Image for which the minimum gray values are to be calculated.

▷ **ImageOpening** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / uint2
Image containing the minimum gray values.

▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *real* / integer
Height of the filter mask.
Default: 11
Suggested values: MaskHeight ∈ {3, 5, 7, 9, 11, 13, 15}
Value range: 1.0 ≤ MaskHeight ≤ 511.0

▷ **MaskWidth** (input_control) . . . . . extent.x ⇝ *real* / integer
Width of the filter mask.
Default: 11
Suggested values: MaskWidth ∈ {3, 5, 7, 9, 11, 13, 15}
Value range: 1.0 ≤ MaskWidth ≤ 511.0

▷ **MaskShape** (input_control) . . . . . string ⇝ *string*
Shape of the mask.
Default: 'octagon'
List of values: MaskShape ∈ {'rectangle', 'rhombus', 'octagon'}

Result

`gray_opening_shape` returns 2 (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

`gray_opening`

`gray_dilation_shape`, `gray_erosion_shape`, `opening`

Module

Foundation

`gray_range_rect` (Image : ImageResult : MaskHeight, MaskWidth :)

Determine the gray value range within a rectangle.

`gray_range_rect` calculates the gray value range, i.e., the difference $(\max - \min)$ of the maximum and minimum gray values, of the input image `Image` within a rectangular mask of size (`MaskHeight`, `MaskWidth`) for each image point. The resulting image is returned in `ImageResult`. If the parameters `MaskHeight` or `MaskWidth` are even, they are changed to the next smaller odd value. At the border of the image the gray values are mirrored.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / cyclic / uint2 / int2 / int4 / real
Image for which the gray value range is to be calculated.

▷ **`ImageResult`** (output_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte / cyclic / uint2 / int2 / int4 / real
Image containing the gray value range.

▷ **`MaskHeight`** (input_control) . . . . . extent.y ⇝ *integer*
Height of the filter mask.
Default: 11
Suggested values: `MaskHeight` ∈ {3, 5, 7, 9, 11, 13, 15}
Value range: 3 ≤ `MaskHeight` ≤ 511 (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskHeight) && MaskHeight < height(Image) * 2

▷ **`MaskWidth`** (input_control) . . . . . extent.x ⇝ *integer*
Width of the filter mask.
Default: 11
Suggested values: `MaskWidth` ∈ {3, 5, 7, 9, 11, 13, 15}
Value range: 3 ≤ `MaskWidth` ≤ 511 (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: odd(MaskWidth) && MaskWidth < width(Image) * 2

Result

`gray_range_rect` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Supports OpenCL compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on domain level.

Alternatives

gray_tophat (Image, SE : ImageTopHat : :)

Perform a gray value top hat transformation on an image.

`gray_tophat` applies a gray value top hat transformation to the input image `Image` with the structuring element `SE`. The image type of the structuring element `SE` must match the image type of the input image `Image`. The gray value top hat transformation of an image i with a structuring element s is defined as

$$tophat(i, s) = i - (i \circ s),$$

i.e., the difference of the image and its opening with s (see `gray_opening`). For the generation of structuring elements, see `read_gray_se`.

The top hat transformation is particularly fast for flat structuring elements, i.e. structuring elements with a constant gray level within their domain.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **SE** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
Structuring element.

▷ **ImageTopHat** (output_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / uint2 / real
Top hat image.

Result

`gray_tophat` returns `2` (`H_MSG_TRUE`) if the structuring element is not the empty region. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on channel level.
- Automatically parallelized on internal data level.

Possible Predecessors

read_gray_se, gen_disc_se, read_image

Possible Successors

threshold

Alternatives

gray_opening

Module

Foundation

read_gray_se (: SE : FileName :)

Load a structuring element for gray morphology.

read_gray_se loads a structuring element for gray morphology from a file. The file names of these structuring elements must end in '.gse' (for gray-scale structuring element). This suffix is automatically appended by read_gray_se to the passed file name, and thus must not be passed. The structuring element's data must be contained in the file in the following format: The first line specifies the data type of the structuring element as byte, uint2 or real (without enclosing quotes). It must match the image type of the image to be processed in subsequent operator calls using this structuring element. The following two numbers in the file determine the width and height of the structuring element and determine a rectangle enclosing the structuring element. Both values must be greater than 0. Then the number of chords of the region to be defined follows. Then the chords themselves follow: Each chord is defined by the row of the chord (L), the column begin (CB) and the column end (CE), separated by a space between them. Then values follow that are regarded as the corresponding values for gray morphology (their number depends on the defined width and height of the structuring element). Values that will not be part of the region of the structuring element (because no chord is defined for this points) must not be omitted. Nevertheless they will be ignored in the resulting structuring element. Structuring elements are stored internally as images with the data type specified above. Normal images can also be used as structuring elements, where the region of the image defines the shape of the structuring element. However, take care not to use too large images, since the runtime is proportional to the area of the image multiplied by the area of the structuring element. Flat structuring elements (i.e. elements with constant gray values) will be executed particularly fast though. The origin of the structuring element lies at half of the defined width and height. For even dimensions the origin will be rounded towards the upper left corner. The structuring element can be saved as image with the help of the operator write_image. However, take care to use an image format that supports alpha channels to save the shape of the structuring element such as 'tiff', 'jp2' or 'png'. These files can then be loaded again with the operator read_image.

Parameters

▷ **SE** (output_object) ..... image ⇝ *object :* byte / uint2 / real
Generated structuring element.

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the file containing the structuring element.
File extension: .gse

Example

```
* Load a byte structuring element of width 3 and height 3 that
* consists of 3 chords at lines 0 (from x=1 to x=1), 1 (from x=0
* to x=2) and 2 (from x=1 to x=1). The (used) grayvalues are
* 0, 0, 1, 0, 0 .
* contents of file 'isod4.gse':
* byte
*  3 3
*
* 3
* 0 1 1
```

```
* 1 0 2
* 2 1 1
*
*  -1  0 -1
*   0  1  0
*  -1  0 -1
read_gray_se (SE, environment('HALCONROOT')+'/filter/isod4')
```

Result

`read_gray_se` returns `2` (`H_MSG_TRUE`) if all parameters are correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

20.2 Region

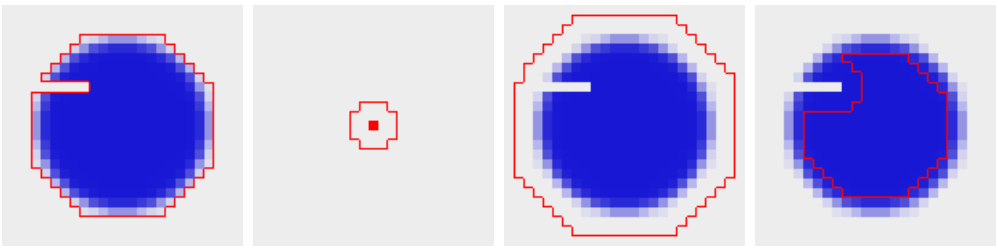
This chapter describes operators of region morphology.

Concept of Region Morphology

Region morphology provides a set of morphological operators that allow to modify or describe the shape of a region. The morphological operators can be used, for example, to connect or disconnect adjacent regions or to smooth the boundary of a region. In the following, we will take a closer look at the morphological operators.

Dilation and Erosion

To dilate or erode an input region, a structuring element is applied to the input region. This structuring element is scanned over the image line-by-line. During dilation the reference point of the structuring element is added to the resulting region whenever the structuring element and the input region have at least one pixel in common. This results in an enlarged region, as shown in the image below. Erosion reduces the area of the input region because the reference point is only added to the resulting region if the structuring element lies completely within the input region. As a result, erosion can alternatively be used to find objects.



(1) (2) (3) (4)

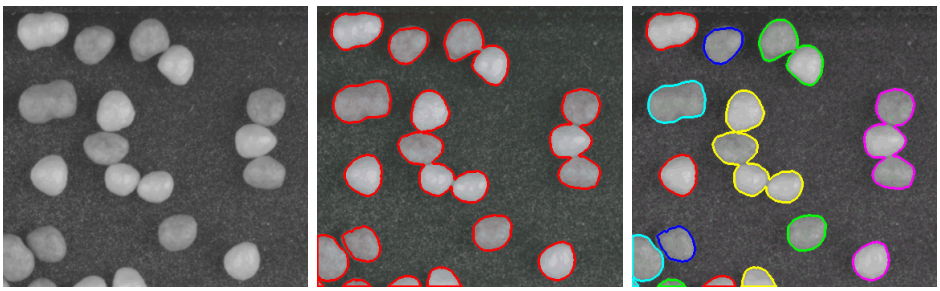
(1) Image with input region, (2) structuring element with reference point in the origin, (3) result of dilating the input region, (4) result of eroding the input region.

These operators can be used to dilate or erode a region:

Morphological Operators		Structuring Element	Reference Point
dilation1	erosion1	arbitrary	origin
minkowski_add1	minkowski_sub1	arbitrary, transposed	origin
dilation2	erosion2	arbitrary	arbitrary
minkowski_add2	minkowski_sub2	arbitrary, transposed	arbitrary
dilation_circle	erosion_circle	circular	origin
dilation_rectangle1	erosion_rectangle1	rectangular	origin

Note that Minkowski addition and dilation are identical if the structuring element is symmetric. The same applies to Minkowski subtraction and erosion. Erosion can be used to separate objects that are attached to each other. In the following, the steps that are required to separate objects are described briefly.

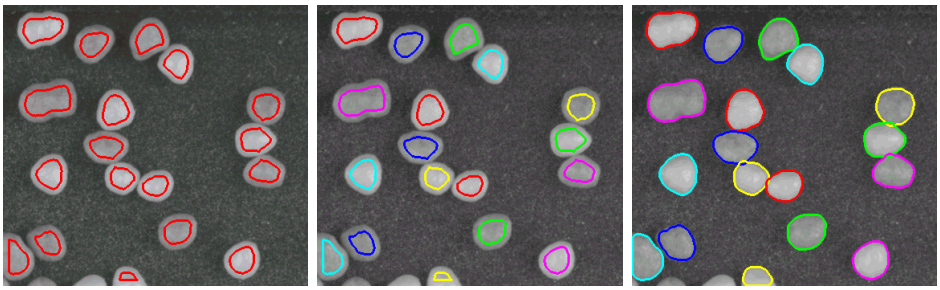
First, the objects of the image must be segmented, for example by using the operator threshold. Next, the operator connection is used to get multiple regions instead of a single region. As you can see in the image (3) below, the result of the connection is unsatisfactory because several objects are merged.



(1) (2) (3)

(1) Image with globular objects, (2) segmented regions, (3) connected components.

This problem can be solved using erosion. As mentioned above, erosion reduces the area of the input region. Thus, if erosion is applied prior to the operator connection, the regions are separated as desired. Lastly, dilation is applied on the separated regions to approximately get the original shape back.

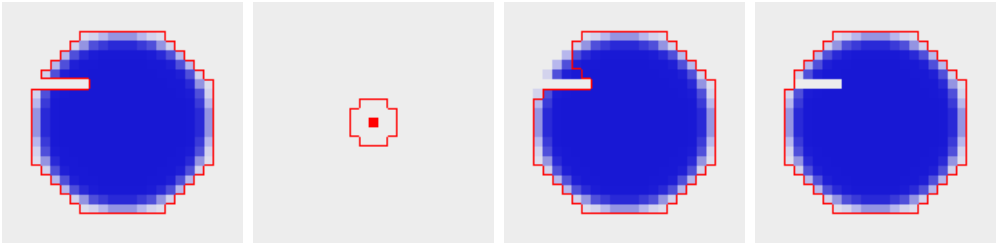


(1) (2) (3)

(1) Segmented regions after erosion, (2) connected components, (3) connected components after dilation.

Opening and Closing

Both operations generate the resulting region by combining dilation and erosion operations. Opening is an erosion followed by a dilation. It is useful to eliminate small unwanted structures. Closing is the opposite of opening, i.e., a dilation followed by an erosion. The closing operator is able to close small gaps, as shown below.



(1) (2) (3) (4)

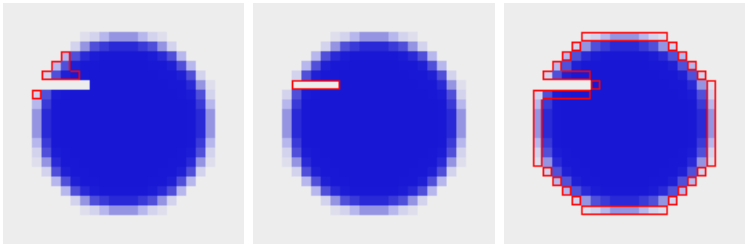
(1) Image with input region, (2) structuring element with reference point, (3) result of applying an opening to the input region, (4) result of applying a closing.

These operators can be used to open or close a region:

Morphological Operators		Structuring Element	Reference Point
opening	closing	arbitrary	origin
opening_circle	closing_circle	circular	origin
opening_rectangle1	closing_rectangle1	rectangular	origin

Further Operators

In addition to the operators mentioned above, you can use top_hat to get the difference between the input region and the result of the opening, or bottom_hat to get the difference between the result of the closing and the input region. Furthermore, you can calculate the boundary of a region with the operator boundary.



(1) (2) (3)

(1) Top hat, (2) bottom hat, (3) boundary.

The operator hit_or_miss can be used to find objects, taking the foreground and the background of the image into account. To remove unwanted branches from a skeleton, pruning is a suitable operator.

Glossary

In the following list, the most important terms that are used in the context of Morphology are described.

input region Region which is modified by morphological operators.

structuring element Region which is used to scan the input region.

bottom_hat (Region, StructElement : RegionBottomHat : :)

Compute the bottom hat of regions.

bottom_hat computes the closing of Region with StructElement. The difference between the result of the closing and the original region is called the bottom hat. In contrast to closing, which merges regions under certain circumstances, bottom_hat computes the regions generated by such a merge.

The position of StructElement is meaningless, since a closing operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be processed.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element (position independent).

▷ **RegionBottomHat** (output_object) ..... region(-array) ⇝ *object*
Result of the bottom hat operator.

Example

```
read_image (Image, 'brake_disk/brake_disk_bike_01')
threshold (Image, Regions, 128, 255)
gen_circle (Circle, 40, 40, 20)
bottom_hat (Regions, Circle, RegionBottomHat)
```

Result

bottom_hat returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region, gen_region_points, gen_region_polygon_filled

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

closing, difference

top_hat, gray_bothat, opening

Module

Foundation

boundary (Region : RegionBorder : BoundaryType :)

Reduce a region to its boundary.

boundary computes the boundary of each input region in Region and returns them in RegionBorder. The parameter BoundaryType determines the type of boundary computation.

The contour computation is done using morphological operations. The resulting output regions consist only of the minimal border of the input regions. Their positions depend on the value of BoundaryType, accepting the following values:

- *'inner'*: The contour lies within the original region.
- *'inner_filled'*: The contour lies within the original region, holes in the interior of the input region are suppressed. Due to algorithm optimization this contours may slightly differ from corresponding ones obtained with *'inner'*.
- *'outer'*: The contour is one pixel outside of the original region.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions for which the boundary is to be computed.

▷ **RegionBorder** (output_object) ..... region(-array) ⇝ *object*
Resulting boundaries.

▷ **BoundaryType** (input_control) ..... string ⇝ *string*
Boundary type.
Default: 'inner'
List of values: `BoundaryType` ∈ {'inner', 'outer', 'inner_filled'}

Example

```
#include "HalconCpp.h"
using namespace Halcon;

main()
{
  HWindow  w;
  HRegion  circ1 = HRegion::GenCircle (20, 10, 10.5);

  circ1.Display (w);
  w.Click ();

  HRegion marg1 = circ1.Boundary ("inner");
  w.SetColor ("red");
  marg1.Display (w);
  w.Click ();

  return(0);
}
```

Complexity

Let A be the area of the input region. Then the runtime complexity for one region is

$$O(3\sqrt{A}) \ .$$

Result

`boundary` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

dilation_circle, erosion_circle, difference

fill_up

Module

Foundation

closing (Region, StructElement : RegionClosing : :)

Close a region.

A closing operation is defined as a dilation followed by a Minkowski subtraction. By applying closing to a region, larger structures remain mostly intact, while small gaps between adjacent regions and holes smaller than StructElement are closed, and the regions' boundaries are smoothed. All closing variants share the property that separate regions are not merged, but remain separate objects. The position of StructElement is meaningless, since a closing operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Attention

closing is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Regions to be closed.
- ▷ **StructElement** (input_object) ..... region ⇝ *object*
  Structuring element (position-invariant).
- ▷ **RegionClosing** (output_object) ..... region(-array) ⇝ *object*
  Closed regions.

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
  cout << "Reproduction of 'closing ()' using " << endl;
  cout << "'dilation()' and 'minkowski_sub1()'" << endl;

  HByteImage img("monkey");
  HWindow    w;

  HRegion      circ = HRegion::GenCircle (10, 10, 1.5);
  HRegionArray regs = (img >= 128).Connection();

  HRegionArray dilreg = regs.Dilation1 (circ, 1);
  HRegionArray minsub = dilreg.MinkowskiSub1 (circ, 1);
```

```
                        img.Display (w);      w.Click ();
  w.SetColor ("red");   regs.Display (w);     w.Click ();
  w.SetColor ("green"); dilreg.Display (w);   w.Click ();
  w.SetColor ("blue");  minsub.Display (w);   w.Click ();

  return(0);
}
```

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(2 \cdot \sqrt{F1} \cdot \sqrt{F2}) \ .$$

Result

`closing` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`, `union1`, `watersheds`, `class_ndim_norm`, `gen_circle`, `gen_ellipse`, `gen_rectangle1`, `gen_rectangle2`, `draw_region`, `gen_region_points`, `gen_region_polygon_filled`

Possible Successors

`reduce_domain`, `select_shape`, `area_center`, `connection`

Alternatives

`closing_circle`

See also

`dilation1`, `erosion1`, `opening`, `minkowski_sub1`

Module

Foundation

`closing_circle` (Region : RegionClosing : Radius :)

Close a region with a circular structuring element.

`closing_circle` behaves analogously to `closing`, i.e., the regions' boundaries are smoothed and holes within a region which are smaller than the circular structuring element of radius `Radius` are closed. The `closing_circle` operation is defined as a dilation followed by a Minkowski subtraction, both with the same circular structuring element.

Attention

`closing_circle` is applied to each input region separately. If gaps between different regions are to be closed, `union1` or `union2` has to be called first.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be closed.

▷ **RegionClosing** (output_object) . . . . . region(-array) ⇝ *object*
Closed regions.

▷ **Radius** (input_control) . . . . . real ⇝ *real* / integer
Radius of the circular structuring element.
Default: 3.5
Suggested values: Radius ∈ {1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5}
Value range: 0.5 ≤ Radius ≤ 511.5 (lin)
Minimum increment: 1.0
Recommended increment: 1.0

Example

```
my_closing_circle(Hobject In, double Radius, Hobject *Out)
{
  Hobject  tmp, StructElement;
  gen_circle(StructElement,100.0,100.0,Radius);
  dilation1(In,StructElement,&tmp,1);
  minkowski_sub1(tmp,StructElement,Out,1);
}
```

Complexity

Let $F1$ be the area of the input region. Then the runtime complexity for one region is:

$$O(4 \cdot \sqrt{F1} \cdot \texttt{Radius}) \ .$$

Result

closing_circle returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

rank_region, fill_up, closing

See also

dilation1, minkowski_sub1, erosion1, opening

Module

Foundation

closing_rectangle1 (Region : RegionClosing : Width, Height :)

Close a region with a rectangular structuring element.

closing_rectangle1 behaves as closing with a rectangular structuring element on the input region Region. The size of the rectangular structuring element is determined by the parameters Width and Height. As is the case for all closing variants, regions' boundaries are smoothed and holes within a region which are smaller than the rectangular structuring element are closed.

Similar to erosion_rectangle1 and dilation_rectangle1 closing_rectangle1 is a very fast operation.

Attention

closing_rectangle1 is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be closed.

▷ **RegionClosing** (output_object) ..... region(-array) ⇝ *object*
Closed regions.

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the structuring rectangle.
Default: 10
Suggested values: Width ∈ {1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200}
Value range: 1 ≤ Width ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the structuring rectangle.
Default: 10
Suggested values: Height ∈ {1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200}
Value range: 1 ≤ Height ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of an input region and H be the height of the rectangle. Then the runtime complexity for one region is:

$$O(2 \cdot \sqrt{F1} \cdot log\_2(H)) \ .$$

Result

closing_rectangle1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm

Possible Successors

reduce_domain, select_shape, area_center, connection

Alternatives

closing

dilation_rectangle1, erosion_rectangle1, opening_rectangle1, gen_rectangle1

Module

Foundation

dilation1 (Region, StructElement : RegionDilation : Iterations :)

Dilate a region.

dilation1 dilates the input regions with a structuring element. By applying dilation1 to a region, its boundary gets smoothed. In the process, the area of the region is enlarged. Furthermore, disconnected regions may be merged. Such regions, however, remain logically distinct region. The dilation is a set-theoretic region operation. It uses the union operation.

Let M (StructElement) and R (Region) be two regions, where M is the structuring element and R is the region to be processed. Furthermore, let m be a point in M. Then the displacement vector $\vec{v}_m = (dx, dy)$ is defined as the difference of the center of gravity of M and the vector $\vec{m}$. Let $t_{\vec{v}_m}(R)$ denote the translation of a region R by a vector $\vec{v}$. Then

$$\texttt{dilation1}(R, M) := \bigcup_{m \in M} t_{-\vec{v}_m}(R)$$

For each point m in M a translation of the region R is performed. The union of all these translations is the dilation of R with M. dilation1 is similar to the operator minkowski_add1, the difference is that in dilation1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of M.

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n - 1$ is used as input for iteration n. From the above definition it follows that an empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Attention

A dilation always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator union1 has to be called first.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be dilated.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element.

▷ **RegionDilation** (output_object) ..... region(-array) ⇝ *object*
Dilated regions.

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \texttt{Iterations}) \ .$$

Result

`dilation1` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

Foundation

dilation2 (Region, StructElement : RegionDilation : Row, Column, Iterations :)

Dilate a region (using a reference point).

`dilation2` dilates the input regions with a structuring element (`StructElement`) having the reference point (`Row`,`Column`). `dilation2` has a similar effect as `dilation1`, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter `Iterations` determines the number of iterations which are to be performed with the structuring element. The result of iteration $n-1$ is used as input for iteration n.

An empty region is generated in case of an empty structuring element.

Structuring elements (`StructElement`) can be generated with operators such as `gen_circle`, `gen_rectangle1`, `gen_rectangle2`, `gen_ellipse`, `draw_region`, `gen_region_polygon`, `gen_region_points`, etc.

Attention

A dilation always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator `union1` has to be called first.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Regions to be dilated.
- ▷ **StructElement** (input_object) ..... region ⇝ *object*
  Structuring element.
- ▷ **RegionDilation** (output_object) ..... region(-array) ⇝ *object*
  Dilated regions.
- ▷ **Row** (input_control) ..... point.y ⇝ *integer*
  Row coordinate of the reference point.
  Default: 0
- ▷ **Column** (input_control) ..... point.x ⇝ *integer*
  Column coordinate of the reference point.
  Default: 0
- ▷ **Iterations** (input_control) ..... integer ⇝ *integer*
  Number of iterations.
  Default: 1
  Suggested values: `Iterations` ∈ {1, 2, 3, 4, 5, 7, 11, 17, 25, 32, 64, 128}
  Value range: 1 ≤ Iterations (lin)
  Minimum increment: 1
  Recommended increment: 1

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \texttt{Iterations}) \ .$$

Result

`dilation2` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

dilation_circle (Region : RegionDilation : Radius :)

Dilate a region with a circular structuring element.

dilation_circle applies a Minkowski addition with a circular structuring element to the input regions Region. Because the circular mask is symmetrical, this is identical to a dilation. The size of the circle used as structuring element is determined by Radius.

The operator results in enlarged regions, smoothed region boundaries, and the holes smaller than the circular mask in the interior of the region are closed. It is useful to select only values like 3.5, 5.5, etc. for Radius in order to avoid a translation of a region, because integer radii result in the circle having a non-integer center of gravity which is rounded to the next integer.

Attention

dilation_circle is applied to each input region separately. If gaps between different regions are to be closed, union1 or union2 has to be called first.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Regions to be dilated.
- ▷ **RegionDilation** (output_object) ..... region(-array) ⇝ *object*
  Dilated regions.
- ▷ **Radius** (input_control) ..... real ⇝ *real* / integer
  Radius of the circular structuring element.
  Default: 3.5
  Suggested values: Radius ∈ {1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5}
  Value range: 0.5 ≤ Radius ≤ 511.5 (lin)
  Minimum increment: 1.0
  Recommended increment: 1.0

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
  cout << "Reproduction of 'dilation_circle ()'" << endl;
  cout << "First = original image " << endl;
  cout << "Blue  = after dilation " << endl;
  cout << "Red   = before dilation " << endl;

  HByteImage img("monkey");
  HWindow    w;

  HRegion      circ   = HRegion::GenCircle (10, 10, 1.5);
  HRegionArray regs   = (img >= 128).Connection();
  HRegionArray minadd = regs.MinkowskiAdd1 (circ, 1);

                        img.Display (w);      w.Click ();
  w.SetColor ("blue");  minadd.Display (w);   w.Click ();
  w.SetColor ("red");   regs.Display (w);     w.Click ();

  return(0);
}
```

Complexity

Let $F1$ be the area of an input region. Then the runtime complexity for one region is:

$$O(2 \cdot \texttt{Radius} \cdot \sqrt{F1}) \ .$$

Result

`dilation_circle` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

dilation_rectangle1 (Region : RegionDilation : Width, Height :)

Dilate a region with a rectangular structuring element.

`dilation_rectangle1` applies a dilation with a rectangular structuring element to the input regions `Region`. The size of the structuring rectangle is `Width` $\times$ `Height`. The operator results in enlarged regions, and the holes smaller than the rectangular mask in the interior of the regions are closed.

`dilation_rectangle1` is a very fast operation because the height of the rectangle enters only logarithmically into the runtime complexity, while the width does not enter at all. This leads to excellent runtime efficiency, even in the case of very large rectangles (edge length > 100).

Attention

`dilation_rectangle1` is applied to each input region separately. If gaps between different regions are to be closed, `union1` or `union2` has to be called first.

To enlarge a region by the same amount in all directions, `Width` and `Height` must be odd. If this is not the case, the region is dilated by a larger amount at the right or at the bottom, respectively, than at the left or at the top.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be dilated.

▷ **RegionDilation** (output_object) ..... region(-array) ⇝ *object*
Dilated regions.

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the structuring rectangle.
Default: 11
Suggested values: Width ∈ {1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201}
Value range: 1 ≤ Width ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the structuring rectangle.
Default: 11
Suggested values: Height ∈ {1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201}
Value range: 1 ≤ Height ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"

main()
{
  cout << "Reproduction of 'dilation_rectangle ()'" << endl;
  cout << "First = original image " << endl;
  cout << "Blue  = after dilation " << endl;
  cout << "Red   = after segmentation " << endl;

  HByteImage img("monkey");
  HWindow    w;

  HRegionArray regs   = (img >= 220).Connection();
  HRegionArray dilreg = regs.DilationRectangle1 (2, 4);

                        img.Display (w);      w.Click ();
  w.SetColor ("blue");  dilreg.Display (w);   w.Click ();
  w.SetColor ("red");   regs.Display (w);     w.Click ();

  return(0);
}
```

Complexity

Let $F1$ be the area of an input region and H be the height of the rectangle. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot ld(H)) \ .$$

Result

dilation_rectangle1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

erosion1 (Region, StructElement : RegionErosion : Iterations :)

Erode a region.

erosion1 erodes the input regions with a structuring element. By applying erosion1 to a region, its boundary gets smoothed. In the process, the area of the region is reduced. Furthermore, connected regions may be split. Such regions, however, remain logically one region. The erosion is a set-theoretic region operation. It uses the intersection operation.

Let M (StructElement) and R (Region) be two regions, where M is the structuring element and R is the region to be processed. Furthermore, let m be a point in M. Then the displacement vector $\vec{v}_m = (dx, dy)$ is defined as the difference of the center of gravity of M and the vector $\vec{m}$. Let $t_{\vec{v}_m}(R)$ denote the translation of a region R by a vector $\vec{v}$. Then

$$\texttt{erosion1}(R, M) := \bigcap_{m \in M} t_{-\vec{v}_m}(R).$$

For each point m in M a translation of the region R is performed. The intersection of all these translations is the erosion of R with M. erosion1 is similar to the operator minkowski_sub1, the difference is that in erosion1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of M.

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n-1$ is used as input for iteration n. From the above definition it follows that the maximum region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be eroded.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element.

▷ **RegionErosion** (output_object) ..... region(-array) ⇝ *object*
Eroded regions.

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \texttt{Iterations}) \ .$$

Result

`erosion1` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

erosion_rectangle1 (Region : RegionErosion : Width, Height :)

Erode a region with a rectangular structuring element.

erosion_rectangle1 applies an erosion with a rectangular structuring element to the input regions Region. The size of the structuring rectangle is Width × Height. The operator results in reduced regions, and the areas smaller than the rectangular mask are eliminated.

erosion_rectangle1 is a very fast operation because the height of the rectangle enters only logarithmically into the runtime complexity, while the width does not enter at all. This leads to excellent runtime efficiency, even in the case of very large rectangles (edge length > 100).

Regions containing small connecting strips between large areas are separated only seemingly. They remain logically one region.

Attention

To reduce a region by the same amount in all directions, Width and Height must be odd. If this is not the case, the region is eroded by a smaller amount at the right or at the bottom, respectively, than at the left or at the top.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be eroded.

▷ **RegionErosion** (output_object) ..... region(-array) ⇝ *object*
Eroded regions.

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the structuring rectangle.
Default: 11
Suggested values: Width ∈ {1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201}
Value range: $1 \leq$ Width ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the structuring rectangle.
Default: 11
Suggested values: Height ∈ {1, 2, 3, 4, 5, 11, 15, 21, 31, 51, 71, 101, 151, 201}
Value range: $1 \leq$ Height ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of an input region and H be the height of the rectangle. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot ld(H)) \ .$$

Result

`erosion_rectangle1` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

hit_or_miss (Region, StructElement1, StructElement2 : RegionHitMiss : Row, Column :)

Hit-or-miss operation for regions.

`hit_or_miss` performs the hit-or-miss-transformation. First, an erosion with the structuring element `StructElement1` is done on the input region `Region`. Then an erosion with the structuring element `StructElement2` is performed on the complement of the input region. The intersection of the two resulting regions is the result `RegionHitMiss` of `hit_or_miss`.

The hit-or-miss-transformation selects precisely the points for which the conditions given by the structuring elements `StructElement1` and `StructElement2` are fulfilled. `StructElement1` determines the condition for the foreground pixels, while `StructElement2` determines the condition for the background pixels. In order to obtain sensible results, `StructElement1` and `StructElement2` must fit like key and lock. In any case, `StructElement1` and `StructElement2` must be disjunct. `Row` and `Column` determine the reference point of the structuring elements.

Structuring elements (`StructElement1`, `StructElement2`) can be generated by calling operators like `gen_region_points`, etc.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be processed.

▷ **StructElement1** (input_object) ..... region ⇝ *object*
Erosion mask for the input regions.

▷ **StructElement2** (input_object) . . . . . region ⇝ *object*
Erosion mask for the complements of the input regions.

▷ **RegionHitMiss** (output_object) . . . . . region(-array) ⇝ *object*
Result of the hit-or-miss operation.

▷ **Row** (input_control) . . . . . point.y ⇝ *integer*
Row coordinate of the reference point.
Default: 16
Suggested values: Row ∈ {0, 16, 32, 128, 256}
Value range: 0 ≤ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) . . . . . point.x ⇝ *integer*
Column coordinate of the reference point.
Default: 16
Suggested values: Column ∈ {0, 16, 32, 128, 256}
Value range: 0 ≤ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of an input region, $F1$ the area of the structuring element 1, and $F2$ the area of the structuring element 2. Then the runtime complexity for one object is:

$$O\left(\sqrt{F} \cdot \left(\sqrt{F1} + \sqrt{F2}\right)\right) \quad .$$

Result

hit_or_miss returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

minkowski_add1 (Region,
StructElement : RegionMinkAdd : Iterations :)

Perform a Minkowski addition on a region.

minkowski_add1 dilates the input regions with a structuring element. By applying minkowski_add1 to a region, its boundary gets smoothed. In the process, the area of the region is enlarged. Furthermore, disconnected regions may be merged. Such regions, however, remain logically distinct region. The Minkowski addition is a set-theoretic region operation. It is based on translations and union operations.

Let M (StructElement) and R (Region) be two regions, where M is the structuring element and R is the region to be processed. Furthermore, let m be a point in M. Then the displacement vector $\vec{v}_m = (dx, dy)$ is defined as the difference of the center of gravity of M and the vector $\vec{m}$. Let $t_{\vec{v}_m}(R)$ denote the translation of a region R by a vector $\vec{v}$. Then

$$\texttt{minkowski\_add1}(R, M) := \bigcup_{m \in M} t_{\vec{v}_m}(R)$$

For each point m in M a translation of the region R is performed. The union of all these translations is the Minkowski addition of R with M. minkowski_add1 is similar to the operator dilation1, the difference is that in dilation1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of M.

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n-1$ is used as input for iteration n. From the above definition it follows that an empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Attention

A Minkowski addition always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator union1 has to be called first.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be dilated.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element.

▷ **RegionMinkAdd** (output_object) ..... region(-array) ⇝ *object*
Dilated regions.

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \texttt{Iterations}) \ .$$

Result

minkowski_add1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, union1, watersheds, class_ndim_norm, gen_circle, gen_ellipse, gen_rectangle1, gen_rectangle2, draw_region, gen_region_points, gen_region_polygon_filled

Possible Successors

minkowski_add2 (Region, StructElement : RegionMinkAdd : Row, Column, Iterations :)

Dilate a region (using a reference point).

minkowski_add2 computes the Minkowski addition of the input regions with a structuring element (StructElement) having the reference point (Row,Column). minkowski_add2 has a similar effect as minkowski_add1, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n-1$ is used as input for iteration n.

An empty region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Attention

A Minkowski addition always results in enlarged regions. Closely spaced regions which may touch or overlap as a result of the dilation are still treated as two separate regions. If the desired behavior is to merge them into one region, the operator union1 has to be called first.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be dilated.

▷ **StructElement** (input_object) . . . . . region ⇝ *object*
Structuring element.

▷ **RegionMinkAdd** (output_object) . . . . . region(-array) ⇝ *object*
Dilated regions.

▷ **Row** (input_control) . . . . . point.y ⇝ *integer*
Row coordinate of the reference point.
Value range: $1 \leq$ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) . . . . . point.x ⇝ *integer*
Column coordinate of the reference point.
Value range: $1 \leq$ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \texttt{Iterations}) \ .$$

Result

minkowski_add2 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

minkowski_sub1 (Region, StructElement : RegionMinkSub : Iterations :)

Erode a region.

minkowski_sub1 computes the Minkowski subtraction of the input regions with a structuring element. By applying minkowski_sub1 to a region, its boundary gets smoothed. In the process, the area of the region is reduced. Furthermore, connected regions may be split. Such regions, however, remain logically one region. The Minkowski subtraction is a set-theoretic region operation. It uses the intersection operation.

Let M (StructElement) and R (Region) be two regions, where M is the structuring element and R is the region to be processed. Furthermore, let m be a point in M. Then the displacement vector $\vec{v}_m = (dx, dy)$ is defined as the difference of the center of gravity of M and the vector $\vec{m}$. Let $t_{\vec{v}_m}(R)$ denote the translation of a region R by a vector $\vec{v}$. Then

$$\texttt{minkowski\_sub1}(R, M) := \bigcap_{m \in M} t_{\vec{v}_m}(R)$$

For each point m in M a translation of the region R is performed. The intersection of all these translations is the Minkowski subtraction of R with M. minkowski_sub1 is similar to the operator erosion1, the difference is that in erosion1 the structuring element is mirrored at the origin. The position of StructElement is meaningless, since the displacement vectors are determined with respect to the center of gravity of M.

The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n-1$ is used as input for iteration n. From the above definition it follows that the maximum region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be eroded.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element.

▷ **RegionMinkSub** (output_object) ..... region(-array) ⇝ *object*
Eroded regions.

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \texttt{Iterations}) \ .$$

Result

minkowski_sub1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

minkowski_sub2 (Region, StructElement : RegionMinkSub : Row, Column, Iterations :)

Erode a region (using a reference point).

minkowski_sub2 computes the Minkowski subtraction of the input regions with a structuring element (StructElement) having the reference point (Row,Column). minkowski_sub2 has a similar effect as minkowski_sub1, the difference is that the reference point of the structuring element can be chosen arbitrarily. The parameter Iterations determines the number of iterations which are to be performed with the structuring element. The result of iteration $n-1$ is used as input for iteration n.

A maximum region is generated in case of an empty structuring element.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be eroded.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element.

▷ **RegionMinkSub** (output_object) ..... region(-array) ⇝ *object*
Eroded regions.

▷ **Row** (input_control) ..... point.y ⇝ *integer*
Row coordinate of the reference point.
Default: 0
Suggested values: Row ∈ {0, 10, 16, 32, 64, 100, 128}
Value range: 0 ≤ Row ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Column** (input_control) ..... point.x ⇝ *integer*
Column coordinate of the reference point.
Default: 0
Suggested values: Column ∈ {0, 10, 16, 32, 64, 100, 128}
Value range: 0 ≤ Column ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Iterations** (input_control) ..... integer ⇝ *integer*
Number of iterations.
Default: 1
Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: 1 ≤ Iterations (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(\sqrt{F1} \cdot \sqrt{F2} \cdot \text{Iterations}) \ .$$

Result

minkowski_sub2 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

gen_circle, gen_rectangle2, gen_region_polygon

Module

Foundation

opening (Region, StructElement : RegionOpening : :)

Open a region.

An opening operation is defined as an erosion followed by a Minkowski addition. By applying opening to a region, larger structures remain mostly intact, while small structures like lines or points are eliminated. In contrast, a closing operation results in small gaps being retained or filled up (see closing).

opening serves to eliminate small regions (smaller than StructElement) and to smooth the boundaries of a region. The position of StructElement is meaningless, since an opening operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be opened.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element (position-invariant).

▷ **RegionOpening** (output_object) ..... region(-array) ⇝ *object*
Opened regions.

Example

