of the different hyperparameters. Note, that certain methods have additional hyperparameters, you find more information in their respective chapter.

As already mentioned, the loss compares the predictions from the network with the given information about the content of the image. The loss now penalizes deviations. Training the network means updating the filter weights in such a way, that the loss has to penalize less, thus the loss result is optimized. To do so, a certain amount of data is taken from the training dataset. For this subset the gradient of the loss is calculated and the network modified in updating its filter weights accordingly. Now this is repeated with the next subset of data till the whole training data is processed. These subsets of the training data are called batches and the size of these subsets, the *'batch_size'*, determines the number of data taken into a batch and as a consequence processed together.

A full iteration over the entire training data is called epoch. It is beneficial to iterate several times over the training data. The number of iterations is defined by `'epochs'`. Thus, `'epochs'` determines how many times the algorithm loops over the training set.

Some models (e.g., anomaly detection) train utilizing the whole dataset at once. For other models, the dataset is processed batch-wise and in order to do so, the SGD (stochastic gradient descent algorithm) or Adam (adaptive moment estimation) can be used. This involves further parameters, which are explained in the following. After every calculation of the loss gradient the filter weights are updated. For this update, there are two important hyperparameters: The *'learning_rate'* λ, determining the weight of the gradient on the updated loss function arguments (the filter weights), and the *'momentum'* μ within the interval $[0, 1)$, specifying the influence of previous updates. More information can be found in the documentation of `train_dl_model_batch`. In simple words, when we update the loss function arguments, we still remember the step we took for the last update. Now, we take a step in direction of the gradient with a length depending to the learning rate; additionally we repeat the step

we did last times, but this time only μ times as long. A visualization is given in the figure below. A too large learning rate might result in divergence of the algorithm, a very small learning rate will take unnecessarily many steps. Therefore, it is customary to start with a larger learning rate and potentially reduce it during training. With a momentum $\mu = 0$, the momentum method has no influence, so only the gradient determines the update vector.



Sketch of the *'learning_rate'* and the *'momentum'* during an actualization step. The gradient step: the learning rate λ times the gradient g (λg - dashed lines). The momentum step: the momentum μ times the previous update vector v (μv - dotted lines). Together, they form the actual step: the update vector v (v - solid lines).

To prevent the neural networks from overfitting (see the part "Risk of Underfitting and Overfitting" below), regularization can be used. With this technique an extra term is added to the loss function. One possible type of regularization is weight decay, for details see the documentation of `train_dl_model_batch`. It works by penalizing large weights, i.e., pushing the weights towards zero. Simply put, this regularization favors simpler models that are less likely to fit to noise in the training data and generalize better. It can be set by the hyperparameter *'weight_prior'*. Choosing its value is a trade-off between the model's ability to generalize, overfitting, and underfitting. If *'weight_prior'* is too small the model might overfit, if it is too large, the model might loose its ability to fit the data well because all weights are effectively zero.

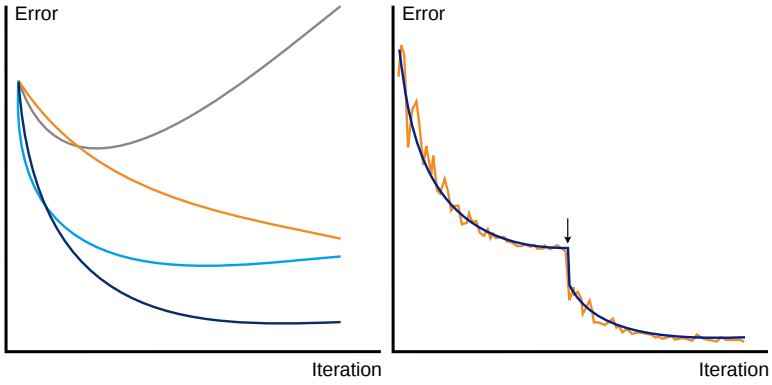
With the training data and all the hyperparameters, there are many different aspects that can have an influence on the outcome of such complex algorithms. To improve the performance of a network, generally the addition of training data also helps. Please note, whether to gather more data is a good solution always depends also on how easily one can do so. Usually, a small additional fraction will not noticeably change the total performance.

Supervising the training

The different DL methods have different results. Accordingly they also use different measures to determine 'how well' a network performs. When training a network, there are behaviors and pitfalls applying to different models, which are described here.

Validation During Training When it comes to the validation of the network performance, it is important to note that this is not a pure optimization problem (see the parts "The Network and the Training Process" and "Setting the Training Parameters" above).

In order to observe the training progress, it is usually helpful to visualize a validation measure, e.g., for the training of a classification network, the error over the samples of a batch. As the samples differ, the difficulty of the assignment task may differ. Thus it may be that the network performs better or worse for the samples of a given batch than for the samples of another batch. So it is normal that the validation measure is not changing smoothly over the iterations. But in total it should improve. Adjusting the hyperparameters *'learning_rate'* and *'momentum'* can help to improve the validation measure again. The following figures show possible scenarios.

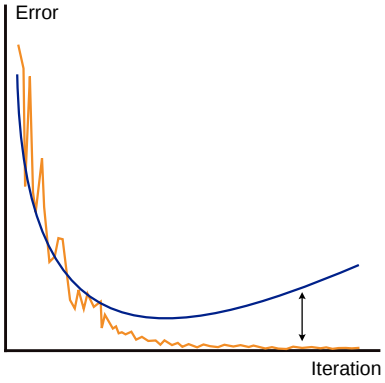


(1) (2)

Sketch of an validation measure during training, here using the error from classification as example. (1) General tendencies for possible outcomes with different *'learning_rate'* values, dark blue: good learning rate, gray: very high learning rate, light blue: high learning rate, orange: low learning rate. (2) Ideal case with a learning rate policy to reduce the *'learning_rate'* value after a given number of iterations. In orange: training error, dark blue: validation error. The arrow marks the iteration, at which the learning rate is decreased.

Risk of Underfitting and Overfitting Underfitting occurs if the model is not able to capture the complexity of the task. It is directly reflected in the validation measure on the training set which stays high.

Overfitting happens when the network starts to 'memorize' training data instead of learning how to generalize. This is shown by a validation measure on the training set which stays good or even improves while the validation measure on the validation set decreases. In such a case, regularization may help. See the explanations of the hyperparameter *'weight_prior'* in the section "Setting the Training Parameters: The Hyperparameters". Note that a similar phenomenon occurs when the model capacity is too high with respect to the data.



Sketch of a possible overfitting scenario, visible on the generalization gap (indicated with the arrow). The error from classification serves as an example for a validation measure.

Confusion Matrix A network infers for an instance a top prediction, the class for which the network deduces the highest affinity. When we know its ground truth class, we can compare the two class affiliations: the predicted one and the correct one. Thereby, the instance differs between the different types of methods, while e.g., in classification the instances are images, in semantic segmentation the instances are single pixels.

When more than two classes are distinguished, one can also reduce the comparison into binary problems. This means, for a given class you just compare if it is the same class (positive) or any other class (negative). For such binary classification problems the comparison is reduced to the following four possible entities (whereof not all are applicable for every method):

- True positives (TP: predicted positive, labeled positive),
- true negatives (TN: predicted negative, labeled negative),
- false positives (FP: predicted positive, labeled negative),
- false negatives (FN: predicted negative, labeled positive).

A confusion matrix is a table with such comparisons. This table makes it easy to see how well the network performs for each class. For every class it lists how many instances have been predicted into which class. E.g., for a classifier distinguishing the three classes 'apple', 'peach', and 'orange', the confusion matrix shows how many images with ground truth class affiliation 'apple' have been classified as 'apple' and how many have been classified as 'peach' or 'orange'. Of course, this is listed for the other classes as well. This example is shown in the figure below. In HALCON, we represent for each class the instances with this ground truth label in a column and the instances predicted to belong to this class in a row.

(1) (2)

An example for a confusion matrices from classification. We see that 68 images of an 'apple' have been classified as such (TP), 60 images showing not an 'apple' have been correctly classified as a 'peach' (30) or 'pear' (30) (TN), 0 images show a 'peach' or a 'pear' but have been classified as an 'apple' (FP) and 24 images of an 'apple' have wrongly been classified as 'peach' (21) or 'pear' (3) (FN). (1) A confusion matrix for all three distinguished classes. It appears as if the network 'confuses' apples and peaches more than all other combinations. (2) The confusion matrix of the binary problem to better visualize the 'apple' class.