```
* Large regions in an aerial picture (beech trees or meadows):
read_image(Image,'forest_road')
threshold(Image,Light,160,255)
gen_circle(StructElement,100,100,10)
* selecting the large regions
opening(Light,StructElement,Large)
* Selecting of edges with certain orientation:
read_image(Image,'fabrik')
sobel_amp(Image,Sobel,'sum_abs',3)
threshold(Sobel,Edges,10,255)
gen_rectangle2(StructElement,100,100,3.07819,20,1)
opening(Edges,StructElement,Direction)
```

Complexity

Let $F1$ be the area of the input region, and $F2$ be the area of the structuring element. Then the runtime complexity for one region is:

$$O(2 \cdot \sqrt{F1} \cdot \sqrt{F2}) \ .$$

Result

`opening` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

Foundation

opening_circle (Region : RegionOpening : Radius :)

Open a region with a circular structuring element.

`opening_circle` is defined as an erosion followed by a Minkowski addition with a circular structuring element (see example). `opening` serves to eliminate small regions (smaller than the circular structuring element) and to smooth the boundaries of a region.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be opened.

▷ **RegionOpening** (output_object) ..... region(-array) ⇝ *object*
Opened regions.

▷ **Radius** (input_control) ..... real ⇝ *real* / integer
Radius of the circular structuring element.
Default: 3.5
Suggested values: `Radius` ∈ {1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5}
Value range: 0.5 ≤ `Radius` ≤ 511.5 (lin)
Minimum increment: 1.0
Recommended increment: 1.0

Example

```
* Large regions in an aerial picture (beech trees or meadows):
read_image (Image, 'forest_road')
threshold (Image, Region, 120, 255)
* Close the small gaps.
closing_circle (Region, RegionClosing, 3.5)
* Select the large regions.
opening_circle (RegionClosing, RegionOpening, 19.5)
```

Complexity

Let $F1$ be the area of the input region. Then the runtime complexity for one region is:

$$O(4 \cdot \sqrt{F1} \cdot \texttt{Radius}) \ .$$

Result

`opening_circle` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`transpose_region`

Module

Foundation

opening_rectangle1 (Region : RegionOpening : Width, Height :)

Open a region with a rectangular structuring element.

`opening_rectangle1` behaves as `opening` with a rectangular structuring element on the input region `Region`. The size of the rectangular structuring element is determined by the parameters `Width` and `Height`. As is the case for all `opening` variants, larger structures are preserved, while small regions like lines or points are eliminated.

Similar to `erosion_rectangle1` and `dilation_rectangle1` `opening_rectangle1` is a very fast operation.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be opened.

▷ **RegionOpening** (output_object) . . . . . region(-array) ⇝ *object*
Opened regions.

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the structuring rectangle.
Default: 10
Suggested values: Width ∈ {1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200}
Value range: 1 ≤ Width ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the structuring rectangle.
Default: 10
Suggested values: Height ∈ {1, 2, 3, 4, 5, 7, 9, 12, 15, 19, 25, 33, 45, 60, 110, 150, 200}
Value range: 1 ≤ Height ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let $F1$ be the area of an input region and H be the height of the rectangle. Then the runtime complexity for one region is:

$$O(2 \cdot \sqrt{F1} \cdot ld(H)) \ .$$

Result

opening_rectangle1 returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Alternatives

opening, gen_rectangle1, dilation_rectangle1, erosion_rectangle1

Module

Foundation

pruning (Region : RegionPrune : Length :)

Prune the branches of a region.

pruning removes branches from a skeleton (Region) having a length less than Length. All other branches are preserved.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be processed.

▷ **RegionPrune** (output_object) ..... region(-array) ⇝ *object*
Result of the pruning operation.

▷ **Length** (input_control) ..... integer ⇝ *integer*
Length of the branches to be removed.
Default: 2
Suggested values: Length ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 17, 20, 30, 40, 50}
Value range: 1 ≤ Length ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of the input region. Then the runtime complexity for one region is

$$O(\texttt{Length} \cdot 3 \cdot \sqrt{F}) \ .$$

Result

pruning returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: set_system('no_object_result',<RegionResult>)
- empty region: set_system('empty_region_result',<RegionResult>)

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

junctions_skeleton

Module

Foundation

top_hat (Region, StructElement : RegionTopHat : :)

Compute the top hat of regions.

top_hat computes the opening of Region with StructElement. The difference between the original region and the result of the opening is called the top hat. In contrast to opening, which splits regions under certain circumstances, top_hat computes the regions removed by such a splitting.

The position of StructElement is meaningless, since an opening operation is invariant with respect to the choice of the reference point.

Structuring elements (StructElement) can be generated with operators such as gen_circle, gen_rectangle1, gen_rectangle2, gen_ellipse, draw_region, gen_region_polygon, gen_region_points, etc.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be processed.

▷ **StructElement** (input_object) ..... region ⇝ *object*
Structuring element (position independent).

▷ **RegionTopHat** (output_object) ..... region(-array) ⇝ *object*
Result of the top hat operator.

Result

`top_hat` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Chapter 21

OCR

21.1 Convolutional Neural Networks

clear_ocr_class_cnn (: : OCRHandle :)

Clear an CNN-based OCR classifier.

clear_ocr_class_cnn clears the OCR classifier given by OCRHandle that was read with read_ocr_class_cnn and frees all memory required for the classifier. After calling clear_ocr_class_cnn, the classifier can no longer be used. The handle OCRHandle becomes invalid.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_cnn(-array) ⇝ *handle*
Handle of the OCR classifier.

Result

If OCRHandle is valid, the operator clear_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

do_ocr_single_class_cnn, do_ocr_multi_class_cnn, do_ocr_word_cnn

See also

read_ocr_class_cnn

Module

OCR/OCV

deserialize_ocr_class_cnn (: : SerializedItemHandle : OCRHandle)

Deserialize a serialized CNN-based OCR classifier.

deserialize_ocr_class_cnn deserializes a CNN-based OCR classifier, that was serialized by serialize_ocr_class_cnn (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **OCRHandle** (output_control) . . . . . ocr_cnn ⇝ *handle*
Handle of the OCR classifier.

Result

If the parameters are valid, the operator deserialize_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_ocr_class_cnn

Possible Successors

do_ocr_single_class_cnn, do_ocr_multi_class_cnn

Module

OCR/OCV

do_ocr_multi_class_cnn (Character, Image : : OCRHandle : Class, Confidence)

Classify multiple characters with an CNN-based OCR classifier.

do_ocr_multi_class_cnn computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence.

In contrast to do_ocr_single_class_cnn, do_ocr_multi_class_cnn can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_cnn to classify single characters. However, do_ocr_multi_class_cnn can only return the best class of each character. Because the confidences can be interpreted as probabilities, it is easier to check whether a character has been classified with too much uncertainty. This is usually not a disadvantage, except in cases where the classes overlap so much that in many cases the second best class must be examined to be able to decide the class of the character. In these cases, do_ocr_single_class_cnn should be used.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

Parameters

▷ **Character** (input_object) . . . . . region(-array) ⇝ *object*
Characters to be recognized.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Gray values of the characters.

▷ **OCRHandle** (input_control) . . . . . ocr_cnn ⇝ *handle*
Handle of the OCR classifier.

▷ **Class** (output_control) . . . . . string(-array) ⇝ *string*
Result of classifying the characters with the CNN.
Number of elements: Class == Character

▷ **Confidence** (output_control) . . . . . real(-array) ⇝ *real*
Confidence of the class of the characters.
Number of elements: Confidence == Character

Result

If the parameters are valid, the operator do_ocr_multi_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

read_ocr_class_cnn

Alternatives

do_ocr_word_cnn, do_ocr_single_class_cnn

Module

OCR/OCV

do_ocr_single_class_cnn (Character, Image : : OCRHandle, Num : Class, Confidence)

Classify a single character with an CNN-based OCR classifier.

do_ocr_single_class_cnn computes the best classification for the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the best Num classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. Because multiple classes may be returned by do_ocr_single_class_cnn, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_cnn must be used.

In most cases, do_ocr_multi_class_cnn should be preferred over do_ocr_single_class_cnn, since do_ocr_multi_class_cnn is typically faster than a loop with do_ocr_single_class_cnn. Furthermore, the resulting confidences can be interpreted as probabilities. They indicate the uncertainty of a character's classification result. The operator do_ocr_single_class_cnn has to be used if the nth-best class has to be examined explicitly for n greater than one.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

Parameters

▷ **Character** (input_object) . . . . . region ⇝ *object*
Character to be recognized.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object : byte / uint2*
Gray values of the character.

▷ **OCRHandle** (input_control) . . . . . ocr_cnn ⇝ *handle*
Handle of the OCR classifier.

▷ **Num** (input_control) . . . . . integer-array ⇝ *integer*
Number of best classes to determine.
Default: 1
Suggested values: Num ∈ {1, 2, 3, 4, 5}

▷ **Class** (output_control) . . . . . string(-array) ⇝ *string*
Result of classifying the character with the CNN.

▷ **Confidence** (output_control) . . . . . real(-array) ⇝ *real*
Confidence(s) of the class(es) of the character.

Example

```
read_image(Image, 'bottle2')
OffsetRow := 100
OffsetCol := 108
read_ocr_class_cnn('Universal_0-9_NoRej.occ', OCRHandle)
* Select each digit and use do_ocr_single_class_cnn to apply OCR
gen_rectangle1(ROI_Date, OffsetRow, OffsetCol, OffsetRow, OffsetCol)
for I := 1 to 6 by 1
  Offset := I % 2 * 10
  smallest_rectangle1(ROI_Date, Row1, Col1, Row2, Col2)
  gen_rectangle1(ROI_Date, OffsetRow, Offset + Col2, OffsetRow + 42, \
  Col2 + Offset + 31)
  do_ocr_single_class_cnn(ROI_Date, Image, OCRHandle, 1, Class, Confidence)
endfor
```

Result

If the parameters are valid, the operator `do_ocr_single_class_cnn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_ocr_class_cnn`

Alternatives

`do_ocr_multi_class_cnn`

Module

OCR/OCV

do_ocr_word_cnn (Character, Image : : OCRHandle, Expression, NumAlternatives, NumCorrections : Class, Confidence, Word, Score)

Classify a related group of characters with an CNN-based OCR classifier.

`do_ocr_word_cnn` works like `do_ocr_multi_class_cnn` insofar as it computes the best class for each of the characters given by the regions `Character` and the gray values `Image` with the OCR classifier `OCRHandle`, and returns the classes in `Class` and the corresponding confidences (probabilities) of the classes in `Confidence`.

In contrast to `do_ocr_multi_class_cnn`, `do_ocr_word_cnn` treats the group of characters as an entity which yields a `Word` by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an `Expression` describing the expected word.

The `Expression` may restrict the word to belong to a predefined lexicon created using `create_lexicon` or `import_lexicon`, or by specifying the name of the lexicon in angular brackets as in *'<mylexicon>'*. If the `Expression` is of any other form, it is interpreted as a regular expression with the same syntax as specified for `tuple_regexp_match`. Note that you will usually want to use an expression of the form '^...$' when using variable quantifiers like '*', to ensure that the entire word is used in the expression. Also note that in contrast to `tuple_regexp_match`, `do_ocr_word_cnn` does **not** support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the `Expression`, `do_ocr_word_cnn` attempts to correct it by considering the `NumAlternatives` best classes for each character. The alternatives used are identical to those returned by `do_ocr_single_class_cnn` for a single character. It does so by testing all possible corrections for which the classification result is changed for at most `NumCorrections` character

regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

$$\texttt{Score} = 1.0 - \texttt{PenaltyCorrections} - \texttt{PenaltyAlternatives}$$

$$\begin{aligned} \texttt{PenaltyCorrections} &= \alpha * \texttt{num\_corr} \\ \texttt{PenaltyAlternatives} &= \alpha * \beta * \texttt{num\_alt} \end{aligned}$$

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

$$\begin{aligned} \alpha &= \frac{1}{\texttt{NumCorrections} + 1} \\ \beta &= \frac{1}{\texttt{NumCorrections} * (\texttt{NumAlternatives} - 1) + 2} \end{aligned}$$

Note that this is a combinatorial score which does **not** reflect the original Confidence of the best Class.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

Parameters

▷ **Character** (input_object) . . . . . region(-array) ⇝ *object*
Characters to be recognized.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Gray values of the characters.

▷ **OCRHandle** (input_control) . . . . . ocr_cnn ⇝ *handle*
Handle of the OCR classifier.

▷ **Expression** (input_control) . . . . . string ⇝ *string*
Expression describing the allowed word structure.

▷ **NumAlternatives** (input_control) . . . . . integer ⇝ *integer*
Number of classes per character considered for the internal word correction.
Default: 3
Suggested values: NumAlternatives ∈ {3, 4, 5}
Value range: 1 ≤ NumAlternatives

▷ **NumCorrections** (input_control) . . . . . integer ⇝ *integer*
Maximum number of corrected characters.
Default: 2
Suggested values: NumCorrections ∈ {1, 2, 3, 4, 5}
Value range: 0 ≤ NumCorrections

▷ **Class** (output_control) . . . . . string(-array) ⇝ *string*
Result of classifying the characters with the CNN.
Number of elements: Class == Character

▷ **Confidence** (output_control) . . . . . real(-array) ⇝ *real*
Confidence of the class of the characters.
Number of elements: Confidence == Character

▷ **Word** (output_control) . . . . . string ⇝ *string*
Word text after classification and correction.

▷ **Score** (output_control) . . . . . real ⇝ *real*
Measure of similarity between corrected word and uncorrected classification results.

Complexity

The complexity of checking all possible corrections is of magnitude $O((n * a)^{min(c,n)})$, where a is the number of alternatives, n is the number of character regions, and c is the number of allowed corrections. However, to guard against a near-infinite loop in case of large n, c is internally clipped to 5, 3, or 1 if $a * n >= 30$, 60, or 90, respectively.

Result

If the parameters are valid, the operator `do_ocr_word_cnn` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_ocr_class_cnn`

Alternatives

`do_ocr_multi_class_cnn`

Module

OCR/OCV

get_params_ocr_class_cnn (: : OCRHandle, GenParamName : GenParamValue)

Return the parameters of a CNN-based OCR classifier.

`get_params_ocr_class_cnn` returns the parameters `GenParamName` of an OCR classifier `OCRHandle` in `GenParamValue`. This is particularly useful if the classifier was read with `read_ocr_class_cnn`. The output of `get_params_ocr_class_cnn` can, for example, be used to check whether a character to be read is contained in the classifier.

Possible values for `GenParamName` are:

'characters': Returns a list of all trained symbols which may be recognized by the CNN-based OCR classifier. Note that if *'characters'* is specified then no other generic parameter is allowed. Otherwise an exception is thrown.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_cnn ⇝ *handle*
Handle of the OCR classifier.

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
A tuple of generic parameter names.
Default: 'characters'
List of values: `GenParamName` ∈ {'characters'}

▷ **GenParamValue** (output_control) . . . . . string(-array) ⇝ *integer* / string
A tuple of generic parameter values.

Result

If the parameters are valid, the operator `get_params_ocr_class_cnn` returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_ocr_class_cnn

Possible Successors

do_ocr_single_class_cnn, do_ocr_multi_class_cnn

Module

OCR/OCV

query_params_ocr_class_cnn (: : OCRHandle : GenParamName)

Get the names of the parameters that can be used in get_params_ocr_class_cnn for a given CNN-based OCR classifier.

The operator query_params_ocr_class_cnn returns the parameter names that can be used to query all parameters for a given CNN-based OCR classifier. The resulting parameter names can be used as input parameter when calling get_params_ocr_class_cnn.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_cnn ⇝ *handle*
Handle of OCR classifier.

▷ **GenParamName** (output_control) ..... string(-array) ⇝ *string*
Names of the generic parameters.

Result

The operator query_params_ocr_class_cnn returns the value 2 (H_MSG_TRUE) if the given handle for the OCR classifier is correct. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_params_ocr_class_cnn

Module

OCR/OCV

read_ocr_class_cnn (: : FileName : OCRHandle)

Read an CNN-based OCR classifier from a file.

read_ocr_class_cnn reads a pretrained OCR classifier based on a convolutional neural network (CNN).

The CNN-based OCR classifier is read with read_ocr_class_cnn and subsequently used for classification with either do_ocr_single_class_cnn, do_ocr_multi_class_cnn, or do_ocr_word_cnn.

HALCON provides a number of pretrained OCR classifiers (see "Solution Guide I", chapter 'OCR', section 'Pretrained OCR Fonts'). These pretrained OCR classifiers make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Note that the pretrained OCR classifiers were trained with symbols that are printed dark on light.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
Default: 'Universal_Rej.occ'
Suggested values: FileName ∈ {'Universal_NoRej.occ', 'Universal_Rej.occ', 'Universal_0-9_NoRej.occ', 'Universal_0-9_Rej.occ', 'Universal_0-9+_NoRej.occ', 'Universal_0-9+_Rej.occ', 'Universal_0-9A-Z_NoRej.occ', 'Universal_0-9A-Z_Rej.occ', 'Universal_0-9A-Z+_NoRej.occ', 'Universal_0-9A-Z+_Rej.occ', 'Universal_A-Z+_NoRej.occ', 'Universal_A-Z+_Rej.occ'}
File extension: .occ, .fnt

▷ **OCRHandle** (output_control) . . . . . ocr_cnn ⇝ *handle*
Handle of the OCR classifier.

Result

If the parameters are valid, the operator read_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

do_ocr_single_class_cnn, do_ocr_multi_class_cnn, do_ocr_word_cnn

See also

get_params_ocr_class_cnn

Module

OCR/OCV

serialize_ocr_class_cnn (: : OCRHandle : SerializedItemHandle)

Serialize a CNN-based OCR classifier

serialize_ocr_class_cnn serializes a CNN-based OCR classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The OCR classifier is defined by the handle OCRHandle. The serialized OCR classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocr_class_cnn.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_cnn ⇝ *handle*
Handle of the OCR classifier.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_ocr_class_cnn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

clear_ocr_class_cnn, fwrite_serialized_item, send_serialized_item, deserialize_ocr_class_cnn

Module

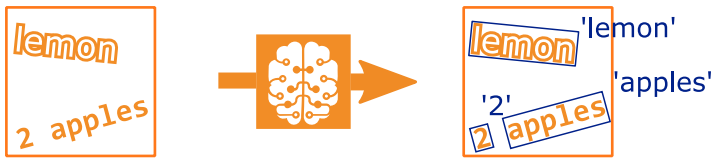
21.2 Deep OCR

This chapter explains how to use deep-learning-based optical character recognition (Deep OCR).

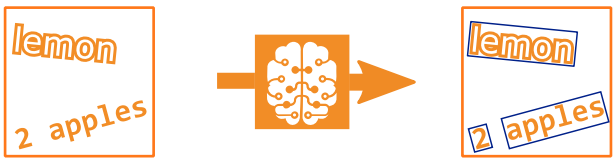
With Deep OCR we want to detect and/or recognize text in an image. Deep OCR detects and recognizes connected characters, which will be referred to as 'words' (in contrast to OCR methods which are used to read single characters).



A possible example for deep-learning-based optical character recognition: Words in an image are detected and recognized.

A Deep OCR model can contain two components, which are dedicated to two distinct tasks, the detection, thus the localization of words, and the recognition of words. By default, a model is created with both components, but the model can also be limited to either task.

HALCON already provides pretrained components, which are suited for a multitude of applications without additional training as the model is trained on a varied dataset and can therefore cope with many different fonts. Information on the available character set and model parameters can be retrieved using get_deep_ocr_param. To further adjust the reading to a specific task, it is possible to retrain the recognition or detection component separately on a given application domain using deep learning operators. Note that only one component can be retrained at a time.



The detection can be fine-tuned for an application by retraining the Deep OCR model with custom data.

The recognition can be fine-tuned for an application by retraining the Deep OCR model with custom data.

The general workflow as well as the retraining are described in the following paragraphs.

General Workflow for Deep OCR Inference

This paragraph describes the workflow how to localize and read words using a Deep OCR model. An application scenario can be seen in the HDevelop example deep_ocr_workflow.hdev.

Creation of the Deep OCR model Create a Deep OCR model containing either one or both of the two model components

- detection_model and

- recognition_model

using the operator create_deep_ocr.

To use a retrained model component instead of the provided one, adjust the created model by setting the retrained model component as *'recognition_model'* or *'detection_model'* using set_deep_ocr_param.

Inference Model parameters regarding, e.g., the used devices, image dimensions, or minimum scores can be set using set_deep_ocr_param.

The Deep OCR model is applied on your acquired images using apply_deep_ocr. The inference results depend on the used model components. See the operator reference of apply_deep_ocr for details regarding which dictionary entries are computed for each model composite.

The inference results can be retrieved from the dictionary DeepOCRResult. Some procedures are provided in order to visualize results and score maps:

- Show location and/or recognized word using dev_display_deep_ocr_results.
- Show location (and, if inferred, recognized word) on preprocessed image using dev_display_deep_ocr_results_preprocessed (if the model contains detection_model).
- Show score maps using dev_display_deep_ocr_score_maps (if the model contains detection_model).

Training and Evaluation of the Model Components

This paragraph describes the retraining and evaluation of the recognition or detection components of a Deep OCR model using custom data. See also the HDevelop examples deep_ocr_recognition_training_workflow.hdev or deep_ocr_detection_training_workflow.hdev for an application scenario.

Preprocess the data This part is about how to preprocess your data. See the section "Data" below for information on what data is to be provided at what stage of the Deep OCR workflow.

1. The information that is to be obtained from the images of your training dataset needs to be transferred. This is done by the procedure
   - read_dl_dataset_ocr_recognition for the recognition component of a Deep OCR model.
   - read_dl_dataset_ocr_detection for the detection component of a Deep OCR model.

   It creates a dictionary DLDataset which serves as a database and stores all necessary information about your data. For more information about datasets, see the chapter Deep Learning / Model.
2. Split the dataset represented by the dictionary DLDataset. This can be done using the procedure
   - split_dl_dataset.
3. The network imposes several requirements on the images. These requirements (for example the image size and gray value range) can be retrieved with
   - get_dl_model_param.

   For this you need to read the model first by using
   - read_dl_model.
4. Now you can preprocess your dataset. For this, you can use the procedure
   - preprocess_dl_dataset.

   To use this procedure, specify the preprocessing parameters as, e.g., the image size. Store all the parameter with their values in a dictionary DLPreprocessParam, for which you can use the procedure
   - create_dl_preprocess_param_from_model.

   We recommend to save this dictionary DLPreprocessParam in order to have access to the preprocessing parameter values later during the inference phase.

Training of the model This part explains how to train the recognition or detection component of a Deep OCR model.

1. Set the training parameters and store them in the dictionary `TrainParam`. This can be done using the procedure
   - `create_dl_train_param`.
2. Train the model. This can be done using the procedure
   - `train_dl_model`.

   The procedure expects:
   - the model handle `DLModelHandle`
   - the dictionary `DLDataset` containing the data information
   - the dictionary `TrainParam` containing the training parameters

Evaluation of the retrained model In this part, we evaluate the Deep OCR model.

1. Set the model parameters which may influence the evaluation.
2. The evaluation can be done conveniently using the procedure
   - `evaluate_dl_model`.

   This procedure expects a dictionary `GenParamEval` with the evaluation parameters.
3. The dictionary `EvaluationResult` holds the evaluation measures. To get a clue on how the retrained model performed against the pretrained model you can compare their evaluation values. To understand the different evaluation measures, see section "Evaluation Measures for Deep OCR Results".

After a successful evaluation the retrained model can be used for inference (see section "General Workflow for Deep OCR Inference" above).

Data

This section gives information on the data that needs to be provided in different stages of the Deep OCR workflow.

We distinguish between data used for training and evaluation, consisting of images with their information about the instances, and data for inference, which are bare images. How the data needs to be provided is explained in the according sections below.

As a basic concept, the model handles data over dictionaries, meaning it receives the input data over a dictionary `DLSample` and returns a dictionary `DLResult` and `DLTrainResult`, respectively. More information on the data handling can be found in the chapter Deep Learning / Model.

Data for training and evaluation The dataset consists of images and corresponding information. They have to be provided in a way the model can process them. Concerning the image requirements, find more information in the section "Images" below.

The training data is used to train and evaluate a network for your specific application. With the aid of this data the network can learn to detect or recognize text samples that resemble text that occurs during inference. The necessary information is given by providing the depicted word for each image.

How the data has to be formatted in HALCON for a DL model is explained in the chapter Deep Learning / Model. In short, a dictionary `DLDataset` serves as a database for the information needed by the training and evaluation procedures.

The data for `DLDataset` can be read using `read_dl_dataset_ocr_recognition` or `read_dl_dataset_ocr_detection` depending on which model type is used.

Dataset based on images with word labels In this case, images with words that are labeled with rotated bounding boxes need to be provided. You can label your data using the MVTec Deep Learning Tool, available from the MVTec website. The dataset must be built as follows:

- `'class_ids'`: class IDs
- `'class_names'`: class names (Needs to contain the class 'word'. All other classes are ignored.)

- 'image_dir': path to the image directory
- 'samples': tuple of dictionaries, one for each sample
  - 'image_file_name': name of the image file
  - 'image_id': image ID
  - 'bbox_col': bounding box column coordinate
  - 'bbox_row': bounding box row coordinate
  - 'bbox_phi': bounding box angle
  - 'bbox_length1': first half edge length of the bounding box
  - 'bbox_length2': second half edge length of the bounding box
  - 'label_custom_data': list of dictionaries containing custom label data for each bounding box
    * 'text' word to be read

Dataset based on word crop images (only recognition)

In this case, only images that are cropped to a single word each are included in the dataset. The dataset must be built as follows:

- 'image_dir': path to the image directory
- 'samples': tuple of dictionaries, one for each sample
  - 'image_file_name': name of the image file
  - 'image_id': image ID
  - 'word': word to be read in the image

The example program deep_ocr_prelabel_dataset.hdev can provide assistance by prelabeling your data.

Your training data should cover the full range of characters that might occur during inference. If a character is not or only very rarely contained in the training dataset the model might not properly learn to recognize that character. To keep track of the character distribution within the dataset the procedure gen_dl_dataset_ocr_recognition_statistics is provided, which generates statistics on how often every single character is contained in your dataset.

You also want enough training data to split it into three subsets, used for training, validation and testing the network. These subsets are preferably independent and identically distributed, see the section "Data" in the chapter Deep Learning.

Images The model poses requirements on the images, such as the dimensions, the gray value range, and the type. See the documentation of read_dl_model for the specific values of the trainable Deep OCR model. For a read model they can be queried with get_dl_model_param. In order to fulfill these requirements, you may have to preprocess your images. Standard preprocessing of an entire sample, including the image, is implemented in preprocess_dl_samples.

Requirements for images used for inference are described in apply_deep_ocr.

Model output The network output depends on the task:

training As output, the operator will return a dictionary DLTrainResult with the current value of the total loss as well as values for all other losses included in your model.

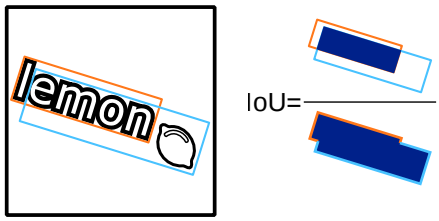
inference and evaluation As output, the network will return a dictionary DLResult for every sample. This dictionary will include the recognized word as well as the candidates and their confidences for every character of the word.

Evaluation Measures for Deep OCR Results

Deep OCR Detection The following evaluation measures are supported in HALCON. To compute these metrics for testing or validation, ground truth annotation is needed.

- Precision, Recall and F-score

  The performance of Deep OCR Detection is evaluated using precision and recall on word boxes. The evaluation uses the intersection over union (IoU) in order to compare ground truth and predicted word boxes. The default IoU threshold for a match is *0.5*, it can be increased or decreased if needed.



(1) (2)

Visual example of the IoU. (1) The input image with the ground truth bounding box (orange) and the predicted bounding box (light blue). (2) The IoU is the ratio between the area intersection and the union.

The precision is the proportion of true positives to all positives (true and false ones). Thus, it is a measure of how thrustworthy the detecor is.

$$\text{precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

The recall is the proportion of the number of correctly detected words to all labeled words.

$$\text{recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

To represent this with a single number, we compute the F-score, the harmonic mean of precision and recall.

$$\text{F-score} = 2 * \frac{\text{precision} * \text{recall}}{\text{precision} + \text{recall}}$$

- Score of Angle Precision (SoAP)
  The SoAP value is a score for the precision of the inferred orientation angles. This score is determined by the angle differences between the inferred bounding boxes (I) and the corresponding ground truth annotations (GT):
  $\text{SoAP} = 1.0 - \frac{1}{\pi}\frac{1}{k} \cdot \sum_k \left|\varphi_k^{\text{I}} - \varphi_k^{\text{GT}}\right|$,
  where the index k runs over all inferred bounding boxes.

Deep OCR Recognition The accuracy for a Deep OCR Recognition task is given as the percentage of correctly read words (CR) to the ground truth words (GT) of a dataset. The accuracy is then defined as:

$$\text{Accuracy} = \frac{\text{CR}}{\text{GT}} * 100$$

apply_deep_ocr (Image : : DeepOcrHandle, Mode : DeepOcrResult)

Apply a Deep OCR model on a set of images for inference.

`apply_deep_ocr` applies the Deep OCR model given by `DeepOcrHandle` on the tuple of input images `Image`. The operator returns `DeepOcrResult`, a tuple with a result dictionary for every input image.

The operator `apply_deep_ocr` poses requirements on the input `Image`:

- Image type: byte.
- Number of channels: 1 or 3.

Further, the operator apply_deep_ocr will preprocess the given Image to match the model specifications. This means, the byte images will be normalized and converted to type real. Further, for Mode = *'auto'* or *'detection'* the input image Image is padded to the model input dimensions and, in case it has only one channel, converted into a three-channel image. For Mode = *'recognition'*, three-channel images are automatically converted to single-channel images.

The parameter Mode specifies a mode and with it, which component is executed. Supported values:

'auto' **(A):** Perform both parts, detection of the word and its recognition.

'detection' **(DET):** Perform only the detection part. Hence, the model will merely localize the word regions within the image.

'recognition' **(REC):** Perform only the recognition part. Hence, the model requires that the image contains solely a tight crop of the word.

Note, the model must have been created with the desired component, see create_deep_ocr.

The output dictionary DeepOcrResult can have entries according to the applied Mode (marked by its abbreviation):

image (A, DET, REC): Preprocessed image.

score_maps (A, DET): Scores given as image with four channels:

- Character score: Score for the character detection.
- Link score: Score for the connection of detected character centers to a connected word.
- Orientation 1: Sine component of the predicted word orientation.
- Orientation 2: Cosine component of the predicted word orientation.

words (A, DET): Dictionary containing the following entries. Thereby, the entries are tuples with a value for every found word.

- word (A): Recognized word.
- char_candidates (A): A dictionary with information for every character of every recognized word. The dictionary contains for every word a key/value pair: The index of the word as key and a tuple of dictionaries as value. Each of these character dictionaries contains the following key/value pairs:
  - 'candidate': Tuple with the best *'recognition_num_char_candidates'* candidates.
  - 'confidence': Softmax based confidence values of the best candidates. Note, these values are not calibrated and should be used with care. They can vary significantly for different models.
- word_image (A): Preprocessed image part containing the word.
- row (A, DET): Localized word: Center point, row coordinate.
- col (A, DET): Localized word: Center point, column coordinate.
- phi (A, DET): Localized word: Angle phi.
- length1 (A, DET): Localized word: Half length of edge 1.
- length2 (A, DET): Localized word: Half length of edge 2.
- line_index (A, DET): Line index of localized word if *'detection_sort_by_line'* set to *'true'*.

The word localization is given by the parameters of an oriented rectangle, see gen_rectangle2 for further information.

word_boxes_on_image (A, DET): Dictionary with the word localization on the coordinate system of the preprocessed images placed in image. The entries are tuples with a value for every found word.

- row (A, DET): Localized word: Center point, row coordinate.
- col (A, DET): Localized word: Center point, column coordinate.
- phi (A, DET): Localized word: Angle phi.
- length1 (A, DET): Localized word: Half length of edge 1.
- length2 (A, DET): Localized word: Half length of edge 2.

The word localization is given by the parameters of an oriented rectangle, see gen_rectangle2 for further information.

word_boxes_on_score_maps (A, DET): Dictionary with the word localization on the coordinate system of the score images placed in score_maps. The entries are the same as for word_boxes_on_image above.

word (REC): Recognized word.

char_candidates (REC): A tuple of dictionaries with information for every character in the recognized word.

Each of these character dictionaries contains the following key/value pairs:

- 'candidate': Tuple with the best *'recognition_num_char_candidates'* candidates.
- 'confidence': Softmax based confidence values of the best candidates. Note, these values are not calibrated and should be used with care. They can vary significantly for different models.

The recognition component can be retrained with custom data in order to further enhance the performance. See OCR / Deep OCR for more information.

Attention

System requirements: To run this operator on GPU (see get_deep_ocr_param), cuDNN and cuBLAS are required. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods". Alternatively, this operator can also be run on CPU.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Input image.

▷ **DeepOcrHandle** (input_control) ..... deep_ocr ⇝ *handle*
Handle of the Deep OCR model.

▷ **Mode** (input_control) ..... string ⇝ *string*
Inference mode.
Default: []
List of values: Mode ∈ {'auto', 'recognition', 'detection'}

▷ **DeepOcrResult** (output_control) ..... dict(-array) ⇝ *handle*
Tuple of result dictionaries.

Result

If the parameters are valid, the operator apply_deep_ocr returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

get_deep_ocr_param, set_deep_ocr_param, create_deep_ocr

Module

OCR/OCV

create_deep_ocr (: : GenParamName, GenParamValue : DeepOcrHandle)

Create a Deep OCR model.

create_deep_ocr creates a Deep OCR model out of pretrained components and returns its handle in DeepOcrHandle. The handle states all parameters needed to run an inference.

A Deep OCR model usually consists of two components that are searched in the directory $HALCONROOT/dl/ by default:

- 'detection_model': detects words (connected characters) in the image.
- 'recognition_model': recognizes the word in the detected image part.

The following options may be set using GenParamName and according GenParamValue:

'mode': Specify a mode and with it, which component is executed. Supported values:

'detection': Perform only the detection part. Hence, the model will merely localize the word regions within the image.

'recognition': Perform only the recognition part. Hence, the model requires that the image contains solely a tight crop of the word.

'auto': Perform both parts, detection of the words and their recognition.

Default: *'auto'*.

The character set, which the model can recognize through its recognition component, can be retrieved using get_deep_ocr_param with *'recognition_alphabet'*.

To get an overview of the Deep OCR workflow see OCR / Deep OCR.

Parameters

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'mode'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
List of values: GenParamValue ∈ {'auto', 'recognition', 'detection'}

▷ **DeepOcrHandle** (output_control) . . . . . deep_ocr ⇝ *handle*
Handle of the Deep OCR model.

Result

If the parameters are valid, the operator create_deep_ocr returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

write_deep_ocr, apply_deep_ocr, get_deep_ocr_param, set_deep_ocr_param

Module

OCR/OCV

get_deep_ocr_param (: : DeepOcrHandle, GenParamName : GenParamValue)

Return the parameters of a Deep OCR model.

get_deep_ocr_param returns the parameter values GenParamValue of GenParamName for the Deep OCR model DeepOcrHandle.

Parameters can apply to the whole model or be specific for a given component. The following table gives an overview, which parameters can be set and which ones retrieved as well as for which model part they apply.

GenParamName	Model	Det. comp.	Recog. comp.
'device'	s	s	s
'detection_device'	–	s g	–
'detection_image_dimensions'	–	g	–
'detection_image_height'	–	s g	–
'detection_image_size'	–	s g	–
'detection_image_width'	–	s g	–
'detection_min_character_score'	–	s g	–
'detection_min_link_score'	–	s g	–
'detection_min_word_area'	–	s g	–
'detection_min_word_score'	–	s g	–
'detection_model'	–	s g	–
'detection_orientation'	–	s g	–
'detection_sort_by_line'	–	s g	–
'detection_tiling'	–	s g	–
'detection_tiling_overlap'	–	s g	–
'recognition_alphabet'	–	–	s g
'recognition_alphabet_internal'	–	–	s g
'recognition_alphabet_mapping'	–	–	s g
'recognition_batch_size'	–	–	s g
'recognition_device'	–	–	s g
'recognition_image_dimensions'	–	–	g
'recognition_image_height'	–	–	g
'recognition_image_width'	–	–	s g
'recognition_model'	–	–	s g
'recognition_num_char_candidates'	–	–	s g

Thereby, the symbols and abbreviations denote the following :

- 's': The parameter can be set using `set_deep_ocr_param`.
- 'g': The parameter can be retrieved using `get_deep_ocr_param`.
- '-': The parameter is not applicable.
- Model: Entire Deep OCR model with all its components.
- Det. comp.: Detection component.
- Recog. comp.: Recognition component.

Only parameters that do not change the model architecture can be set after the model has been optimized with `optimize_dl_model_for_inference`. A list of these parameters can be found at `optimize_dl_model_for_inference`. In the following the parameters are described, sorted according to the part of the model they apply to:

Entire model:

'device':
Handle of the device on which the model will be executed. To get a tuple of handles of all available potentially Deep-OCR-capable compute devices use `query_available_dl_devices`.
Note, the device can be reset for an individual component, in which case only the possibly remaining part of the model (e.g., the remaining component) will be executed on the device of this handle.
Default: Handle of the default device, thus the GPU with index *0* when querying a list using `get_system` with *'cuda_devices'*. If no device is available, this is an empty tuple.

Detection component:

'detection_device':
This parameter will set the device on which the detection component of the Deep OCR model is executed. For a further description, see *'device'*.
Default: The same value as for *'device'*.

'detection_image_dimensions':
Tuple containing the image dimensions (*'detection_image_width'*, *'detection_image_height'*, number of channels) the detection component will process.
The input image is scaled to *'detection_image_dimensions'* such that the original aspect ratio is preserved. The scaled image is padded with gray value *0* if necessary. Therefore, changing the *'detection_image_height'* or *'detection_image_width'* can influence the results.
Default: [*1024*, *1024*, *3*]

'detection_image_height':
Height of the images the detection component will process. This means, the network preserves the aspect ratio of the input image by scaling it to a maximum of this height before processing it. Thus this size can influence the results.
The model architecture requires that the height is a multiple of 32. If this is not the case, the height is rounded up to the nearest integer multiple of 32.
Suggested values: *768*, *1024*, *1280*
Default: *1024*

'detection_image_size':
Tuple containing the image size (*'detection_image_width'*, *'detection_image_height'*) the detection component will process.
Default: [*1024*, *1024*]

'detection_image_width':
Width of the images the detection component will process. This means, the network preserves the aspect ratio of the input image by scaling it to a maximum of this width before processing it. Thus this size can influence the results.
The model architecture requires that the width is a multiple of 32. If this is not the case, the width is rounded up to the nearest integer multiple of 32.
Suggested values: *768*, *1024*, *1280*
Default: *1024*

'detection_min_character_score':
The parameter *'detection_min_character_score'* specifies the lower threshold used for the character score map to estimate the dimensions of the characters. By adjusting the parameter, suggested instances can be split up or neighboring instances can be merged.
Value range: $\in [0, 1]$.
Default: *0.5*

'detection_min_link_score':
The parameter *'detection_min_link_score'* defines the minimum link score required between two localized characters to recognize these characters as coherent word.
Value range: $\in [0, 1]$.
Default: *0.3*

'detection_min_word_area':
The parameter *'detection_min_word_area'* defines the minimum size that a localized word must have in order to be suggested. This parameter can be used to filter suggestions that are too small.
Value range: ≥ 0.
Default: *10*.

'detection_min_word_score':
The parameter *'detection_min_word_score'* defines the minimum score a localized instance must contain to be suggested as valid word. With this parameter uncertain words can be filtered out.
Value range: $\in [0, 1]$.
Default: *0.7*

'detection_model':
The operator `get_deep_ocr_param` returns the handle of the Deep OCR model component for word detection. Using `set_deep_ocr_param` it is possible to either specify a handle, filename or special string. As a special string only *'default'* and *'compact'* are allowed. In case of *'default'* the default pretrained word detection component is loaded (i.e. *'pretrained_deep_ocr_detection.hdl'*). In case of *'compact'*, a more efficient word detection component

is loaded (i.e. *'pretrained_deep_ocr_detection_compact.hdl'*). If the given value is a string the model is loaded internally and the batch size is set to *1*.
Suggested values: *'default'*, *'compact'*, filename.
Default: *'default'*

'detection_orientation':
This parameter allows to set a predefined orientation angle for the word detection. To revert to default behavior using the internal orientation estimation, *'detection_orientation'* is set to *'auto'*.
Value range: $(-\pi, \pi]$.
Default: *'auto'*

'detection_sort_by_line':
The words are sorted line-wise based on the orientation of the localized word instances. If the parameter *'detection_sort_by_line'* is set to *'false'*, the results will not be sorted.
Default: *'true'*

'detection_tiling':
The input image is automatically split into overlapping tile images of size *'detection_image_size'*, which are processed separately by the detection component. This allows processing images that are much larger than the actual *'detection_image_size'* without having to zoom the input image. Thus, if *'detection_tiling'* = 'true', the input image will not be zoomed before processing it.
Default: *'false'*

'detection_tiling_overlap':
This parameter defines how much neighboring tiles overlap when input images are split (see *'detection_tiling'*). The overlap is given in pixels.
Value range: ≥ 0.
Default: *64*

Recognition component:

'recognition_alphabet':
The character set that can be recognized by the Deep OCR model.
It contains all characters that are not mapped to the Blank character of the internal alphabet (see parameters *'recognition_alphabet_mapping'* and *'recognition_alphabet_internal'*).
The alphabet can be changed or extended if needed. Changing the alphabet with this parameter will edit the internal alphabet and mapping in such a way that it tries to keep the length of the internal alphabet unchanged. After changing the alphabet, it is recommended to retrain the model on application specific data (see the HDevelop example `deep_ocr_recognition_training_workflow.hdev`). Previously unknown characters will need more training data.
Note, that if the length of the internal alphabet changes, the last model layers have to be randomly initialized and thus the output of the model will be random strings (see *'recognition_alphabet_internal'*). In that case it is required to retrain the model.

'recognition_alphabet_internal':
The full character set which the Deep OCR recognition component has been trained on.
The first character of the internal alphabet is a special character. In the pretrained model this character is specified as Blank (U+2800) and is not to be confused with a space. The Blank is never returned in a word output but can occur in the reported character candidates. It is required and cannot be omitted. If the internal alphabet is changed, the first character has to be the Blank. Furthermore, if *'recognition_alphabet'* is used to change the alphabet, the Blank symbol is added automatically to the character set.
The length of this tuple corresponds to the depth of the last convolution layer in the model. If the length changes, the last convolution layer and all layers after it have to be resized and potentially reinitialized randomly. After such a change, it is required to retrain the model (see HDevelop example `deep_ocr_recognition_training_workflow.hdev`).
It is recommend to use the parameter *'recognition_alphabet'* to change the alphabet, as it will automatically try to preserve the length of the internal alphabet.

'recognition_alphabet_mapping':
Tuple of integer indices.
It is a mapping that is applied by the model during the decoding step of each word. The mapping overwrites a character of *'recognition_alphabet_internal'* with the character at the specified index in *'recognition_alphabet_internal'*.

In the decoding step each prediction is mapped according to the index specified in this tuple. The tuple has to be of same length as the tuple *'recognition_alphabet_internal'*. Each integer index of the mapping has to be within *0* and |*'recognition_alphabet_internal'*|-1.
In some applications it can be helpful to map certain characters onto other characters. E.g. if only numeric words occur in an application it might be helpful to map the character "O" to the "0" character without the need to retrain the model.
If an entry contains a *0*, the corresponding character in *'recognition_alphabet_internal'* will not be decoded in the word.

'recognition_batch_size':
Number of images in a batch that is transferred to device memory and processed in parallel in the recognition component. For further details, please refer to the reference documentation of `apply_dl_model` with respect to the parameter *'batch_size'*. This parameter can be used to optimize the runtime of `apply_deep_ocr` on a given dl device. If the recognition component has to process multiple inputs (words), processing multiple inputs in parallel can result in a faster execution of `apply_deep_ocr`. Note, however, that a higher *'recognition_batch_size'* will require more device memory.
Default: *1*

'recognition_device':
This parameter will set the device on which the recognition component of the Deep OCR model is executed. For a further description, see *'device'*.
Default: The same value as for *'device'*.

'recognition_image_dimensions':
Tuple containing the image dimensions (*'recognition_image_width'*, *'recognition_image_height'*, number of channels) the recognition component will process.
This means, the network will first zoom the input image part to *'recognition_image_height'* while maintaining the aspect ratio of the input. If the width of the resulting image is smaller than *'recognition_image_width'*, the image part is padded with gray value *0* on the right. If it is larger, the image is zoomed to *'recognition_image_width'*.
Default: [*120*, *32*, *1*]

'recognition_image_height':
Height of the images the recognition component will process.
Default: *32*

'recognition_image_width':
Width of the images the recognition component will process.
Default: *120*

'recognition_model':
The operator `get_deep_ocr_param` returns the handle of the Deep OCR model component for word recognition.
Using `set_deep_ocr_param` it is possible to either specify a handle, filename or *'default'*. In case of *'default'* the pretrained word recognition component is loaded (i.e. *'pretrained_deep_ocr_recognition.hdl'*). If the given value is a string the model is loaded internally and the batch size is set to *1*.
Suggested values: *'default'*, filename.
Default: *'default'*

'recognition_num_char_candidates':
Controls the number of reported character candidates in the result of the operator `apply_deep_ocr`.
Default: *3*

Parameters

▷ **`DeepOcrHandle`** (input_control) ..... deep_ocr ⇝ *handle*
Handle of the Deep OCR model.

▷ **`GenParamName`** (input_control) ..... attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'recognition_model'
List of values: `GenParamName` ∈ {'detection_device', 'detection_image_dimensions', 'detection_image_height', 'detection_image_size', 'detection_image_width', 'detection_min_character_score', 'detection_min_link_score', 'detection_min_word_area', 'detection_min_word_score', 'detection_model', 'detection_orientation', 'detection_sort_by_line', 'detection_tiling', 'detection_tiling_overlap', 'recognition_alphabet', 'recognition_alphabet_internal',

'recognition_alphabet_mapping', 'recognition_batch_size', 'recognition_device', 'recognition_image_dimensions', 'recognition_image_height', 'recognition_image_width', 'recognition_model', 'recognition_num_char_candidates'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *integer* / handle / string / real
Value of the generic parameter.

Result

If the parameters are valid, the operator `get_deep_ocr_param` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

read_deep_ocr (: : FileName : DeepOcrHandle)

Read a Deep OCR model from a file.

The operator `read_deep_ocr` reads a Deep OCR model. Such models have to be in the HALCON format. As a result, the handle `DeepOcrHandle` is returned.

The model is loaded from the file `FileName`. This file is thereby searched in the directory `$HALCONROOT/dl/` as well as in the currently used directory. The default HALCON file extension for Deep OCR models is `'.hdo'`.

Please note that the values of runtime specific parameters are not written to file, see `write_deep_ocr`. As a consequence when reading a model these parameters are initialized with their default value, see `get_deep_ocr_param`.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
Filename
File extension: `.hdo`

▷ **DeepOcrHandle** (output_control) . . . . . deep_ocr ⇝ *handle*
Handle of the Deep OCR model.

Result

If the parameters are valid, the operator `read_deep_ocr` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

set_deep_ocr_param (: : DeepOcrHandle, GenParamName, GenParamValue :)

Set the parameters of a Deep OCR model.

set_deep_ocr_param sets the parameters GenParamName of the Deep OCR model DeepOcrHandle to the values GenParamValue.

The possible parameters are listed and described in get_deep_ocr_param. An overview of the Deep OCR workflow is given in OCR / Deep OCR.

Attention

System requirements: To successfully set *'gpu'* parameters, cuDNN and cuBLAS are required, i.e., to set the parameter GenParamName *'device'* to a GPU. For further details, please refer to the "Installation Guide", paragraph "Requirements for Deep Learning and Deep-Learning-Based Methods".

Parameters

▷ **DeepOcrHandle** (input_control) . . . . . deep_ocr ⇝ *handle*
Handle of the Deep OCR model.

▷ **GenParamName** (input_control) . . . . . attribute.name ⇝ *string*
Name of the generic parameter.
Default: 'detection_image_width'
List of values: GenParamName ∈ {'device', 'detection_device', 'detection_image_height', 'detection_image_size', 'detection_image_width', 'detection_min_character_score', 'detection_min_link_score', 'detection_min_word_area', 'detection_min_word_score', 'detection_model', 'detection_orientation', 'detection_sort_by_line', 'detection_tiling', 'detection_tiling_overlap', 'recognition_alphabet', 'recognition_alphabet_internal', 'recognition_alphabet_mapping', 'recognition_batch_size', 'recognition_device', 'recognition_image_width', 'recognition_model', 'recognition_num_char_candidates'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *real* / string / integer / handle
Value of the generic parameter.
Default: 1024
Suggested values: GenParamValue ∈ {0, 10, 50, 100, 200, 512, 768, 1024, 1280, 0.3, 0.4, 0.5, 0.6, 0.7, 'true', 'false', 'auto', 'compact', 'default', 'pretrained_deep_ocr_detection.hdl', 'pretrained_deep_ocr_detection_compact.hdl', 'pretrained_deep_ocr_recognition.hdl'}

Result

If the parameters are valid, the operator set_deep_ocr_param returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

write_deep_ocr (: : DeepOcrHandle, FileName :)

Write a Deep OCR model in a file.

write_deep_ocr writes the Deep OCR model DeepOcrHandle to the file given by FileName. Please note that the runtime specific parameters *'gpu'*, *'runtime'*, and *'runtime_init'* are not written.

The default HALCON file extension for Deep OCR models is '.hdo'.

The Deep OCR model can be read with read_deep_ocr.

Parameters

▷ **DeepOcrHandle** (input_control) ..... deep_ocr ⇝ *handle*
Handle of the Deep OCR model.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Filename
File extension: .hdo

Result

If the parameters are valid, the operator write_deep_ocr returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_deep_ocr, set_deep_ocr_param

Possible Successors

clear_handle

Module

OCR/OCV

21.3 K-Nearest Neighbors

clear_ocr_class_knn (: : OCRHandle :)

Clear an OCR classifier.

clear_ocr_class_knn clears the OCR classifier given by OCRHandle that was created with create_ocr_class_knn and frees all memory required for the classifier. After calling clear_ocr_class_knn, the classifier can no longer be used. The handle OCRHandle becomes invalid.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_knn ⇝ *handle*
Handle of the OCR classifier.

Result

If OCRHandle is valid, the operator clear_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

OCR/OCV

create_ocr_class_knn (: : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, GenParamName, GenParamValue : OCRHandle)

Create an OCR classifier using a k-Nearest Neighbor (k-NN) classifier.

create_ocr_class_knn creates an OCR classifier that uses a k-Nearest Neighbor (k-NN). The handle of the k-NN classifier is returned in OCRHandle.

For a description on how a k-NN works, see create_class_knn.

The length of the feature vector of the k-NN is determined from the features that are used for the OCR, which are passed in Features. The features are described below. The number of classes is determined from the names of the characters which are passed in Characters.

Features can contain a tuple of several feature names. Each of these names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., *'pixel_invar'*). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by WidthCharacter and HeightCharacter. The interpolation to be used for the transformation is determined by Interpolation. It has the same meaning as in affine_trans_image. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, Interpolation = *'constant'* should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, large sizes will cause small segmentation errors to have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, which results in characters are zoomed differently than the characters in the training set. In most applications, sizes between 6×8 and 10×14 should be used.

The parameter Features can contain the following feature names for the classification of the characters.

'default': *'ratio'* and *'pixel_invar'* are selected.

'pixel': Gray values of the character (WidthCharacter $\times$ HeightCharacter features).

'pixel_invar': Gray values of the character with maximum scaling of the gray values (WidthCharacter $\times$ HeightCharacter features).

'pixel_binary': Region of the character as a binary image zoomed to a size of WidthCharacter $\times$ HeightCharacter (WidthCharacter $\times$ HeightCharacter features).

'gradient_8dir': Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a 5×5 grid are extracted from each channel. These samples are used as features (200 features).

'projection_horizontal': Horizontal projection of the gray values (see gray_projections, HeightCharacter features).

'projection_horizontal_invar': Maximally scaled horizontal projection of the gray values (HeightCharacter features).

'projection_vertical': Vertical projection of the gray values (see gray_projections, WidthCharacter features).

'projection_vertical_invar': Maximally scaled vertical projection of the gray values (WidthCharacter features).

'ratio': Aspect ratio of the character (see height_width_ratio, 1 feature).

'anisometry': Anisometry of the character (see eccentricity, 1 feature).

'width': Width of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).

'height': Height of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).

'zoom_factor': Difference in size between the character and the values WidthCharacter and HeightCharacter (not scale-invariant, 1 feature).

'foreground': Fraction of pixels in the foreground (1 feature).

'foreground_grid_9': Fraction of pixels in the foreground in a 3×3 grid within the smallest enclosing rectangle of the character (9 features).

'foreground_grid_16': Fraction of pixels in the foreground in a 4×4 grid within the smallest enclosing rectangle of the character (16 features).

'compactness': Compactness of the character (see compactness, 1 feature).

'convexity': Convexity of the character (see convexity, 1 feature).

'moments_region_2nd_invar': Normalized 2nd moments of the character (see moments_region_2nd_invar, 3 features).

'moments_region_2nd_rel_invar': Normalized 2nd relative moments of the character (see moments_region_2nd_rel_invar, 2 features).

'moments_region_3rd_invar': Normalized 3rd moments of the character (see moments_region_3rd_invar, 4 features).

'moments_central': Normalized central moments of the character (see moments_region_central, 4 features).

'moments_gray_plane': Normalized gray value moments and the angle of the gray value plane (see moments_gray_plane, 4 features).

'phi': Sinus and cosinus of the orientation (angle) of the character (see elliptic_axis, 2 feature).

'num_connect': Number of connected components (see connect_and_holes, 1 feature).

'num_holes': Number of holes (see connect_and_holes, 1 feature).

'cooc': Values of the binary cooccurrence matrix (see gen_cooc_matrix, 8 features).

'num_runs': Number of runs in the region normalized by the height (1 feature).

'chord_histo': Frequency of the runs per row (not scale-invariant, HeightCharacter features).

After the classifier has been created, it is trained using trainf_ocr_class_knn. After this, the classifier can be saved using write_ocr_class_knn. Alternatively, the classifier can be used immediately after training to classify characters using do_ocr_single_class_knn or do_ocr_multi_class_knn.

A comparison of the k-NN and the support vector machine (SVM) (see create_ocr_class_svm) typically shows that SVMs are generally slower at training, especially for huge training sets, but achieve slightly better recognition rates than k-NNs. Please note that this guideline assumes optimal tuning of the parameters of the SVM.

Parameters

▷ **WidthCharacter** (input_control) . . . . . integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 8
Suggested values: WidthCharacter ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: 4 ≤ WidthCharacter ≤ 20

▷ **HeightCharacter** (input_control) . . . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 10
Suggested values: HeightCharacter ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: 4 ≤ HeightCharacter ≤ 20

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Interpolation mode for the zooming of the characters.
Default: 'constant'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

▷ **Features** (input_control) . . . . . string(-array) ⇝ *string*
Features to be used for classification.
Default: 'default'
List of values: Features ∈ {'default', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir', 'projection_horizontal', 'projection_horizontal_invar', 'projection_vertical', 'projection_vertical_invar', 'ratio', 'anisometry', 'width', 'height', 'zoom_factor', 'foreground', 'foreground_grid_9', 'foreground_grid_16', 'compactness', 'convexity', 'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'moments_gray_plane', 'phi', 'num_connect', 'num_holes', 'cooc', 'num_runs', 'chord_histo'}

▷ **Characters** (input_control) . . . . . string-array ⇝ *string*
All characters of the character set to be read.
Default: ['0','1','2','3','4','5','6','7','8','9']

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
This parameter is not yet supported.
Default: []
List of values: GenParamName ∈ {[]}

▷ **GenParamValue** (input_control) . . . . . number-array ⇝ *integer* / string
This parameter is not yet supported.
Default: []
List of values: GenParamValue ∈ {[]}

▷ **OCRHandle** (output_control) . . . . . ocr_knn ⇝ *handle*
Handle of the k-NN classifier.

Example

```
read_image (Image, 'letters')
* Segment the image.
binary_threshold(Image,&Region, 'otsu', 'dark', &UsedThreshold);
dilation_circle (Region, RegionDilation, 3.5)
connection (RegionDilation, ConnectedRegions)
intersection (ConnectedRegions, Region, RegionIntersection)
sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
* Generate the training file.
count_obj (Characters, Number)
Classes := []
for J := 0 to 25 by 1
    Classes := [Classes,gen_tuple_const(20,chr(ord('a')+J))]
endfor
Classes := [Classes,gen_tuple_const(20,'.')]
write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_knn (8, 10, 'constant', 'default', CharacterNames, \
```

```
                      [], [], OCRHandle)
trainf_ocr_class_knn (OCRHandle, 'letters.trf', [], [])
* Re-classify the characters in the image.
do_ocr_multi_class_knn (Characters, Image, OCRHandle, Class, Confidence)
```

Result

If the parameters are valid, the operator `create_ocr_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`trainf_ocr_class_knn`

Alternatives

`create_ocr_class_svm`

Module

OCR/OCV

deserialize_ocr_class_knn (: : SerializedItemHandle : OCRHandle)

Deserialize a serialized k-NN-based OCR classifier.

`deserialize_ocr_class_knn` deserializes a k-NN-based OCR classifier, that was serialized by `serialize_ocr_class_knn` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created OCR classifier with the handle `OCRHandle`.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **OCRHandle** (output_control) ..... ocr_knn ⇝ *handle*
Handle of the OCR classifier.

Result

If the parameters are valid, the operator `deserialize_ocr_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

do_ocr_multi_class_knn (Character, Image : : OCRHandle : Class, Confidence)

Classify multiple characters with an k-NN classifier.

do_ocr_multi_class_knn computes the best class for each of the characters given by the regions Character and the gray values Image with the k-NN classifier OCRHandle and returns the classes in Class and the corresponding confidence of the classes in Confidence. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification of the single characters. In contrast to do_ocr_single_class_knn, do_ocr_multi_class_knn can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_knn to classify single characters. However, do_ocr_multi_class_knn can only return the best class of each character.

Before calling do_ocr_multi_class_knn, the classifier must be trained with trainf_ocr_class_knn.

Parameters

- ▷ **Character** (input_object) ..... region(-array) ⇝ *object*
  Characters to be recognized.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
  Gray values of the characters.
- ▷ **OCRHandle** (input_control) ..... ocr_knn ⇝ *handle*
  Handle of the k-NN classifier.
- ▷ **Class** (output_control) ..... string(-array) ⇝ *string*
  Result of classifying the characters with the k-NN.
  Number of elements: Class == Character
- ▷ **Confidence** (output_control) ..... real(-array) ⇝ *real*
  Confidence of the class of the characters.
  Number of elements: Confidence == Character

Result

If the parameters are valid, the operator do_ocr_multi_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

create_ocr_class_knn, classify_class_knn

Module

OCR/OCV

do_ocr_single_class_knn (Character, Image : : OCRHandle, NumClasses, NumNeighbors : Class, Confidence)

Classify a single character with an OCR classifier.

do_ocr_single_class_knn uses the OCR-k-NN classifier OCRHandle to determine the best training samples for the features of the character given by the region Character and the gray values Image and returns their classes in Class and the corresponding confidences in Confidence. If the first NumNeighbors training vectors have different classes, maximally NumClasses classes are returned sorted by frequency and weighted distance. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification. The confidence can be only computed robustly if NumNeighbors is large enough.

Because multiple classes may be returned by do_ocr_single_class_knn, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_knn must be used. Before calling do_ocr_single_class_knn, the classifier must be trained with trainf_ocr_class_knn or select_feature_set_trainf_knn. If all NumNeighbors neighbors are of the same class, only one class is returned.

Parameters

- ▷ **Character** (input_object) ..... region ⇝ *object*
  Character to be recognized.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
  Gray values of the character.
- ▷ **OCRHandle** (input_control) ..... ocr_knn ⇝ *handle*
  Handle of the k-NN classifier.
- ▷ **NumClasses** (input_control) ..... integer-array ⇝ *integer*
  Number of maximal classes to determine.
  Default: 1
  Suggested values: NumClasses ∈ {1, 2, 3, 4, 5}
- ▷ **NumNeighbors** (input_control) ..... integer-array ⇝ *integer*
  Number of neighbors to consider.
  Default: 1
  Suggested values: NumNeighbors ∈ {1, 2, 3, 4, 5}
- ▷ **Class** (output_control) ..... string(-array) ⇝ *string*
  Results of classifying the character with the k-NN.
- ▷ **Confidence** (output_control) ..... real(-array) ⇝ *real*
  Confidence(s) of the class(es) of the character.

Result

If the parameters are valid, the operator do_ocr_single_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_ocr_class_knn, classify_class_knn

Module

OCR/OCV

do_ocr_word_knn (Character, Image : : OCRHandle, Expression, NumAlternatives, NumCorrections : Class, Confidence, Word, Score)

Classify a related group of characters with an OCR classifier.

do_ocr_word_knn works like do_ocr_multi_class_knn insofar as it computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle, and returns the classes in Class and the corresponding confidences of the classes in Confidence. The confidences lie between 0.0 and 1.0. The larger the value, the more reliable is the classification of the single characters.

In contrast to do_ocr_multi_class_knn, do_ocr_word_knn treats the group of characters as an entity which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an Expression describing the expected word.

The Expression may restrict the word to belong to a predefined lexicon created using create_lexicon or import_lexicon, by specifying the name of the lexicon in angular brackets as in *'<mylexicon>'*. If the Expression is of any other form, it is interpreted as a regular expression with the same syntax as specified for tuple_regexp_match. Note that you will usually want to use an expression of the form '^...$' when using variable quantifiers like '*', to ensure that the entire word is used in the expression. Also note that in contrast to tuple_regexp_match, do_ocr_word_knn does **not** support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the Expression, do_ocr_word_knn attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives used are identical to those returned by do_ocr_single_class_knn for a single character. It does so by testing all possible corrections for which the classification result is changed for at most NumCorrections character regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

$$\mathtt{Score} = 1.0 - \mathtt{PenaltyCorrections} - \mathtt{PenaltyAlternatives}$$

$$\begin{aligned} \mathtt{PenaltyCorrections} &= \alpha * \mathtt{num\_corr} \\ \mathtt{PenaltyAlternatives} &= \alpha * \beta * \mathtt{num\_alt} \end{aligned}$$

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

$$\begin{aligned} \alpha &= \frac{1}{\mathtt{NumCorrections} + 1} \\ \beta &= \frac{1}{\mathtt{NumCorrections} * (\mathtt{NumAlternatives} - 1) + 2} \end{aligned}$$

Note that this is a combinatorial score which does **not** reflect the original Confidence of the best Class.

Parameters

▷ **Character** (input_object) . . . . . region(-array) ⇝ *object*
Characters to be recognized.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Gray values of the characters.

▷ **OCRHandle** (input_control) . . . . . ocr_knn ⇝ *handle*
Handle of the OCR classifier.

▷ **Expression** (input_control) . . . . . string ⇝ *string*
Expression describing the allowed word structure.

▷ **NumAlternatives** (input_control) . . . . . integer ⇝ *integer*
Number of classes per character considered for the internal word correction.
Default: 3
Suggested values: NumAlternatives ∈ {3, 4, 5}
Value range: 1 ≤ NumAlternatives ≤ 5

▷ **NumCorrections** (input_control) . . . . . integer ⇝ *integer*
Maximum number of corrected characters.
Default: 2
Suggested values: NumCorrections ∈ {1, 2, 3, 4, 5}
Value range: 0 ≤ NumCorrections ≤ 5

▷ **Class** (output_control) . . . . . string(-array) ⇝ *string*
Result of classifying the characters with the k-NN.
Number of elements: Class == Character

▷ **Confidence** (output_control) . . . . . real(-array) ⇝ *real*
Confidence of the class of the characters.
Number of elements: Confidence == Character

▷ **Word** (output_control) . . . . . string ⇝ *string*
Word text after classification and correction.

▷ **Score** (output_control) . . . . . real ⇝ *real*
Measure of similarity between corrected word and uncorrected classification results.

Complexity

The complexity of checking all possible corrections is of magnitude $O((n * a)^{min(c,n)})$, where a is the number of alternatives, n is the number of character regions, and c is the number of allowed corrections. However, to guard against a near-infinite loop in case of large n, c is internally clipped to 5, 3, or 1 if $a * n >= 30$, 60, or 90, respectively.

Result

If the parameters are valid, the operator do_ocr_word_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

get_features_ocr_class_knn (Character : : OCRHandle,
Transform : Features)

Compute the features of a character.

get_features_ocr_class_knn computes the features of the character given by Character with the k-NN classifier OCRHandle and returns them in Features. In contrast to do_ocr_single_class_knn and do_ocr_multi_class_knn, the character is passed as a single image object. Hence, before calling get_features_ocr_class_knn, reduce_domain must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in create_ocr_class_knn

for the classifier should be applied (Transform = *'true'*) or whether the untransformed features should be returned (Transform = *'false'*). get_features_ocr_class_knn can be used to inspect the features that are used for the classification.

Parameters

- ▷ **Character** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
  Input character.
- ▷ **OCRHandle** (input_control) . . . . . ocr_knn ⇝ *handle*
  Handle of the k-NN classifier.
- ▷ **Transform** (input_control) . . . . . string ⇝ *string*
  Should the feature vector be transformed with the preprocessing?
  Default: 'true'
  List of values: Transform ∈ {'true', 'false'}
- ▷ **Features** (output_control) . . . . . real-array ⇝ *real*
  Feature vector of the character.

Result

If the parameters are valid, the operator get_features_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_ocr_class_knn

Module

OCR/OCV

get_params_ocr_class_knn (: : OCRHandle : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, Preprocessing, NumTrees)

Return the parameters of an OCR classifier.

get_params_ocr_class_knn returns the parameters of an OCR classifier that were specified when the classifier was created with create_ocr_class_knn. This is particularly useful if the classifier was read with read_ocr_class_knn. The output of get_params_ocr_class_knn can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see create_ocr_class_knn and trainf_ocr_class_knn.

Parameters

- ▷ **OCRHandle** (input_control) . . . . . ocr_knn ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **WidthCharacter** (output_control) . . . . . integer ⇝ *integer*
  Width of the rectangle to which the gray values of the segmented character are zoomed.
- ▷ **HeightCharacter** (output_control) . . . . . integer ⇝ *integer*
  Height of the rectangle to which the gray values of the segmented character are zoomed.
- ▷ **Interpolation** (output_control) . . . . . string ⇝ *string*
  Interpolation mode for the zooming of the characters.
- ▷ **Features** (output_control) . . . . . string(-array) ⇝ *string*
  Features to be used for classification.
- ▷ **Characters** (output_control) . . . . . string-array ⇝ *string*
  Characters of the character set to be read.

▷ **Preprocessing** (output_control) . . . . . string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
▷ **NumTrees** (output_control) . . . . . integer ⇝ *integer*
Number of different trees used during the classification.

Result

If the parameters are valid, the operator `get_params_ocr_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

read_ocr_class_knn (: : FileName : OCRHandle)

Read an OCR classifier from a file.

`read_ocr_class_knn` reads an OCR classifier that has been stored with `write_ocr_class_knn`.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
File extension: `.onc`, `.okc`, `.fnt`
▷ **OCRHandle** (output_control) . . . . . ocr_knn ⇝ *handle*
Handle of the OCR classifier.

Result

If the parameters are valid, the operator `read_ocr_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

select_feature_set_trainf_knn (: : TrainingFile, FeatureList, SelectionMethod, Width, Height, GenParamName, GenParamValue : OCRHandle, FeatureSet, Score)

Select an optimal combination of features to classify OCR data.

select_feature_set_trainf_knn selects an optimal combination of features, to classify the data given in the training file TrainingFile with a k-Nearest Neighbor classifier, for details see create_ocr_class_knn.

Possible features are all OCR features listed and explained in create_ocr_class_knn. All candidates which should be tested can be specified in FeatureList. A subset of these features is returned as selected features in FeatureSet.

select_feature_set_trainf_knn is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator select_feature_set_knn.

The selection method SelectionMethod is either a greedy search *'greedy'* (iteratively add the feature with highest gain) or the dynamically oscillating search *'greedy_oscillating'* (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method *'greedy'* is generally preferable, since it is faster. Only in cases when a large training set is available the method *'greedy_oscillating'* might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in Score.

The k-NN classifier can be parametrized using the following values in GenParamName and GenParamValue:

'num_neighbors': The number of minimally evaluated nodes, increase this value for high dimensional data.
Suggested values: *1*, *2*, *5*, *10*
Default: *1*

'num_trees': Number of search trees in the k-NN classifier
Suggested values: *1*, *4*, *10*
Default: *4*

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_knn may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the training files.
Default: ''
File extension: .trf, .otr

▷ **FeatureList** (input_control) ..... string(-array) ⇝ *string*
List of features that should be considered for selection.
Default: ['zoom_factor','ratio','width','height','foreground','foreground_grid_9','foreground_grid_16', 'anisometry','compactness','convexity','moments_region_2nd_invar','moments_region_2nd_rel_invar', 'moments_region_3rd_invar','moments_central','phi','num_connect','num_holes','projection_horizontal', 'projection_vertical','projection_horizontal_invar','projection_vertical_invar','chord_histo','num_runs', 'pixel','pixel_invar','pixel_binary','gradient_8dir','cooc','moments_gray_plane']
List of values: FeatureList ∈ {'default', 'zoom_factor', 'ratio', 'width', 'height', 'foreground', 'foreground_grid_9', 'foreground_grid_16', 'anisometry', 'compactness', 'convexity', 'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'phi', 'num_connect', 'num_holes', 'projection_horizontal', 'projection_vertical', 'projection_horizontal_invar', 'projection_vertical_invar', 'chord_histo', 'num_runs', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir', 'cooc', 'moments_gray_plane'}

▷ **SelectionMethod** (input_control) ..... string ⇝ *string*
Method to perform the selection.
Default: 'greedy'
List of values: SelectionMethod ∈ {'greedy', 'greedy_oscillating'}

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 15

▷ **Height** (input_control) ..... integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 16

▷ **GenParamName** (input_control) ..... string-array ⇝ *string*
Names of generic parameters to configure the selection process and the classifier.
Default: []
List of values: GenParamName ∈ {'num_neighbors'}

▷ **GenParamValue** (input_control) ..... number-array ⇝ *real* / integer / string
Values of generic parameters to configure the selection process and the classifier.
Default: []
Suggested values: GenParamValue ∈ {1, 2, 3}

▷ **OCRHandle** (output_control) ..... ocr_knn ⇝ *handle*
Trained OCR-k-NN classifier.

▷ **FeatureSet** (output_control) ..... string-array ⇝ *string*
Selected feature set, contains only entries from FeatureList.

▷ **Score** (output_control) ..... real-array ⇝ *real*
Achieved score using tow-fold cross-validation.

Result

If the parameters are valid, the operator select_feature_set_trainf_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Alternatives

select_feature_set_trainf_svm, select_feature_set_trainf_mlp

Module

OCR/OCV

serialize_ocr_class_knn (: : OCRHandle : SerializedItemHandle)

Serialize a k-NN-based OCR classifier.

serialize_ocr_class_knn serializes a k-NN-based OCR classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocr_class_knn is converted to a serialized item. The OCR classifier is defined by the handle OCRHandle. The serialized OCR classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocr_class_knn.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_knn ⇝ *handle*
Handle of the OCR classifier.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`trainf_ocr_class_knn`, `read_ocr_class_knn`

Possible Successors

Module

OCR/OCV

trainf_ocr_class_knn (: : OCRHandle, TrainingFile, GenParamName, GenParamValue :)

Trains an k-NN classifier for an OCR task.

`trainf_ocr_class_knn` trains the k-NN classifier `OCRHandle` with the training characters stored in the OCR training files given by `TrainingFile`. The training files must have been created, e.g., using `write_ocr_trainf`, before calling `trainf_ocr_class_knn`. Please, note that training characters that have no corresponding class in the classifier `OCRHandle` are discarded.

The following options may be set using `GenParamName` and `GenParamValue`, respectively:

'num_trees' Sets the number of search trees. A higher number of trees improves the accuracy of the search, but also increases the runtime.
Default: *4*.

'normalization' Activates the data normalization, if set to *'true'*. This will change the stored training data permanently. Therefore, adding data after the training is not possible.
List of values: *'true'*, *'false'*.
Default: *'false'*.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **TrainingFile** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: 'ocr.trf'
File extension: `.trf`, `.otr`

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of the generic parameters that can be adjusted for the k-NN classifier creation.
Default: []
List of values: GenParamName ∈ {'num_trees', 'normalization'}

▷ **GenParamValue** (input_control) . . . . . number-array ⇝ *integer* / string / real
Values of the generic parameters that can be adjusted for the k-NN classifier creation.
Default: []
Suggested values: GenParamValue ∈ {4, 5, 'false', 'true'}

Example