Glossary

In the following, we describe the most important terms used in the context of deep learning:

Adam Adam (adaptive moment estimation) is a first-order gradient-based optimization algorithm for stochastic objective functions, which computes individual adaptive learning rates. In the deep learning methods this algorithm can be used to minimize the loss function.

anchor Anchors are fixed bounding boxes. They serve as reference boxes, with the aid of which the network proposes bounding boxes for the objects to be localized.

annotation An annotation is the ground truth information, what a given instance in the data represents, in a way recognizable for the network. This is e.g., the bounding box and the corresponding label for an instance in object detection.

anomaly An anomaly means something deviating from the norm, something unknown.

backbone A backbone is a part of a pretrained classification network. Its task is to generate various feature maps, for what reason the classifying layer has been removed.

batch size - hyperparameter *'batch_size'* The dataset is divided into smaller subsets of data, which are called batches. The batch size determines the number of images taken into a batch and thus processed simultaneously.

bounding box Bounding boxes are rectangular boxes used to define a part within an image and to specify the localization of an object within an image.

class agnostic Class agnostic means without the knowledge of the different classes.

In HALCON, we use it for reduction of overlapping predicted bounding boxes. This means, for a class agnostic bounding box suppression the suppression of overlapping instances is done ignoring the knowledge of classes, thus strongly overlapping instances get suppressed independently of their class.

change strategy A change strategy denotes the strategy, when and how hyperparameters are changed during the training of a DL model.

class Classes are discrete categories (e.g., 'apple', 'peach', 'pear') that the network distinguishes. In HALCON, the class of an instance is given by its appropriate annotation.

classifier In the context of deep learning we refer to the term classifier as follows. The classifier takes an image as input and returns the inferred confidence values, expressing how likely the image belongs to every distinguished class. E.g., the three classes 'apple', 'peach', and 'pear' are distinguished. Now we give an image of an apple to the classifier. As a result, the confidences 'apple': 0.92, 'peach': 0.07, and 'pear': 0.01 could be returned.

COCO COCO is an abbreviation for "common objects in context", a large-scale object detection, segmentation, and captioning dataset. There is a common file format for each of the different annotation types.

confidence Confidence is a number expressing the affinity of an instance to a class. In HALCON the confidence is the probability, given in the range of [0,1]. Alternative name: score

confusion matrix A confusion matrix is a table which compares the classes predicted by the network (top-1) with the ground truth class affiliations. It is often used to visualize the performance of the network on a validation or test set.

Convolutional Neural Networks (CNNs) Convolutional Neural Networks are neural networks used in deep learning, characterized by the presence of at least one convolutional layer in the network. They are particularly successful for image classification.

data We use the term data in the context of deep learning for instances to be recognized (e.g., images) and their appropriate information concerning the predictable characteristics (e.g., the labels in case of classification).

data augmentation Data augmentation is the generation of altered copies of samples within a dataset. This is done in order to augment the richness of the dataset, e.g., through flipping or rotating.

dataset: training, validation, and test set With dataset we refer to the complete set of data used for a training. The dataset is split into three, if possible disjoint, subsets:

- The training set contains the data on which the algorithm optimizes the network directly.
- The validation set contains the data to evaluate the network performance during training.
- The test set is used to test possible inferences (predictions), thus to test the performance on data without any influence on the network optimization.

deep learning The term "deep learning" was originally used to describe the training of neural networks with multiple hidden layers. Today it is rather used as a generic term for several different concepts in machine learning. In HALCON, we use the term deep learning for methods using a neural network with multiple hidden layers.

epoch In the context of deep learning, an epoch is a single training iteration over the entire training data, i.e., over all batches. Iterations over epochs should not be confused with the iterations over single batches (e.g., within an epoch).

errors In the context of deep learning, we refer to error when the inferred class of an instance does not match the real class (e.g., the ground truth label in case of classification). Within HALCON, we use the term error in deep learning when we refer to the top-1 error.

feature map A feature map is the output of a given layer

feature pyramid A feature pyramid is simply a group of feature maps, whereby every feature map origins from another level, i.e., it is smaller than its preceding levels

head Heads are subnetworks. For certain architectures they attach on selected pyramid levels. These subnetworks proceed information from previous parts of the total network in order to generate spatially resolved output, e.g., for the class predictions. Thereof they generate the output of the total network and therewith constitute the input of the losses.

hyperparameter Like every machine learning model, CNNs contain many formulas with many parameters. During training the model learns from the data in the sense of optimizing the parameters. However, such models can have other, additional parameters, which are not directly learned during the regular training. These

parameters have values set before starting the training. We refer to this last type of parameters as hyperparameters in order to distinguish them from the network parameters that are optimized during training. Or from another point of view, hyperparameters are solver-specific parameters.

Prominent examples are the initial learning rate or the batch size.

inference phase The inference phase is the stage when a trained network is applied to predict (infer) instances (which can be the total input image or just a part of it) and eventually their localization. Unlike during the training phase, the network is not changed anymore in the inference phase.

in-distribution In-distribution refers to data that comes from the same underlying distribution as the data on which a model was trained. When a model encounters in-distribution data during inference , the data is similar in terms of its statistical properties, features, and patterns to what the model has seen before during training.

intersection over union The intersection over union (IoU) is a measure to quantify the overlap of two areas. We can determine the parts common in both areas, the intersection, as well as the united areas, the union. The IoU is the ratio between the two areas intersection and union.

The application of this concept may differ between the methods.

label Labels are arbitrary strings used to define the class of an image. In HALCON these labels are given by the image name (eventually followed by a combination of underscore and digits) or by the directory name, e.g., 'apple_01.png', 'pear.png', 'peach/01.png'.

layer and hidden layer A layer is a building block in a neural network, thus performing specific tasks (e.g., convolution, pooling, etc., for further details we refer to the "`Solution Guide on Classification`"). It can be seen as a container, which receives weighted input, transforms it, and returns the output to the next layer. Input and output layers are connected to the dataset, i.e., the images or the labels, respectively. All layers in between are called hidden layers.

learning rate - hyperparameter *'learning_rate'* The learning rate is the weighting, with which the gradient is considered when updating the arguments of the loss function. In simple words, when we want to optimize a function, the gradient tells us the direction in which we shall optimize and the learning rate determines how far along this direction we step.

Alternative names: λ, step size

level The term level is used to denote within a feature pyramid network the whole group of layers, whose feature maps have the same width and height. Thereby the input image represents level 0.

loss A loss function compares the prediction from the network with the given information, what it should find in the image (and, if applicable, also where), and penalizes deviations. This loss function is the function we optimize during the training process to adapt the network to a specific task.

Alternative names: objective function, cost function, utility function

momentum - hyperparameter *'momentum'* The momentum $\mu \in [0, 1)$ is used for the optimization of the loss function arguments. When the loss function arguments are updated (after having calculated the gradient), a fraction μ of the previous update vector (of the past iteration step) is added. This has the effect of damping oscillations. We refer to the hyperparameter μ as momentum. When μ is set to 0, the momentum method has no influence. In simple words, when we update the loss function arguments, we still remember the step we did for the last update. Now we go a step in direction of the gradient with a length according to the learning rate and additionally we repeat the step we did last time, but this time only μ times as long.

non-maximum suppression In object detection, non-maximum suppression is used to suppress overlapping predicted bounding boxes. When different instances overlap more than a given threshold value, only the one with the highest confidence value is kept while the other instances, not having the maximum confidence value, are suppressed.

Out-of-Distribution Out-of-Distribution refers to data that significantly differs from the data on which a model was trained. When a model encounters out-of-distribution data during inference, the data's statistical properties, features, or patterns are unfamiliar to the model, leading to potential challenges in making accurate predictions.

overfitting Overfitting happens when the network starts to 'memorize' training data instead of learning how to find general rules for the classification. This becomes visible when the model continues to minimize error on the training set but the error on the validation set increases. Since most neural networks have a huge amount of weights, these networks are particularly prone to overfitting.

regularization - hyperparameter *'weight_prior'* Regularization is a technique to prevent neural networks from overfitting by adding an extra term to the loss function. It works by penalizing large weights, i.e., pushing the weights towards zero. Simply put, regularization favors simpler models that are less likely to fit to noise in the training data and generalize better. In HALCON, regularization is controlled via the parameter *'weight_prior'*.