```
* Train an OCR classifier
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_knn (8, 10, 'constant', 'default', CharacterNames, [],\
                      [], OCRHandle)
trainf_ocr_class_knn (OCRHandle, 'ocr.trf', [], [])
write_ocr_class_knn (OCRHandle, 'ocr.omc')
```

Result

If the parameters are valid, the operator trainf_ocr_class_knn returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

train_class_knn

Module

OCR/OCV

write_ocr_class_knn (: : OCRHandle, FileName :)

Write a k-NN classifier for an OCR task to a file.

write_ocr_class_knn writes the k-NN classifier for an OCR task with the OCRHandle to the file given by FileName. If a file extension is not specified in FileName the default extension '.onc' is appended to FileName. write_ocr_class_knn is typically called after the classifier has been trained with trainf_ocr_class_knn. The classifier can be read with read_ocr_class_knn.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_knn ⇝ *handle*
Handle of the k-NN classifier for an OCR task.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name.
File extension: .onc

Result

If the parameters are valid, the operator `write_ocr_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

21.4 Lexica

clear_lexicon (: : LexiconHandle :)

Clear a lexicon.

`clear_lexicon` clears a lexicon and releases its resources.

Parameters

▷ **LexiconHandle** (input_control) . . . . . lexicon ⇝ *handle*
Handle of the lexicon.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- LexiconHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

See also

`create_lexicon`

Module

OCR/OCV

create_lexicon (: : Name, Words : LexiconHandle)

Create a lexicon from a tuple of words.

create_lexicon creates a new lexicon based on a tuple of Words. By specifying a unique textual Name, you can later refer to the lexicon from syntax expressions like those used, e.g., by do_ocr_word_mlp.

Note that lexicon support in HALCON is currently not aimed at natural languages. Rather, it is intended as a post-processing step in OCR applications that only need to distinguish between a limited set of not more than a few thousand valid words, e.g., country or product names. MVTec itself does not provide any lexica.

Parameters

▷ **Name** (input_control) . . . . . string ⇝ *string*
Unique name for the new lexicon.
Default: 'lex1'

▷ **Words** (input_control) . . . . . string-array ⇝ *string*
Word list for the new lexicon.
Default: ['word1','word2','word3']

▷ **LexiconHandle** (output_control) . . . . . lexicon ⇝ *handle*
Handle of the lexicon.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

do_ocr_word_mlp, do_ocr_word_svm

Alternatives

import_lexicon

See also

lookup_lexicon, suggest_lexicon

Module

OCR/OCV

import_lexicon (: : Name, FileName : LexiconHandle)

Create a lexicon from a text file.

import_lexicon creates a new lexicon based on a list of words in the file specified by FileName. The format of the file is a simple text file with one word per line. By specifying a unique textual Name, you can later refer to the lexicon from syntax expressions like those used, e.g., by do_ocr_word_mlp.

Note that lexicon support in HALCON is currently not aimed at natural languages. Rather, it is intended as a post-processing step in OCR applications that only need to distinguish between a limited set of not more than a few thousand valid words, e.g., country or product names. When the lexicon file contains entries with special, non-ASCII characters, it is expected to be encoded in UTF-8. However, old lexicon files which use the local 8-bit encoding, can still be loaded as long as they contain at least one byte sequence, which cannot be misinterpreted as UTF-8 character. MVTec itself does not provide any lexica.

Parameters

▷ **Name** (input_control) . . . . . string ⇝ *string*
Unique name for the new lexicon.
Default: 'lex1'

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
Name of a text file containing words for the new lexicon.
Default: 'words.txt'
File extension: `.txt`

▷ **LexiconHandle** (output_control) . . . . . lexicon ⇝ *handle*
Handle of the lexicon.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`do_ocr_word_mlp`, `do_ocr_word_svm`

Alternatives

`create_lexicon`

See also

`lookup_lexicon`, `suggest_lexicon`

Module

OCR/OCV

inspect_lexicon (: : LexiconHandle : Words)

Query all words from a lexicon.

`inspect_lexicon` returns a tuple of all words in the lexicon in the parameter `Words`.

Parameters

▷ **LexiconHandle** (input_control) . . . . . lexicon ⇝ *handle*
Handle of the lexicon.

▷ **Words** (output_control) . . . . . string(-array) ⇝ *string*
List of all words.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`lookup_lexicon`

See also

`create_lexicon`

Module

OCR/OCV

lookup_lexicon (: : LexiconHandle, Word : Found)

Check if a word is contained in a lexicon.

lookup_lexicon checks whether Word is contained in the lexicon LexiconHandle, and returns 1 in Found if the word is found, otherwise 0.

Parameters

▷ **LexiconHandle** (input_control) . . . . . lexicon ⇝ *handle*
Handle of the lexicon.

▷ **Word** (input_control) . . . . . string ⇝ *string*
Word to be looked up.
Default: 'word'

▷ **Found** (output_control) . . . . . integer ⇝ *integer*
Result of the search.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

suggest_lexicon

See also

create_lexicon

Module

OCR/OCV

suggest_lexicon (: : LexiconHandle, Word : Suggestion, NumCorrections)

Find a similar word in a lexicon.

suggest_lexicon compares Word to all words in the lexicon and calculates the minimum number of edit operations NumCorrections required to transform Word into a word from the lexicon. Valid edit operations are the insertion, deletion and replacement of characters. The most similar word found in the lexicon is returned in Suggestion. If there are multiple words with the same minimum number of corrections, only the first of those words is returned.

Parameters

▷ **LexiconHandle** (input_control) . . . . . lexicon ⇝ *handle*
Handle of the lexicon.

▷ **Word** (input_control) . . . . . string ⇝ *string*
Word to be looked up.
Default: 'word'

▷ **Suggestion** (output_control) . . . . . string ⇝ *string*
Most similar word found in the lexicon.

▷ **NumCorrections** (output_control) . . . . . integer ⇝ *integer*
Difference between the words in edit operations.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

lookup_lexicon, tuple_str_distance

Module

OCR/OCV

21.5 Neural Nets

clear_ocr_class_mlp (: : OCRHandle :)

Clear an OCR classifier.

clear_ocr_class_mlp clears the OCR classifier given by OCRHandle that was created with create_ocr_class_mlp and frees all memory required for the classifier. After calling clear_ocr_class_mlp, the classifier can no longer be used. The handle OCRHandle becomes invalid.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_mlp(-array) ⇝ *handle*
Handle of the OCR classifier.

Result

If OCRHandle is valid, the operator clear_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

OCR/OCV

create_ocr_class_mlp (: : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, NumHidden, Preprocessing, NumComponents, RandSeed : OCRHandle)

Create an OCR classifier using a multilayer perceptron.

create_ocr_class_mlp creates an OCR classifier that uses a multilayer perceptron (MLP). The handle of the OCR classifier is returned in OCRHandle.

For a description on how an MLP works, see create_class_mlp. create_ocr_class_mlp creates an MLP with OutputFunction = *'softmax'*. The length of the feature vector of the MLP (NumInput in create_class_mlp) is determined from the features that are used for the OCR, which are passed in Features. The features are described below. The number of units in the hidden layer is determined by

NumHidden. The number of output variables of the MLP (NumOutput in create_class_mlp) is determined from the names of the characters to be used in the OCR, which are passed in Characters. As described with create_class_mlp, the parameters Preprocessing and NumComponents can be used to specify a preprocessing of the data (i.e., the feature vectors). The OCR already approximately normalizes the features. Hence, Preprocessing can typically be set to *'none'*. The parameter RandSeed has the same meaning as in create_class_mlp. Furthermore, like for general MLP classifiers (see create_class_mlp and set_regularization_params_class_mlp), it may be desirable to regularize OCR classifiers. This can be achieved by calling set_regularization_params_ocr_class_mlp before training the OCR classifier. In addition, like for general MLP classifiers (see create_class_mlp and set_rejection_params_class_mlp), it might be desirable to equip the OCR classifiers with the capability to reject unknown characters. The rejection class is by convention an additional symbol chr(26) that must be provided in Characters. The parameters of the rejection class can be set by calling set_rejection_params_ocr_class_mlp before training the OCR classifier.

The features to be used for the classification are determined by Features. Features can contain a tuple of several feature names. Each of these feature names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., *'pixel_invar'*). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by WidthCharacter and HeightCharacter. The interpolation to be used for the transformation is determined by Interpolation. It has the same meaning as in affine_trans_image. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, Interpolation = *'constant'* should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, large sizes will lead to the fact that small segmentation errors will have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, which leads to the fact that the character is zoomed differently than the characters in the training set. In most applications, sizes between 6×8 and 10×14 should be used.

The parameter Features can contain the following feature names for the classification of the characters.

'default' *'ratio'* and *'pixel_invar'* are selected.

'pixel' Gray values of the character (WidthCharacter $\times$ HeightCharacter features).

'pixel_invar' Gray values of the character with maximum scaling of the gray values (WidthCharacter $\times$ HeightCharacter features).

'pixel_binary' Region of the character as a binary image zoomed to a size of WidthCharacter $\times$ HeightCharacter (WidthCharacter $\times$ HeightCharacter features).

'gradient_8dir' Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a 5×5 grid are extracted from each channel. These samples are used as features (200 features).

'projection_horizontal' Horizontal projection of the gray values (see gray_projections, HeightCharacter features).

'projection_horizontal_invar' Maximally scaled horizontal projection of the gray values (HeightCharacter features).

'projection_vertical' Vertical projection of the gray values (see gray_projections, WidthCharacter features).

'projection_vertical_invar' Maximally scaled vertical projection of the gray values (WidthCharacter features).

'ratio' Aspect ratio of the character (see height_width_ratio, 1 feature).

'anisometry' Anisometry of the character (see eccentricity, 1 feature).

'width' Width of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).

'height' Height of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).

'zoom_factor' Difference in size between the character and the values of WidthCharacter and HeightCharacter (not scale-invariant, 1 feature).

'foreground' Fraction of pixels in the foreground (1 feature).

'foreground_grid_9' Fraction of pixels in the foreground in a 3×3 grid within the smallest enclosing rectangle of the character (9 features).

'foreground_grid_16' Fraction of pixels in the foreground in a 4×4 grid within the smallest enclosing rectangle of the character (16 features).

'compactness' Compactness of the character (see `compactness`, 1 feature).

'convexity' Convexity of the character (see `convexity`, 1 feature).

'moments_region_2nd_invar' Normalized 2nd moments of the character (see `moments_region_2nd_invar`, 3 features).

'moments_region_2nd_rel_invar' Normalized 2nd relative moments of the character (see `moments_region_2nd_rel_invar`, 2 features).

'moments_region_3rd_invar' Normalized 3rd moments of the character (see `moments_region_3rd_invar`, 4 features).

'moments_central' Normalized central moments of the character (see `moments_region_central`, 4 features).

'moments_gray_plane' Normalized gray value moments and the angle of the gray value plane (see `moments_gray_plane`, 4 features).

'phi' Sinus and cosinus of the orientation (angle) of the character (see `elliptic_axis`, 2 feature).

'num_connect' Number of connected components (see `connect_and_holes`, 1 feature).

'num_holes' Number of holes (see `connect_and_holes`, 1 feature).

'cooc' Values of the binary cooccurrence matrix (see `gen_cooc_matrix`, 8 features).

'num_runs' Number of runs in the region normalized by the height (1 feature).

'chord_histo' Frequency of the runs per row (not scale-invariant, `HeightCharacter` features).

After the classifier has been created, it is trained using `trainf_ocr_class_mlp`. After this, the classifier can be saved using `write_ocr_class_mlp`. Alternatively, the classifier can be used immediately after training to classify characters using `do_ocr_single_class_mlp` or `do_ocr_multi_class_mlp`.

HALCON provides a number of pretrained OCR classifiers (see the "`Solution Guide I`", chapter 'OCR', section 'Pretrained OCR Fonts'). These pretrained OCR classifiers can be read directly with `read_ocr_class_mlp` and make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Therefore, it is recommended to try if one of the pretrained OCR classifiers can be used successfully. If this is the case, it is not necessary to create and train an OCR classifier.

A comparison of the MLP and the support vector machine (SVM) (see `create_ocr_class_svm`) typically shows that SVMs are generally faster at training, especially for huge training sets, and achieve slightly better recognition rates than MLPs. The MLP is faster at classification and should therefore be preferred in time critical applications. Please note that this guideline assumes optimal tuning of the parameters.

Parameters

▷ **`WidthCharacter`** (input_control) . . . . . integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 8
Suggested values: `WidthCharacter` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: $4 \leq$ `WidthCharacter` ≤ 20

▷ **`HeightCharacter`** (input_control) . . . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 10
Suggested values: `HeightCharacter` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: $4 \leq$ `HeightCharacter` ≤ 20

▷ **`Interpolation`** (input_control) . . . . . string ⇝ *string*
Interpolation mode for the zooming of the characters.
Default: 'constant'
List of values: `Interpolation` ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

▷ **Features** (input_control) . . . . . string(-array) ⇝ *string*
Features to be used for classification.
Default: 'default'
List of values: Features ∈ {'default', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir', 'projection_horizontal', 'projection_horizontal_invar', 'projection_vertical', 'projection_vertical_invar', 'ratio', 'anisometry', 'width', 'height', 'zoom_factor', 'foreground', 'foreground_grid_9', 'foreground_grid_16', 'compactness', 'convexity', 'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'moments_gray_plane', 'phi', 'num_connect', 'num_holes', 'cooc', 'num_runs', 'chord_histo'}

▷ **Characters** (input_control) . . . . . string-array ⇝ *string*
All characters of the character set to be read.
Default: ['0','1','2','3','4','5','6','7','8','9']

▷ **NumHidden** (input_control) . . . . . integer ⇝ *integer*
Number of hidden units of the MLP.
Default: 80
Suggested values: NumHidden ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 120, 150}
Restriction: NumHidden >= 1

▷ **Preprocessing** (input_control) . . . . . string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'none'
List of values: Preprocessing ∈ {'none', 'normalization', 'principal_components', 'canonical_variates'}

▷ **NumComponents** (input_control) . . . . . integer ⇝ *integer*
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = *'none'* and Preprocessing = *'normalization'*).
Default: 10
Suggested values: NumComponents ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumComponents >= 1

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed value of the random number generator that is used to initialize the MLP with random values.
Default: 42

▷ **OCRHandle** (output_control) . . . . . ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

Example

```
read_image (Image, 'letters')
* Segment the image.
binary_threshold(Image,&Region, 'otsu', 'dark', &UsedThreshold);
dilation_circle (Region, RegionDilation, 3.5)
connection (RegionDilation, ConnectedRegions)
intersection (ConnectedRegions, Region, RegionIntersection)
sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
* Generate the training file.
count_obj (Characters, Number)
Classes := []
for J := 0 to 25 by 1
    Classes := [Classes,gen_tuple_const(20,chr(ord('a')+J))]
endfor
Classes := [Classes,gen_tuple_const(20,'.')]
write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 20, \
                      'none', 81, 42, OCRHandle)
trainf_ocr_class_mlp (OCRHandle, 'letters.trf', 100, 0.01, 0.01, Error, \
                      ErrorLog)
* Re-classify the characters in the image.
do_ocr_multi_class_mlp (Characters, Image, OCRHandle, Class, Confidence)
```

Result

If the parameters are valid, the operator `create_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`trainf_ocr_class_mlp`, `set_regularization_params_ocr_class_mlp`, `set_rejection_params_ocr_class_mlp`

Alternatives

`create_ocr_class_svm`

Module

OCR/OCV

deserialize_ocr_class_mlp (: : SerializedItemHandle : OCRHandle)

Deserialize a serialized MLP-based OCR classifier.

`deserialize_ocr_class_mlp` deserializes a MLP-based OCR classifier, that was serialized by `serialize_ocr_class_mlp` (see `fwrite_serialized_item` for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle `SerializedItemHandle`. The deserialized values are stored in an automatically created OCR classifier with the handle `OCRHandle`.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **OCRHandle** (output_control) ..... ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

Result

If the parameters are valid, the operator `deserialize_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

do_ocr_multi_class_mlp (Character, Image : : OCRHandle : Class, Confidence)

Classify multiple characters with an OCR classifier.

do_ocr_multi_class_mlp computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. In contrast to do_ocr_single_class_mlp, do_ocr_multi_class_mlp can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_mlp to classify single characters. However, do_ocr_multi_class_mlp can only return the best class of each character. Because the confidences can be interpreted as probabilities (see classify_class_mlp and evaluate_class_mlp), and it is therefore easy to check whether a character has been classified with too much uncertainty, this is usually not a disadvantage, except in cases where the classes overlap so much that in many cases the second best class must be examined to be able to decide the class of the character. In these cases, do_ocr_single_class_mlp should be used.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

Before calling do_ocr_multi_class_mlp, the classifier must be trained with trainf_ocr_class_mlp.

Parameters

- ▷ **Character** (input_object) ..... region(-array) ⇝ *object*
  Characters to be recognized.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object* : byte / uint2
  Gray values of the characters.
- ▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **Class** (output_control) ..... string(-array) ⇝ *string*
  Result of classifying the characters with the MLP.
  Number of elements: Class == Character
- ▷ **Confidence** (output_control) ..... real(-array) ⇝ *real*
  Confidence of the class of the characters.
  Number of elements: Confidence == Character

Result

If the parameters are valid, the operator do_ocr_multi_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

OCR/OCV

do_ocr_single_class_mlp (Character, Image : : OCRHandle, Num : Class, Confidence)

Classify a single character with an OCR classifier.

do_ocr_single_class_mlp computes the best Num classes of the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence. Because multiple classes may be returned by do_ocr_single_class_mlp, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_mlp must be used. Because do_ocr_multi_class_mlp typically is faster than a loop with do_ocr_single_class_mlp and because the confidences can be interpreted as probabilities (see classify_class_mlp and evaluate_class_mlp), and it is therefore easy to check whether a character has been classified with too much uncertainty, in most cases do_ocr_multi_class_mlp should be used, unless the second-best class should be examined explicitly.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

Before calling do_ocr_single_class_mlp, the classifier must be trained with trainf_ocr_class_mlp.

Parameters

- ▷ **Character** (input_object) ..... region ⇝ *object*
  Character to be recognized.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object* : byte / uint2
  Gray values of the character.
- ▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **Num** (input_control) ..... integer-array ⇝ *integer*
  Number of best classes to determine.
  Default: 1
  Suggested values: Num ∈ {1, 2, 3, 4, 5}
- ▷ **Class** (output_control) ..... string(-array) ⇝ *string*
  Result of classifying the character with the MLP.
- ▷ **Confidence** (output_control) ..... real(-array) ⇝ *real*
  Confidence(s) of the class(es) of the character.

Result

If the parameters are valid, the operator do_ocr_single_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

do_ocr_word_mlp (Character, Image : : OCRHandle, Expression, NumAlternatives, NumCorrections : Class, Confidence, Word, Score)

Classify a related group of characters with an OCR classifier.

do_ocr_word_mlp works like do_ocr_multi_class_mlp insofar as it computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle, and returns the classes in Class and the corresponding confidences (probabilities) of the classes in Confidence.

In contrast to do_ocr_multi_class_mlp, do_ocr_word_mlp treats the group of characters as an entity which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an Expression describing the expected word.

The Expression may restrict the word to belong to a predefined lexicon created using create_lexicon or import_lexicon, by specifying the name of the lexicon in angular brackets as in *'<mylexicon>'*. If the Expression is of any other form, it is interpreted as a regular expression with the same syntax as specified for tuple_regexp_match. Note that you will usually want to use an expression of the form '^...$' when using variable quantifiers like '*', to ensure that the entire word is used in the expression. Also note that in contrast to tuple_regexp_match, do_ocr_word_mlp does **not** support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the Expression, do_ocr_word_mlp attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives used are identical to those returned by do_ocr_single_class_mlp for a single character. It does so by testing all possible corrections for which the classification result is changed for at most NumCorrections character regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many classes with higher confidences have been ignored in order to match the Expression:

$$\mathtt{Score} = 1.0 - \mathtt{PenaltyCorrections} - \mathtt{PenaltyAlternatives}$$

$$\begin{aligned} \mathtt{PenaltyCorrections} &= \alpha * \mathtt{num\_corr} \\ \mathtt{PenaltyAlternatives} &= \alpha * \beta * \mathtt{num\_alt} \end{aligned}$$

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

$$\begin{aligned} \alpha &= \frac{1}{\mathtt{NumCorrections} + 1} \\ \beta &= \frac{1}{\mathtt{NumCorrections} * (\mathtt{NumAlternatives} - 1) + 2} \end{aligned}$$

Note that this is a combinatorial score which does **not** reflect the original Confidence of the best Class.

A string of the number '\032' (alternatively displayed as '\0x1A') in Class signifies that the region has been classified as rejection class.

Parameters

- ▷ **Character** (input_object) ..... region(-array) ⇝ *object*
  Characters to be recognized.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
  Gray values of the characters.
- ▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **Expression** (input_control) ..... string ⇝ *string*
  Expression describing the allowed word structure.

▷ **NumAlternatives** (input_control) ..... integer ⇝ *integer*
Number of classes per character considered for the internal word correction.
Default: 3
Suggested values: NumAlternatives ∈ {3, 4, 5}
Value range: 1 ≤ NumAlternatives

▷ **NumCorrections** (input_control) ..... integer ⇝ *integer*
Maximum number of corrected characters.
Default: 2
Suggested values: NumCorrections ∈ {1, 2, 3, 4, 5}
Value range: 0 ≤ NumCorrections

▷ **Class** (output_control) ..... string(-array) ⇝ *string*
Result of classifying the characters with the MLP.
Number of elements: Class == Character

▷ **Confidence** (output_control) ..... real(-array) ⇝ *real*
Confidence of the class of the characters.
Number of elements: Confidence == Character

▷ **Word** (output_control) ..... string ⇝ *string*
Word text after classification and correction.

▷ **Score** (output_control) ..... real ⇝ *real*
Measure of similarity between corrected word and uncorrected classification results.

Complexity

The complexity of checking all possible corrections is of magnitude $O((n * a)^{min(c,n)})$, where a is the number of alternatives, n is the number of character regions, and c is the number of allowed corrections. However, to guard against a near-infinite loop in case of large n, c is internally clipped to 5, 3, or 1 if $a * n >= 30$, 60, or 90, respectively.

Result

If the parameters are valid, the operator do_ocr_word_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_ocr_class_mlp, classify_class_mlp

Module

OCR/OCV

get_features_ocr_class_mlp (Character : : OCRHandle, Transform : Features)

Compute the features of a character.

get_features_ocr_class_mlp computes the features of the character given by Character with the OCR classifier OCRHandle and returns them in Features. In contrast to do_ocr_single_class_mlp and do_ocr_multi_class_mlp, the character is passed as a single image object. Hence, before calling get_features_ocr_class_mlp, reduce_domain must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in create_ocr_class_mlp for the classifier should be applied (Transform = *'true'*) or whether the untransformed features should be returned (Transform = *'false'*). get_features_ocr_class_mlp can be used to inspect the features that are used for the classification.

Parameters

▷ **Character** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input character.

▷ **OCRHandle** (input_control) . . . . . ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **Transform** (input_control) . . . . . string ⇝ *string*
Should the feature vector be transformed with the preprocessing?
Default: 'true'
List of values: `Transform` ∈ {'true', 'false'}

▷ **Features** (output_control) . . . . . real-array ⇝ *real*
Feature vector of the character.

Result

If the parameters are valid, the operator `get_features_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

get_params_ocr_class_mlp (: : OCRHandle : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, NumHidden, Preprocessing, NumComponents)

Return the parameters of an OCR classifier.

`get_params_ocr_class_mlp` returns the parameters of an OCR classifier that were specified when the classifier was created with `create_ocr_class_mlp`. This is particularly useful if the classifier was read with `read_ocr_class_mlp`. The output of `get_params_ocr_class_mlp` can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see `create_ocr_class_mlp`.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **WidthCharacter** (output_control) . . . . . integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.

▷ **HeightCharacter** (output_control) . . . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.

▷ **Interpolation** (output_control) . . . . . string ⇝ *string*
Interpolation mode for the zooming of the characters.

▷ **Features** (output_control) . . . . . string(-array) ⇝ *string*
Features to be used for classification.

▷ **Characters** (output_control) . . . . . string-array ⇝ *string*
Characters of the character set to be read.

▷ **NumHidden** (output_control) . . . . . integer ⇝ *integer*
Number of hidden units of the MLP.

▷ **Preprocessing** (output_control) ..... string ⇝ *string*
Type of preprocessing used to transform the feature vectors.

▷ **NumComponents** (output_control) ..... integer ⇝ *integer*
Preprocessing parameter: Number of transformed features.

Result

If the parameters are valid, the operator `get_params_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

OCR/OCV

get_prep_info_ocr_class_mlp (: : OCRHandle, TrainingFile, Preprocessing : InformationCont, CumInformationCont)

Compute the information content of the preprocessed feature vectors of an OCR classifier.

`get_prep_info_ocr_class_mlp` computes the information content of the training vectors that have been transformed with the preprocessing given by `Preprocessing`. `Preprocessing` can be set to *'principal_components'* or *'canonical_variates'*. The OCR classifier `OCRHandle` must have been created with `create_ocr_class_mlp`. The preprocessing methods are described with `create_class_mlp`. The information content is derived from the variations of the transformed components of the feature vector, i.e., it is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (`NumInput` for *'principal_components'* and $\min(\texttt{NumOutput}-1, \texttt{NumInput})$ for *'canonical_variates'*, see `create_class_mlp`), and is returned in `InformationCont` as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the n-th component of `CumInformationCont`, i.e., `CumInformationCont` contains the sums of the first n elements of `InformationCont`. To use `get_prep_info_ocr_class_mlp`, a sufficient number of samples must be stored in the training files given by `TrainingFile` (see `write_ocr_trainf`).

`InformationCont` and `CumInformationCont` can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent x% (e.g., 90%) of the total data. This can be decided easily from the first value of `CumInformationCont` that lies above x%. The number thus obtained can be used as the value for `NumComponents` in a new call to `create_ocr_class_mlp`. The call to `get_prep_info_ocr_class_mlp` already requires the creation of a classifier, and hence the setting of `NumComponents` in `create_ocr_class_mlp` to an initial value. However, if `get_prep_info_ocr_class_mlp` is called it is typically not known how many components are relevant, and hence how to set `NumComponents` in this call. Therefore, the following two-step approach should typically be used to select `NumComponents`: In a first step, a classifier with the maximum number for `NumComponents` is created (`NumInput` for *'principal_components'* and $\min(\texttt{NumOutput}-1, \texttt{NumInput})$ for *'canonical_variates'*). Then, the training samples are saved in a training file using `write_ocr_trainf`. Subsequently, `get_prep_info_ocr_class_mlp` is used to determine the information content of the components, and with this `NumComponents`. After this, a new classifier with the desired number of components is created, and the classifier is trained with `trainf_ocr_class_mlp`.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the training files.
Default: 'ocr.trf'
File extension: `.trf`, `.otr`

▷ **Preprocessing** (input_control) ..... string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'principal_components'
List of values: `Preprocessing` ∈ {'principal_components', 'canonical_variates'}

▷ **InformationCont** (output_control) ..... real-array ⇝ *real*
Relative information content of the transformed feature vectors.

▷ **CumInformationCont** (output_control) ..... real-array ⇝ *real*
Cumulative information content of the transformed feature vectors.

Example

```
* Create the initial OCR classifier.
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 80, \
                      'canonical_variates', |CharacterNames|, 42, OCRHandle)
* Get the information content of the transformed feature vectors.
get_prep_info_ocr_class_mlp (OCRHandle, 'ocr.trf', 'canonical_variates', \
                             InformationCont, CumInformationCont)
* Determine the number of transformed components.
* NumComp = [...]
* Create the final OCR classifier.
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 80, \
                      'canonical_variates', NumComp, 42, OCRHandle)
* Train the final classifier.
trainf_ocr_class_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, ErrorLog)
write_ocr_class_mlp (OCRHandle, 'ocr.omc')
```

Result

If the parameters are valid, the operator `get_prep_info_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

`get_prep_info_ocr_class_mlp` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_regularization_params_ocr_class_mlp (: : OCRHandle, GenParamName : GenParamValue)

Return the regularization parameters of an OCR classifier.

get_regularization_params_ocr_class_mlp returns the regularization parameters of an OCR classifier that were specified with set_regularization_params_ocr_class_mlp. Furthermore, get_regularization_params_ocr_class_mlp returns the parameters that were determined by an automatic determination of the regularization parameters. For a description of the parameters, see set_regularization_params_ocr_class_mlp.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **GenParamName** (input_control) ..... string ⇝ *string*
Name of the regularization parameter to return.
Default: 'weight_prior'
List of values: GenParamName ∈ {'weight_prior', 'num_well_determined_params', 'fraction_well_determined_params', 'num_outer_iterations', 'num_inner_iterations'}

▷ **GenParamValue** (output_control) ..... number(-array) ⇝ *real* / integer
Value of the regularization parameter.

Result

If the parameters are valid, the operator get_regularization_params_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Return the rejection class parameters of an OCR classifier.

get_rejection_params_ocr_class_mlp returns the rejection class parameters of an OCR classifier that were specified with set_rejection_params_ocr_class_mlp. For a description of the parameters, see set_rejection_params_ocr_class_mlp and set_rejection_params_class_mlp.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **GenParamName** (input_control) ..... string(-array) ⇝ *string*
Name of the general parameter.
Default: 'sampling_strategy'
List of values: GenParamName ∈ {'sampling_strategy', 'hyperbox_tolerance', 'rejection_sample_factor', 'random_seed', 'rejection_class_index'}

▷ **GenParamValue** (output_control) ..... string(-array) ⇝ *string*
Value of the general parameter.

Result

If the parameters are valid, the operator `get_rejection_params_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

Module

OCR/OCV

read_ocr_class_mlp (: : FileName : OCRHandle)

Read an OCR classifier from a file.

`read_ocr_class_mlp` reads an OCR classifier that has been stored with `write_ocr_class_mlp`. Since the training of an OCR classifier can consume a relatively long time, the classifier is typically trained in an offline process and written to a file with `write_ocr_class_mlp`. In the online process the classifier is read with `read_ocr_class_mlp` and subsequently used for classification with `do_ocr_single_class_mlp` or `do_ocr_multi_class_mlp`.

HALCON provides a number of pretrained OCR classifiers (see the "`Solution Guide I`", chapter 'OCR', section 'Pretrained OCR Fonts'). These pretrained OCR classifiers make it possible to read a wide variety of different fonts without the need to train an OCR classifier. Note that the pretrained OCR classifiers were trained with symbols that are printed dark on light.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
Suggested values: `FileName` ∈ {'Document_0-9_NoRej.omc', 'Document_0-9_Rej.omc', 'Document_0-9A-Z_NoRej.omc', 'Document_0-9A-Z_Rej.omc', 'Document_A-Z+_NoRej.omc', 'Document_A-Z+_Rej.omc', 'Document_NoRej.omc', 'Document_Rej.omc', 'DotPrint_0-9_NoRej.omc', 'DotPrint_0-9_Rej.omc', 'DotPrint_0-9+_NoRej.omc', 'DotPrint_0-9+_Rej.omc', 'DotPrint_0-9A-Z_NoRej.omc', 'DotPrint_0-9A-Z_Rej.omc', 'DotPrint_A-Z+_NoRej.omc', 'DotPrint_A-Z+_Rej.omc', 'DotPrint_NoRej.omc', 'DotPrint_Rej.omc', 'HandWritten_0-9_NoRej.omc', 'HandWritten_0-9_Rej.omc', 'Industrial_0-9_NoRej.omc', 'Industrial_0-9_Rej.omc', 'Industrial_0-9+_NoRej.omc', 'Industrial_0-9+_Rej.omc', 'Industrial_0-9A-Z_NoRej.omc', 'Industrial_0-9A-Z_Rej.omc', 'Industrial_A-Z+_NoRej.omc', 'Industrial_A-Z+_Rej.omc', 'Industrial_NoRej.omc', 'Industrial_Rej.omc', 'OCRA_0-9_NoRej.omc', 'OCRA_0-9_Rej.omc', 'OCRA_0-9A-Z_NoRej.omc', 'OCRA_0-9A-Z_Rej.omc', 'OCRA_A-Z+_NoRej.omc', 'OCRA_A-Z+_Rej.omc', 'OCRA_NoRej.omc', 'OCRA_Rej.omc', 'OCRB_0-9_NoRej.omc', 'OCRB_0-9_Rej.omc', 'OCRB_0-9A-Z_NoRej.omc', 'OCRB_0-9A-Z_Rej.omc', 'OCRB_A-Z+_NoRej.omc', 'OCRB_A-Z+_Rej.omc', 'OCRB_NoRej.omc', 'OCRB_passport_NoRej.omc', 'OCRB_passport_Rej.omc', 'OCRB_Rej.omc', 'Pharma_0-9_NoRej.omc', 'Pharma_0-9_Rej.omc', 'Pharma_0-9+_NoRej.omc', 'Pharma_0-9+_Rej.omc', 'Pharma_0-9A-Z_NoRej.omc', 'Pharma_0-9A-Z_Rej.omc', 'Pharma_NoRej.omc', 'Pharma_Rej.omc', 'SEMI_NoRej.omc', 'SEMI_Rej.omc'}
File extension: `.omc`, `.fnt`

▷ **OCRHandle** (output_control) . . . . . ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

Result

If the parameters are valid, the operator `read_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

select_feature_set_trainf_mlp (: : TrainingFile, FeatureList, SelectionMethod, Width, Height, GenParamName, GenParamValue : OCRHandle, FeatureSet, Score)

Selects an optimal combination of features to classify OCR data.

`select_feature_set_trainf_mlp` selects an optimal combination of features, to classify the OCR data given in the training file `TrainingFile` with a multilayer perceptron, for details see `create_ocr_class_mlp`.

Possible features are all OCR features listed and explained in `create_ocr_class_mlp`. All candidates which should be tested can be specified in `FeatureList`. A subset of these features is returned as selected features in `FeatureSet`.

`select_feature_set_trainf_mlp` is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator `select_feature_set_mlp`.

The selection method `SelectionMethod` is either a greedy search *'greedy'* (iteratively add the feature with highest gain) or the dynamically oscillating search *'greedy_oscillating'* (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method *'greedy'* is generally preferable, since it is faster. Only in cases when a large training set is available the method *'greedy_oscillating'* might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in `Score`.

The parameters `GenParamName` and `GenParamValue` allow to adapt the setting of the number of hidden neurons in the MLP with *'num_hidden'*. The default value is *80*, a higher value leads to longer training times but might lead to a more expressive classifier.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator `select_feature_set_trainf_mlp` may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ **TrainingFile** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: ”
File extension: `.trf`, `.otr`

▷ **FeatureList** (input_control) . . . . . string(-array) ⇝ *string*
List of features that should be considered for selection.
Default: [’zoom_factor’,’ratio’,’width’,’height’,’foreground’,’foreground_grid_9’,’foreground_grid_16’, ’anisometry’,’compactness’,’convexity’,’moments_region_2nd_invar’,’moments_region_2nd_rel_invar’, ’moments_region_3rd_invar’,’moments_central’,’phi’,’num_connect’,’num_holes’,’projection_horizontal’, ’projection_vertical’,’projection_horizontal_invar’,’projection_vertical_invar’,’chord_histo’,’num_runs’, ’pixel’,’pixel_invar’,’pixel_binary’,’gradient_8dir’,’cooc’,’moments_gray_plane’]
List of values: `FeatureList` ∈ {’default’, ’zoom_factor’, ’ratio’, ’width’, ’height’, ’foreground’, ’foreground_grid_9’, ’foreground_grid_16’, ’anisometry’, ’compactness’, ’convexity’, ’moments_region_2nd_invar’, ’moments_region_2nd_rel_invar’, ’moments_region_3rd_invar’, ’moments_central’, ’phi’, ’num_connect’, ’num_holes’, ’projection_horizontal’, ’projection_vertical’, ’projection_horizontal_invar’, ’projection_vertical_invar’, ’chord_histo’, ’num_runs’, ’pixel’, ’pixel_invar’, ’pixel_binary’, ’gradient_8dir’, ’cooc’, ’moments_gray_plane’}

▷ **SelectionMethod** (input_control) . . . . . string ⇝ *string*
Method to perform the selection.
Default: ’greedy’
List of values: `SelectionMethod` ∈ {’greedy’, ’greedy_oscillating’}

▷ **Width** (input_control) . . . . . integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 15

▷ **Height** (input_control) . . . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 16

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of generic parameters to configure the selection process and the classifier.
Default: []
List of values: `GenParamName` ∈ {’nu’}

▷ **GenParamValue** (input_control) . . . . . number-array ⇝ *real* / integer / string
Values of generic parameters to configure the selection process and the classifier.
Default: []
Suggested values: `GenParamValue` ∈ {’0.1’}

▷ **OCRHandle** (output_control) . . . . . ocr_mlp ⇝ *handle*
Trained OCR-MLP classifier.

▷ **FeatureSet** (output_control) . . . . . string-array ⇝ *string*
Selected feature set, contains only entries from `FeatureList`.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
Achieved score using tow-fold cross-validation.

Result

If the parameters are valid, the operator `select_feature_set_trainf_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Alternatives

Module

OCR/OCV

select_feature_set_trainf_mlp_protected (: : TrainingFile, Password, FeatureList, SelectionMethod, Width, Height, GenParamName, GenParamValue : OCRHandle, FeatureSet, Score)

Select an optimal combination of features to classify OCR data from a (protected) training file.

select_feature_set_trainf_mlp_protected selects an optimal combination of features to classify the data given in the training files TrainingFile with a multilayer perceptron (MLP). Its functionality corresponds to the functionality of select_feature_set_trainf_mlp, with the addition that select_feature_set_trainf_mlp_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator's functionality see select_feature_set_trainf_mlp. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_mlp_protected may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the training files.
Default: ''
File extension: .trf, .otr

▷ **Password** (input_control) ..... string(-array) ⇝ *string*
Passwords for protected training files.

▷ **FeatureList** (input_control) ..... string(-array) ⇝ *string*
List of features that should be considered for selection.
Default: ['zoom_factor','ratio','width','height','foreground','foreground_grid_9','foreground_grid_16', 'anisometry','compactness','convexity','moments_region_2nd_invar','moments_region_2nd_rel_invar', 'moments_region_3rd_invar','moments_central','phi','num_connect','num_holes','projection_horizontal', 'projection_vertical','projection_horizontal_invar','projection_vertical_invar','chord_histo','num_runs', 'pixel','pixel_invar','pixel_binary','gradient_8dir','cooc','moments_gray_plane']
List of values: FeatureList ∈ {'default', 'zoom_factor', 'ratio', 'width', 'height', 'foreground', 'foreground_grid_9', 'foreground_grid_16', 'anisometry', 'compactness', 'convexity', 'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'phi', 'num_connect', 'num_holes', 'projection_horizontal', 'projection_vertical', 'projection_horizontal_invar', 'projection_vertical_invar', 'chord_histo', 'num_runs', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir', 'cooc', 'moments_gray_plane'}

▷ **SelectionMethod** (input_control) ..... string ⇝ *string*
Method to perform the selection.
Default: 'greedy'
List of values: SelectionMethod ∈ {'greedy', 'greedy_oscillating'}

▷ **Width** (input_control) ..... integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 15

▷ **Height** (input_control) . . . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 16

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of generic parameters to configure the selection process and the classifier.
Default: []
List of values: GenParamName ∈ {'nu'}

▷ **GenParamValue** (input_control) . . . . . number-array ⇝ *real* / integer / string
Values of generic parameters to configure the selection process and the classifier.
Default: []
Suggested values: GenParamValue ∈ {'0.1'}

▷ **OCRHandle** (output_control) . . . . . ocr_mlp ⇝ *handle*
Trained OCR-MLP classifier.

▷ **FeatureSet** (output_control) . . . . . string-array ⇝ *string*
Selected feature set, contains only entries from FeatureList.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
Achieved score using tow-fold cross-validation.

Result

If the parameters are valid, the operator select_feature_set_trainf_mlp_protected returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

OCR/OCV

serialize_ocr_class_mlp (: : OCRHandle : SerializedItemHandle)

Serialize a MLP-based OCR classifier.

serialize_ocr_class_mlp serializes a MLP-based OCR classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocr_class_mlp is converted to a serialized item. The OCR classifier is defined by the handle OCRHandle. The serialized OCR classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocr_class_mlp.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_regularization_params_ocr_class_mlp (: : OCRHandle, GenParamName, GenParamValue :)

Set the regularization parameters of an OCR classifier.

`set_regularization_params_ocr_class_mlp` sets the regularization parameters of the OCR classifier passed in `OCRHandle`. The regularization parameter to be set is specified with `GenParamName`. Its value is specified with `GenParamValue`.

As described at `create_class_mlp`, it may be desirable to regularize the OCR classifier (i.e., the MLP of the OCR classifier) to enforce a smoother transition of the confidences between the different classes and to prevent overfitting of the OCR classifier to the training data. To achieve this, a penalty for large MLP weights (which are the main reason for very sharp transitions between classes) can be added to the training of the OCR classifier in `trainf_ocr_class_mlp` by setting `GenParamName` to *'weight_prior'* and setting `GenParamValue` to a value > 0. Furthermore, the regularization parameters can be determined automatically. For details, see `set_regularization_params_class_mlp`. If the regularization parameters should be determined automatically, please carefully note the advice in `set_regularization_params_class_mlp` on how to select the parameters `NumHidden` of the MLP and *'num_outer_iterations'* and on the memory and runtime implications of automatically determining the regularization parameters on the runtime of the training of the OCR classifier.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **GenParamName** (input_control) ..... string ⇝ *string*
Name of the regularization parameter to return.
Default: 'weight_prior'
List of values: `GenParamName` ∈ {'weight_prior', 'num_outer_iterations', 'num_inner_iterations'}

▷ **GenParamValue** (input_control) ..... number(-array) ⇝ *real* / integer
Value of the regularization parameter.
Default: 1.0
Suggested values: `GenParamValue` ∈ {0.01, 0.1, 1.0, 10.0, 100.0, 0, 1, 2, 3, 5, 10, 15, 20}

Example

Possible Successors

`get_regularization_params_ocr_class_mlp`, `trainf_ocr_class_mlp`

Module

OCR/OCV

set_rejection_params_ocr_class_mlp (: : OCRHandle, GenParamName, GenParamValue :)

Set the rejection class parameters of an OCR classifier.

`set_rejection_params_ocr_class_mlp` sets the rejection class parameters of the OCR classifier passed in `OCRHandle`. The parameter to be set is specified with `GenParamName`. Its value is specified with `GenParamValue`. For some OCR applications it is important to know, if a letter to be classified is similar to the training set or not. If a letter is different to the training set, then it can be classified a rejection class. This additional rejection class must be specified as an additional character in `create_ocr_class_mlp`. For details on how to specify a rejection class, see `set_rejection_params_class_mlp`.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **GenParamName** (input_control) ..... string(-array) ⇝ *string*
Name of the general parameter.
Default: 'sampling_strategy'
List of values: `GenParamName` ∈ {'sampling_strategy', 'hyperbox_tolerance', 'rejection_sample_factor', 'random_seed', 'rejection_class_index'}

▷ **GenParamValue** (input_control) ..... string(-array) ⇝ *string*
Value of the general parameter.
Default: 'hyperbox_around_all_classes'
List of values: `GenParamValue` ∈ {'no_rejection_class', 'hyperbox_around_all_classes', 'hyperbox_around_each_class', 'hyperbox_ring_around_each_class'}

Result

If the parameters are valid, the operator `set_rejection_params_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Possible Successors

`trainf_ocr_class_mlp`

Module

OCR/OCV

`trainf_ocr_class_mlp` (: : `OCRHandle`, `TrainingFile`, `MaxIterations`, `WeightTolerance`, `ErrorTolerance` : `Error`, `ErrorLog`)

Train an OCR classifier.

`trainf_ocr_class_mlp` trains the OCR classifier `OCRHandle` with the training characters stored in the OCR training files given by `TrainingFile`. The training files must have been created, e.g., using `write_ocr_trainf`, before calling `trainf_ocr_class_mlp`.

The remaining parameters have the same meaning as in `train_class_mlp` and are described in detail with `train_class_mlp`. A regularization of the OCR classifier and an automatic determination of the regularization parameters (see `set_regularization_params_ocr_class_mlp`) is taken into account during the training. Furthermore, if a rejection class has been specified using `set_rejection_params_ocr_class_mlp`, before the actual training the samples for the rejection class are generated.

Please note that training characters that have no corresponding class in the classifier `OCRHandle` are discarded.

Parameters

▷ **`OCRHandle`** (input_control) . . . . . ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **`TrainingFile`** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: 'ocr.trf'
File extension: `.trf`, `.otr`

▷ **`MaxIterations`** (input_control) . . . . . integer ⇝ *integer*
Maximum number of iterations of the optimization algorithm.
Default: 200
Suggested values: `MaxIterations` ∈ {20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300}

▷ **`WeightTolerance`** (input_control) . . . . . real ⇝ *real*
Threshold for the difference of the weights of the MLP between two iterations of the optimization algorithm.
Default: 1.0
Suggested values: `WeightTolerance` ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
Restriction: WeightTolerance >= 1.0e-8

▷ **`ErrorTolerance`** (input_control) . . . . . real ⇝ *real*
Threshold for the difference of the mean error of the MLP on the training data between two iterations of the optimization algorithm.
Default: 0.01
Suggested values: `ErrorTolerance` ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
Restriction: ErrorTolerance >= 1.0e-8

▷ **`Error`** (output_control) . . . . . real ⇝ *real*
Mean error of the MLP on the training data.

▷ **ErrorLog** (output_control) . . . . . real-array ⇝ *real*
Mean error of the MLP on the training data as a function of the number of iterations of the optimization algorithm.

Example

```
* Train an OCR classifier
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_mlp (8, 10, 'constant', 'default', CharacterNames, 80, \
                      'none', 81, 42, OCRHandle)
trainf_ocr_class_mlp (OCRHandle, 'ocr.trf', 100, 1, 0.01, Error, ErrorLog)
write_ocr_class_mlp (OCRHandle, 'ocr.omc')
```

Result

If the parameters are valid, the operator `trainf_ocr_class_mlp` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

`trainf_ocr_class_mlp` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change `Preprocessing` to *'normalization'*. Another solution can be to add more training samples.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

OCR/OCV

trainf_ocr_class_mlp_protected (: : OCRHandle, TrainingFile, Password, MaxIterations, WeightTolerance, ErrorTolerance : Error, ErrorLog)

Train an OCR classifier with data from a (protected) training file.

`trainf_ocr_class_mlp_protected` trains the OCR classifier `OCRHandle` with the training data stored in the OCR training files given by `TrainingFile`. Its functionality corresponds to the functionality of `trainf_ocr_class_mlp`, with the addition that `trainf_ocr_class_mlp_protected` can process unprotected and protected training files. Protected training files can be used only with the correct user password `Password`. If the number of passwords `Password` equals 1, then every input file `TrainingFile` is checked

with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator's functionality see `trainf_ocr_class_mlp`. The concept of protecting OCR training data in HALCON is described in `protect_ocr_trainf`.

Parameters

▷ **`OCRHandle`** (input_control) . . . . . ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **`TrainingFile`** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: 'ocr.trf'
File extension: `.trf`, `.otr`

▷ **`Password`** (input_control) . . . . . string(-array) ⇝ *string*
Passwords for protected training files.

▷ **`MaxIterations`** (input_control) . . . . . integer ⇝ *integer*
Maximum number of iterations of the optimization algorithm.
Default: 200
Suggested values: `MaxIterations` ∈ {20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300}

▷ **`WeightTolerance`** (input_control) . . . . . real ⇝ *real*
Threshold for the difference of the weights of the MLP between two iterations of the optimization algorithm.
Default: 1.0
Suggested values: `WeightTolerance` ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
Restriction: WeightTolerance >= 1.0e-8

▷ **`ErrorTolerance`** (input_control) . . . . . real ⇝ *real*
Threshold for the difference of the mean error of the MLP on the training data between two iterations of the optimization algorithm.
Default: 0.01
Suggested values: `ErrorTolerance` ∈ {1.0, 0.1, 0.01, 0.001, 0.0001, 0.00001}
Restriction: ErrorTolerance >= 1.0e-8

▷ **`Error`** (output_control) . . . . . real ⇝ *real*
Mean error of the MLP on the training data.

▷ **`ErrorLog`** (output_control) . . . . . real-array ⇝ *real*
Mean error of the MLP on the training data as a function of the number of iterations of the optimization algorithm.

Result

If the parameters are valid, the operator `trainf_ocr_class_mlp_protected` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

`trainf_ocr_class_mlp_protected` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change `Preprocessing` to *'normalization'*. Another solution can be to add more training samples.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

OCR/OCV

write_ocr_class_mlp (: : OCRHandle, FileName :)

Write an OCR classifier to a file.

write_ocr_class_mlp writes the OCR classifier OCRHandle to the file given by FileName. If a file extension is not specified in FileName the default extension '.omc' is appended to FileName. write_ocr_class_mlp is typically called after the classifier has been trained with trainf_ocr_class_mlp. The classifier can be read with read_ocr_class_mlp.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_mlp ⇝ *handle*
Handle of the OCR classifier.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
File name.
File extension: .omc

Result

If the parameters are valid, the operator write_ocr_class_mlp returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

21.6 Segmentation

clear_text_model (: : TextModel :)

Clear a text model.

clear_text_model clears the text model in TextModel and frees all underlying memory.

Parameters

▷ **TextModel** (input_control) . . . . . text_model(-array) ⇝ *handle*
Text model to be cleared.

Result

`clear_text_model` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

clear_text_result (: : TextResultID :)

Clear a text result.

`clear_text_result` clears the text result in `TextResultID` and frees all underlying memory.

Parameters

▷ **TextResultID** (input_control) . . . . . text_result(-array) ⇝ *handle*
Text result to be cleared.

Result

`clear_text_result` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextResultID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

create_text_model_reader (: : Mode, OCRClassifier : TextModel)

Create a text model.

`create_text_model_reader` creates a `TextModel`, which describes the text to be segmented with `find_text`.

The parameter value of Mode determines which text segmentation approach is used. Possible values are *'auto'* and *'manual'*.

Typically, the parameter Mode should be set to *'auto'* because this mode is more stable and requires less configuration effort. Note that in this case, also an OCR classifier must be passed in OCRClassifier. Only if one of the following restrictions apply, Mode must be set to *'manual'*:

- The segmentation of text which has strong local variations of the polarity is required. For example, due to reflections, engraved text often has strong local variations.
- No suitable OCR classifier is available (see below).

If Mode = *'auto'*, find_text is able to extract text of arbitrary size. It is possible to restrict the search to characters with specific attributes, see set_text_model_param for details. In particular, if the text to be segmented contains dot printed characters, the text model parameter *'dot_print'* must be set to *'true'*. Furthermore, an OCR classifier must be passed in OCRClassifier. This OCR classifier must be based on a convolutional neural network (CNN) or a multilayer perceptron (MLP). Moreover, it is strongly recommended to use a CNN based OCR classifier with rejection class or a MLP based classifiers that has been trained with regularization parameters (see set_regularization_params_ocr_class_mlp and provides a rejection class (see set_rejection_params_ocr_class_mlp). A suitable OCR classifier can either be read with read_ocr_class_cnn or read_ocr_class_mlp, or be created with create_ocr_class_mlp. It is also possible to pass a string containing the path to a pretrained OCR classifier or an OCR classifier that has been stored with write_ocr_class_mlp.

To enable text segmentation when Mode = *'manual'*, reasonable parameters for the text model, including the expected character height and width, must be set using set_text_model_param. In this case, the value of OCRClassifier is ignored.

The parameters of the TextModel can be set and queried with set_text_model_param and get_text_model_param.

Since memory is allocated for the text model during the call of create_text_model_reader and during the following operations, the model should be freed explicitly by the operator clear_text_model as soon as it is no longer used.

Parameters

▷ **Mode** (input_control) . . . . . string ⇝ *string*
The Mode of the text model.
Default: 'auto'
List of values: Mode ∈ {'manual', 'auto'}

▷ **OCRClassifier** (input_control) . . . . . string ⇝ *string* / integer
OCR Classifier.
Default: 'Universal_Rej.occ'
Suggested values: OCRClassifier ∈ {'Document_Rej.omc', 'Document_0-9_Rej.omc', 'Document_0-9A-Z_Rej.omc', 'Document_A-Z+_Rej.omc', 'DotPrint_Rej.omc', 'DotPrint_0-9_Rej.omc', 'DotPrint_0-9+_Rej.omc', 'DotPrint_0-9A-Z_Rej.omc', 'DotPrint_A-Z+_Rej.omc', 'HandWritten_0-9_Rej.omc', 'Industrial_Rej.omc', 'Industrial_0-9_Rej.omc', 'Industrial_0-9+_Rej.omc', 'Industrial_0-9A-Z_Rej.omc', 'Industrial_A-Z+_Rej.omc', 'OCRA_Rej.omc', 'OCRA_0-9_Rej.omc', 'OCRA_0-9A-Z_Rej.omc', 'OCRA_A-Z+_Rej.omc', 'OCRB_Rej.omc', 'OCRB_0-9_Rej.omc', 'OCRB_0-9A-Z_Rej.omc', 'OCRB_A-Z+_Rej.omc', 'OCRB_passport_Rej.omc', 'Pharma_Rej.omc', 'Pharma_0-9_Rej.omc', 'Pharma_0-9+_Rej.omc', 'Pharma_0-9A-Z_Rej.omc', 'SEMI_Rej.omc', 'Universal_Rej.occ', 'Universal_0-9_Rej.occ', 'Universal_0-9+_Rej.occ', 'Universal_0-9A-Z_Rej.occ', 'Universal_0-9A-Z+_Rej.occ', 'Universal_A-Z+_Rej.occ'}

▷ **TextModel** (output_control) . . . . . text_model ⇝ *handle*
New text model.

Example

```
read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
```

```
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)
```

Result

`create_text_model_reader` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

`clear_text_model`

Module

OCR/OCV

find_text (Image : : TextModel : TextResultID)

Find text in an image.

`find_text` finds text specified by the `TextModel` in the `Image` and returns the result in `TextResultID`. Specific results of `TextResultID` can be obtained with `get_text_result` and `get_text_object`.

The text results in `TextResultID` differ, depending on how `Mode` was set when creating the `TextModel` with `create_text_model_reader`.

For a text model with `Mode` = *'auto'* `find_text` extracts and classifies text of arbitrary size within the `Image`. It is possible to restrict the search to characters with specific attributes, see `set_text_model_param` for details.

For a text model with `Mode` = *'manual'* reasonable parameters for the text model, including the expected character height and width, need to be set using `set_text_model_param`. Furthermore, the `Image` is preprocessed such that character like structures are enhanced. The resulting compensated image can be queried from `TextResultID` if *'persistence'* was set to *'true'* in `TextModel`.

Both the text models with `Mode` = *'auto'* and `Mode` = *'manual'* apply various thresholds to the input image and segment character candidates based on region and gray value features. These candidates are further clustered to lines. Each line is individually completed and tested if it fulfills the constraints of a text line. Text models with `Mode` set to *'auto'* require a text line to consist of at least two characters, whereas text models with `Mode` set to *'manual'* require a text line to consist of at least three characters. In a further step, punctuations and separators are added if the correspondent parameters were set via `set_text_model_param`. Finally, if `TextModel` contains *'text_line_structure'* entries, the completed line is fitted to these structures.

`find_text` finds text which is roughly horizontally aligned in `Image`. `text_line_orientation` and `rotate_image` can be used to achieve this alignment.

Since memory is allocated for the text result during the call of `find_text` and during the following operations, the text result should be freed explicitly by the operator `clear_text_result` as soon as it is no longer used.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image.

▷ **TextModel** (input_control) . . . . . text_model ⇝ *handle*
Text model specifying the text to be segmented.

▷ **TextResultID** (output_control) . . . . . text_result ⇝ *handle*
Result of the segmentation.

Example

```
read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)
```

Result

If the parameters are valid, the operator `find_text` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

get_text_model_param (: : TextModel, GenParamName : GenParamValue)

Query parameters of a text model.

`get_text_model_param` queries the parameters of `TextModel`. With the exception of *'ocr_classifier'*, all valid parameters can be queried. See `set_text_model_param` for a detailed description of the possible values for `GenParamName` and `GenParamValue`.

Parameters

▷ **TextModel** (input_control) ..... text_model ⇝ *handle*
Text model.

▷ **GenParamName** (input_control) ..... string ⇝ *string*
Parameters to be queried.
Default: 'min_contrast'
Suggested values: `GenParamName` ∈ {'add_fragments', 'dot_print', 'dot_print_max_dot_gap', 'dot_print_min_char_gap', 'dot_print_tight_char_spacing', 'eliminate_border_blobs', 'max_char_height', 'max_char_width', 'max_stroke_width', 'min_char_height', 'min_char_width', 'min_contrast', 'min_stroke_width', 'num_classes', 'polarity', 'return_punctuation', 'return_separators', 'return_whole_line', 'separate_touching_chars', 'text_line_separators', 'text_line_structure', 'text_line_structure_0', 'text_line_structure_1', 'text_line_structure_2', 'manual_add_fragments', 'manual_base_line_tolerance', 'manual_char_height', 'manual_char_width', 'manual_eliminate_border_blobs', 'manual_eliminate_horizontal_lines', 'manual_fragment_size_min', 'manual_is_dotprint', 'manual_is_imprinted', 'manual_max_line_num', 'manual_persistence', 'manual_polarity', 'manual_return_punctuation', 'manual_return_separators', 'manual_stroke_width', 'manual_text_line_structure', 'manual_text_line_structure_0', 'manual_text_line_structure_1', 'manual_text_line_structure_2', 'manual_uppercase_only'}

▷ **GenParamValue** (output_control) . . . . . string(-array) ⇝ *integer* / real / string
Values of Parameters.

Result

If the input parameters are set correctly, the operator `get_text_model_param` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`get_text_object ( : Characters : TextResultID, ResultName : )`

Query an iconic value of a text segmentation result.

`get_text_object` queries the iconic result `ResultName` of `TextResultID` returned by `find_text`. The possible parameter values for `ResultName` differ, depending on the text model used within the text segmentation process of `find_text`.

In the following, first the possible parameter values for text models with `Mode` = *'auto'* are listed, and then those for text models with `Mode` = *'manual'*.

The following results can be queried:

- Result objects for text segmentation with text models with `Mode` = *'auto'*
  For each polarity, the text lines are independently sorted from top to bottom and left to right. The character within the text lines are sorted from left to right.

  'all_lines': Returns all characters in all segmented text lines.

  ['line', LineIndex]: Returns all characters within the text line specified by *LineIndex*. For example, *['line', 0]* returns the first line.

  ['element', Index]: Returns the character at position *Index*. For example, *['element', 0]* returns the first character.
- Result objects for text segmentation with text models with `Mode` = *'manual'*

  'manual_all_lines': Returns all characters in all segmented text lines. The text lines are sorted from top to bottom and left to right. The characters within the text lines are sorted from left to right.

  ['manual_line', Index]: Returns all characters within the text line specified by *Index* (e.g., *['manual_line',0]* to return the first line). The characters within the text line are sorted from left to right.

  If *'manual_persistence'* was activated for the text model used to create `TextResultID`, the following additional value can be queried:

  'manual_compensated_image': the enhanced image used for segmentation.

Parameters

▷ **Characters** (output_object) . . . . . object(-array) ⇝ *object*
Returned result.

▷ **TextResultID** (input_control) . . . . . text_result ⇝ *handle*
Text result.

▷ **ResultName** (input_control) . . . . . string(-array) ⇝ *string* / integer
Name of the result to be returned.
Default: 'all_lines'
List of values: `ResultName` ∈ {'all_lines', 'element', 'line', 'manual_all_lines', 'manual_line', 'manual_compensated_image'}

Example

```
read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)
```

Result

If the parameters are valid, the operator `get_text_object` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`find_text`

`get_text_result`

Module

Foundation

get_text_result (: : TextResultID, ResultName : ResultValue)

Query a control value of a text segmentation result.

`get_text_result` queries the control result `ResultName` of `TextResultID` returned by `find_text`. The possible parameter values for `ResultName` differ, depending on the text model used within the text segmentation process of `find_text`.

In the following, first the possible parameter values for text models with `Mode` = *'auto'* are listed, and then those for text models with `Mode` = *'manual'*.

The following results can be queried:

- **Results for text segmentation with text models with Mode = 'auto'**
  For each polarity, the text lines are independently sorted from top to bottom and left to right. The character within the text lines are sorted from left to right.

  'num_lines': Number of lines found.

  'num_classes': Number of best classes stored for each character. Depending on the number of classes of the used classifier this value might be smaller than the one set in the text model, see `set_text_model_param`.

  'class': Classification results of all segmented characters with the OCR classifier contained in the corresponding text model. Note that if the classifier was trained with rejection class, `get_text_result` returns the second best result for characters that are classified as rejection class.

  ['class', n]: Similar to *'class'*, except that the class with the (n+1)-highest confidence is returned. For example, *['class', 0]* returns for each character the class with the highest confidence. Moreover, in contrast to *'class'*, the rejection class can be returned if the classifier contained in the corresponding text model was trained with rejection class.

['class_line', LineIndex]: Classification results of the characters within the text line specified by *LineIndex* with the OCR classifier contained in the corresponding text model. For example, *['class_line', 0]* returns the character classes within the first text line. Note that if the classifier was trained with rejection class, `get_text_result` returns the second best result for characters that are classified as rejection class.

['class_line', LineIndex, n]: Similar to *['class_line', LineIndex]*, except that the classes with the (n+1)-highest confidences are returned. For example, *['class_line', LineIndex, 0]* returns for each character in the text line specified by *LineIndex* the class with the highest confidence. Moreover, in contrast to *['class_line', LineIndex]*, the rejection class can be returned if the classifier contained in the corresponding text model was trained with rejection class.

['class_element', Index]: Classification result of the character at position *Index* with the OCR classifier contained in the corresponding text model. For example *['class_element', 0]* returns the *'num_classes'* best classes (sorted by confidence) of the first character.

'confidence': Returns the confidences of the classes for all segmented characters, see *'class'*.

['confidence', n]: Returns the confidences of the classes with the (n+1)-highest confidence, see *['class', n]*.

['confidence_line', LineIndex]: Returns the confidences of the classes of all characters within the text line specified by *LineIndex*, see *['class_line', LineIndex]*.

['confidence_line', LineIndex, n]: Returns the confidences of the classes with the (n+1)-highest confidence for all characters within the text line specified by *LineIndex*, see *['class_line', LineIndex, n]*.

['confidence_element', Index]: Returns the confidences corresponding to the classes of the character at position *Index*, see *['class_element', Index]*.

'polarity': Returns the polarity of all segmented characters.

['polarity_line', LineIndex]: Returns the polarity of the characters in the segmented text line specified by *LineIndex*. For example, *['polarity_line', 0]* returns the polarity within the first text line.

['polarity_element', Index]: Returns the polarity of the character at the position *Index*. For example *['polarity_char', 0]* returns the polarity of the first character.

- **Results for text segmentation with text models with Mode = 'manual'**

  'manual_num_lines': Number of lines found.

  If *'manual_persistence'* was activated for the text model used to create `TextResultID`, the following additional value can be queried:

  'manual_thresholds': The thresholds used for segmentation.

Parameters

▷ **`TextResultID`** (input_control) . . . . . text_result ⇝ *handle*
Text result.

▷ **`ResultName`** (input_control) . . . . . string(-array) ⇝ *string* / integer
Name of the result to be returned.
Default: 'class'
List of values: `ResultName` ∈ {'class', 'class_element', 'class_line', 'confidence', 'confidence_element', 'confidence_line', 'polarity', 'polarity_element', 'polarity_line', 'num_classes', 'num_lines', 'manual_num_lines', 'manual_thresholds'}

▷ **`ResultValue`** (output_control) . . . . . string(-array) ⇝ *integer* / real / string
Value of ResultName.

Example

```
read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)
```

Result

If the parameters are valid, the operator `get_text_result` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_text_object

Module

Foundation

segment_characters (Region, Image : ImageForeground, RegionForeground : Method, EliminateLines, DotPrint, StrokeWidth, CharWidth, CharHeight, ThresholdOffset, Contrast : UsedThreshold)

Segments characters in a given region of an image.

This operator is used to segment characters in a given Region of an Image. The Region is only used to reduce the working area. The segmented characters are returned in RegionForeground.

Two different methods to detect the characters are supplied. All segmentation methods assume that the text is darker than the background. If this is not the case, please invert the image with invert_image.

The parameter Method determines the algorithm for text segmentation. The possible values are

'local_contrast_best' This method extracts text that differ locally from the background. Therefore, it is suited for images with inhomogeneous illumination. The enhancement of the text borders, leads to a more accurate determination of the outline of the text. Which is especially useful if the background is highly textured. The parameter Contrast defines the minimum contrast,i.e., the minimum gray value difference between symbols and background.

'local_auto_shape' The minimum contrast is estimated automatically such that the number of very small regions is reduced. This method is especially suitable for noisy images. The parameter ThresholdOffset can be used to adjust the threshold. Let $g(x, y)$ be the gray value at position (x, y) in the input Image. The threshold condition is determined by:

$g(x, y) \leq$ UsedThreshold $+$ ThresholdOffset.

Select EliminateLines if the extraction of characters is disturbed by lines that are horizontal or vertical with respect to the lines of text and set its value to *'true'*. The elimination is influenced by the maximum of CharWidth and the maximum of CharHeight. For further information see the description of these parameters.

DotPrint: Should be set to *'true'* if dot prints should be read, else to *'false'*.

StrokeWidth: Specifies the stroke width of the text. It is used to calculate internally used mask sizes to determine the characters. This mask sizes are also influenced through the parameters DotPrint, the average CharWidth, and the average CharHeight.

CharWidth: This can be a tuple with up to three values. The first value is the average width of a character. The second is the minimum width of a character and the third is the maximum width of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on the average CharWidth. The same is the case if the maximum is not set. Some examples:

[10] sets the average character width to 10, the minimum and maximum are calculated by the operator.

[10,-1,20] sets the average character width to 10, the minimum value is calculated by the system, and the maximum is set to 20.

[10,5,20] sets the average character width to 10, the minimum to 5, and the maximum to 20.

CharHeight: This can be a tuple with up to three values. The first value is the average height of a character. The second is the minimum height of a character and the third is the maximum height of a character. If the minimum is

not set or equal -1, the operator automatically sets these value depending on the average `CharHeight`. The same is the case if the maximum is not set. Some examples:

[10] sets the average character height to 10, the minimum and maximum are calculated by the operator.

[10,-1,20] sets the average character height to 10, the minimum value is calculated by the system, and the maximum is set to 20.

[10,5,20] this sets the average character height to 10, the minimum to 5, and the maximum to 20.

`ThresholdOffset`: This parameter can be used to adjust the threshold, which is used when the segmentation method *'local_auto_shape'* is chosen.

`Contrast`: Defines the minimum contrast between the text and the background. This parameter is used if the segmentation method *'local_contrast_best'* is selected.

`UsedThreshold`: After the execution, this parameter returns the threshold used to segment the characters.

`ImageForeground` returns the image that was internally used for the segmentation.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Area in the image where the text lines are located.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image.

▷ **ImageForeground** (output_object) . . . . . image(-array) ⇝ *object :* byte / uint2
Image used for the segmentation.

▷ **RegionForeground** (output_object) . . . . . singlechannelregion(-array) ⇝ *object*
Region of characters.

▷ **Method** (input_control) . . . . . string ⇝ *string*
Method to segment the characters.
Default: 'local_auto_shape'
List of values: `Method` ∈ {'local_contrast_best', 'local_auto_shape'}

▷ **EliminateLines** (input_control) . . . . . string ⇝ *string*
Eliminate horizontal and vertical lines?
Default: 'false'
List of values: `EliminateLines` ∈ {'true', 'false'}

▷ **DotPrint** (input_control) . . . . . string ⇝ *string*
Should dot print characters be detected?
Default: 'false'
List of values: `DotPrint` ∈ {'true', 'false'}

▷ **StrokeWidth** (input_control) . . . . . string ⇝ *string*
Stroke width of a character.
Default: 'medium'
List of values: `StrokeWidth` ∈ {'ultra_light', 'light', 'medium', 'bold'}

▷ **CharWidth** (input_control) . . . . . integer-array ⇝ *integer*
Width of a character.
Default: 25
Value range: 1 ≤ CharWidth

▷ **CharHeight** (input_control) . . . . . integer-array ⇝ *integer*
Height of a character.
Default: 25
Value range: 1 ≤ CharHeight

▷ **ThresholdOffset** (input_control) . . . . . integer ⇝ *integer*
Value to adjust the segmentation.
Default: 0

▷ **Contrast** (input_control) . . . . . integer ⇝ *integer*
Minimum gray value difference between text and background.
Default: 10

▷ **UsedThreshold** (output_control) . . . . . integer(-array) ⇝ *integer*
Threshold used to segment the characters.

Example

```
for Index := 1 to 5 by 1
  read_image (Image, 'dot_print_rotated/dot_print_rotated_'+Index$'02d')
  text_line_orientation (Image, Image, 50, rad(-30), rad(30), \
                         OrientationAngle)
  rotate_image (Image, ImageRotate, deg(-OrientationAngle), 'constant')
  segment_characters (ImageRotate, ImageRotate, ImageForeground, \
                      RegionForeground, 'local_auto_shape', 'false', \
                      'false', 'medium', 25, 25, 0, 10, UsedThreshold)
endfor
```

Result

If the input parameters are set correctly, the operator `segment_characters` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`text_line_orientation`

Possible Successors

`select_characters`, `connection`

Alternatives

`threshold`

Module

Foundation

`select_characters` (Region : RegionCharacters : DotPrint, StrokeWidth, CharWidth, CharHeight, Punctuation, DiacriticMarks, PartitionMethod, PartitionLines, FragmentDistance, ConnectFragments, ClutterSizeMax, StopAfter :)

Selects characters from a given region.

`select_characters` selects from a given `Region` the areas which might be characters and returns them in `RegionCharacters`. This is done by using features like `StrokeWidth`, `DotPrint`, the size of the characters and some more. The given `Region` should be united, else every `Region` is processed separately. Thus do not call `connection` before calling `select_characters`, because then fragments or dots would not be connected to a character. If you have more than one region with text, you can of course handle them without merging them. The `Region` for `select_characters` typically comes from `segment_characters` but also any other segmentation operators can be used.

The process of the selection can be partitioned into four parts. All steps are influenced by the parameters `StrokeWidth`, `CharHeight`, and `CharWidth`. If you loose small objects like dots, adapt the minimum `CharWidth` and the minimum `CharHeight`. But some parameters affect the result of a certain step in particular. A closer description follows below. With the parameter `StopAfter` you can terminate after a specified step.

In the first step, *'step1_select_candidates'*, `CharWidth` and the `CharHeight` are used to select the candidates. The result of this step is also affected by `ClutterSizeMax`.

In the next step, *'step2_partition_characters'*, the parameter `PartitionMethod` and the parameter `PartitionLines` influence the result.

Step three, *'step3_connect_fragments'*, uses the parameters ConnectFragments and DotPrint. If dot-printed characters have to be detected and some dots are not connected to the character, there are two ways to overcome this problem: You can increase the FragmentDistance and/or decrease the StrokeWidth.

In the last step, *'step4_select_characters'*, the result is affected by the parameters DiacriticMarks and Punctuation.

DotPrint: Should be set to *'true'* if dot prints should be read, else to *'false'*.

StrokeWidth: Specifies the stroke width of the text. It is used to calculate internally used mask sizes to determine the characters. This mask sizes are also influenced through the parameters DotPrint, the average CharWidth, and the average CharHeight.

CharWidth: This can be a tuple with up to three values. The first value is the average width of a character. The second is the minimum width of a character and the third is the maximum width of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on average CharWidth. The same is the case if the maximum is not set. Some examples:

[10] sets the average character width to 10, the minimum and maximum are calculated by the operator.

[10,-1,20] sets the average character width to 10, the minimum value is calculated by the system, and the maximum is set to 20.

[10,5,20] sets the average character width to 10, the minimum to 5, and the maximum to 20.

CharHeight: This can be a tuple with up to three values. The first value is the average height of a character. The second is the minimum height of a character and the third is the maximum height of a character. If the minimum is not set or equal -1, the operator automatically sets these value depending on average CharHeight. The same is the case if the maximum is not set. Some examples:

[10] sets the average character height to 10, the minimum and maximum are calculated by the operator.

[10,-1,20] sets the average character height to 10 the minimum value is calculated by the system and the maximum is set to 20.

[10,5,20] this sets the average character height to 10, the minimum to 5 and the maximum to 20.

Punctuation: Set this parameter to *'true'* if the operator also has to detect punctuation marks (e.g., .,:'‘"), otherwise they will be suppressed.

DiacriticMarks: Set this parameter to *'true'* if the text in your application contains diacritic marks (e.g., â,é,ö), or to *'false'* to suppress them.

PartitionMethod: If neighboring characters are printed close to each other, they may be partly merged. With this parameter you can specify the method to partition such characters. The possible values are *'none'*, which means no partitioning is performed. *'fixed_width'* means that the partitioning assumes a constant character width. If the width of the extracted region is well above the average CharWidth, the region is split into parts that have the given average CharWidth. The partitioning starts at the left border of the region. *'variable_width'* means that the characters are partitioned at the position where they have the thinnest connection. This method can be selected for characters that are printed with a variable-width font or if many consecutive characters are extracted as one symbol. It could be helpful to call text_line_slant and/or use text_line_orientation before calling select_characters.

PartitionLines: If some text lines or some characters of different text lines are connected, set this parameter to *'true'*.

FragmentDistance: This parameter influences the connection of character fragments. If too much is connected, set the parameter to *'narrow'* or *'medium'*. In the case that more fragments should be connected, set the parameter to *'medium'* or *'wide'*. The connection is also influenced by the maximum of CharWidth and CharHeight. See also ConnectFragments.

ConnectFragments: Set this parameter to *'true'* if the extracted symbols are fragmented, i.e., if a symbol is not extracted as one region but broken up into several parts. See also FragmentDistance and StopAfter in the step *'step3_connect_fragments'*.

ClutterSizeMax: If the extracted characters contain clutter, i.e., small regions near the actual symbols, increase this value. If parts of the symbols are missing, decrease this value.

StopAfter: Use this parameter in the case the operator does not produce the desired results. By modifying this value the operator stops after the execution of the selected step and provides the corresponding results. To end on completion, set StopAfter to *'completion'*.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Region of text lines in which to select the characters.

▷ **RegionCharacters** (output_object) . . . . . region(-array) ⇝ *object*
Selected characters.

▷ **DotPrint** (input_control) . . . . . string ⇝ *string*
Should dot print characters be detected?
Default: 'false'
List of values: `DotPrint` ∈ {'true', 'false'}

▷ **StrokeWidth** (input_control) . . . . . string ⇝ *string*
Stroke width of a character.
Default: 'medium'
List of values: `StrokeWidth` ∈ {'ultra_light', 'light', 'medium', 'bold'}

▷ **CharWidth** (input_control) . . . . . integer-array ⇝ *integer*
Width of a character.
Default: 25
Value range: 1 ≤ CharWidth

▷ **CharHeight** (input_control) . . . . . integer-array ⇝ *integer*
Height of a character.
Default: 25
Value range: 1 ≤ CharHeight

▷ **Punctuation** (input_control) . . . . . string ⇝ *string*
Add punctuation?
Default: 'false'
List of values: `Punctuation` ∈ {'true', 'false'}

▷ **DiacriticMarks** (input_control) . . . . . string ⇝ *string*
Exist diacritic marks?
Default: 'false'
List of values: `DiacriticMarks` ∈ {'true', 'false'}

▷ **PartitionMethod** (input_control) . . . . . string ⇝ *string*
Method to partition neighbored characters.
Default: 'none'
List of values: `PartitionMethod` ∈ {'none', 'fixed_width', 'variable_width'}

▷ **PartitionLines** (input_control) . . . . . string ⇝ *string*
Should lines be partitioned?
Default: 'false'
List of values: `PartitionLines` ∈ {'true', 'false'}

▷ **FragmentDistance** (input_control) . . . . . string ⇝ *string*
Distance of fragments.
Default: 'medium'
List of values: `FragmentDistance` ∈ {'narrow', 'medium', 'wide'}

▷ **ConnectFragments** (input_control) . . . . . string ⇝ *string*
Connect fragments?
Default: 'false'
List of values: `ConnectFragments` ∈ {'true', 'false'}

▷ **ClutterSizeMax** (input_control) . . . . . integer ⇝ *integer*
Maximum size of clutter.
Default: 0
Value range: 0 ≤ ClutterSizeMax

▷ **StopAfter** (input_control) . . . . . string ⇝ *string*
Stop execution after this step.
Default: 'completion'
List of values: `StopAfter` ∈ {'step1_select_candidates', 'step2_partition_characters', 'step3_connect_fragments', 'step4_select_characters', 'completion'}

Example