Alternative names: regularization parameter, weight decay parameter, λ (note that in HALCON we use λ for the learning rate and within formulas the symbol α for the regularization parameter).

retraining We define retraining as updating the weights of an already pretrained network, i.e., during retraining the network learns the specific task.

Alternative names: fine-tuning.

solver The solver optimizes the network by updating the weights in a way to optimize (i.e., minimize) the loss.

stochastic gradient descent (SGD) SGD is an iterative optimization algorithm for differentiable functions. A key feature of the SGD is to calculate the gradient only based on a single batch containing stochastically sampled data and not all data. In the deep learning methods this algorithm can be used to calculate the gradient to optimize (i.e., minimize) the loss function.

top-k error The classifier infers for a given image class confidences of how likely the image belongs to every distinguished class. Thus, for an image we can sort the predicted classes according to the confidence value the classifier assigned. The top-k error tells the ratio of predictions where the ground truth class is not within the k predicted classes with highest probability. In the case of top-1 error, we check if the target label matches the prediction with the highest probability. In the case of top-3 error, we check if the target label matches one of the top 3 predictions (the 3 labels getting the highest probability for this image).

Alternative names: top-k score

transfer learning Transfer learning refers to the technique where a network is built upon the knowledge of an already existing network. In concrete terms this means taking an already (pre)trained network with its weights and adapt the output layer to the respective application to get your network. In HALCON, we also see the following retraining step as a part of transfer learning.

underfitting Underfitting occurs when the model over-generalizes. In other words it is not able to describe the complexity of the task. This is directly reflected in the error on the training set, which does not decrease significantly.

weights In general weights are the free parameters of the network, which are altered during the training due to the optimization of the loss. A layer with weights multiplies or adds them with its input values. In contrast to hyperparameters, weights are optimized and thus changed during the training.

Further Information

Get an introduction to deep learning or learn about datasets for deep learning and many other topics in interactive online courses at our MVTec Academy .

```
get_dl_device_param ( : : DLDeviceHandle,
    GenParamName : GenParamValue )
```

Return the parameters of a deep-learning-capable hardware device.

`get_dl_device_param` returns the parameter values `GenParamValue` of `GenParamName` for the deep-learning-capable hardware device (hereafter referred to as device) `DLDeviceHandle`. See `query_available_dl_devices` for details about deep-learning-capable hardware devices.

Supported values for `GenParamName` are:

'calibration_precisions': Specifies the unit data types that can be used for a calibration of a deep learning model.
List of values: *'int8'*.

'cast_precisions': Specifies the unit data types that can be used for a cast of a deep learning model.

When changing the data type the calibration does not require any images.

List of values: *'float32'*, *'float16'*.

'conversion_supported': Returns *'true'* if unit data types for either a calibration or a cast of a deep learning model are available. Returns *'false'* in any other case.

'id': The ID of the device. Within each inference engine, the IDs of its supported devices are unique. The same holds for devices supported through HALCON.

'inference_only': Indicates if the device can only be used to infer deep learning models (*'true'*) or also supports training or gradient-based operations (*'false'*).

'ai_accelerator_interface': AI Accelerator Interface (AI^2) on which this unit `DLDeviceHandle` is executed. In case the device is directly supported by HALCON, the value *'none'* is returned.

List of values: *'tensorrt'*, *'openvino'*, *'none'*.

'info': Dictionary containing additional information on the device.

Restriction: Only for devices that are supported via an AI2-interface.

'name': Name of the device.

'optimize_for_inference_params': Dictionary with default-defined conversion parameters for a calibration or cast operation of a deep learning model. The entries can be changed.

In case no parameter applies to the set device, an empty dictionary is returned.

Restriction: Only for devices that are supported via an AI2-interface.

'precisions': Specifies the data types that the unit supports for the weights and/or activations of a deep-learning-based model.

List of values: *'float32'*, *'float16'*, *'int8'*.

'settable_device_params': Dictionary with settable device parameters.

Restriction: Only for devices that are supported via an AI2-interface.

'type': Type of the device.

Parameters

▷ **`DLDeviceHandle`** (input_control) . . . . . dl_device ⇝ *handle*
Handle of the deep-learning-capable hardware device.

▷ **`GenParamName`** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'type'
List of values: `GenParamName` ∈ {'calibration_precisions', 'cast_precisions', 'conversion_supported', 'id', 'ai_accelerator_interface', 'inference_only', 'info', 'name', 'optimize_for_inference_params', 'precisions', 'settable_device_params', 'type'}

▷ **`GenParamValue`** (output_control) . . . . . attribute.name(-array) ⇝ *string* / real / integer
Value of the generic parameter.

Result

If the parameters are valid, the operator `get_dl_device_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`query_available_dl_devices`

Possible Successors

`set_dl_model_param`

Module

Foundation

```
optimize_dl_model_for_inference ( : : DLModelHandle,
    DLDeviceHandle, Precision, DLSamples,
    GenParam : DLModelHandleConverted, ConversionReport )
```

Optimize a model for inference on a device via the AI²-interface.

The operator `optimize_dl_model_for_inference` optimizes the input model `DLModelHandle` for inference on the device `DLDeviceHandle` and returns the optimized model in `DLModelHandleConverted`. This operator has two distinct functionalities: Casting the model precision to `Precision` and calibrating the model based on the given samples `DLSamples`. Additionally in either case the model architecture may be optimized for the `DLDeviceHandle`.

The parameter `DLDeviceHandle` specifies the deep learning device for which the model is optimized. Whether the device supports optimization can be determined using `get_dl_device_param` with *'conversion_supported'*. After a successful execution, `optimize_dl_model_for_inference` sets the parameter *'precision_is_converted'* to *'true'* for the output model `DLModelHandleConverted`. In addition, the device in `DLDeviceHandle` is automatically set for the model if it supports the precision set by the parameter `Precision`. Whether the device supports the requested precision can be determined using `get_dl_device_param` with *'precisions'*.

The parameter `Precision` specifies the precision to which the model should be converted to. By default, models that are delivered by HALCON have the `Precision` *'float32'*. The following values are supported for `Precision`:

- *'float32'*
- *'float16'*
- *'int8'*

The parameter `DLSamples` specifies the samples on which the calibration is based. As a consequence they should be representative. It is recommended to provide them from the training split. For most applications 10-20 samples per class are sufficient to achieve good results.

Note, the samples are not needed for a pure cast operation. In this case, an empty tuple can be passed over for `DLSamples`.

The parameter `GenParam` specifies additional, device specific parameters and their values. Which parameters to set for the given `DLDeviceHandle` in `GenParam` and their default values can be queried via the `get_dl_device_param` operator with the *'optimize_for_inference_params'* parameter.

Note, certain devices also expect only an empty dictionary.

The parameter `ConversionReport` returns a report dictionary with information about the conversion.

Attention

This operator can only be used via an AI²-interface. Furthermore, after optimization only parameters that do not change the underlying architecture of the model can be set for `DLModelHandleConverted`.

For `set_dl_model_param`, this includes the following parameters:

- 'Any': *'device'*, *'meta_data'*, *'runtime'*
- 'anomaly_detection': *'standard_deviation_factor'*
- 'classification': *'class_names'*, *'ood_threshold'*
- 'ocr_detection': *'min_character_score'*, *'min_link_score'*, *'min_word_score'*, *'orientation'*, *'sort_by_line'*, *'tiling'*, *'tiling_overlap'*
- 'ocr_recognition': *'alphabet'*, *'alphabet_internal'*, *'alphabet_mapping'*
- 'gc_anomaly_detection': *'anomaly_score_tolerance'*
- 'detection': *'class_names'*, *'max_num_detections'*, *'max_overlap'*, *'max_overlap_class_agnostic'*, *'min_confidence'*
- 'segmentation': *'class_names'*

For `set_deep_ocr_param`, this includes the following parameters:

- *'device'*, *'runtime'*

- *'detection_min_character_score'*, *'detection_min_link_score'*, *'detection_min_word_score'*,
- *'detection_orientation'*, *'detection_sort_by_line'*,
- *'detection_tiling'*, *'detection_tiling_overlap'*
- *'recognition_alphabet'*, *'recognition_alphabet_internal'*, *'recognition_alphabet_mapping'*

For `set_deep_counting_model_param`, this includes the following parameters:

- *'device'*
- *'max_overlap'*, *'min_score'*

Only the AI^2-interface that was used to optimize can be set using *'device'* or the *'runtime'*. Additional restrictions may apply to these parameters to ensure that the underlying architecture of the model does not change.