```
for Index := 1 to 5 by 1
  read_image (Image, 'dot_print_rotated/dot_print_rotated_'+Index$'02d')
  text_line_orientation (Image, Image, 50, rad(-30), rad(30), \
                         OrientationAngle)
  rotate_image (Image, ImageRotate, deg(-OrientationAngle), 'constant')
  segment_characters (ImageRotate, ImageRotate, ImageForeground, \
                      RegionForeground, 'local_auto_shape', 'false', \
                      'false', 'medium', 25, 25, 0, 10, UsedThreshold)
  select_characters (RegionForeground, RegionCharacters, 'true', \
                     'ultra_light', [60,1,100], [60,1,100], 'false', \
                     'false', 'none', 'true', 'wide', 'true', 0, 'completion')
endfor
```

Result

If the input parameters are set correctly, the operator `select_characters` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`segment_characters`, `text_line_slant`

Possible Successors

`do_ocr_single_class_mlp`, `do_ocr_multi_class_mlp`

Alternatives

`connection`

Module

Foundation

set_text_model_param (: : TextModel, GenParamName, GenParamValue :)

Set parameters of a text model.

`set_text_model_param` sets parameters of a text model. The list of allowed parameter values for `GenParamName` differs, depending on which `Mode` was set when creating the text model with `create_text_model_reader`. In the following, first the parameter values for text models with `Mode` = *'auto'* are listed, and then those for text models with `Mode` = *'manual'*.

The name and value of a parameter must be given in `GenParamName` and `GenParamValue`. The following values are possible:

- **Parameters of text models with Mode = 'auto'**
  - **Segmentation behavior**

    'min_contrast': The minimal contrast the characters have to their surrounding background.
    Value range: integer or float value between *1* and *255* for byte images and between *1* and *65.535* for uint2 images.
    Default: *15*

    'polarity': *'dark_on_light'* if the text to be segmented is darker than its background, *'light_on_dark'* if the text to be segmented is lighter than its background, and *'both'* if both kinds of text are to be segmented.
    List of values: *'dark_on_light'*, *'light_on_dark'*, *'both'*
    Default: *'both'*

'eliminate_border_blobs': *'true'* if regions that are touching the border of the image domain should be discarded, otherwise *'false'*.
List of values: *'true'*, *'false'*
Default: *'false'*

'add_fragments': *'true'* if fragments, such as the dot on the 'i', should be added to the segmented characters, otherwise *'false'*. Be aware, that this can cause noise to be added to the segmented characters.
List of values: *'true'*, *'false'*
Default: *'true'*

'separate_touching_chars': Controls the handling of pairs or small groups of neighboring characters that are segmented as one single region. When selecting *'standard'* or *'enhanced'*, such regions are detected and separated into two or more single characters. While the *'enhanced'* method yields more accurate results, the *'standard'* method is less complex and thus faster. If *'separate_touching_chars'* is set to *'false'*, no separation of touching characters is performed.
Remark: If *'enhanced'* is selected, the file *find_text_support.hotc* from the ocr subdirectory of the root directory of the HALCON installation is needed. It is also possible to place this file in the current working directory.
List of values: *'false'*, *'standard'*, *'enhanced'*
Default: *'standard'*

– **Character size**

'min_char_height': The minimal height of the characters in pixel. If text of arbitrary height is to be segmented, *'auto'* may be passed. Note that *'min_char_height'* refers to characters only. The height of punctuation marks or separators is not restricted by *'min_char_height'*.
Default: *'auto'*
Restriction: integer or float value greater or equal to *1*.

'max_char_height': The maximal height of the characters in pixel. If text of arbitrary height is to be segmented, *'auto'* may be passed. Note that *'max_char_height'* refers to characters only. The height of punctuation marks or separators is not restricted by *'max_char_height'*.
Default: *'auto'*
Restriction: integer or float value greater or equal to *1*.

'min_char_width': The minimal width of the characters in pixel. If text of arbitrary width is to be segmented, *'auto'* may be passed. Note that *'min_char_width'* refers to characters only. The width of punctuation marks or separators is not restricted by *'min_char_width'*.
Default: *'auto'*
Restriction: integer or float value greater or equal to *1*.

'max_char_width': The maximal width of the characters in pixel. If text of arbitrary width is to be segmented, *'auto'* may be passed. Note that *'max_char_width'* refers to characters only. The width of punctuation marks or separators is not restricted by *'max_char_width'*.
Default: *'auto'*
Restriction: integer or float value greater or equal to *1*.

'min_stroke_width': The minimal stroke width of the characters in pixel. If the minimal stroke width is to be estimated within the text segmentation process automatically, *'auto'* may be passed. Note that *'min_stroke_width'* refers to characters only. The stroke width of punctuation marks or separators is not restricted by *'min_stroke_width'*.
Default: *'auto'*
Restriction: integer or float value greater or equal to *1*.

'max_stroke_width': The maximal stroke width of the characters in pixel. If the maximal stroke width is to be estimated within the text segmentation process automatically, *'auto'* may be passed. Note that *'max_stroke_width'* refers to characters only. The stroke width of punctuation marks or separators is not restricted by *'max_stroke_width'*.
Default: *'auto'*
Restriction: integer or float value greater or equal to *1*.

– **Special characters**

'return_punctuation': *'true'* if small punctuation marks that lie close to the base line of the corresponding text line (e.g., dots or commas) are to be returned. *'false'* if no such punctuations should be returned.
List of values: *'true'*, *'false'*
Default: *'true'*

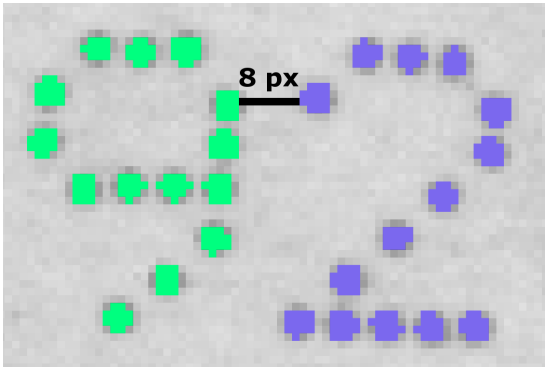
'return_separators': *'true'* if separators such as a minus or the equality sign should be returned as well. *'false'* if no separators should be returned.
List of values: *'true'*, *'false'*
Default: *'true'*

– **Handling of dot prints**

'dot_print': *'true'* if the text to be segmented contains dot printed characters, otherwise *'false'*.
List of values: *'true'*, *'false'*
Default: *'false'*

'dot_print_tight_char_spacing': *'true'* if the gap between adjacent characters is smaller than the largest gap between two dots within a single character, otherwise *'false'*. If *'dot_print'* is set to *'false'* this parameter does not have any effect. In cases where the minimal gap size between characters is exactly known, *'dot_print_min_char_gap'* can be set instead. In this case the value of *'dot_print_tight_char_spacing'* is ignored.
List of values: *'true'*, *'false'*
Default: *'false'*

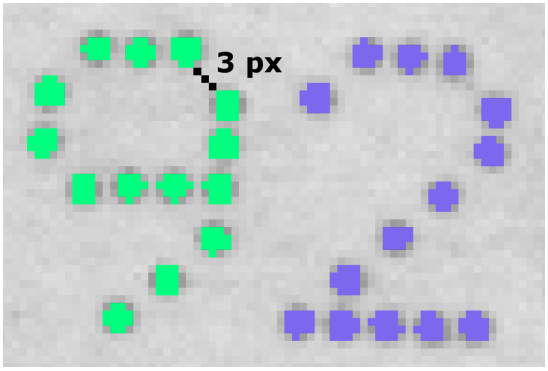
'dot_print_min_char_gap': The minimal gap size between two characters in pixel. This parameter can be used to improve the text result in cases where the minimal gap size between characters is smaller than the maximal gap size between dots within characters. If the minimal character gap size is not known or is bigger than the maximal dot gap size, *'auto'* may be passed. If *'dot_print'* is set to *'false'* this parameter does not have any effect. In cases where the minimal gap size between characters is not known but the characters are printed close to each other, *'dot_print_tight_char_spacing'* might be used instead.



Here, the minimal gap size between characters is 8 pixel.

Default: *'auto'*
Restriction: integer or float value greater or equal to *0*.

'dot_print_max_dot_gap': The maximal gap size between two dots within a character in pixel. If arbitrary dot printed characters are to be segmented, *'auto'* may be passed. If *'dot_print'* is set to *'false'* this parameter does not have any effect. In cases where the maximal dot gap size is larger than or equal to the minimal gap size between characters, *'dot_print_tight_char_spacing'* or *'dot_print_min_char_gap'* should be set accordingly. Setting *'dot_print_max_dot_gap'* can reduce the runtime of `find_text` significantly.



Here, the maximal gap size between dots is 3 pixel.

Default: *'auto'*
Restriction: integer or float value greater or equal to *1*.

– **Line structures**

'text_line_structure': To simplify the search for specific structures (e.g., dates or serial numbers) within the segmented text, it is possible to define text line structures. For each text line the distances between the characters are calculated, and based on these distances, the text line is divided into text blocks. Short characters such as '.', '_' and '-' are ignored in this process and treated as spaces. Furthermore, it is possible to define user specific separators which are also ignored. See the description of *'text_line_separators'* for details. It is then tested if any of the user defined text line structures fit the resulting text blocks.
For example, if the text to be found is a date with two characters for month, day, and year the structure would be '2 2 2'. If the year may consist of two or four characters, the structure would be '2 2 2-4', indicating that the last character block consists of two to four characters. It is possible to provide more than one structure to match by appending an index to the parameter name, e.g., *'text_line_structure_0'*, *'text_line_structure_1'*. If *'text_line_structure'* is set to an empty string *' '*, the text to be found may have any structure.
Please observe, that every text line structure which is found, is saved as a unique text line within the text result. Hence, when calling `get_text_object`, a 'line' then refers to a valid text line structure. If the whole text line containing the text line structure is to be returned instead, it is possible to set *'return_whole_line'* accordingly.
Default: *' '*

'text_line_separators': A string containing the list of characters which are to be ignored in the process of finding text line structures, see *'text_line_structure'* for further details. Please note, user specific separators need to be valid characters within the used OCR classifier. For example, if *':'* and '\' are to be ignored, *':\\'* should be passed. Please observe, that '\' escapes any special symbol to treat it as a literal, and hence '\\' needs to be passed to use '\' as a separator.
Suggested values: *'/'*, *':'*, *':\\'*, *':\\/:'*
Default: *' '*

'return_whole_line': *'false'* if only the segmented text line structures are to be returned as text lines. *'true'* if each whole text line containing a text line structure is to be returned in text lines.
List of values: *'true'*, *'false'*
Default: *'false'*

– **OCR classifier**

'ocr_classifier': The OCR classifier used within `find_text` for text segmentation and classification. An initial classifier is set when the text model is created. See `create_text_model_reader` for more information about the required OCR Classifier.

'num_classes': The number of best classes to be stored for each character (e.g., if *'num_classes'* is set to 2, `find_text` returns the classification results with the highest and second highest confidence). If *'num_classes'* exceeds the number of classes of the classifier stored in the text model, *'num_classes'* is decreased accordingly. The actual number of classes can be queried by `get_text_result`. For classifiers with rejection class, *'num_classes'* should be at least 2 in order to be able to use the second best result if a character is classified as rejection class.
Default: *2*
Restriction: integer or float value greater or equal to *1*.

- **Parameters of text models with Mode = 'manual'**

'manual_char_height': Height of the characters in pixel. Refers to an uppercase character.
Default: *30*

'manual_char_width': Width of the characters in pixel. Refers to an uppercase character.
Default: *20*

'manual_stroke_width': Stroke width of the characters in pixel.
Default: *4.0*

'manual_base_line_tolerance': Maximum base line deviation of the characters (in percent of *'manual_char_height'*).
Default: *0.15*

'manual_polarity': *'dark_on_light'* if the text to be segmented is darker than its background, otherwise *'light_on_dark'*.
Default: *'dark_on_light'*

'manual_uppercase_only': *'true'* if the text to be segmented contains uppercase characters or numbers only, otherwise *'false'*.
Default: *'false'*

'manual_is_dotprint': *'true'* if the text to be segmented is a dotprint, otherwise *'false'*.
Default: *'false'*

'manual_is_imprinted': *'true'* if the text to be segmented suffers of local changes of polarity due to reflections, otherwise *'false'*. **Default:** *'false'*

'manual_eliminate_horizontal_lines': *'true'* if there are longer horizontal structures close to the text to be segmented, otherwise *'false'*. **Default:** *'false'*

'manual_eliminate_border_blobs': *'true'* if regions that are touching the border of the image domain should be discarded, otherwise *'false'*.
Default: *'false'*

'manual_max_line_num': Maximum number of lines to be found. Zero or negative values indicate no limitation. Setting *'manual_max_line_num'* to a low value may strongly improve the runtime of `find_text`.
Default: no limitation

'manual_return_punctuation': *'true'* if punctuation marks (e.g., dots or comma) should be added to the segmented characters.
Default: *'true'*

'manual_return_separators': *'true'* if separators such as a minus or the equality sign should be added to the segmented characters.
Default: *'true'*

'manual_add_fragments': *'true'* if fragments, such as the dot on the 'i', should be added to the segmented characters. Be aware, that this can cause noise to be added to the segmented characters.
Default: *'true'*

'manual_fragment_size_min': minimum area of fragment regions that are added if *'manual_add_fragments'* is set to *'true'*.
Default: *1*

'manual_text_line_structure': specifies the structure of the text to be found to reduce the search space and to avoid false positives. The structure is a string that contains the number of characters for every character block and spaces between these character blocks. For example, if the text to be found is a date with two characters for month, day, and year the structure would be '2 2 2'. If the year may also consist of four characters the structure would be '2 2 2-4', indicating that the last character block consists of two to four characters. It is possible to provide more than one structure to match by appending an index to the parameter name, e.g., *'manual_text_line_structure_0'*, *'manual_text_line_structure_1'*. If *'manual_text_line_structure'* is set to an empty string ' ', the text to be found may have any structure.
Default: ' '

'manual_persistence': *'true'* if selected intermediate results should be kept with the output result of `find_text`.

Parameters

▷ **`TextModel`** (input_control) . . . . . text_model ⇝ *handle*
Text model.

▷ **`GenParamName`** (input_control) . . . . . string(-array) ⇝ *string*
Names of the parameters to be set.
Default: 'min_contrast'
Suggested values: `GenParamName` ∈ {'add_fragments', 'dot_print', 'dot_print_max_dot_gap', 'dot_print_min_char_gap', 'dot_print_tight_char_spacing', 'eliminate_border_blobs', 'max_char_height', 'max_char_width', 'max_stroke_width', 'min_char_height', 'min_char_width', 'min_contrast', 'min_stroke_width', 'num_classes', 'ocr_classifier', 'polarity', 'return_punctuation', 'return_separators', 'return_whole_line', 'separate_touching_chars', 'text_line_separators', 'text_line_structure', 'text_line_structure_0', 'text_line_structure_1', 'text_line_structure_2', 'manual_add_fragments', 'manual_base_line_tolerance', 'manual_char_height', 'manual_char_width', 'manual_eliminate_border_blobs', 'manual_eliminate_horizontal_lines', 'manual_fragment_size_min', 'manual_is_dotprint', 'manual_is_imprinted', 'manual_max_line_num', 'manual_persistence', 'manual_polarity', 'manual_return_punctuation', 'manual_return_separators', 'manual_stroke_width', 'manual_text_line_structure', 'manual_text_line_structure_0', 'manual_text_line_structure_1', 'manual_text_line_structure_2', 'manual_uppercase_only'}

▷ **`GenParamValue`** (input_control) . . . . . string(-array) ⇝ *integer* / real / string
Values of the parameters to be set.
Default: 10
Suggested values: `GenParamValue` ∈ {'true', 'false', 'dark_on_light', 'light_on_dark', 'both', 'auto',

'standard', 'enhanced'}

Example

```
read_image (Image, 'numbers_scale')
create_text_model_reader ('auto', 'Document_Rej.omc', TextModel)
* Optionally specify text properties
set_text_model_param (TextModel, 'min_char_height', 20)
find_text (Image, TextModel, TextResultID)
* Return character regions and corresponding classification results
get_text_object (Characters, TextResultID, 'all_lines')
get_text_result (TextResultID, 'class', Class)
```

Result

If the input parameters are set correctly, the operator `set_text_model_param` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- TextModel

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_text_model_reader`

Possible Successors

`find_text`

`get_text_model_param`

Module

OCR/OCV

text_line_orientation (Region, Image : : CharHeight, OrientationFrom, OrientationTo : OrientationAngle)

Determines the orientation of a text line or paragraph.

`text_line_orientation` determines the orientation of a single text line or a paragraph in relation to the horizontal image axis. If the orientation of a single text line should be determined, the range for the `OrientationFrom` and `OrientationTo` should be in the interval from -pi/4 to pi/4.

The parameter `Region` specifies the area of the image in which the text lines are located. The `Region` is only used to reduce the working area. To determine the slant, the gray values inside that area are used. The text lines are segmented by the operator `text_line_orientation` itself. If more than one region is passed, the numerical values of the orientation angle are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

`CharHeight` specifies the approximately height of the existing text lines in the region `Region`. It's assumed, that the text lines are darker than the background.

The search area can be restricted by the parameters `OrientationFrom` and `OrientationTo`, whereby also the runtime of the operator is influenced.

With the calculated angle OrientationAngle and operators like affine_trans_image, the region Region of the image Image can be rotated such, that the text lines lie horizontally in the image. This may simplify the character segmentation for OCR applications.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Area of text lines.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object* : byte / uint2
  Input image.
- ▷ **CharHeight** (input_control) ..... integer ⇝ *integer*
  Height of the text lines.
  Default: 25
  Value range: 1 ≤ CharHeight
  Restriction: CharHeight >= 1
- ▷ **OrientationFrom** (input_control) ..... angle.rad ⇝ *real*
  Minimum rotation of the text lines.
  Default: -0.523599
  Value range: -3.141593 ≤ OrientationFrom ≤ 3.141593
  Restriction: OrientationFrom <= OrientationTo
- ▷ **OrientationTo** (input_control) ..... angle.rad ⇝ *real*
  Maximum rotation of the text lines.
  Default: 0.523599
  Value range: -3.141593 ≤ OrientationTo ≤ 3.141593
  Restriction: OrientationFrom <= OrientationTo && OrientationTo < OrientationFrom + pi
- ▷ **OrientationAngle** (output_control) ..... angle.rad(-array) ⇝ *real*
  Calculated rotation angle of the text lines.

Example

```
read_image(Image,'letters')
text_line_orientation(Image,Image,50,rad(-80),rad(80),OrientationAngle)
rotate_image(Image,ImageRotate,-OrientationAngle/rad(180)*180,'constant')
```

Result

If the input parameters are set correctly, the operator text_line_orientation returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

rotate_image, affine_trans_image, affine_trans_image_size

Module

Foundation

text_line_slant (Region, Image : : CharHeight, SlantFrom, SlantTo : SlantAngle)

Determines the slant of characters of a text line or paragraph.

text_line_slant determines the slant of a single text line or a paragraph.

The parameter Region specifies the area of the image in which the text lines are located. The Region is only used to reduce the working area. To determine the slant, the gray values inside that area are used. The text lines are segmented by the operator text_line_slant itself. If more than one region is passed, the numerical values of

the orientation angle are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

CharHeight specifies the approximately high of the existing text lines in the region Region. It's assumed, that the text lines are darker than the background.

The search area can be restricted by the parameters SlantFrom and SlantTo, whereby also the runtime of the operator is influenced.

With the calculated slant angle SlantAngle and operators for affine transformations, the slant can be removed from the characters. This may simplify the character separation for OCR applications. To work correctly all characters of a region should have nearly the same slant.

Parameters

- ▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
  Area of text lines.
- ▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image.
- ▷ **CharHeight** (input_control) . . . . . integer ⇝ *integer*
  Height of the text lines.
  Default: 25
  Value range: 1 ≤ CharHeight
- ▷ **SlantFrom** (input_control) . . . . . angle.rad ⇝ *real*
  Minimum slant of the characters
  Default: -0.523599
  Value range: -0.785398 ≤ SlantFrom ≤ 0.785398
  Restriction: SlantFrom <= SlantTo
- ▷ **SlantTo** (input_control) . . . . . angle.rad ⇝ *real*
  Maximum slant of the characters
  Default: 0.523599
  Value range: -0.785398 ≤ SlantTo ≤ 0.785398
  Restriction: SlantFrom <= SlantTo
- ▷ **SlantAngle** (output_control) . . . . . angle.rad(-array) ⇝ *real*
  Calculated slant of the characters in the region

Example

```
hom_mat2d_identity(HomMat2DIdentity)
read_image(Image,'dot_print_slanted')
* correct slant
text_line_slant(Image,Image,50,rad(-45),rad(45),SlantAngle)
hom_mat2d_slant(HomMat2DIdentity,-SlantAngle,'x',0,0,HomMat2DSlant)
affine_trans_image(Image,Image,HomMat2DSlant,'constant','true')
```

Result

If the input parameters are set correctly, the operator text_line_slant returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

hom_mat2d_slant, affine_trans_image, affine_trans_image_size

Module

Foundation

21.7 Support Vector Machines

clear_ocr_class_svm (: : OCRHandle :)

Clear an SVM-based OCR classifier.

clear_ocr_class_svm clears the OCR classifier given by OCRHandle and frees all memory required for the classifier. After calling clear_ocr_class_svm, the classifier can no longer be used. The handle OCRHandle becomes invalid.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_svm(-array) ⇝ *handle*
Handle of the OCR classifier.

Result

If OCRHandle is valid the operator clear_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

OCR/OCV

create_ocr_class_svm (: : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, KernelType, KernelParam, Nu, Mode, Preprocessing, NumComponents : OCRHandle)

Create an OCR classifier using a support vector machine.

create_ocr_class_svm creates an OCR classifier that uses a support vector machine (SVM). The handle of the OCR classifier is returned in OCRHandle.

For a description on how an SVM works, see create_class_svm. create_ocr_class_svm creates an SVM for classification with the classification mode given by Mode. The length of the feature vector of the SVM (NumFeatures in create_class_svm) is determined from the features that are used for the OCR, which are passed in Features. The features are described below. The kernel is parametrized with KernelType, KernelParam and Nu like in create_class_svm. The number of classes of the SVM (NumClasses in create_class_svm) is determined from the names of the characters to be used in the OCR, which are passed in Characters. As described with create_class_svm, the parameters Preprocessing and NumComponents can be used to specify a preprocessing of the data (i.e., the feature vectors). For the sake of numerical stability, Preprocessing can typically be set to *'normalization'*. In order to speed up classification time, *'principal_components'* or *'canonical_variates'* can be used, as the number of input features can be significantly reduced without deterioration of the recognition rate.

The features to be used for the classification are determined by Features. Features can contain a tuple of feature names. Each of these feature names results in one or more features to be calculated for the classifier. Some of the feature names compute gray value features (e.g., *'pixel_invar'*). Because a classifier requires a constant number of features (input variables), a character to be classified is transformed to a standard size, which is determined by WidthCharacter and HeightCharacter. The interpolation to be used for the transformation is determined by Interpolation. It has the same meaning as in affine_trans_image. The interpolation should be chosen such that no aliasing effects occur in the transformation. For most applications, Interpolation = *'constant'* should be used. It should be noted that the size of the transformed character is not chosen too large, because the generalization properties of the classifier may become bad for large sizes. In particular, for large sizes small segmentation errors will have a large influence on the computed features if gray value features are used. This happens because segmentation errors will change the smallest enclosing rectangle of the regions, thus the character is zoomed differently than the characters in the training set. In most applications, sizes between 6×8 and 10×14 should be used.

The parameter Features can contain the following feature names for the classification of the characters.

'default' *'ratio'* and *'pixel_invar'* are selected.

'pixel' Gray values of the character (WidthCharacter × HeightCharacter features).

'pixel_invar' Gray values of the character with maximum scaling of the gray values (WidthCharacter × HeightCharacter features).

'pixel_binary' Region of the character as a binary image zoomed to a size of WidthCharacter × HeightCharacter (WidthCharacter × HeightCharacter features).

'gradient_8dir' Gradients are computed on the character image. The gradient directions are discretized into 8 directions. The amplitude image is decomposed into 8 channels according to these discretized directions. 25 samples on a 5×5 grid are extracted from each channel. These samples are used as features (200 features).

'projection_horizontal' Horizontal projection of the gray values (see gray_projections, HeightCharacter features).

'projection_horizontal_invar' Maximally scaled horizontal projection of the gray values (HeightCharacter features).

'projection_vertical' Vertical projection of the gray values (see gray_projections, WidthCharacter features).

'projection_vertical_invar' Maximally scaled vertical projection of the gray values (WidthCharacter features).

'ratio' Aspect ratio of the character (see height_width_ratio, 1 feature).

'anisometry' Anisometry of the character (see eccentricity, 1 feature).

'width' Width of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).

'height' Height of the character before scaling the character to the standard size (not scale-invariant, see height_width_ratio, 1 feature).

'zoom_factor' Difference in size between the character and the values of WidthCharacter and HeightCharacter (not scale-invariant, 1 feature).

'foreground' Fraction of pixels in the foreground (1 feature).

'foreground_grid_9' Fraction of pixels in the foreground in a 3×3 grid within the smallest enclosing rectangle of the character (9 features).

'foreground_grid_16' Fraction of pixels in the foreground in a 4×4 grid within the smallest enclosing rectangle of the character (16 features).

'compactness' Compactness of the character (see compactness, 1 feature).

'convexity' Convexity of the character (see convexity, 1 feature).

'moments_region_2nd_invar' Normalized 2nd moments of the character (see moments_region_2nd_invar, 3 features).

'moments_region_2nd_rel_invar' Normalized 2nd relative moments of the character (see moments_region_2nd_rel_invar, 2 features).

'moments_region_3rd_invar' Normalized 3rd moments of the character (see moments_region_3rd_invar, 4 features).

'moments_central' Normalized central moments of the character (see `moments_region_central`, 4 features).

'moments_gray_plane' Normalized gray value moments and the angle of the gray value plane (see `moments_gray_plane`, 4 features).

'phi' Orientation (angle) of the character (see `elliptic_axis`, 1 feature).

'num_connect' Number of connected components (see `connect_and_holes`, 1 feature).

'num_holes' Number of holes (see `connect_and_holes`, 1 feature).

'cooc' Values of the binary cooccurrence matrix (see `gen_cooc_matrix`, 12 features).

'num_runs' Number of runs in the region normalized by the height (1 feature).

'chord_histo' Frequency of the runs per row (not scale-invariant, `HeightCharacter` features).

After the classifier has been created, it is trained using `trainf_ocr_class_svm`. After this, the classifier can be saved using `write_ocr_class_svm`. Alternatively, the classifier can be used immediately after training to classify characters using `do_ocr_single_class_svm` or `do_ocr_multi_class_svm`.

A comparison of SVM and the multi-layer perceptron (MLP) (see `create_ocr_class_mlp`) typically shows that SVMs are generally faster at training, especially for huge training sets, and achieve slightly better recognition rates than MLPs. The MLP is faster at classification and should therefore be preferred in time critical applications. Please note that this guideline assumes optimal tuning of the parameters.

Parameters

▷ **`WidthCharacter`** (input_control) . . . integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 8
Suggested values: `WidthCharacter` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: 4 ≤ `WidthCharacter` ≤ 20

▷ **`HeightCharacter`** (input_control) . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 10
Suggested values: `HeightCharacter` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 16, 20}
Value range: 4 ≤ `HeightCharacter` ≤ 20

▷ **`Interpolation`** (input_control) . . . string ⇝ *string*
Interpolation mode for the zooming of the characters.
Default: 'constant'
List of values: `Interpolation` ∈ {'nearest_neighbor', 'bilinear', 'bicubic', 'constant', 'weighted'}

▷ **`Features`** (input_control) . . . string(-array) ⇝ *string*
Features to be used for classification.
Default: 'default'
List of values: `Features` ∈ {'default', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir', 'projection_horizontal', 'projection_horizontal_invar', 'projection_vertical', 'projection_vertical_invar', 'ratio', 'anisometry', 'width', 'height', 'zoom_factor', 'foreground', 'foreground_grid_9', 'foreground_grid_16', 'compactness', 'convexity', 'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'moments_gray_plane', 'phi', 'num_connect', 'num_holes', 'cooc', 'num_runs', 'chord_histo'}

▷ **`Characters`** (input_control) . . . string-array ⇝ *string*
All characters of the character set to be read.
Default: ['0','1','2','3','4','5','6','7','8','9']

▷ **`KernelType`** (input_control) . . . string ⇝ *string*
The kernel type.
Default: 'rbf'
List of values: `KernelType` ∈ {'linear', 'rbf', 'polynomial_inhomogeneous', 'polynomial_homogeneous'}

▷ **`KernelParam`** (input_control) . . . real ⇝ *real*
Additional parameter for the kernel function.
Default: 0.02
Suggested values: `KernelParam` ∈ {0.01, 0.02, 0.05, 0.1, 0.5}

▷ **Nu** (input_control) ..... real ⇝ *real*
Regularization constant of the SVM.
Default: 0.05
Suggested values: Nu ∈ {0.0001, 0.001, 0.01, 0.05, 0.1, 0.2, 0.3}
Restriction: Nu > 0.0 && Nu < 1.0

▷ **Mode** (input_control) ..... string ⇝ *string*
The mode of the SVM.
Default: 'one-versus-one'
List of values: Mode ∈ {'one-versus-all', 'one-versus-one'}

▷ **Preprocessing** (input_control) ..... string ⇝ *string*
Type of preprocessing used to transform the feature vectors.
Default: 'normalization'
List of values: Preprocessing ∈ {'none', 'normalization', 'principal_components', 'canonical_variates'}

▷ **NumComponents** (input_control) ..... integer ⇝ *integer*
Preprocessing parameter: Number of transformed features (ignored for Preprocessing = *'none'* and Preprocessing = *'normalization'*).
Default: 10
Suggested values: NumComponents ∈ {1, 2, 3, 4, 5, 8, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Restriction: NumComponents >= 1

▷ **OCRHandle** (output_control) ..... ocr_svm ⇝ *handle*
Handle of the OCR classifier.

Example

```
read_image (Image, 'letters')
* Segment the image.
binary_threshold(Image,&Region, 'otsu', 'dark', &UsedThreshold);
dilation_circle (Region, RegionDilation, 3.5)
connection (RegionDilation, ConnectedRegions)
intersection (ConnectedRegions, Region, RegionIntersection)
sort_region (RegionIntersection, Characters, 'character', 'true', 'row')
* Generate the training file.
count_obj (Characters, Number)
Classes := []
for J := 0 to 25 by 1
    Classes := [Classes,gen_tuple_const(20,chr(ord('a')+J))]
endfor
Classes := [Classes,gen_tuple_const(20,'.')]
write_ocr_trainf (Characters, Image, Classes, 'letters.trf')
* Generate and train the classifier.
read_ocr_trainf_names ('letters.trf', CharacterNames, CharacterCount)
create_ocr_class_svm (8, 10, 'constant', 'default', CharacterNames, \
                      'rbf', 0.01, 0.01, 'one-versus-all', \
                      'principal_components', 10, OCRHandle)
trainf_ocr_class_svm (OCRHandle, 'letters.trf', 0.001, 'default')
* Re-classify the characters in the image.
do_ocr_multi_class_svm (Characters, Image, OCRHandle, Class)
```

Result

If the parameters are valid the operator create_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

trainf_ocr_class_svm

deserialize_ocr_class_svm (: : SerializedItemHandle : OCRHandle)

Deserialize a serialized SVM-based OCR classifier.

deserialize_ocr_class_svm deserializes a SVM-based OCR classifier, that was serialized by serialize_ocr_class_svm (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized OCR classifier is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created OCR classifier with the handle OCRHandle.

Parameters

- ▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
  Handle of the serialized item.
- ▷ **OCRHandle** (output_control) ..... ocr_svm ⇝ *handle*
  Handle of the OCR classifier.

Result

If the parameters are valid, the operator deserialize_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

OCR/OCV

do_ocr_multi_class_svm (Character, Image : : OCRHandle : Class)

Classify multiple characters with an SVM-based OCR classifier.

do_ocr_multi_class_svm computes the best class for each of the characters given by the regions Character and the gray values Image with the SVM-based OCR classifier OCRHandle and returns the classes in Class. In contrast to do_ocr_single_class_svm, do_ocr_multi_class_svm can classify multiple characters in one call, and therefore typically is faster than a loop that uses do_ocr_single_class_svm

to classify single characters. However, do_ocr_multi_class_svm can only return the best class of each character. Before calling do_ocr_multi_class_svm, the classifier must be trained with trainf_ocr_class_svm.

Parameters

- ▷ **Character** (input_object) ..... region(-array) ⇝ *object*
  Characters to be recognized.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object* : byte / uint2
  Gray values of the characters.
- ▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **Class** (output_control) ..... string(-array) ⇝ *string*
  Result of classifying the characters with the SVM.

Result

If the parameters are valid the operator do_ocr_multi_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

create_ocr_class_svm, classify_class_svm

Module

OCR/OCV

do_ocr_single_class_svm (Character, Image : : OCRHandle, Num : Class)

Classify a single character with an SVM-based OCR classifier.

do_ocr_single_class_svm computes the best Num classes of the character given by the region Character and the gray values Image with the OCR classifier OCRHandle and returns the classes in Class. Because multiple classes may be returned by do_ocr_single_class_svm, Character may only contain a single region (a single character). If multiple characters should be classified in a single call, do_ocr_multi_class_svm must be used. Before calling do_ocr_single_class_svm, the classifier must be trained with trainf_ocr_class_svm.

Parameters

- ▷ **Character** (input_object) ..... region ⇝ *object*
  Character to be recognized.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object* : byte / uint2
  Gray values of the character.
- ▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **Num** (input_control) ..... integer-array ⇝ *integer*
  Number of best classes to determine.
  Default: 1
  Suggested values: Num ∈ {1, 2, 3, 4, 5}

▷ **Class** (output_control) . . . . . string(-array) ⇝ *string*
Result of classifying the character with the SVM.

Result

If the parameters are valid the operator do_ocr_single_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_ocr_class_svm, classify_class_svm

Module

OCR/OCV

do_ocr_word_svm (Character, Image : : OCRHandle, Expression, NumAlternatives, NumCorrections : Class, Word, Score)

Classify a related group of characters with an OCR classifier.

do_ocr_word_svm works like do_ocr_multi_class_svm insofar as it computes the best class for each of the characters given by the regions Character and the gray values Image with the OCR classifier OCRHandle, and returns the results in Class.

In contrast to do_ocr_multi_class_svm, do_ocr_word_svm treats the group of characters as an entity which yields a Word by concatenating the class names for each character region. This allows to restrict the allowed classification results on a textual level by specifying an Expression describing the expected word.

The Expression may restrict the word to belong to a predefined lexicon created using create_lexicon or import_lexicon, by specifying the name of the lexicon in angular brackets as in *'<mylexicon>'*. If the Expression is of any other form, it is interpreted as a regular expression with the same syntax as specified for tuple_regexp_match. Note that you will usually want to use an expression of the form '^...$' when using variable quantifiers like '*', to ensure that the entire word is used in the expression. Also note that in contrast to tuple_regexp_match, do_ocr_word_svm does **not** support passing extra options in an expression tuple.

If the word derived from the best class for each character does not match the Expression, do_ocr_word_svm attempts to correct it by considering the NumAlternatives best classes for each character. The alternatives used are identical to those returned by do_ocr_single_class_svm for a single character. It does so by testing all possible corrections for which the classification result is changed for at most NumCorrections character regions. Note that NumAlternatives and NumCorrections affect the complexity of the algorithm, so that in some cases internal restrictions are made. See the section 'Complexity' below for further information.

In case the Expression is a lexicon and the above procedure did not yield a result, the most similar word in the lexicon is returned as long as it requires less than NumCorrections edit operations for the correction (see suggest_lexicon).

The resulting word is graded by a Score between 0.0 (no correction found) and 1.0 (original word correct). The Score is lowered by adding a penalty according to the number of corrected characters and another (minor) penalty depending on how many better classes have been ignored in order to match the Expression:

$$\mathtt{Score} = 1.0 - \mathtt{PenaltyCorrections} - \mathtt{PenaltyAlternatives}$$

$$\begin{aligned} \mathtt{PenaltyCorrections} &= \alpha * \mathtt{num\_corr} \\ \mathtt{PenaltyAlternatives} &= \alpha * \beta * \mathtt{num\_alt} \end{aligned}$$

with num_corr being the actual number of applied corrections and num_alt the total number of discarded alternatives.

$$\alpha = \frac{1}{\texttt{NumCorrections} + 1}$$
$$\beta = \frac{1}{\texttt{NumCorrections} * (\texttt{NumAlternatives} - 1) + 2}$$

Parameters

▷ **Character** (input_object) . . . . . region(-array) ⇝ *object*
Characters to be recognized.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Gray values of the characters.

▷ **OCRHandle** (input_control) . . . . . ocr_svm ⇝ *handle*
Handle of the OCR classifier.

▷ **Expression** (input_control) . . . . . string ⇝ *string*
Expression describing the allowed word structure.

▷ **NumAlternatives** (input_control) . . . . . integer ⇝ *integer*
Number of classes per character considered for the internal word correction.
Default: 3
Suggested values: NumAlternatives ∈ {3, 4, 5}
Value range: 1 ≤ NumAlternatives

▷ **NumCorrections** (input_control) . . . . . integer ⇝ *integer*
Maximum number of corrected characters.
Default: 2
Suggested values: NumCorrections ∈ {1, 2, 3, 4, 5}
Value range: 0 ≤ NumCorrections

▷ **Class** (output_control) . . . . . string(-array) ⇝ *string*
Result of classifying the characters with the SVM.
Number of elements: Class == Character

▷ **Word** (output_control) . . . . . string ⇝ *string*
Word text after classification and correction.

▷ **Score** (output_control) . . . . . real ⇝ *real*
Measure of similarity between corrected word and uncorrected classification results.

Complexity

The complexity of checking all possible corrections is of magnitude $O((n * a)^{min(c,n)})$, where a is the number of alternatives, n is the number of character regions, and c is the number of allowed corrections. However, to guard against a near-infinite loop in case of large n, c is internally clipped to 5, 3, or 1 if $a * n >= 30$, 60, or 90, respectively.

Result

If the parameters are valid, the operator do_ocr_word_svm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_ocr_class_svm, classify_class_svm

Module

OCR/OCV

get_features_ocr_class_svm (Character : : OCRHandle, Transform : Features)

Compute the features of a character.

get_features_ocr_class_svm computes the features of the character given by Character with the OCR classifier OCRHandle and returns them in Features. In contrast to do_ocr_single_class_svm and do_ocr_multi_class_svm, the character is passed as a single image object. Hence, before calling get_features_ocr_class_svm, reduce_domain must typically be called. The parameter Transform determines whether the feature transformation specified with Preprocessing in create_ocr_class_svm for the classifier should be applied (Transform = *'true'*) or whether the untransformed features should be returned (Transform = *'false'*). get_features_ocr_class_svm can be used to inspect the features that are used for the classification.

Parameters

- ▷ **Character** (input_object) ..... singlechannelimage ⇝ *object* : byte / uint2
  Input character.
- ▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **Transform** (input_control) ..... string ⇝ *string*
  Should the feature vector be transformed with the preprocessing?
  Default: 'true'
  List of values: Transform ∈ {'true', 'false'}
- ▷ **Features** (output_control) ..... real-array ⇝ *real*
  Feature vector of the character.

Result

If the parameters are valid the operator get_features_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_ocr_class_svm

Module

OCR/OCV

get_params_ocr_class_svm (: : OCRHandle : WidthCharacter, HeightCharacter, Interpolation, Features, Characters, KernelType, KernelParam, Nu, Mode, Preprocessing, NumComponents)

Return the parameters of an OCR classifier.

get_params_ocr_class_svm returns the parameters of an OCR classifier that were specified when the classifier was created with create_ocr_class_svm. This is particularly useful if the classifier was read with read_ocr_class_svm. The output of get_params_ocr_class_svm can, for example, be used to check whether a character to be read is contained in the classifier. For a description of the parameters, see create_ocr_class_svm.

Parameters

- ▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **WidthCharacter** (output_control) ..... integer ⇝ *integer*
  Width of the rectangle to which the gray values of the segmented character are zoomed.
- ▷ **HeightCharacter** (output_control) ..... integer ⇝ *integer*
  Height of the rectangle to which the gray values of the segmented character are zoomed.
- ▷ **Interpolation** (output_control) ..... string ⇝ *string*
  Interpolation mode for the zooming of the characters.
- ▷ **Features** (output_control) ..... string(-array) ⇝ *string*
  Features to be used for classification.
- ▷ **Characters** (output_control) ..... string-array ⇝ *string*
  Characters of the character set to be read.
- ▷ **KernelType** (output_control) ..... string ⇝ *string*
  The kernel type.
- ▷ **KernelParam** (output_control) ..... real ⇝ *real*
  Additional parameters for the kernel function.
- ▷ **Nu** (output_control) ..... real ⇝ *real*
  Regularization constant of the SVM.
- ▷ **Mode** (output_control) ..... string ⇝ *string*
  The mode of the SVM.
- ▷ **Preprocessing** (output_control) ..... string ⇝ *string*
  Type of preprocessing used to transform the feature vectors.
- ▷ **NumComponents** (output_control) ..... integer ⇝ *integer*
  Preprocessing parameter: Number of transformed features (ignored for `Preprocessing` = *'none'* and `Preprocessing` = *'normalization'*).

Result

If the parameters are valid the operator `get_params_ocr_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

get_prep_info_ocr_class_svm (: : OCRHandle, TrainingFile, Preprocessing : InformationCont, CumInformationCont)

Compute the information content of the preprocessed feature vectors of an SVM-based OCR classifier.

`get_prep_info_ocr_class_svm` computes the information content of the training vectors that have been transformed with the preprocessing given by `Preprocessing`. `Preprocessing` can be set to *'principal_components'* or *'canonical_variates'*. The OCR classifier `OCRHandle` must have been created with `create_ocr_class_svm`. The preprocessing methods are described with `create_class_svm`.

The information content is derived from the variations of the transformed components of the feature vector, i.e., it is computed solely based on the training data, independent of any error rate on the training data. The information content is computed for all relevant components of the transformed feature vectors (NumFeatures for *'principal_components'* and $\min(\texttt{NumClasses} - 1, \texttt{NumFeatures})$ for *'canonical_variates'*, see create_class_svm), and is returned in InformationCont as a number between 0 and 1. To convert the information content into a percentage, it simply needs to be multiplied by 100. The cumulative information content of the first n components is returned in the n-th component of CumInformationCont, i.e., CumInformationCont contains the sums of the first n elements of InformationCont. To use get_prep_info_ocr_class_svm, a sufficient number of samples must be stored in the training files given by TrainingFile (see write_ocr_trainf).

InformationCont and CumInformationCont can be used to decide how many components of the transformed feature vectors contain relevant information. An often used criterion is to require that the transformed data must represent x% (e.g., 90%) of the total data. This can be decided easily from the first value of CumInformationCont that lies above x%. The number thus obtained can be used as the value for NumComponents in a new call to create_ocr_class_svm. The call to get_prep_info_ocr_class_svm already requires the creation of a classifier, and hence the setting of NumComponents in create_ocr_class_svm to an initial value. However, if get_prep_info_ocr_class_svm is called it is typically not known how many components are relevant, and hence how to set NumComponents in this call. Therefore, the following two-step approach should typically be used to select NumComponents: In a first step, a classifier with the maximum number for NumComponents is created (NumFeatures for *'principal_components'* and $\min(\texttt{NumClasses}-1, \texttt{NumFeatures})$ for *'canonical_variates'*). Then, the training samples are saved in a training file using write_ocr_trainf. Subsequently, get_prep_info_ocr_class_svm is used to determine the information content of the components, and with this NumComponents. After this, a new classifier with the desired number of components is created, and the classifier is trained with trainf_ocr_class_svm.

Parameters

- ▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
  Handle of the OCR classifier.
- ▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
  Names of the training files.
  Default: 'ocr.trf'
  File extension: .trf, .otr
- ▷ **Preprocessing** (input_control) ..... string ⇝ *string*
  Type of preprocessing used to transform the feature vectors.
  Default: 'principal_components'
  List of values: Preprocessing ∈ {'principal_components', 'canonical_variates'}
- ▷ **InformationCont** (output_control) ..... real-array ⇝ *real*
  Relative information content of the transformed feature vectors.
- ▷ **CumInformationCont** (output_control) ..... real-array ⇝ *real*
  Cumulative information content of the transformed feature vectors.

Example