Parameters

▷ **DLModelHandle** (input_control) . . . . . dl_model ⇝ *handle*
Input model.

▷ **DLDeviceHandle** (input_control) . . . . . dl_device(-array) ⇝ *handle*
Device handle used for optimization.

▷ **Precision** (input_control) . . . . . string ⇝ *string*
Precision the model shall be converted to.

▷ **DLSamples** (input_control) . . . . . dict-array ⇝ *handle*
Samples required for optimization.

▷ **GenParam** (input_control) . . . . . dict ⇝ *handle*
Parameter dict for optimization.

▷ **DLModelHandleConverted** (output_control) . . . . . dl_model ⇝ *handle*
Output model with new precision.

▷ **ConversionReport** (output_control) . . . . . dict ⇝ *handle*
Output report for conversion.

Result

If the parameters are valid, the operator `optimize_dl_model_for_inference` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`train_dl_model_batch`, `query_available_dl_devices`

Possible Successors

`set_dl_model_param`, `apply_dl_model`

Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
3D Metrology, OCR/OCV, Matching, Deep Learning Enhanced, Deep Learning Professional

query_available_dl_devices (: : GenParamName, GenParamValue : DLDeviceHandles)

Get list of deep-learning-capable hardware devices.

`query_available_dl_devices` returns a list of handles. Each handle refers to a deep-learning-capable hardware device (hereafter referred to as device) that can be used for inference or training of a deep learning model. For each returned device, every parameter mentioned in `GenParamName` must be equal to at least one

of its corresponding values that appear in GenParamValue. A parameter can have more than one value by duplicating its name in GenParamName and adding different corresponding value in GenParamValue.

A deep-learning-capable device is either supported directly through HALCON or through an AI^2-interface.

The devices that are supported directly through HALCON are equivalent to those that can be set to a deep learning model via set_dl_model_param using *'runtime'* = *'cpu'* or *'runtime'* = *'gpu'*. HALCON provides an internal implementation for the inference or training of a deep learning model for those devices. See Deep Learning for more details.

Devices that are supported through the AI^2-interface can also be set to a deep learning model using set_dl_model_param. In this case the inference is not executed by HALCON but by the device itself.

query_available_dl_devices returns a handle for each deep-learning-capable device supported through HALCON and through an inference engine.

If a device is supported through HALCON and one or several inference engines, query_available_dl_devices returns a handle for HALCON and for each inference engine.

GenParamName can be used to filter for the devices. All GenParamName that are gettable by get_dl_device_param and that do not return a handle-typed value for GenParamValue are supported for filtering. See the operator reference of get_dl_device_param for the list of gettable parameters. In addition, the following values are supported:

'runtime': The devices, which are directly supported by HALCON for this device type.

List of values: *'cpu'*, *'gpu'*.

GenParamName can have multiple entries for the same value. In this case filter combines the entries with a logical *'or'*. Please see the example code below for some examples how to use the filter.

Parameters

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'calibration_precisions', 'cast_precisions', 'conversion_supported', 'id', 'ai_accelerator_interface', 'inference_only', 'name', 'optimize_for_inference_params', 'precisions', 'runtime', 'settable_device_params', 'type'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
Suggested values: GenParamValue ∈ {}

▷ **DLDeviceHandles** (output_control) . . . . . dl_device(-array) ⇝ *handle*
Tuple of DLDevice handles

Example

```
* Query all deep-learning-capable hardware devices
query_available_dl_devices ([], [], DLDeviceHandles)

* Query all GPUs with ID 0 or 2
query_available_dl_devices (['type', 'id', 'id'], ['gpu', 0, 2],\
                            DLDeviceHandles)

* Query the unique GPU with ID 1 supported by HALCON
query_available_dl_devices (['runtime', 'id'], ['gpu', 1], DLDeviceHandles)
```

Result

If the parameters are valid, the operator query_available_dl_devices returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

get_dl_device_param

Module

Foundation

set_dl_device_param (: : DLDeviceHandle, GenParamName, GenParamValue :)

Set the parameters of a deep-learning-capable hardware device.

set_dl_device_param sets the parameter values GenParamValue for GenParamName for the deep-learning-capable hardware device (hereafter referred to as device) DLDeviceHandle. See query_available_dl_devices for details about deep-learning-capable hardware devices.

Parameters

▷ **DLDeviceHandle** (input_control) . . . . . dl_device ⇝ *handle*
Handle of the deep-learning-capable hardware device.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'settable_device_params'}

▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *string* / real / integer / handle
Value of the generic parameter.

Result

If the parameters are valid, the operator set_dl_device_param returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

9.1 Anomaly Detection and Global Context Anomaly Detection

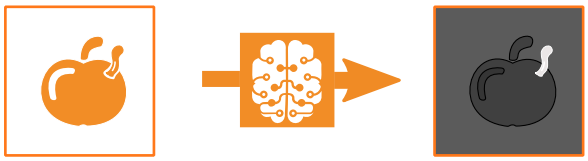
This chapter explains how to use anomaly detection and Global Context Anomaly Detection based on deep learning.

With those two methods we want to detect whether or not an image contains anomalies. An anomaly means something deviating from the norm, something unknown.

An anomaly detection or Global Context Anomaly Detection model learns common features of images without anomalies. The trained model will infer, how likely an input image contains only learned features or if the image contains something different. Latter one is interpreted as an anomaly. This inference result is returned as a gray value image. The pixel values therein indicate how likely the corresponding pixels in the input image pixels show an anomaly.

We differentiate between two model types that can be used:

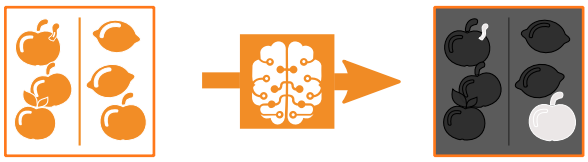
Anomaly Detection With anomaly detection (model type *'anomaly_detection'*) structural anomalies are targeted, thus any feature that was not learned during training. This can, e.g., include scratches, cracks or contamination.



A possible example for anomaly detection: Every pixel of the input image gets assigned a value that indicates how likely the pixel is to be an anomaly. The worm is not part of the worm-free apples the model has seen during training and therefore its pixels get a much higher score.

Global Context Anomaly Detection Global Context Anomaly Detection (model type *'gc_anomaly_detection'*) comprises two tasks:

- **Detecting structural anomalies**
  As described for anomaly detection above, structural anomalies primarily include unknown features, like scratches, cracks or contamination.
- **Detecting logical anomalies**
  Logical anomalies are detected if constraints regarding the image content are violated. This can, e.g., include a wrong number or wrong position of objects in an image.

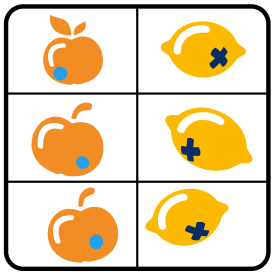


A possible example for Global Context Anomaly Detection: Every pixel of the input image gets assigned a value that indicates how likely the pixel is to be an anomaly. Thereby two different types of anomalies can be detected, structural and logical ones. Structural anomaly: One apple contains a worm, which differs from the apples the model has seen during training. Logical anomaly: One apple is sorted among lemons. Although the apple itself is intact, the logical constraint is violated, as the model has only seen images with correctly sorted fruit during training.