```
* Create the initial OCR classifier.
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_svm (8, 10, 'constant', 'default', CharacterNames, \
                      'rbf', 0.01, 0.01, 'one-versus-one', \
                      'principal_components', 81, OCRHandle)
* Get the information content of the transformed feature vectors.
get_prep_info_ocr_class_svm (OCRHandle, 'ocr.trf', 'principal_components', \
                             InformationCont, CumInformationCont)
* Determine the number of transformed components.
* NumComp = [...]
* Create the final OCR classifier.
create_ocr_class_svm (8, 10, 'constant', 'default', CharacterNames, \
                      'rbf', 0.01, 0.01,'one-versus-one', \
                      'principal_components', NumComp, OCRHandle)
* Train the final classifier.
```

```
trainf_ocr_class_svm (OCRHandle, 'ocr.trf', 0.001, 'default')
write_ocr_class_svm (OCRHandle, 'ocr.osc')
```

Result

If the parameters are valid the operator `get_prep_info_ocr_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

`get_prep_info_ocr_class_svm` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

OCR/OCV

get_support_vector_num_ocr_class_svm

```
get_support_vector_num_ocr_class_svm ( : : OCRHandle : NumSupportVectors, NumSVPerSVM )
```

Return the number of support vectors of an OCR classifier.

`get_support_vector_num_ocr_class_svm` returns in `NumSupportVectors` the number of support vectors that are stored in the support vector machine (SVM) given by `OCRHandle`. `get_support_vector_num_ocr_class_svm` should be called before the labels of individual support vectors are read out with `get_support_vector_ocr_class_svm`, e.g., for visualizing which of the training data become a SV (see `get_support_vector_ocr_class_svm`). The number of SVs in each classifier is listed in `NumSVPerSVM`. The reason that its sum differs from the number obtained in `NumSupportVectors` is that SV evaluations are reused throughout different binary sub-SVMs.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
OCR handle.

▷ **NumSupportVectors** (output_control) ..... integer ⇝ *integer*
Total number of support vectors.

▷ **NumSVPerSVM** (output_control) ..... integer-array ⇝ *integer*
Number of SV of each sub-SVM.

Result

If the parameters are valid the operator `get_sample_num_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_ocr_class_svm

Module

OCR/OCV

get_support_vector_ocr_class_svm (: : OCRHandle, IndexSupportVector : Index)

Return the index of a support vector from a trained OCR classifier that is based on support vector machines.

The operator get_support_vector_ocr_class_svm maps support vectors of a trained SVM-based OCR classifier (given in OCRHandle) to the original training data set. The index of the SV is specified with IndexSupportVector. The index is counted from 0, i.e., IndexSupportVector must be a number between 0 and NumSupportVectors − 1, where NumSupportVectors can be determined with get_support_vector_num_ocr_class_svm. The index of this SV in the training data is returned in Index. get_support_vector_ocr_class_svm can, for example, be used to visualize the support vectors. To do so, the train file that has been used to train the SVM must be read with read_ocr_trainf. The value returned in Index must be incremented by *1* and can then be used to select the support vectors with select_obj from the training characters. If more than one train file has been used in trainf_ocr_class_svm Index behaves as if all train files had been merged into one train file with concat_ocr_trainf.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
OCR handle.

▷ **IndexSupportVector** (input_control) ..... integer-array ⇝ *integer*
Number of stored support vectors.

▷ **Index** (output_control) ..... real ⇝ *real*
Index of the support vector in the training set.

Result

If the parameters are valid the operator get_support_vector_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

read_ocr_class_svm (: : FileName : OCRHandle)

Read a SVM-based OCR classifier from a file.

read_ocr_class_svm reads an OCR classifier that has been stored with write_ocr_class_svm. Since the training of an OCR classifier can consume a relatively long time, the classifier is typically trained in an offline process and written to a file with write_ocr_class_svm. In the online process the classifier is read

with read_ocr_class_svm and subsequently used for classification with do_ocr_single_class_svm or do_ocr_multi_class_svm.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
File extension: .osc, .fnt

▷ **OCRHandle** (output_control) . . . . . ocr_svm ⇝ *handle*
Handle of the OCR classifier.

Result

If the parameters are valid the operator read_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

Module

OCR/OCV

reduce_ocr_class_svm (: : OCRHandle, Method, MinRemainingSV, MaxError : OCRHandleReduced)

Approximate a trained SVM-based OCR classifier by a reduced SVM.

reduce_ocr_class_svm reduces the classification time of an SVM based OCR classifier OCRHandle by returning a reduced copy of it in OCRHandleReduced. The parameters Method, MinRemainingSV and MaxError have the same meaning as in reduce_class_svm and are described there. Please note that classification time can also be significantly reduced with a preprocessing step in create_ocr_class_svm, which possibly introduces less errors.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_svm ⇝ *handle*
Original handle of SVM-based OCR-classifier.

▷ **Method** (input_control) . . . . . string ⇝ *string*
Type of postprocessing to reduce number of SVs.
Default: 'bottom_up'
List of values: Method ∈ {'bottom_up'}

▷ **MinRemainingSV** (input_control) . . . . . integer ⇝ *integer*
Minimum number of remaining SVs.
Default: 2
Suggested values: MinRemainingSV ∈ {2, 3, 4, 5, 7, 10, 15, 20, 30, 50}
Restriction: MinRemainingSV >= 2

▷ **MaxError** (input_control) . . . . . real ⇝ *real*
Maximum allowed error of reduction.
Default: 0.001
Suggested values: MaxError ∈ {0.0001, 0.0002, 0.0005, 0.001, 0.002, 0.005, 0.01, 0.02, 0.05}
Restriction: MaxError > 0.0

▷ **OCRHandleReduced** (output_control) . . . . . ocr_svm ⇝ *handle*
SVMHandle of reduced OCR classifier.

Result

If the parameters are valid the operator reduce_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

select_feature_set_trainf_svm (: : TrainingFile, FeatureList, SelectionMethod, Width, Height, GenParamName, GenParamValue : OCRHandle, FeatureSet, Score)

Selects an optimal combination of features to classify OCR data.

select_feature_set_trainf_svm selects an optimal combination of features, to classify the data given in the training file TrainingFile with a Support Vector Machine (SVM), for details see create_ocr_class_svm.

Possible features are all OCR features listed and explained in create_ocr_class_svm. All candidates which should be tested can be specified in FeatureList. A subset of these features is returned as selected features in FeatureSet.

select_feature_set_trainf_svm is specialized on OCR problems and only supports the features in the list mentioned before. In order to use other features, please use the more general operator select_feature_set_svm.

The selection method SelectionMethod is either a greedy search *'greedy'* (iteratively add the feature with highest gain) or the dynamically oscillating search *'greedy_oscillating'* (add the feature with highest gain and test then if any of the already added features can be left out without great loss). The method *'greedy'* is generally preferable, since it is faster. Only in cases when a large training set is available the method *'greedy_oscillating'* might return better results.

The optimization criterion is the classification rate of a two-fold cross-validation of the training data. The best achieved value is returned in Score.

The parameters *'nu'* and *'gamma'* for the SVM that is used to classify can be set to *'auto'* by using the parameters GenParamName and GenParamValue. If they are set to *'auto'*, the estimated optimal *'nu'* and/or *'gamma'* is estimated. The automatic estimation of *'nu'* and *'gamma'* can take a substantial amount of time (up to days, depending on the data set and the number of features). Alternatively, a certain value for both can be set the same way. An explanation of the parameters *'nu'* and *'gamma'* as the kernel parameter of the radial basis function (RBF) kernel can be found in create_class_svm.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator `select_feature_set_trainf_svm` may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ **`TrainingFile`** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: ”
File extension: `.trf`, `.otr`

▷ **`FeatureList`** (input_control) . . . . . string(-array) ⇝ *string*
List of features that should be considered for selection.
Default: [’zoom_factor’,’ratio’,’width’,’height’,’foreground’,’foreground_grid_9’,’foreground_grid_16’, ’anisometry’,’compactness’,’convexity’,’moments_region_2nd_invar’,’moments_region_2nd_rel_invar’, ’moments_region_3rd_invar’,’moments_central’,’phi’,’num_connect’,’num_holes’,’projection_horizontal’, ’projection_vertical’,’projection_horizontal_invar’,’projection_vertical_invar’,’chord_histo’,’num_runs’, ’pixel’,’pixel_invar’,’pixel_binary’,’gradient_8dir’,’cooc’,’moments_gray_plane’]
List of values: `FeatureList` ∈ {’default’, ’zoom_factor’, ’ratio’, ’width’, ’height’, ’foreground’, ’foreground_grid_9’, ’foreground_grid_16’, ’anisometry’, ’compactness’, ’convexity’, ’moments_region_2nd_invar’, ’moments_region_2nd_rel_invar’, ’moments_region_3rd_invar’, ’moments_central’, ’phi’, ’num_connect’, ’num_holes’, ’projection_horizontal’, ’projection_vertical’, ’projection_horizontal_invar’, ’projection_vertical_invar’, ’chord_histo’, ’num_runs’, ’pixel’, ’pixel_invar’, ’pixel_binary’, ’gradient_8dir’, ’cooc’, ’moments_gray_plane’}

▷ **`SelectionMethod`** (input_control) . . . . . string ⇝ *string*
Method to perform the selection.
Default: ’greedy’
List of values: `SelectionMethod` ∈ {’greedy’, ’greedy_oscillating’}

▷ **`Width`** (input_control) . . . . . integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 15

▷ **`Height`** (input_control) . . . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 16

▷ **`GenParamName`** (input_control) . . . . . string-array ⇝ *string*
Names of generic parameters to configure the selection process and the classifier.
Default: []
List of values: `GenParamName` ∈ {’nu’, ’gamma’}

▷ **`GenParamValue`** (input_control) . . . . . number-array ⇝ *real* / integer / string
Values of generic parameters to configure the selection process and the classifier.
Default: []
Suggested values: `GenParamValue` ∈ {’auto’, ’0.1’, ’0.3’}

▷ **`OCRHandle`** (output_control) . . . . . ocr_svm ⇝ *handle*
Trained OCR-SVM Classifier.

▷ **`FeatureSet`** (output_control) . . . . . string-array ⇝ *string*
Selected feature set, contains only entries from `FeatureList`.

▷ **`Score`** (output_control) . . . . . real-array ⇝ *real*
Achieved score using tow-fold cross-validation.

Result

If the parameters are valid, the operator `select_feature_set_trainf_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

select_feature_set_trainf_svm_protected, select_feature_set_svm

Module

OCR/OCV

select_feature_set_trainf_svm_protected (: : TrainingFile, Password, FeatureList, SelectionMethod, Width, Height, GenParamName, GenParamValue : OCRHandle, FeatureSet, Score)

Select an optimal combination of features to classify OCR data from a (protected) training file.

select_feature_set_trainf_svm_protected selects an optimal combination of features to classify the data given in the training files TrainingFile with a support vector machine (SVM). Its functionality corresponds to the functionality of select_feature_set_trainf_svm, with the addition that select_feature_set_trainf_svm_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator's functionality see select_feature_set_trainf_svm. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Attention

This operator may take considerable time, depending on the size of the data set in the training file, and the number of features.

Please note, that this operator should not be called, if only a small set of training data is available. Due to the risk of overfitting the operator select_feature_set_trainf_svm_protected may deliver a classifier with a very high score. However, the classifier may perform poorly when tested.

Parameters

▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the training files.
Default: ''
File extension: .trf, .otr

▷ **Password** (input_control) ..... string(-array) ⇝ *string*
Passwords for protected training files.

▷ **FeatureList** (input_control) ..... string(-array) ⇝ *string*
List of features that should be considered for selection.
Default: ['zoom_factor','ratio','width','height','foreground','foreground_grid_9','foreground_grid_16', 'anisometry','compactness','convexity','moments_region_2nd_invar','moments_region_2nd_rel_invar', 'moments_region_3rd_invar','moments_central','phi','num_connect','num_holes','projection_horizontal', 'projection_vertical','projection_horizontal_invar','projection_vertical_invar','chord_histo','num_runs', 'pixel','pixel_invar','pixel_binary','gradient_8dir','cooc','moments_gray_plane']
List of values: FeatureList ∈ {'default', 'zoom_factor', 'ratio', 'width', 'height', 'foreground', 'foreground_grid_9', 'foreground_grid_16', 'anisometry', 'compactness', 'convexity', 'moments_region_2nd_invar', 'moments_region_2nd_rel_invar', 'moments_region_3rd_invar', 'moments_central', 'phi', 'num_connect', 'num_holes', 'projection_horizontal', 'projection_vertical', 'projection_horizontal_invar', 'projection_vertical_invar', 'chord_histo', 'num_runs', 'pixel', 'pixel_invar', 'pixel_binary', 'gradient_8dir', 'cooc', 'moments_gray_plane'}

▷ **SelectionMethod** (input_control) ..... string ⇝ *string*
Method to perform the selection.
Default: 'greedy'
List of values: SelectionMethod ∈ {'greedy', 'greedy_oscillating'}

▷ **Width** (input_control) . . . . . integer ⇝ *integer*
Width of the rectangle to which the gray values of the segmented character are zoomed.
Default: 15

▷ **Height** (input_control) . . . . . integer ⇝ *integer*
Height of the rectangle to which the gray values of the segmented character are zoomed.
Default: 16

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of generic parameters to configure the selection process and the classifier.
Default: []
List of values: GenParamName ∈ {'nu', 'gamma'}

▷ **GenParamValue** (input_control) . . . . . number-array ⇝ *real* / integer / string
Values of generic parameters to configure the selection process and the classifier.
Default: []
Suggested values: GenParamValue ∈ {'auto', '0.1', '0.3'}

▷ **OCRHandle** (output_control) . . . . . ocr_svm ⇝ *handle*
Trained OCR-SVM Classifier.

▷ **FeatureSet** (output_control) . . . . . string-array ⇝ *string*
Selected feature set, contains only entries from FeatureList.

▷ **Score** (output_control) . . . . . real-array ⇝ *real*
Achieved score using tow-fold cross-validation.

Result

If the parameters are valid, the operator select_feature_set_trainf_svm_protected returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

See also

select_feature_set_trainf_svm, select_feature_set_svm

Module

OCR/OCV

serialize_ocr_class_svm (: : OCRHandle : SerializedItemHandle)

Serialize a SVM-based OCR classifier

serialize_ocr_class_svm serializes a SVM-based OCR classifier (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_ocr_class_svm is converted to a serialized item. The OCR classifier is defined by the handle OCRHandle. The serialized OCR classifier is returned by the handle SerializedItemHandle and can be deserialized by deserialize_ocr_class_svm.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_svm ⇝ *handle*
Handle of the OCR classifier.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_ocr_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

trainf_ocr_class_svm (: : OCRHandle, TrainingFile, Epsilon, TrainMode :)

Train an OCR classifier.

`trainf_ocr_class_svm` trains the OCR classifier `OCRHandle` with the training characters stored in the OCR training files given by `TrainingFile`. The training files must have been created, e.g., using `write_ocr_trainf`, before calling `trainf_ocr_class_svm`. The parameters `Epsilon` and `TrainMode` have the same meaning as in `train_class_svm`. Please, note that training characters that have no corresponding class in the classifier `OCRHandle` are discarded.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_svm ⇝ *handle*
Handle of the OCR classifier.

▷ **TrainingFile** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: 'ocr.trf'
File extension: `.trf`, `.otr`

▷ **Epsilon** (input_control) . . . . . real ⇝ *real*
Stop parameter for training.
Default: 0.001
Suggested values: `Epsilon` ∈ {0.00001, 0.0001, 0.001, 0.01, 0.1}

▷ **TrainMode** (input_control) . . . . . number ⇝ *string* / integer
Mode of training.
Default: 'default'
List of values: `TrainMode` ∈ {'default', 'add_sv_to_train_set'}

Example

```
* Train an OCR classifier
```

```
read_ocr_trainf_names ('ocr.trf', CharacterNames, CharacterCount)
create_ocr_class_svm (8, 10, 'constant', 'default', CharacterNames, \
                      'rbf', 0.01, 0.01, 'one-versus-one', \
                      'normalization', 81, OCRHandle)
trainf_ocr_class_svm (OCRHandle, 'ocr.trf', 0.001, 'default')
write_ocr_class_svm (OCRHandle, 'ocr.osc')
```

Result

If the parameters are valid the operator `trainf_ocr_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

`trainf_ocr_class_svm` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change `Preprocessing` to *'normalization'*. Another solution can be to add more training samples.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

OCR/OCV

trainf_ocr_class_svm_protected (: : OCRHandle, TrainingFile, Password, Epsilon, TrainMode :)

Train an OCR classifier with data from a (protected) training file.

`trainf_ocr_class_svm_protected` trains the OCR classifier `OCRHandle` with the training data stored in the OCR training files given by `TrainingFile`. Its functionality corresponds to the functionality of `trainf_ocr_class_svm`, with the addition that `trainf_ocr_class_svm_protected` can process unprotected and protected training files. Protected training files can be used only with the correct user password `Password`. If the number of passwords `Password` equals 1, then every input file `TrainingFile` is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator's functionality see `trainf_ocr_class_svm`. The concept of protecting OCR training data in HALCON is described in `protect_ocr_trainf`.

Parameters

▷ **OCRHandle** (input_control) . . . . . ocr_svm ⇝ *handle*
Handle of the OCR classifier.

▷ **TrainingFile** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: 'ocr.trf'
File extension: `.trf`, `.otr`

▷ **Password** (input_control) . . . . . string(-array) ⇝ *string*
Passwords for protected training files.

▷ **Epsilon** (input_control) . . . . . real ⇝ *real*
Stop parameter for training.
Default: 0.001
Suggested values: `Epsilon` ∈ {0.00001, 0.0001, 0.001, 0.01, 0.1}

▷ **TrainMode** (input_control) . . . . . number ⇝ *string* / integer
Mode of training.
Default: 'default'
List of values: `TrainMode` ∈ {'default', 'add_sv_to_train_set'}

Result

If the parameters are valid the operator `trainf_ocr_class_svm_protected` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

`trainf_ocr_class_svm_protected` may return the error 9211 (Matrix is not positive definite) if `Preprocessing` = *'canonical_variates'* is used. This typically indicates that not enough training samples have been stored for each class. In this case we recommend to change `Preprocessing` to *'normalization'*. Another solution can be to add more training samples.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- OCRHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

OCR/OCV

write_ocr_class_svm (: : OCRHandle, FileName :)

Write an OCR classifier to a file.

`write_ocr_class_svm` writes the OCR classifier `OCRHandle` to the file given by `FileName`. If a file extension is not specified in `FileName`, the default extension `'.osc'` is appended to

FileName. write_ocr_class_svm is typically called after the classifier has been trained with trainf_ocr_class_svm. The classifier can be read with read_ocr_class_svm.

Parameters

▷ **OCRHandle** (input_control) ..... ocr_svm ⇝ *handle*
Handle of the OCR classifier.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
File name.
File extension: .osc

Result

If the parameters are valid the operator write_ocr_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

21.8 Training Files

append_ocr_trainf (Character, Image : : Class, TrainingFile :)

Add characters to a training file.

The operator append_ocr_trainf serves to prepare the training with the operator trainf_ocr_class_mlp or trainf_ocr_class_svm. Hereby regions, representing characters, including their gray values (region and pixel) and the corresponding class name will be written into a file. An arbitrary number of regions within one image is supported. For each character (region) in Character the corresponding class name must be specified in Class. The gray values are passed via the parameter Image. In contrast to the operator write_ocr_trainf the characters are appended to an existing file using the same training file format as this file. If the file does not exist, a new file is generated. In this case, the file format can be chosen by the parameter *'ocr_trainf_version'* of the operator set_system. If no file extension is specified in TrainingFile, the extension '.trf' is appended to the name.

Parameters

▷ **Character** (input_object) ..... region(-array) ⇝ *object*
Characters to be trained.

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
Gray values of the characters.

▷ **Class** (input_control) ..... string(-array) ⇝ *string*
Class (name) of the characters.

▷ **TrainingFile** (input_control) ..... filename.write ⇝ *string*
Name of the training file.
Default: 'train_ocr'
File extension: .trf, .otr

Example

```
char       name[128];
char       class[128];

read_image(&Image,"character.tiff");
binary_threshold(Image,&Dark, 'otsu', 'dark', &UsedThreshold);
connection(Dark,&Character);
count_obj(Character,&num);
create_tuple(&Class,num);
open_window(0,0,-1,-1,0,"","",&WindowHandle);
set_color(WindowHandle,"red");
for (i=0; i<num; i++) {
  select_obj(Character,&SingleCharacter,i);
  disp_region(SingleCharacter,WindowHandle);
  printf("class of character %d ?\n",i);
  scanf("%s\n",class);
  append_ocr_trainf(Character,Image,name,class);
}
```

Result

If the parameters are correct, the operator `append_ocr_trainf` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

`concat_ocr_trainf ( : : SingleFiles, ComposedFile : )`

Concat training files.

The operator `concat_ocr_trainf` stores all characters which are contained in the files `SingleFiles` into a new file with the name `ComposedFile`. The file format can be defined by the parameter *'ocr_trainf_version'* of the operator `set_system`. If no file extension is specified in `ComposedFile`, the extension '.trf' is appended to the file name. It is not possible to use any of the files in `SingleFiles` as the new file `ComposedFile`.

Parameters

▷ **`SingleFiles`** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the single training files.
Default: ''
File extension: `.trf`, `.otr`

▷ **`ComposedFile`** (input_control) ..... filename.write ⇝ *string*
Name of the composed training file.
Default: 'all_characters'
File extension: `.trf`

Result

If the parameters are correct, the operator `concat_ocr_trainf` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`protect_ocr_trainf` (: : `TrainingFile`, `Password`, `TrainingFileProtected` :)

Protection of training data.

Obtaining training data for an OCR classifier can be a complicated and time consuming activity. Thus, training data is valuable and there might be the necessity to protect its usage. The general idea is to prevent protected OCR training data from being reviewed or modified in any way and to ensure that its usage, e.g., training an OCR classifier, is restricted by a user password.

The approach in HALCON is to obtain OCR training data in the usual way, then write it to an unprotected OCR training file using, e.g., `write_ocr_trainf`, and afterwards create a new file containing the OCR training data protected with a user password. Protected training files can be used with a set of special operators that also require the correct password in order to be able to process the data, e.g., for training an OCR classifier.

It is important to keep in mind that data in a protected OCR training file cannot be reviewed or modified in any way, thus it is important to keep the original, unprotected, training data files.

Protected OCR training data can be used for training of multilayer perceptron (MLP) classifiers and support vector machine (SVM) classifiers.

`protect_ocr_trainf` protects the OCR training data contained in the file `TrainingFile` and writes it to the protected training data file `TrainingFileProtected`. The protection is done with the user password `Password`. The same password has to be used afterwards in order to use the protected OCR training data, e.g., by the operators `trainf_ocr_class_mlp_protected` or `read_ocr_trainf_names_protected`. Empty passwords (or passwords containing the empty string) are not allowed. If the number of passwords `Password` equals 1, then every output file `TrainingFileProtected` is protected with that password, otherwise the number of passwords has to be equal to the number of input and output files and the output file at position n is protected with the password at position n.

Parameters

▷ **`TrainingFile`** (input_control) ..... filename.read ⇝ *string*
Names of the training files.
Default: ”
File extension: `.trf`, `.otr`

▷ **`Password`** (input_control) ..... string(-array) ⇝ *string*
Passwords for protecting the training files.

▷ **`TrainingFileProtected`** (input_control) ..... filename.write ⇝ *string*
Names of the protected training files.
File extension: `.trf`

Result

If the parameters are correct, the operator `protect_ocr_trainf` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

OCR/OCV

read_ocr_trainf (: Characters : TrainingFile : CharacterNames)

Read training characters from files and convert to images.

read_ocr_trainf reads all characters from the specified file names and converts them into images. The default HALCON file extension for the OCR training file is 'trf'. The domain is defined according to the foreground of the characters (as specified in write_ocr_trainf). The names of the characters are returned in CharacterNames. If more than one file name is given the files are processed in the order of the file names.

Parameters

▷ **Characters** (output_object) ..... image-array ⇝ *object :* byte / uint2
Images read from file.

▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the training files.
Default: ''
File extension: .trf, .otr

▷ **CharacterNames** (output_control) ..... string-array ⇝ *string*
Names of the read characters.

Result

If the parameter values are correct the operator read_ocr_trainf returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_ocr_trainf_names (: : TrainingFile : CharacterNames, CharacterCount)

Query which characters are stored in a training file.

read_ocr_trainf_names extracts the names and frequency of all characters in the specified training files.

Parameters

▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the training files.
Default: ”
File extension: .trf, .otr

▷ **CharacterNames** (output_control) ..... string(-array) ⇝ *string*
Names of the read characters.

▷ **CharacterCount** (output_control) ..... integer(-array) ⇝ *integer*
Number of characters.

Result

If the parameter values are correct the operator read_ocr_trainf_names returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_ocr_trainf_names_protected (: : TrainingFile, Password : CharacterNames, CharacterCount)

Query which characters are stored in a (protected) training file.

read_ocr_trainf_names_protected extracts the names and frequency of all characters in the specified training files. Its functionality corresponds to the functionality of read_ocr_trainf_names, with the addition that read_ocr_trainf_names_protected can process unprotected and protected training files. Protected training files can be used only with the correct user password Password. If the number of passwords Password equals 1, then every input file TrainingFile is checked with that password, otherwise the number of passwords has to be equal to the number of input files and the input file at position n is checked with the password at position n. For unprotected training files the passwords are ignored.

For a more detailed description of the operator’s functionality see read_ocr_trainf_names. The concept of protecting OCR training data in HALCON is described in protect_ocr_trainf.

Parameters

▷ **TrainingFile** (input_control) ..... filename.read(-array) ⇝ *string*
Names of the training files.
Default: ”
File extension: .trf, .otr

▷ **Password** (input_control) ..... string(-array) ⇝ *string*
Passwords for protected training files.

▷ **CharacterNames** (output_control) ..... string(-array) ⇝ *string*
Names of the read characters.

▷ **CharacterCount** (output_control) . . . . . integer(-array) ⇝ *integer*
Number of characters.

Result

If the parameter values are correct the operator `read_ocr_trainf_names_protected` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

read_ocr_trainf_select (: Characters : TrainingFile, SearchNames : FoundNames)

Read training specific characters from files and convert to images.

`read_ocr_trainf_select` reads the characters given in `SearchNames` from the specified files and converts them into images. It works similar to `read_ocr_trainf` but here the characters which are extracted can be specified.

Parameters

▷ **Characters** (output_object) . . . . . image-array ⇝ *object :* byte / uint2
Images read from file.

▷ **TrainingFile** (input_control) . . . . . filename.read(-array) ⇝ *string*
Names of the training files.
Default: ”
File extension: `.trf`, `.otr`

▷ **SearchNames** (input_control) . . . . . string(-array) ⇝ *string*
Names of the characters to be extracted.
Default: ’0’

▷ **FoundNames** (output_control) . . . . . string(-array) ⇝ *string*
Names of the read characters.

Result

If the parameter values are correct the operator `read_ocr_trainf_select` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_ocr_trainf (Character, Image : : Class, TrainingFile :)

Storing of training characters into a file.

The operator write_ocr_trainf serves to prepare the training with the operator trainf_ocr_class_mlp or trainf_ocr_class_svm. Hereby regions, representing characters, including their gray values (region and pixel) and the corresponding class name will be written into a file. An arbitrary number of regions within one image is supported. For each character (region) in Character the corresponding class name must be specified in Class. The gray values are passed via the parameter Image. If no file extension is specified in TrainingFile the extension '.trf' is appended to the file name. The version of the file format used for writing data can be defined by the parameter *'ocr_trainf_version'* of the operator set_system.

Parameters

- ▷ **Character** (input_object) ..... region(-array) ⇝ *object*
  Characters to be trained.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
  Gray values of the characters.
- ▷ **Class** (input_control) ..... string(-array) ⇝ *string*
  Class (name) of the characters.
- ▷ **TrainingFile** (input_control) ..... filename.write ⇝ *string*
  Name of the training file.
  Default: 'train_ocr'
  File extension: .trf

Result

If the parameters are correct, the operator write_ocr_trainf returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

write_ocr_trainf_image (Character : : Class, TrainingFile :)

Write characters into a training file.

The operator write_ocr_trainf_image is used to prepare the training with the operator trainf_ocr_class_mlp or trainf_ocr_class_svm. Hereby regions, representing characters, including their gray values (region and pixel) and the corresponding class name will be written into a file. An arbitrary number of regions within one image is supported. For each character (region) in Character the corresponding class name must be specified in Class. If no file extension is specified in TrainingFile the extension '.trf' is appended to the file name. In contrast to write_ocr_trainf one image per character is passed. The domain of this image defines the pixels which belong to the character. The file format can be defined by the parameter *'ocr_trainf_version'* of the operator set_system.

Parameters

▷ **Character** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2
Characters to be trained.

▷ **Class** (input_control) . . . . . string(-array) ⇝ *string*
Class (name) of the characters.

▷ **TrainingFile** (input_control) . . . . . filename.write ⇝ *string*
Name of the training file.
Default: 'train_ocr'
File extension: `.trf`

Result

If the parameters are correct, the operator `write_ocr_trainf_image` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

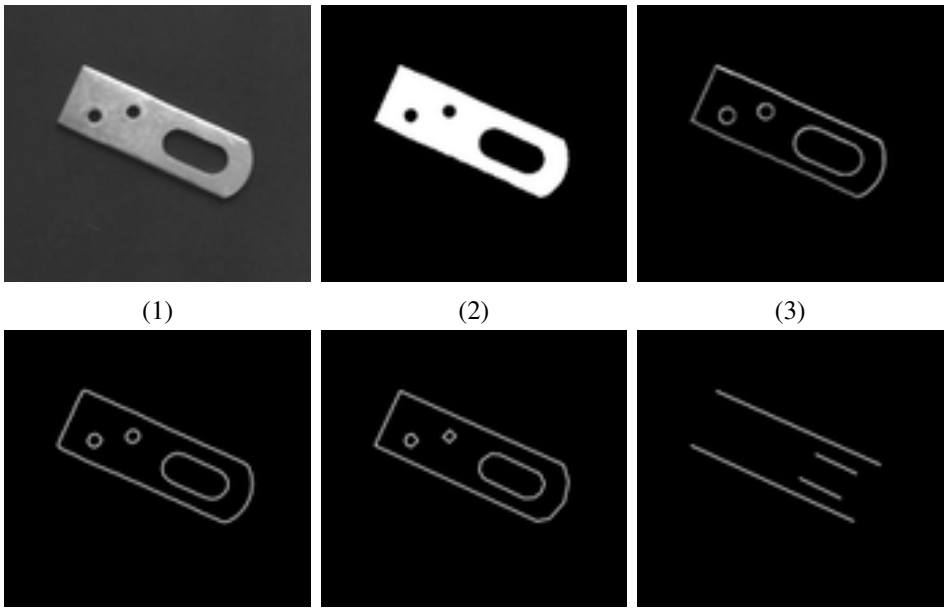
Chapter 22

Object

This chapter contains operators that can be used to either query information related to iconic objects or to manipulate iconic objects.

Available Iconic Objects

HALCON provides different kinds of iconic objects that are suitable for different needs:



(1) (2) (3)

(4) (5) (6)

Within the image of a metal part (1) a region (2), an ROI that is created using the dilated boundary of the region (3), contours (4), polygons (5), and parallels (6) are extracted.

Images: An image consists of one to multiple channels, i.e., matrices of similar size that contain gray values of various pixel types. Images are the major source for most machine vision tasks.

Regions: A region is defined as a set of pixels. The pixels of a region do not need to be connected. This means that even an arbitrary collection of pixels can be handled as a single region. Region processing is suitable, e.g., to apply a blob analysis within images or to define a region of interest (ROI) for following subpixel-precise operations.

XLDs: XLD is the abbreviation for eXtended Line Description and comprises all contour and polygon based data. Note that XLD contours are returned or used by many HALCON operators whereas XLD polygons and XLD parallels are needed only in special cases. A contour is a sequence of subpixel-accurate 2D control points that are connected by lines. Typically, the distance between control points is about one pixel. XLD objects contain, besides the control points, so-called local and global attributes. Typical examples for these

are, e.g., the edge amplitude of a control point or the regression parameters of a contour segment. Contour processing is suitable, e.g., for subpixel-precise measurements. Subpixel-precise operations can be faster if they are applied within an ROI.

Further Information

See the "Quick Guide" for further details about the available data structures.

22.1 Information

compare_obj (Objects1, Objects2 : : Epsilon : IsEqual)

Compare iconic objects regarding equality.

The operator compare_obj compares iconic objects regarding equality. The iconic objects are passed in the two input parameters Objects1 and Objects2 in form of (possibly mixed) tuples of images, regions, or XLDs. The n-th object in Objects1 is compared to the n-th object in Objects2 (for all n). If the two passed object tuples have the same length and if all objects are equal, the parameter IsEqual is set to 1, otherwise to 0.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Depending on the type of the input objects, different conditions must be met for the equality of two objects. In the following, the conditions for each possible iconic object are listed:

Images: For all channels, the gray values of the respective pixels must not differ by more than Epsilon. Note that images are only compared within their domain (ROI) and they are only equal if they have the same domain (ROI).

Regions: The regions must be equal. The parameter Epsilon has no effect for the comparison of regions.

XLD contours: XLD contours must have the same number of points and attributes. The point coordinates and the attribute values must not differ by more than Epsilon.

XLD polygons: XLD polygons must have the same number of line segments. The length and the orientation of these segments as well as the coordinates of the control points must not differ by more than Epsilon.

XLD parallels and extended XLD parallels: XLD parallels must have an identical index of the start and end line segment of the parallels of the first polygon (P1) and the second polygon (P2) as well as identical pointers to the underlying contours.

Modified XLD parallels: For modified XLD parallels, the same conditions apply as for XLD parallels and extended XLD parallels. Furthermore, the distances between the line segments of the parallel polygons must be identical.

Note that compare_obj compares all objects regarding their actual content. In contrast test_equal_obj compares only regions regarding their actual content while for all other objects their location in memory is compared.

Parameters

▷ **Objects1** (input_object) ..... object(-array) ⇝ *object*
Reference objects.

▷ **Objects2** (input_object) ..... object(-array) ⇝ *object*
Test objects.

▷ **Epsilon** (input_control) ..... number ⇝ *real* / integer
Maximum allowed difference between two gray values or coordinates etc.
Default: 0.0
Suggested values: Epsilon ∈ {0.0, 1.e-5}

▷ **IsEqual** (output_control) ..... integer ⇝ *integer*
Boolean result value.

Result

The operator compare_obj returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input objects available) is set via the operator set_system(::'no_object_result',<Result>:). If the number of objects differs an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

count_obj (Objects : : : Number)

Number of objects in a tuple.

The operator `count_obj` determines for the object parameter `Objects` the number of objects it contains. In this connection it should be noted that object is not the same as connection component (see `connection`). For example, the number of objects of one region consisting of three parts that are not connected is 1.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **Objects** (input_object) ..... object-array ⇝ *object*
Objects to be examined.

▷ **Number** (output_control) ..... integer ⇝ *integer*
Number of objects in the tuple `Objects`.

Complexity

Runtime complexity: $O(|\texttt{Objects}|)$.

Result

`count_obj` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`copy_obj`, `obj_to_integer`, `connection`, `set_system`

Module

Foundation

get_channel_info (Object : : Request, Channel : Information)

Information about the components of an image object.

The operator `get_channel_info` gives information about the components of an image object. The following requests (`Request`) are currently possible:

'creator' Output of the names of the procedures which initially created the image components (not the object).

'type' Output of the type of image component (`byte`, `int1`, `int2`, `uint2` `int4`, `real`, `direction`, `cyclic`, `complex`, `vector_field`). The component 0 is of type 'region' or 'xld'.

In the tuple Channel the numbers of the components about which information is required are stated. After carrying out get_channel_info, Information contains a tuple of strings (one string per entry in Channel) with the required information.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **Object** (input_object) . . . . . object ⇝ *object*
Image object to be examined.

▷ **Request** (input_control) . . . . . string ⇝ *string*
Required information about object components.
Default: 'creator'
List of values: Request ∈ {'creator', 'type'}

▷ **Channel** (input_control) . . . . . channel(-array) ⇝ *integer*
Components to be examined (0 for region/XLD).
Default: 0
Suggested values: Channel ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8}

▷ **Information** (output_control) . . . . . string(-array) ⇝ *string*
Requested information.

Result

If the parameters are correct the operator get_channel_info returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_image

See also

count_relation

Module

Foundation

get_obj_class (Object : : : Class)

Name of the class of an image object.

get_obj_class returns the name of the corresponding class to each object. The following classes are possible:

'image' Object with region (definition domain) and at least one channel.

'region' Object with a region without gray values.

'xld_cont' XLD object as contour

'xld_poly' XLD object as polygon

'xld_parallel' XLD object with parallel polygons

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **Object** (input_object) ..... object(-array) ⇝ *object*
Image objects to be examined.
▷ **Class** (output_control) ..... string(-array) ⇝ *string*
Name of class.

Result

If the parameter values are correct the operator `get_obj_class` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`disp_image`, `disp_region`, `disp_xld`

See also

`get_channel_info`, `count_relation`

Module

Foundation

test_equal_obj (Objects1, Objects2 : : : IsEqual)

Compare image objects regarding equality.

The operator `test_equal_obj` compares the regions and gray value components of all objects of the two input parameters. The n-th object in `Objects1` is compared to the n-th object in `Objects2` (for all n). If all corresponding regions are equal and the number of regions is also identical the parameter `IsEqual` is set to TRUE, otherwise FALSE.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

Image matrices and XLDs are not compared regarding their contents. Thus, two images or XLDs, respectively, are “equal” if they are located at the same place in the storage. By contrast, regions that are not located at the same place in the storage are compared regarding their actual contents. If the input parameters are empty and the behavior was set via the operator `set_system(::'no_object_result','true':)`, the parameter `IsEqual` is set to TRUE, since all input (= empty set) is equal.

Parameters

▷ **Objects1** (input_object) ..... object-array ⇝ *object*
Test objects.
▷ **Objects2** (input_object) ..... object-array ⇝ *object*
Comparative objects.
▷ **IsEqual** (output_control) ..... integer ⇝ *integer*
Boolean result value.

Complexity

If F is the area of a region the runtime complexity is $O(1)$ or $O(sqrt(F))$ if the result is TRUE and $O(sqrt(F))$ if the result is FALSE.

Result

The operator `test_equal_obj` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. The behavior in case of empty input (no input objects available) is set via the operator `set_system(::'no_object_result',<Result>:)`. If the number of objects differs an exception is raised. Else `test_equal_obj` returns `2` (`H_MSG_TRUE`)

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

compare_obj, test_equal_region

Module

Foundation

22.2 Manipulation

clear_obj (Objects : : :)

Delete an iconic object from the HALCON database.

clear_obj deletes iconic objects, which are no longer needed, from the HALCON database. It should be noted that clear_obj is the only way to delete objects from the database, and hence to reclaim their memory, in HALCON/C. In all other HALCON language interfaces, clear_obj **must not** be used because objects are destroyed automatically through appropriate destructors.

Images and regions are normally used by several iconic objects at the same time (uses less memory!). This has the consequence that a region or an image is only deleted if all objects using it have been deleted.

The operator reset_obj_db can be used to reset the system and clear all remaining iconic objects.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

Regarding the use of local variables in HALCON/C: When exiting a subroutine, the local variables are deleted, but the HALCON database is not updated. To update the database and thus free the memory, you must explicitly clear the local objects from the database before exiting the subroutine.

Parameters

▷ **Objects** (input_object) ..... object(-array) ⇝ *object*
Objects to be deleted.

Result

clear_obj returns 2 (H_MSG_TRUE) if all objects are contained in the HALCON database. If not all objects are valid (e.g., already cleared), an exception is raised, which also clears all valid objects. The operator set_check ('~clear') can be used to suppress the raising of this exception. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

reset_obj_db

See also

set_check

Module

none

concat_obj (Objects1, Objects2 : ObjectsConcat : :)

Concatenate two iconic object tuples.

concat_obj concatenates the two tuples of iconic objects Objects1 and Objects2 into a new tuple of iconic objects ObjectsConcat. Hence, this tuple contains all the iconic objects of the two input tuples:

ObjectsConcat = [Objects1,Objects2]

In ObjectsConcat, the objects of Objects1 are stored first, followed by the objects of Objects2, i.e., the order of the objects is preserved. Note that only references to the corresponding images and regions are stored in ObjectsConcat, i.e., no new memory is allocated. Furthermore, this means that modifications of input images, e.g., with set_grayval, overpaint_gray, or overpaint_region directly affect the images of the output tuple ObjectsConcat and vice versa.

concat_obj should not be confused with union1 or union2, in which regions are merged, i.e., in which the number of objects is modified.

concat_obj can be used to concatenate objects of different image object types (e.g., images and XLD contours) into a single object. This is only recommended if it is necessary to accumulate in a single object variable, for example, the results of an image processing sequence. It should be noted that the only operators that can handle such object tuples of mixed type are concat_obj, copy_obj, select_obj, and disp_obj.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

- ▷ **Objects1** (input_object) ..... object(-array) ⇝ *object*
  Object tuple 1.
- ▷ **Objects2** (input_object) ..... object(-array) ⇝ *object*
  Object tuple 2.
- ▷ **ObjectsConcat** (output_object) ..... object-array ⇝ *object*
  Concatenated objects.

Example