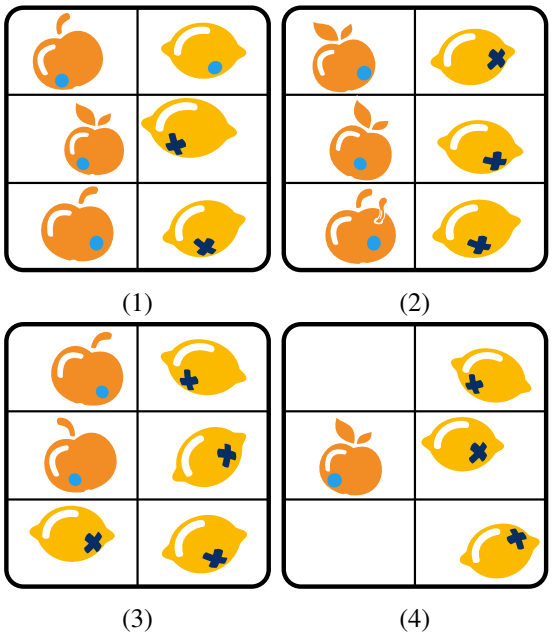
The Global Context Anomaly Detection model consists of two subnetworks. The model can be reduced to one of the subnetworks, in order to improve the runtime and memory consumption. This is recommended if a single subnetwork performs well enough. See the parameter *'gc_anomaly_networks'* in `get_dl_model_param` for details. After setting *'gc_anomaly_networks'*, the model needs to be evaluated again, since this parameter can change the Global Context Anomaly Detection performance significantly.

- **Local subnetwork**
  This subnetwork is used to detect anomalies that affect the image on a smaller, local scale. It is designed to detect structural anomalies but can find logical anomalies as well. Thus, if an anomaly can be recognized by analyzing single patches of an image, it is detected by the local component of the model. See the description of the parameter *'patch_size'* in `get_dl_model_param` for information on how to define the local scale of this subnetwork.

- **Global subnetwork**
  This subnetwork is used to detect anomalies that affect the image on a large, or global scale. It is designed to detect logical anomalies but can find structural anomalies as well. Thus, if you need to see most or all of the image to recognize an anomaly, it is detected by the global component of the model.



Training image of an exemplary task. Apples and lemons are intact, sorted correctly, and tagged with the correct sticker.



Some anomalies that can be detected with Global Context Anomaly Detection: (1) Logical anomaly, most likely detected by the local subnetwork (wrong sticker). (2) Structural anomaly, most likely detected by local subnetwork (wormy apple). (3) Logical anomaly, most likely detected by global subnetwork (wrong sorting). (4) Logical anomaly, most likely detected by global subnetwork (missing apples).

General Workflow

In this paragraph, we describe the general workflow for an anomaly detection or Global Context Anomaly Detection task based on deep learning.

Preprocess the data This part is about how to preprocess your data.

1. The information content of your dataset needs to be converted. This is done by the procedure
   - `read_dl_dataset_anomaly`.

   It creates a dictionary `DLDataset` which serves as a database and stores all necessary information about your data. For more information about the data and the way it is transferred, see the section "Data" below and the chapter Deep Learning / Model.
2. Split the dataset represented by the dictionary `DLDataset`. This can be done using the procedure
   - `split_dl_dataset`.
3. The network imposes several requirements on the images. These requirements (for example the image size and gray value range) can be retrieved with

- get_dl_model_param.

For this you need to read the model first by using

- read_dl_model.

4. Now you can preprocess your dataset. For this, you can use the procedure

   - preprocess_dl_dataset.

   In case of custom preprocessing, this procedure offers guidance on the implementation.
   To use this procedure, specify the preprocessing parameters as, e.g., the image size. Store all the parameter with their values in a dictionary DLPreprocessParam, for which you can use the procedure

   - create_dl_preprocess_param.

   We recommend to save this dictionary DLPreprocessParam in order to have access to the preprocessing parameter values later during the inference phase.

Training of the model This part explains how to train a model.

1. Set the training parameters and store them in the dictionary TrainParam. This can be done using the procedure

   - create_dl_train_param.

2. Train the model. This can be done using the procedure

   - train_dl_model.

   The procedure

   - adapts models of type *'gc_anomaly_detection'* to the image statistics of the dataset calling the procedure normalize_dl_gc_anomaly_features,
   - calls the corresponding training operator train_dl_model_anomaly_dataset (*'anomaly_detection'*) or train_dl_model_batch (*'gc_anomaly_detection'*), respectively.

   The procedure expects:

   - the model handle DLModelHandle
   - the dictionary DLDataset containing the data information
   - the dictionary TrainParam containing the training parameters

3. Normalize the network. This step is only necessary when using a Global Context Anomaly Detection model. The anomaly scores need to be normalized by applying the procedure

   - normalize_dl_gc_anomaly_scores.

   This needs to be done in order to get reasonable results when applying a threshold on the anomaly scores later (see section "Specific Parameters" below).

Evaluation of the trained model In this part, we evaluate the trained model.

1. Set the model parameters which may influence the evaluation.
2. The evaluation can be done conveniently using the procedure

   - evaluate_dl_model.

   This procedure expects a dictionary GenParam with the evaluation parameters.
3. The dictionary EvaluationResult holds the desired evaluation measures.

Inference on new images This part covers the application of an anomaly detection or Global Context Anomaly Detection model. For a trained model, perform the following steps:

1. Request the requirements the model imposes on the images using the operator

   - get_dl_model_param

   or the procedure

   - create_dl_preprocess_param_from_model.

2. Set the model parameter described in the section “Model Parameters” below, using the operator
   - `set_dl_model_param`.
3. Generate a data dictionary `DLSample` for each image. This can be done using the procedure
   - `gen_dl_samples_from_images`.
4. Every image has to be preprocessed the same way as for the training. For this, you can use the procedure
   - `preprocess_dl_samples`.

   When you saved the dictionary `DLPreprocessParam` during the preprocessing step, you can directly use it as input to specify all parameter values.
5. Apply the model using the operator
   - `apply_dl_model`.
6. Retrieve the results from the dictionary `DLResult`.

Data

We distinguish between data used for training, evaluation, and inference on new images.

As a basic concept, the model handles data by dictionaries, meaning it receives the input data from a dictionary `DLSample` and returns a dictionary `DLResult` and `DLTrainResult`, respectively. More information on the data handling can be found in the chapter Deep Learning / Model.

Classes In anomaly detection and Global Context Anomaly Detection there are exactly two classes:

- *'ok'*, meaning without anomaly, class ID *0*.
- *'nok'*, meaning with anomaly, class ID *1* (on pixel values with an ID *>0*, see the subsection “Data for evaluation” below).

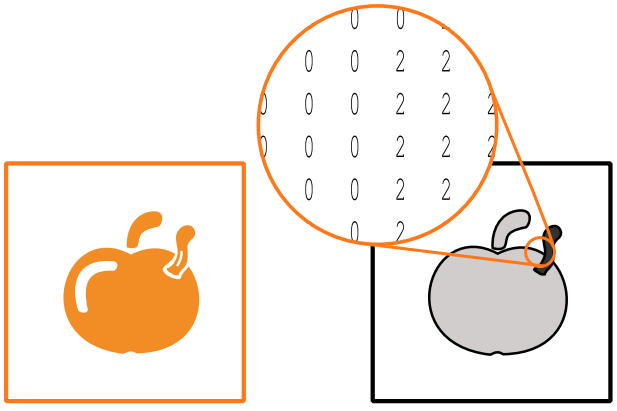
These classes apply to the whole image as well as single pixels.

Data for training This dataset consists only of images without anomalies and the corresponding information. They have to be provided in a way the model can process them. Concerning the image requirements, find more information in the section “Images” below.

The training data is used to train a model for your specific task. With the aid of this data the model can learn which features the images without anomalies have in common.

Data for evaluation This dataset should include images without anomalies but it can also contain images with anomalies. Every image within this set needs a ground truth label `image_label` specifying the class of the image (see the section above). This indicates if the image shows an anomaly (*'nok'*) or not (*'ok'*).

Evaluating the model performance on finding anomalies can visually also be done on pixel level if an image `anomaly_file_name` is included in the `DLSample` dictionary. In this image `anomaly_file_name` every pixel indicates the class ID, thus if the corresponding pixel in the input image shows an anomaly (pixel value > *0*) or not (pixel value equal to *0*).



Scheme of anomaly_file_name. For visibility, gray values are used to represent numbers. (1) Input image. (2) The corresponding anomaly_file_name providing the class annotations, *0*: *'ok'* (white and light gray), *2*: *'nok'* (dark gray).

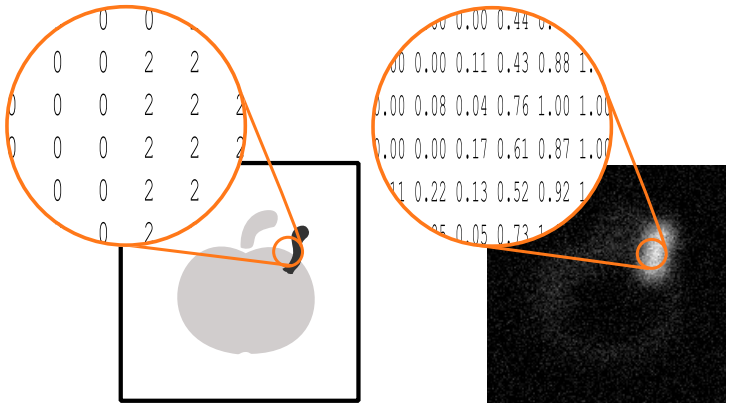
Images The model poses requirements on the images, such as the dimensions, the gray value range, and the type. The specific values depend on the model itself. See the documentation of read_dl_model for the specific values of different models. For a read model they can be queried with get_dl_model_param. In order to fulfill these requirements, you may have to preprocess your images. Standard preprocessing of an entire sample, including the image, is implemented in preprocess_dl_samples. In case of custom preprocessing these procedure offers guidance on the implementation.

Model output The training output differs depending on the used model type:

- Anomaly detection: As training output, the operator train_dl_model_anomaly_dataset will return a dictionary DLTrainResult with the best obtained error received during training and the epoch in which this error was achieved.
- Global Context Anomaly Detection: As training output, the operator train_dl_model_batch will return a dictionary DLTrainResult with the current value of the total loss as well as values for all other losses included in your model.

As inference and evaluation output, the model will return a dictionary DLResult for every sample. For anomaly detection and Global Context Anomaly Detection, this dictionary includes the following extra entries:

- anomaly_score: A score indicating how likely the entire image is to contain an anomaly. This score is based on the pixel scores given in anomaly_image.
  For Global Context Anomaly Detection, depending on the used subnetworks, the anomaly score can also be calculated by the local (anomaly_score_local) and the global (anomaly_score_global) subnetwork only. The anomaly_score is by default equal to the maximum of anomaly_image. The parameter anomaly_score_tolerance can be used to ignore a fraction of outliers in the anomaly_image when calculating the anomaly_score.
- anomaly_image: An image, where the value of each pixel indicates how likely its corresponding pixel in the input image shows an anomaly (see the illustration below). For anomaly detection the values are $\in [0, 1]$, whereas there are no constraints for Global Context Anomaly Detection. Depending on the used subnetworks, when using Global Context Anomaly Detection, an anomaly image can also be calculated by the local (anomaly_image_local) or the global (anomaly_image_global) subnetwork only.



(1) (2)

Scheme of anomaly_image. For visualization purpose, gray values are used to represent numbers. (1) The anomaly_file_name providing the class annotations, *0*: *'ok'* (white and light gray), *2*: *'nok'* (dark gray) (2) The corresponding anomaly_image.

Specific Parameters

For an anomaly detection or Global Context Anomaly Detection model, the model parameters as well as the hyperparameters are set using set_dl_model_param. The model parameters are explained in more detail in

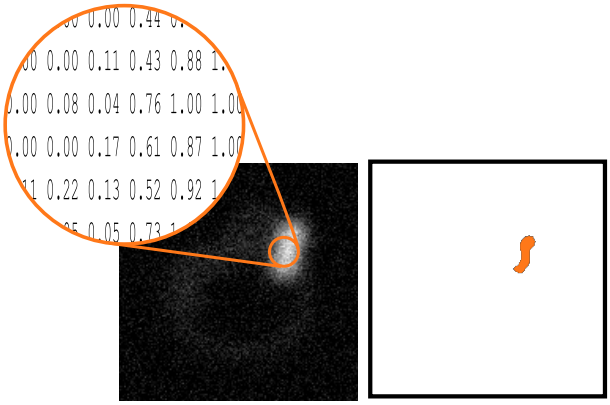
get_dl_model_param. As the training for an anomaly detection model is done utilizing the full dataset at once and not batch-wise, certain parameters as e.g., *'batch_size_multiplier'* have no influence.

The model returns scores but classifies neither pixel nor image as showing an anomaly or not. For this classification, thresholds need to be given, setting the minimum score for a pixel or image to be regarded as anomalous. You can estimate possible thresholds using the procedure compute_dl_anomaly_thresholds. Applying these thresholds can be done with the procedure threshold_dl_anomaly_results. As results the procedure adds the following (threshold depending) entries into the dictionary DLResult of a sample:

anomaly_class
: The predicted class of the entire image (for the given threshold). For Global Context Anomaly Detection, depending on the used subnetworks, the anomaly class can also be calculated by the local (anomaly_class_local) and the global (anomaly_class_global) subnetwork only.

anomaly_class_id
: ID of the predicted class of the entire image (for the given threshold). For Global Context Anomaly Detection, depending on the used subnetworks, the anomaly class ID can also be calculated by the local (anomaly_class_id_local) and the global (anomaly_class_id_global) subnetwork only.

anomaly_region
: Region consisting of all the pixels that are regarded as showing an anomaly (for the given threshold, see the illustration below). For Global Context Anomaly Detection, depending on the used subnetworks, the anomaly region can also be calculated by the local (anomaly_region_local) and the global (anomaly_region_global) subnetwork only.



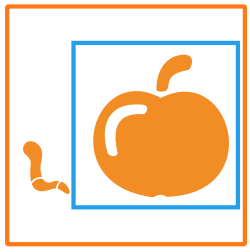
(1) (2)

Scheme of anomaly_region. For visualization purpose, gray values are used to represent numbers. (1) The anomaly_image with the obtained pixel scores. (2) The corresponding anomaly_region.

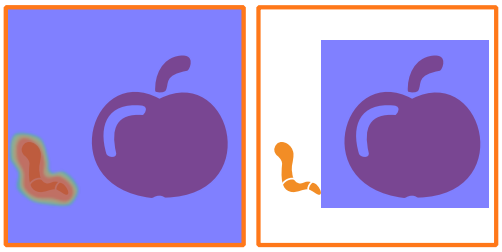
Domain Handling During Inference

A restriction of the search area can be done by reducing the domain of the input images (e.g., reduce_domain). The way preprocess_dl_samples handles the domain is set using the preprocessing parameter 'domain_handling'. The parameter 'domain_handling' should be used in a way that only essential information is passed on to the network for inference. For instance, use 'keep_domain' to exclude unwanted anomalies in the background when computing the anomaly score and image.

The following images show how an input image with reduced domain is inferred after the preprocessing step depending on the set 'domain_handling'.



Input image for inference with domain (blue).



(1) (2)

(1) anomaly_image after inference with 'full_domain' (result: *'nok'*), (2) anomaly_image after inference with 'keep_domain' (result: *'ok'*).

train_dl_model_anomaly_dataset (: : DLModelHandle, DLSamples, DLTrainParam : DLTrainResult)

Train a deep learning model for anomaly detection.

The operator train_dl_model_anomaly_dataset performs the training of a deep learning model with *'type'='anomaly_detection'* contained in DLModelHandle (for deep learning models with *'type'='gc_anomaly_detection'* see train_dl_model_batch).

This operator processes the full training dataset at once. This is in contrast to the operator train_dl_model_batch. The iterations over the dataset are performed internally by the operator. Consequently, you only need to call this operator once with the full training dataset to train your anomaly detection model.

The training dataset is handed over in the tuple of dictionaries DLSamples. See the chapter Deep Learning / Model for further information to the used dictionaries and their keys. The operator expects within the training dataset only images without anomaly to train the anomaly detection model.

The dictionary DLTrainParam can be used to change the hyperparameters. The following values are supported:

- max_num_epochs: This parameter specifies the maximum number of epochs performed during training. In case the criterion specified by error_threshold is reached in an earlier epoch, the training will terminate regardless.
  Restriction: max_num_epochs >=*1*.
  Default: max_num_epochs = *30*.
- error_threshold: This parameter is a termination criterion for the training. If the training error is less than the specified error_threshold, the training terminates successfully.
  Restriction:
  0.0 <= error_threshold <= *1.0*.
  Default: error_threshold = *0.001*.
- domain_ratio: This parameter determines the percentage of information of each image used for training. Since images tend to contain an abundance of information, it is advisable to reduce its amount. Additionally, reducing domain_ratio can decrease the time needed for training. Please note, however, sufficient information needs to remain and therefore this value should not be set too small either. Otherwise the training result might not be satisfactory or the training itself might even fail.
  Restriction: *0.0* < domain_ratio <= *1.0*.
  Default: domain_ratio = *0.1*.
- regularization_noise: This parameter can be set to regularize the training in order to improve robustness.
  Restriction: regularization_noise >=*0.0*.
  Default: regularization_noise = *0.0*.

The output dictionary DLTrainResult contains the following values:

- final_error: The best error received during training.
- final_epoch The epoch in which the error final_error was achieved.

Attention

The operator `train_dl_model_anomaly_dataset` internally calls functions that might not be deterministic. Therefore, results from multiple calls of `train_dl_model_anomaly_dataset` can slightly differ, although the same input values have been used.

System requirements: To run this operator on GPU by setting *'runtime'* to *'gpu'* (see `get_dl_model_param`), cuDNN and cuBLAS are required. For further details, please refer to the "`Installation Guide`", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods". Alternatively, this operator can also be run on CPU by setting *'runtime'* to *'cpu'*.

Parameters

- ▷ **`DLModelHandle`** (input_control) ..... dl_model ⇝ *handle*
  Deep learning model handle.
- ▷ **`DLSamples`** (input_control) ..... dict-array ⇝ *handle*
  Tuple of Dictionaries with input images and corresponding information.
- ▷ **`DLTrainParam`** (input_control) ..... dict ⇝ *handle*
  Parameter for training the anomaly detection model.
  Default: []
- ▷ **`DLTrainResult`** (output_control) ..... dict ⇝ *handle*
  Dictionary with the train result data.

Result

If the parameters are valid, the operator `train_dl_model_anomaly_dataset` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

`read_dl_model`, `set_dl_model_param`, `get_dl_model_param`

Possible Successors

`apply_dl_model`

`apply_dl_model`

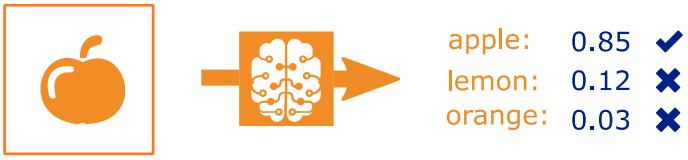
Module

Foundation. This operator uses dynamic licensing (see the 'Installation Guide'). Which of the following modules is required depends on the specific usage of the operator:
Deep Learning Professional

9.2 Classification

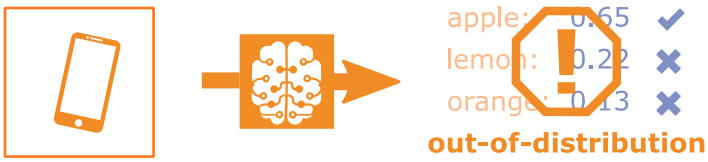
This chapter explains how to use classification based on deep learning, both for the training and inference phases.

Classification based on deep learning is a method, in which an image gets a set of confidence values assigned. These confidence values indicate how likely the image belongs to each of the distinguished classes. Thus, if we regard only the top prediction, classification means to assign a specific class out of a given set of classes to an image. This is illustrated in the following schema.



A possible classification example, in which the network distinguishes three classes. The input image gets confidence values assigned for each of the three distinguished classes: 'apple' 0.85, 'lemon' 0.03, and 'orange' 0.12. The top prediction tells us, the image is recognized as 'apple'.

Out-of-Distribution Detection for classification is a method for identifying inputs which differ significantly from the classes the model was trained on. It is crucial for ensuring model safety and robustness. Out-of-Distribution Detection helps to filter potentially problematic cases for further review. This is illustrated in the following schema.



A possible example of classification with the addition of Out-of-Distribution Detection. The object in the inference image differs significantly from the data used to train the network. In addition to the confidence values for the three classes to be distinguished ('apple' 0.65, 'lemon' 0.22, and 'orange' 0.13), the network also indicates that the image does not belong to any of the three trained classes (Out-of-Distribution).

In order to do your specific task, thus to classify your data into the classes you want to have distinguished, the classifier has to be trained accordingly. In HALCON, we use a technique called transfer learning (see also the chapter Deep Learning). Hence, we provide pretrained networks, representing classifiers which have been trained on huge amounts of labeled image data. These classifiers have been trained and tested to perform well on industrial image classification tasks. One of these classifiers, already trained for general classifications, is now retrained for your specific task. For this, the classifier needs to know, which classes are to be distinguished and how such examples look like. This is represented by your dataset, i.e., your images with the corresponding ground truth labels. More information on the data requirements can be found in the section "Data".

In HALCON, classification with deep learning is implemented within the more general deep learning model. For more information to the latter one, see the chapter Deep Learning / Model. For the specific system requirements in order to apply deep learning, please refer to the HALCON "`Installation Guide`".

The following sections are introductions to the general workflow needed for classification, information related to the involved data and parameters, and explanations to the evaluation measures.

General Workflow

In this paragraph, we describe the general workflow for a classification task based on deep learning. It is subdivided into the four parts preprocessing of the data, training of the model, evaluation of the trained model, and inference on new images. Thereby we assume, your dataset is already labeled, see also the section "Data" below. Have a look at the HDevelop example series `classify_pill_defects_deep_learning` for an application.

Preprocess the data This part is about how to preprocess your data. The single steps are also shown in the HDevelop example `classify_pill_defects_deep_learning_1_preprocess.hdev`.

1. The information what is to be found in which image of your training dataset needs to be transferred. This is done by the procedure
   - `read_dl_dataset_classification`.

   Thereby a dictionary `DLDataset` is created, which serves as a database and stores all necessary information about your data. For more information about the data and the way it is transferred, see the section "Data" below and the chapter Deep Learning / Model.
2. Split the dataset represented by the dictionary `DLDataset`. This can be done using the procedure
   - `split_dl_dataset`.

   The resulting split will be saved over the key `split` in each sample entry of `DLDataset`.
3. Read in a pretrained network using the operator
   - `read_dl_model`.

   This operator is likewise used when you want to read your own trained networks, after you saved them with `write_dl_model`.

   The network will impose several requirements on the images, as the image dimensions and the gray value range. The default values are listed in `read_dl_model`. These are the values with which the networks have been pretrained. The network architectures allow different image dimensions, which can be set with `set_dl_model_param`, but depending on the network a change may make a retraining necessary. The actually set values can be retrieved with

- get_dl_model_param.

4. Now you can preprocess your dataset. For this, you can use the procedure
   - preprocess_dl_dataset.

   In case of custom preprocessing, this procedure offers guidance on the implementation.

   To use this procedure, specify the preprocessing parameters as e.g., the image size. Store all the parameters with their values in a dictionary DLPreprocessParam, wherefore you can use the procedure
   - create_dl_preprocess_param.

   We recommend to save this dictionary DLPreprocessParam in order to have access to the preprocessing parameter values later during the inference phase.

Training of the model This part is about how to train a classifier. The single steps are also shown in the HDevelop example classify_pill_defects_deep_learning_2_train.hdev.

1. Set the training parameters and store them in the dictionary TrainParam. These parameters include:
   - the hyperparameters, for an overview see the chapter Deep Learning.
   - parameters for possible data augmentation (optional).
   - parameters for the evaluation during training.
   - parameters for the visualization of training results.
   - parameters for serialization.

   This can be done using the procedure
   - create_dl_train_param.
2. Train the model. This can be done using the procedure
   - train_dl_model.

   The procedure expects:
   - the model handle DLModelHandle
   - the dictionary with the data information DLDataset
   - the dictionary with the training parameter TrainParam
   - the information, over how many epochs the training shall run.

   In case the procedure train_dl_model is used, the total loss as well as optional evaluation measures are visualized.

Evaluation of the trained model In this part we evaluate the trained classifier. The single steps are also shown in the HDevelop example classify_pill_defects_deep_learning_3_evaluate.hdev.

1. The evaluation can conveniently be done using the procedure
   - evaluate_dl_model.
2. The dictionary EvaluationResult holds the asked evaluation measures. You can visualize your evaluation results using the procedure
   - dev_display_classification_evaluation.
3. A heatmap can be generated for specified samples using
   (a) the operator gen_dl_model_heatmap
   (b) the procedure gen_dl_model_classification_heatmap

Fit model to Out-of-Distribution Detection (optional) In this part, we extend the trained classifier so it can detect out-of-distribution data. The single steps are also shown in the HDevelop example detect_out_of_distribution_samples_for_classification.hdev.

1. Fitting the Out-of-Distribution Detection using
   - fit_dl_out_of_distribution.
2. *Optional step:* Add out-of-distribution data to the dataset for evaluation, using the procedure
   - add_dl_out_of_distribution_data.

3. Rerun the evaluation using the procedure
   - `evaluate_dl_model`.
4. The dictionary `EvaluationResult` holds the asked evaluation measures. You can visualize your evaluation results using the procedure
   - `dev_display_classification_evaluation`.

Inference on new images This part covers the application of a deep-learning-based classification model. The single steps are also shown in the HDevelop example `classify_pill_defects_deep_learning_4_infer.hdev`.

1. Set the parameters as e.g., *'batch_size'* using the operator
   - `set_dl_model_param`.
2. Generate a data dictionary `DLSample` for each image. This can be done using the procedure
   - `gen_dl_samples_from_images`.
3. Preprocess the images as done for the training. We recommend to do this using the procedure
   - `preprocess_dl_samples`.

   When you saved the dictionary `DLPreprocessParam` during the preprocessing step, you can directly use it as input to specify all parameter values.
4. Apply the model using the operator
   - `apply_dl_model`.
5. Retrieve the results from the dictionary *'DLResultBatch'*.

Data

We distinguish between data used for training and data for inference. Latter one consists of bare images. But for the former one you already know to which class the images belong and provide this information over the corresponding labels.

As a basic concept, the model handles data over dictionaries, meaning it receives the input data over a dictionary `DLSample` and returns a dictionary `DLResult` and `DLTrainResult`, respectively. More information on the data handling can be found in the chapter Deep Learning / Model.

Data for training and evaluation The dataset consists of images and corresponding information. They have to be provided in a way the model can process them. Concerning the image requirements, find more information in the section "Images" below.

The training data is used to train and evaluate a network for your specific task. With the aid of this data the classifier can learn which classes are to be distinguished and how their representatives look like. In classification, the image is classified as a whole. Therefore, the training data consists of images and their ground truth labels, thus the class you say this image belongs to. Note that the images should be as representative as possible for your task. There are different ways possible, how to store and retrieve this information. How the data has to be formatted in HALCON for a DL model is explained in the chapter Deep Learning / Model. In short, a dictionary `DLDataset` serves as a database for the information needed by the training and evaluation procedures. The procedure `read_dl_dataset_classification` supports the following sources of the ground truth label for an image:

- The last directory name containing the image
- The file name.

For training a classifier, we use a technique called transfer learning (see the chapter Deep Learning). For this, you need less resources, but still a suitable set of data. While in general the network should be more reliable when trained on a larger dataset, the amount of data needed for training also depends on the complexity of the task. You also want enough training data to split it into three subsets, used for training, validation, and testing the network. These subsets are preferably independent and identically distributed, see the section "Data" in the chapter Deep Learning.

Images Regardless of the application, the network poses requirements on the images regarding e.g., the image dimensions. The specific values depend on the network itself and can be queried with `get_dl_model_param`. In order to fulfill these requirements, you may have to preprocess your images. Standard preprocessing is implemented in `preprocess_dl_dataset` and in `preprocess_dl_samples` for a single sample, respectively. In case of custom preprocessing these procedures offer guidance on the implementation.

Network output The network output depends on the task:

training As output, the operator will return a dictionary `DLTrainResult` with the current value of the total loss as well as values for all other losses included in your model.

inference and evaluation As output, the network will return a dictionary `DLResult` for every sample. For classification, this dictionary will include for each input image a tuple with the confidence values for every class to be distinguished in decreasing order and a second tuple with the corresponding class IDs.

Interpreting the Classification Results

When we classify an image, we obtain a set of confidence values, telling us the affinity of the image to every class. It is also possible to compute the following values.

Confusion Matrix, Precision, Recall, and F-score In classification whole images are classified. As a consequence, the instances of a confusion matrix are images. See the chapter Deep Learning for explanations on confusion matrices.

You can generate a confusion matrix with the aid of the procedures `gen_confusion_matrix` and `gen_interactive_confusion_matrix`. Thereby, the interactive procedure gives you the possibility to select examples of a specific category, but it does not work with exported code.

From such a confusion matrix you can derive various values. The precision is the proportion of all correct predicted positives to all predicted positives (true and false ones). Thus, it is a measure of how many positive predictions really belong to the selected class.

$$\text{precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

The recall, also called the "true positive rate", is the proportion of all correct predicted positives to all real positives. Thus, it is a measure of how many samples belonging to the selected class were predicted correctly as positives.

$$\text{recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

A classifier with high recall but low precision finds most members of positives (thus members of the class), but at the cost of also classifying many negatives as member of the class. A classifier with high precision but low recall is just the opposite, classifying only few samples as positives, but most of these predictions are correct. An ideal classifier with high precision and high recall will classify many samples as positive with a high accuracy.

To represent this with a single number, we compute the F1-score, the harmonic mean of precision and recall. Thus, it is a measure of the classifier's accuracy.

$$\text{F1-score} = 2 * \frac{\text{precision} * \text{recall}}{\text{precision} + \text{recall}}$$

For the example from the confusion matrix shown in Deep Learning we get for the class 'apple' the values precision: 1.00 (= 68/(68+0+0)), recall: 0.74 (= 68/(68+21+3)), and F1-score: 0.85 (=2*(1.00*0.74)/(1.00+0.74)).

fit_dl_out_of_distribution (: : DLModelHandle, DLDataset, GenParam :)

Extend a deep learning model for Out-of-Distribution Detection.

fit_dl_out_of_distribution extends a trained deep learning model DLModelHandle of *'type'* = *'classification'* for Out-of-Distribution Detection. This functionality allows the model to detect samples that differ significantly from the classes it was trained on, known as "Out-of-Distribution" (OOD) samples.

When apply_dl_model is called subsequently, the results will include the following additional entries related to Out-of-Distribution Detection:

'ood_result': Indicates whether the sample is predicted as out-of-distribution.

'ood_score': Indicates how much the sample differs from the trained classes. The higher this score, the more likely it is that the sample is out-of-distribution.

'ood_threshold': If *'ood_score'* exceeds this threshold, the sample is predicted as out-of-distribution. The out-of-distribution threshold is computed during the execution of fit_dl_out_of_distribution and stored within the model handle DLModelHandle as 'ood_threshold'. If required, the threshold can be adjusted manually using the operator set_dl_model_param.

For fit_dl_out_of_distribution to work properly, it is important that DLDataset is the same dataset with the same split and preprocessing parameters, as the one used for training DLModelHandle. It is crucial that the provided dataset DLDataset contains diverse and sufficient samples for each class to ensure reliable Out-of-Distribution Detection. If the dataset is too small or lacks variation, fit_dl_out_of_distribution may return an error. In such cases, additional training data should be added to the dataset.

fit_dl_out_of_distribution can be applied to any classification model supported by HALCON. For models created using Deep Learning / Framework operators or read from an ONNX model file, Out-of-Distribution Detection compatibility may vary depending on the architecture.

The performance of the model for Out-of-Distribution Detection can be evaluated using the procedure evaluate_dl_model. To evaluate the model on out-of-distribution data, these can be added to the DLDataset using the procedure add_dl_out_of_distribution_data, allowing for testing whether the model can accurately separate in-distribution from out-of-distribution data. Adjustments to the *'ood_threshold'* will affect evaluation results. Therefore, it is recommended to re-evaluate the model after making such changes.

GenParam is a dictionary for setting generic parameters. Currently no generic parameters are supported.

Attention

If fit_dl_out_of_distribution is called for a model that has already been extended with Out-of-Distribution Detection, the previous internal calculations are discarded and the model is adapted anew

Certain modifications to the model, such as changing the number of classes or continuing training of the model, cannot be performed once the model has been extended for Out-of-Distribution Detection. To make such changes possible, the model internal Out-of-Distribution Detection must first be removed from the model using the parameter *'clear_ood'* in set_dl_model_param. Once removed, fit_dl_out_of_distribution can be called again to re-enable Out-of-Distribution Detection.

Parameters

▷ **DLModelHandle** (input_control) ..... dl_model ⇝ *handle*
Handle of a deep learning classification model.

▷ **DLDataset** (input_control) ..... dict ⇝ *handle*