```
/* generate a tuple of a circle and a rectangle */

gen_circle(&Circle,200.0,400.0,23.0);
gen_rectangle1(&Rectangle,23.0,44.0,203.0,201.0);
concat_obj(Circle,Rectangle,&CircleAndRectangle);
disp_region(CircleAndRectangle,WindowHandle);
```

Complexity

Runtime complexity: $O(|\text{Objects1}| + |\text{Objects2}|)$;

Memory complexity of the result objects: $O(|\text{Objects1}| + |\text{Objects2}|)$

Result

concat_obj returns 2 (H_MSG_TRUE) if all objects are contained in the HALCON database. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

count_obj, copy_obj, select_obj, disp_obj

Module

Foundation

copy_obj (Objects : ObjectsSelected : Index, NumObj :)

Copy an iconic object in the HALCON database.

copy_obj copies NumObj iconic objects beginning with index Index (starting with 1) from the iconic input object tuple Objects to the output object ObjectsSelected. If -1 is passed for NumObj all objects beginning with Index are copied. No new storage is allocated for the regions and images. Instead, new objects containing references to the existing objects are created. The number of objects in an object tuple can be queried with the operator count_obj.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **Objects** (input_object) ..... object(-array) ⇝ *object*
Objects to be copied.

▷ **ObjectsSelected** (output_object) ..... object(-array) ⇝ *object*
Copied objects.

▷ **Index** (input_control) ..... integer ⇝ *integer*
Starting index of the objects to be copied.
Default: 1
Suggested values: Index ∈ {1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500, 1000, 2000, 5000}
Value range: 1 ≤ Index
Restriction: Index <= number(Objects)

▷ **NumObj** (input_control) ..... integer ⇝ *integer*
Number of objects to be copied or -1.
Default: 1
Suggested values: NumObj ∈ {-1, 1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500, 1000, 2000, 5000}
Value range: -1 ≤ NumObj
Restriction: NumObj + Index - 1 <= number(Objects) && NumObj != 0

Example

```
gen_circle (Circles, [100,200,400], [200,100,400], [100,100,50])
copy_obj (Circles, CircleCopy, 2, 3)
erosion_circle (CircleCopy, CircleErosion, 15.5)
dev_set_color ('red')
dev_set_draw ('fill')
dev_display(Circles)
dev_set_color ('white')
dev_set_draw ('margin')
dev_display (CircleCopy)
dev_set_color ('green')
dev_display (CircleErosion)
```

Complexity

Runtime complexity: $O(|\text{Objects}| + \text{NumObj})$;

Memory complexity of the result object: $O(\text{NumObj})$

Result

copy_obj returns 2 (H_MSG_TRUE) if all objects are contained in the HALCON database and all parameters are correct. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

count_obj

Alternatives

select_obj

See also

count_obj, concat_obj, obj_to_integer, copy_image

Module

Foundation

gen_empty_obj (: EmptyObject : :)

Create an empty object tuple.

The operator gen_empty_obj creates an empty tuple. This means that the output parameter does not contain any objects. Thus, the operator count_obj returns 0. However, clear_obj can be called for the output. It should be noted that no objects must not be confused with an empty region. In case of an empty region, i.e. a region with 0 pixels count_obj returns the value 1.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **EmptyObject** (output_object) ..... object ⇝ *object*
No objects.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

insert_obj (Objects, ObjectsInsert : ObjectsExtended : Index :)

Insert objects into an iconic object tuple.

insert_obj inserts the elements of ObjectsInsert at Index into the object tuple Objects and returns the result in ObjectsExtended.

Index must contain a single integer value. Note that, in contrast to control tuples, indices of object tuple elements start at 1. The length of ObjectsExtended is the sum of the length of Objects and ObjectsInsert. It is allowed to mix images, regions and XLDs in Objects and ObjectsInsert.

Parameters

▷ **Objects** (input_object) ..... object(-array) ⇝ *object*
Input object tuple.

▷ **ObjectsInsert** (input_object) ..... object(-array) ⇝ *object*
Object tuple to insert.

▷ **ObjectsExtended** (output_object) ..... object(-array) ⇝ *object*
Extended object tuple.

▷ **Index** (input_control) ..... number ⇝ *integer*
Index to insert objects.

Example

```
gen_image_const (Image1, 'byte', 1, 1)
gen_image_const (Image3, 'byte', 3, 3)
concat_obj (Image1, Image3, Images)
gen_image_const (Image, 'byte', 2, 2)
insert_obj (Images, Image, Images, 2)
```

Complexity

Typical runtime complexity: $O(|\texttt{Objects}| + |\texttt{ObjectsInsert}|)$.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

count_obj, select_obj, copy_obj, remove_obj

Module

Foundation

integer_to_obj (: Objects : SurrogateTuple :)

Convert an "integer number" into an iconic object.

integer_to_obj is the inverse operator to obj_to_integer. All surrogates of objects passed in SurrogateTuple are stored as objects. In contrast to obj_to_integer, the objects are duplicated. integer_to_obj is intended especially for use in HALCON/C, because iconic objects and control parameters are treated differently in C. Please note that if you pass the value *0* in SurrogateTuple, the program will crash because *0* is no valid pointer.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

The objects are duplicated in the database.

Parameters

▷ **Objects** (output_object) ..... object(-array) ⇝ *object*
Created objects.

▷ **SurrogateTuple** (input_control) ..... pointer(-array) ⇝ *integer*
Tuple of object surrogates.

Result

integer_to_obj returns 2 (H_MSG_TRUE) if all parameters are correct, i.e., if they are valid object keys. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

obj_to_integer

Module

Foundation

obj_diff (Objects, ObjectsSub : ObjectsDiff : :)

Calculate the difference of two object tuples.

obj_diff calculates the set-theoretic difference of two object tuples:

(objects in Objects) − (objects in ObjectsSub)

The resulting object tuple ObjectsDiff is defined as the input tuple Objects with all objects from ObjectsSub removed.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

Image matrices and XLDs are not compared regarding their contents. Thus, two images or XLDs, respectively, are "equal" if they are located at the same place in the storage. By contrast, regions that are not located at the same place in the storage are compared regarding their actual contents.

Parameters

- ▷ **Objects** (input_object) ..... object(-array) ⇝ *object*
  Object tuple 1.
- ▷ **ObjectsSub** (input_object) ..... object(-array) ⇝ *object*
  Object tuple 2.
- ▷ **ObjectsDiff** (output_object) ..... object(-array) ⇝ *object*
  Objects from Objects that are not part of ObjectsSub.

Result

obj_diff always returns 2 (H_MSG_TRUE).

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

test_equal_obj, count_obj, copy_obj, select_obj

Module

Foundation

obj_to_integer (Objects : : Index, Number : SurrogateTuple)

Convert an iconic object into an "integer number."

obj_to_integer stores Number, starting at index Index, of the database keys of the input object Objects as integer numbers in the output parameter SurrogateTuple. If -1 is passed for Number all objects beginning with Index are copied. This facilitates a direct access to an arbitrary element of Objects. In conjunction with count_obj (returns the number of objects in Objects) the elements of Objects can be processed successively. The objects are not duplicated by obj_to_integer and thus must not be cleared by clear_obj.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Attention

The objects' data is not duplicated.

Parameters

▷ **Objects** (input_object) . . . . . object(-array) ⇝ *object*
Objects for which the surrogates are to be returned.

▷ **Index** (input_control) . . . . . integer ⇝ *integer*
Starting index of the surrogates to be returned.
Default: 1
Value range: 1 ≤ Index

▷ **Number** (input_control) . . . . . integer ⇝ *integer*
Number of surrogates to be returned.
Default: -1
Restriction: Number == -1 || Number + Index <= number(Objects)

▷ **SurrogateTuple** (output_control) . . . . . pointer(-array) ⇝ *integer*
Tuple containing the surrogates.

Example

```
* Access the i-th element:
obj_to_integer(Objects,i,1,Surrogat)
```

Complexity

Runtime complexity: $O(|\texttt{Objects}| + \texttt{Number})$

Result

`obj_to_integer` returns 2 (`H_MSG_TRUE`) if all parameters are correct. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`copy_obj`, `select_obj`, `copy_image`, `gen_image_proto`

See also

`integer_to_obj`, `count_obj`

Module

Foundation

remove_obj (Objects : ObjectsReduced : Index :)

Remove objects from an iconic object tuple.

`remove_obj` removes the elements referred by `Index` from the tuple `Objects` and returns the rest in the tuple `ObjectsReduced`. `Index` determines the index of the elements to remove. Note that, in contrast to control tuples, indices for the object tuple elements start at 1, i.e. the first tuple element has got the index 1. Duplicates and indices out of range are ignored.

Parameters

▷ **Objects** (input_object) . . . . . object(-array) ⇝ *object*
Input object tuple.

▷ **ObjectsReduced** (output_object) . . . . . object(-array) ⇝ *object*
Remaining object tuple.

▷ **Index** (input_control) . . . . . number(-array) ⇝ *integer*
Indices of the objects to be removed.

Example

```
gen_empty_obj (Images)
for Index := 1 to 10 by 1
  gen_image_const (Image, 'byte', Index, Index)
  concat_obj (Images, Image, Images)
endfor

remove_obj (Images, Images, [7, 4])
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

select_obj

See also

count_obj, select_obj, copy_obj, insert_obj

Module

Foundation

replace_obj (Objects, ObjectsReplace : Replaced : Index :)

Replaces one or more elements of an iconic object tuple.

replace_obj replaces one or more elements of the iconic input tuple Objects and returns them with Replaced. At this, Index determines the indices of the elements and ObjectsReplace the corresponding objects to replace. The parameter Index must contain one or more integer values (any floating point number must represent an integer value without fraction). Indices of iconic object elements start at 1. If ObjectsReplace contains only one value, this value will be replaced at all indices of Index. If a value of Index is greater than the length of the iconic input object tuple Objects, Replaced will be extended accordingly and initialized with empty regions.

Exception: Empty input object

If either Index or ObjectsReplace is empty and the other is not, an exception is raised. If both are empty, the output object tuple Replaced corresponds to the input Objects. If both are not empty, but the input Objects is, the empty object will be extended as described above.

Parameters

- ▷ **Objects** (input_object) ..... object(-array) ⇝ *object*
  Iconic Input Object.
- ▷ **ObjectsReplace** (input_object) ..... object(-array) ⇝ *object*
  Element(s) to replace.
- ▷ **Replaced** (output_object) ..... object(-array) ⇝ *object*
  Tuple with replaced elements.
- ▷ **Index** (input_control) ..... number(-array) ⇝ *integer*
  Index/Indices of elements to be replaced.

Example

```
gen_empty_obj (Images)
for Index := 1 to 10 by 1
  gen_image_const (Image, 'byte', Index, Index)
  concat_obj (Images, Image, Images)
```

```
endfor
gen_empty_obj (Replace)

replace_obj (Images, Replace, Images, 1)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

select_obj

See also

count_obj, select_obj, copy_obj, insert_obj

Module

Foundation

select_obj (Objects : ObjectSelected : Index :)

Select objects from an object tuple.

select_obj copies the iconic objects with the indices given by Index (starting with 1) from the iconic input object tuple Objects to the output object ObjectSelected. No new storage is allocated for the regions and images. Instead, new objects containing references to the existing objects are created. The number of objects in an object tuple can be queried with the operator count_obj.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **Objects** (input_object) ..... object(-array) ⇝ *object*
Input objects.

▷ **ObjectSelected** (output_object) ..... object(-array) ⇝ *object*
Selected objects.

▷ **Index** (input_control) ..... integer(-array) ⇝ *integer*
Indices of the objects to be selected.
Default: 1
Suggested values: Index ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 50, 100, 200, 500, 1000, 2000, 5000}
Restriction: Index >= 1

Example

```
/* Access to all Regions */

count_obj(Regions,&Num);
for (i=1; i<=Num; i++)
{
  select_obj(Regions,&Single,i);
  T_get_region_polygon(Single,5.0,&Row,&Column);
  T_disp_polygon(WindowHandleTuple,Row,Column);
  destroy_tuple(Row);
  destroy_tuple(Column);
}
```

Complexity

Runtime complexity: $O(|\text{Objects}|)$

Result

`select_obj` returns `2` (`H_MSG_TRUE`) if all objects are contained in the HALCON database and all parameters are correct. If the input is empty the behavior can be set via `set_system(::'no_object_result',<Result>:)`. If necessary, an exception is raised.

Execution Information

- Supports objects on compute devices.
- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 23

Regions

To learn more about the basic concept of regions in HALCON you can also see the example program `halcon_basic_concepts.hdev`.

23.1 Access

get_region_contour (Region : : : Rows, Columns)

Access the contour of an object.

The operator `get_region_contour` returns the contour of a region. A contour is a result of line (`Rows`) and column coordinates (`Columns`), describing the boundary of the region. The contour lies on the region. It starts at the smallest line number. In that line at the pixel with the largest column index. The rotation direction is clockwise. The first pixel of the contour is identical with the last. Holes of the region are ignored. The operator `get_region_contour` returns the coordinates in the form of tuples. An empty region is passed as empty tuple.

Attention

Holes of the region are ignored. Only one region may be passed, and this region must have exactly one connection component.

Parameters

- ▷ **Region** (input_object) ..... region ⇝ *object*
  Output region.
- ▷ **Rows** (output_control) ..... contour.y-array ⇝ *integer*
  Line numbers of the contour pixels.
- ▷ **Columns** (output_control) ..... contour.x-array ⇝ *integer*
  Column numbers of the contour pixels.
  Number of elements: Columns == Rows

Result

The operator `get_region_contour` normally returns the value `2` (`H_MSG_TRUE`). If more than one connection component is passed an exception is raised. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

copy_obj, get_region_polygon

Module

Foundation

get_region_convex (Region : : : Rows, Columns)

Access convex hull as contour.

The operator get_region_convex returns the convex hull of a region as polygon. The polygon is the minimum result of line (Rows) and column coordinates (Columns) describing the hull of the region. The polygon pixels lie on the region. The polygon starts at the smallest line number; in this line at the pixel with the largest column index. The rotation direction is clockwise. The first pixel of the polygon is identical with the last. The operator get_region_convex returns the coordinates in the form of tuples. An empty region is passed as empty tuple.

Parameters

▷ **Region** (input_object) . . . . . region ⇝ *object*
Output region.

▷ **Rows** (output_control) . . . . . contour.y-array ⇝ *integer*
Line numbers of contour pixels.

▷ **Columns** (output_control) . . . . . contour.x-array ⇝ *integer*
Column numbers of the contour pixels.
Number of elements: Columns == Rows

Result

The operator get_region_convex returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, skeleton, dyn_threshold

Possible Successors

disp_polygon

Alternatives

select_obj, get_region_contour

Module

Foundation

get_region_points (Region : : : Rows, Columns)

Access the pixels of a region.

The operator get_region_points returns the region data in the form of coordinate lists. The coordinates are sorted in the following order:

$$(r_1, c_1) \leq (r_2, c_2) := (r_1 < r_2) \quad \vee \quad (r_1 = r_2) \wedge (c1 \leq c2)$$

get_region_points returns the coordinates in the form of tuples. An empty region is passed as empty tuple.

Attention

Only one region may be passed.

Parameters

▷ **Region** (input_object) . . . . . region ⇝ *object*
This region is accessed.

▷ **Rows** (output_control) . . . . . coordinates.y-array ⇝ *integer*
Line numbers of the pixels in the region

▷ **Columns** (output_control) . . . . . coordinates.x-array ⇝ *integer*
Column numbers of the pixels in the region.
Number of elements: Columns == Rows

Result

The operator `get_region_points` normally returns the value `2` (`H_MSG_TRUE`). If more than one connection component is passed an exception is raised. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_region_polygon (Region : : Tolerance : Rows, Columns)

Polygon approximation of a region.

The operator `get_region_polygon` calculates a polygon to approximate the edge of a region. A polygon is a sequence of line (`Rows`) and column coordinates (`Columns`). It describes the contour of the region. Only the base points of the polygon are returned. The parameter `Tolerance` indicates how large the maximum distance between the polygon and the edge of the region may be. Holes of the region are ignored. The operator `get_region_polygon` returns the coordinates in the form of tuples.

Attention

Holes of the region are ignored. Only one region may be passed, and this region must have exactly one connection component.

Parameters

▷ **Region** (input_object) . . . . . region ⇝ *object*
Region to be approximated.

▷ **Tolerance** (input_control) . . . . . number ⇝ *real* / integer
Maximum distance between the polygon and the edge of the region.
Default: 5.0
Suggested values: `Tolerance` ∈ {0.0, 2.0, 5.0, 10.0}
Value range: 0.0 ≤ Tolerance (lin)
Minimum increment: 0.01
Recommended increment: 1.0

▷ **Rows** (output_control) . . . . . polygon.y-array ⇝ *integer*
Line numbers of the base points of the contour.

▷ **Columns** (output_control) ..... polygon.x-array ⇝ *integer*
Column numbers of the base points of the contour.
Number of elements: Columns == Rows

Result

The operator `get_region_polygon` normally returns the value `2` (`H_MSG_TRUE`). If more than one connection component is passed an exception is raised. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_region_runs (Region : : : Row, ColumnBegin, ColumnEnd)

Access the runlength coding of a region.

The operator `get_region_runs` returns the region data in the form of chord tuples. The chord representation is caused by examining a region line by line with ascending line number (= from "top" to "bottom"). Every line is passed from left to right (ascending column number); storing all starting and ending points of region segments (= chords). Thus a region can be described by a sequence of chords, a chord being defined by line number, starting and ending points (column number). The operator `get_region_runs` returns the three components of the chords in the form of tuples. In case of an empty region three empty tuples are returned.

Attention

Only one region may be passed.

Parameters

▷ **Region** (input_object) ..... region ⇝ *object*
Output region.

▷ **Row** (output_control) ..... chord.y-array ⇝ *integer*
Line numbers of the chords.

▷ **ColumnBegin** (output_control) ..... chord.x1-array ⇝ *integer*
Column numbers of the starting points of the chords.
Number of elements: ColumnBegin == Row

▷ **ColumnEnd** (output_control) ..... chord.x2-array ⇝ *integer*
Column numbers of the ending points of the chords.
Number of elements: ColumnEnd == Row

Result

The operator `get_region_runs` normally returns the value `2` (`H_MSG_TRUE`). If more than one region is passed an exception is raised. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

23.2 Creation

gen_checker_region (: RegionChecker : WidthRegion, HeightRegion, WidthPattern, HeightPattern :)

Create a checkered region.

The operator gen_checker_region returns a checkered region. Every black field of the checkerboard belongs to the region. The horizontal and vertical expansion of the region is limited by WidthRegion, HeightRegion respectively, the size of the fields of the checkerboard by WidthPattern × HeightPattern.

Attention

If a very small pattern is chosen (WidthPattern < 4) the created region requires much storage.

Parameters

▷ **RegionChecker** (output_object) . . . . . region ⇝ *object*
Created checkerboard region.

▷ **WidthRegion** (input_control) . . . . . extent.x ⇝ *integer*
Largest occurring x value of the region.
Default: 511
Suggested values: WidthRegion ∈ {10, 20, 31, 63, 127, 255, 300, 400, 511}
Value range: 1 ≤ WidthRegion (lin)
Minimum increment: 1
Recommended increment: 10

▷ **HeightRegion** (input_control) . . . . . extent.y ⇝ *integer*
Largest occurring y value of the region.
Default: 511
Suggested values: HeightRegion ∈ {10, 20, 31, 63, 127, 255, 300, 400, 511}
Value range: 1 ≤ HeightRegion (lin)
Minimum increment: 1
Recommended increment: 10

▷ **WidthPattern** (input_control) . . . . . extent.x ⇝ *integer*
Width of a field of the checkerboard.
Default: 64
Suggested values: WidthPattern ∈ {1, 2, 4, 8, 16, 20, 32, 64, 100, 128, 200, 300, 500}
Value range: 1 ≤ WidthPattern (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: WidthPattern < WidthRegion

▷ **HeightPattern** (input_control) . . . . . extent.y ⇝ *integer*
Height of a field of the checkerboard.
Default: 64
Suggested values: HeightPattern ∈ {1, 2, 4, 8, 16, 20, 32, 64, 100, 128, 200, 300, 500}
Value range: 1 ≤ HeightPattern (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: HeightPattern < HeightRegion

Example

```
gen_checker_region(Checker,512,512,32,64)
dev_set_draw('fill')
dev_display (Checker)
```

Complexity

The required storage (in bytes) for the region is:

$O((\texttt{WidthRegion} * \texttt{HeightRegion})/\texttt{WidthPattern})$

Result

The operator gen_checker_region returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

paint_region

reduce_domain

Module

Foundation

gen_circle (: Circle : Row, Column, Radius :)

Create a circle.

The operator gen_circle generates one or more circles described by the center and Radius. If several circles shall be generated the coordinates must be passed in the form of tuples.

gen_circle only creates symmetric circles. To achieve this, the radius is internally rounded down to a multiple of 0.5. If an integer number is specified for the radius (i.e., 1, 2, 3, ...) an even diameter is obtained, and hence the circle can only be symmetric with respect to a center with coordinates that have a fractional part of 0.5. Consequently, internally the coordinates of the center are adapted to the closest coordinates that have a fractional part of 0.5. Here, integer coordinates are rounded down to the next smaller values with a fractional part of 0.5. For odd diameters (i.e., radius = 1.5, 2.5, 3.5, ...), the circle can only be symmetric with respect to a center with integer coordinates. Hence, internally the coordinates of the center are rounded to the nearest integer coordinates. It should be noted that the above algorithm may lead to the fact that circles with an even diameter are *not* contained in circles with the next larger odd diameter, even if the coordinates specified in Row and Column are identical.

If the circle extends beyond the image edge it is clipped to the current image format if the value of the system flag *'clip_region'* is set to *'true'* (set_system).

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Attention

For speed reasons, the resulting region may contain additional pixels at the border and some individual pixels at the border may be missing. This may lead to an inconsistency between the operators smallest_circle and gen_circle.

Parameters

▷ **Circle** (output_object) . . . . . region(-array) ⇝ *object*
Generated circle.

▷ **Row** (input_control) . . . . . circle.center.y(-array) ⇝ *real* / integer
Line index of center.
Default: 200.0
Suggested values: Row ∈ {0.0, 10.0, 50.0, 100.0, 200.0, 300.0}
Value range: 1.0 ≤ Row ≤ 1024.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Column** (input_control) . . . . . circle.center.x(-array) ⇝ *real* / integer
Column index of center.
Default: 200.0
Suggested values: Column ∈ {0.0, 10.0, 50.0, 100.0, 200.0, 300.0}
Value range: 1.0 ≤ Column ≤ 1024.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Radius** (input_control) . . . . . circle.radius(-array) ⇝ *real* / integer
Radius of circle.
Default: 100.5
Suggested values: Radius ∈ {1.0, 1.5, 2.0, 2.5, 3, 3.5, 4, 4.5, 5.5, 6.5, 7.5, 9.5, 11.5, 15.5, 20.5, 25.5, 31.5, 50.5}
(lin)
Restriction: Radius > 0.0

Example

```
read_image(Image,'fabrik')
gen_circle(Circle,300.0,200.0,150.5)
reduce_domain(Image,Circle,Mask)
dev_clear_window ()
dev_display (Mask)
```

Complexity

Runtime complexity: $O(\texttt{Radius} * 2)$

Storage complexity (byte): $O(\texttt{Radius} * 8)$

Result

If the parameter values are correct, the operator gen_circle returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>). If an empty region is created by clipping (the circle is completely outside of the image format) the operator set_system ('store_empty_region',<'true'/'false'>) determines whether the empty region is put out.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

paint_region, reduce_domain

Alternatives

See also

disp_circle, set_shape, smallest_circle, reduce_domain

Module

Foundation

gen_circle_sector (: CircleSector : Row, Column, Radius, StartAngle, EndAngle :)

Create a circle sector.

The operator gen_circle_sector generates one or more circles sectors described by the center, Radius, StartAngle and EndAngle. If several circle sectors shall be generated the coordinates must be passed in the form of tuples.

gen_circle_sector only creates symmetric circle sectors with respect to the center of coordinates. To achieve this, the radius is internally rounded down to a multiple of 0.5. If an integer number is specified for the radius (i.e., 1, 2, 3, ...) an even diameter is obtained, and hence the circle can only be symmetric with respect to a center with coordinates that have a fractional part of 0.5. Consequently, internally the coordinates of the center are adapted to the closest coordinates that have a fractional part of 0.5. Here, integer coordinates are rounded down to the next smaller values with a fractional part of 0.5. For odd diameters (i.e., radius = 1.5, 2.5, 3.5, ...), the circle can only be symmetric with respect to a center with integer coordinates. Hence, internally the coordinates of the center are rounded to the nearest integer coordinates. It should be noted that the above algorithm may lead to the fact that circles with an even diameter are *not* contained in circles with the next larger odd diameter, even if the coordinates specified in Row and Column are identical.
The angles are given in radians in mathematically positive direction. See the examples illustrated in the figure below. Note, *'rad(360)'* is equivalent to *0*. As a consequence a sector with StartAngle = *0* and EndAngle = *'rad(360)'* results in an empty region.

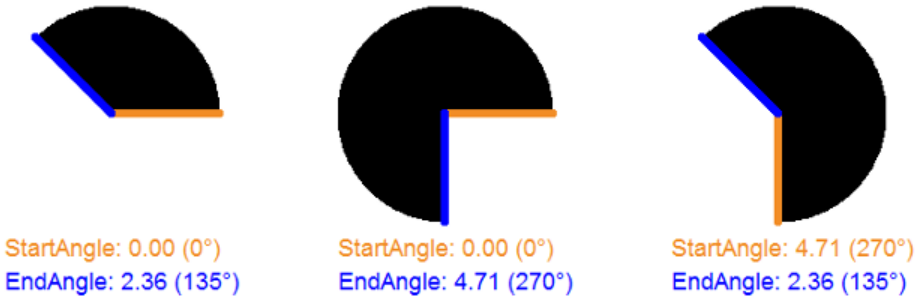

Illustration of different possible angle combinations.

If the circle extends beyond the image edge it is clipped to the current image format if the value of the system flag *'clip_region'* is set to *'true'* (set_system).

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **CircleSector** (output_object) . . . . . region(-array) ⇝ *object*
Generated circle sector.

▷ **Row** (input_control) . . . . . coordinates.y(-array) ⇝ *real* / integer
Line index of center.
Default: 200.0
Suggested values: Row ∈ {0.0, 10.0, 50.0, 100.0, 200.0, 300.0}
Value range: 1.0 ≤ Row ≤ 1024.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Column** (input_control) . . . . . coordinates.x(-array) ⇝ *real* / integer
Column index of center.
Default: 200.0
Suggested values: Column ∈ {0.0, 10.0, 50.0, 100.0, 200.0, 300.0}
Value range: 1.0 ≤ Column ≤ 1024.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Radius** (input_control) . . . . . number(-array) ⇝ *real* / integer
Radius of circle.
Default: 100.5
Suggested values: Radius ∈ {1.0, 1.5, 2.0, 2.5, 3, 3.5, 4, 4.5, 5.5, 6.5, 7.5, 9.5, 11.5, 15.5, 20.5, 25.5, 31.5, 50.5}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: Radius > 0.0

▷ **StartAngle** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
Start angle of the circle sector.
Default: 0.0
Suggested values: StartAngle ∈ {0.0, 0.785398, 1.5708, 2.35619, 3.14159, 3.92699, 4.71239, 5.49779, 6.28318}
Value range: 0 ≤ StartAngle ≤ 6.28318 (lin)

▷ **EndAngle** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
End angle of the circle sector.
Default: 3.14159
Suggested values: EndAngle ∈ {0.0, 0.785398, 1.5708, 2.35619, 3.14159, 3.92699, 4.71239, 5.49779, 6.28318}
Value range: 0 ≤ EndAngle ≤ 6.28318 (lin)

Example

```
read_image(Image,'fabrik')
gen_circle_sector(CircleSector,300.0,200.0,150.5,0,rad(120))
reduce_domain(Image,CircleSector,Mask)
dev_clear_window ()
dev_display (Mask)
```

Complexity

Runtime complexity: $O(\texttt{Radius} * 2)$

Storage complexity (byte): $O(\texttt{Radius} * 8)$

Result

If the parameter values are correct, the operator gen_circle_sector returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>). If an empty region is created by clipping (the circle is completely outside of the image format) the operator set_system ('store_empty_region',<'true'/'false'>) determines whether the empty region is put out.

gen_ellipse (: Ellipse : Row, Column, Phi, Radius1, Radius2 :)

Create an ellipse.

The operator gen_ellipse generates one or more ellipses with the center (Row, Column), the orientation Phi and the half-radii (half axes) Radius1 and Radius2. The angle is indicated in arc measure according to the x axis in mathematically positive direction. More than one region can be created by passing tuples of parameter values.

The center must be located within the image coordinates. The coordinate system runs from (0,0) (upper left corner) to (Width-1,Height-1). See get_system and reset_obj_db in this context. If the ellipse reaches beyond the edge of the image it is clipped to the current image format according to the value of the system flag *'clip_region'* (set_system).

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **Ellipse** (output_object) . . . . . region(-array) ⇝ *object*
Created ellipse(s).

▷ **Row** (input_control) . . . . . ellipse.center.y(-array) ⇝ *real* / integer
Line index of center.
Default: 200.0
Suggested values: Row ∈ {0.0, 10.0, 20.0, 50.0, 100.0, 256.0, 300.0, 400.0}
Value range: 1.0 ≤ Row ≤ 1024.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Column** (input_control) . . . . . ellipse.center.x(-array) ⇝ *real* / integer
Column index of center.
Default: 200.0
Suggested values: Column ∈ {0.0, 10.0, 20.0, 50.0, 100.0, 256.0, 300.0, 400.0}
Value range: 1.0 ≤ Column ≤ 1024.0 (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Phi** (input_control) . . . . . ellipse.angle.rad(-array) ⇝ *real* / integer
Orientation of the longer radius (Radius1).
Default: 0.0
Suggested values: Phi ∈ {-1.178097, -0.785398, -0.392699, 0.0, 0.392699, 0.785398, 1.178097}
Value range: -1.178097 ≤ Phi ≤ 1.178097 (lin)

▷ **Radius1** (input_control) . . . . . ellipse.radius1(-array) ⇝ *real* / integer
Longer radius.
Default: 100.0
Suggested values: Radius1 ∈ {2.0, 5.0, 10.0, 20.0, 50.0, 100.0, 256.0, 300.0, 400.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: Radius1 > 0

▷ **Radius2** (input_control) . . . . . ellipse.radius2(-array) ⇝ *real* / integer
Shorter radius.
Default: 60.0
Suggested values: Radius2 ∈ {1.0, 2.0, 4.0, 5.0, 10.0, 20.0, 50.0, 100.0, 256.0, 300.0, 400.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: Radius2 > 0 && Radius2 <= Radius1

Example

```
read_image (Image, 'fabrik')
```

```
gen_ellipse (Ellipse, 200, 200, rad(10), 160, 90)
reduce_domain (Image, Ellipse, ImageReduced)
dev_clear_window ()
dev_display (ImageReduced)
```

Complexity

Runtime complexity: $O(\texttt{Radius1} * 2)$

Storage complexity (byte): $O(\texttt{Radius1} * 8)$

Result

If the parameter values are correct, the operator `gen_ellipse` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised. The clipping according to the current image format is set via the operator `set_system ('clip_region',<'true'/'false'>)`.

Minimum increment: 1.0
Recommended increment: 10.0

▷ **Phi** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
Orientation of the longer radius (Radius1).
Default: 0.0
Suggested values: Phi ∈ {-1.5707, -1.1781, -0.785398, -0.392699, 0.0, 0.392699, 0.785398, 1.1781, 1.5707}
Value range: -1.570796 ≤ Phi ≤ 1.570796 (lin)
Restriction: - pi / 2 <= Phi <= pi / 2

▷ **Radius1** (input_control) . . . . . number(-array) ⇝ *real* / integer
Longer radius.
Default: 100.0
Suggested values: Radius1 ∈ {2.0, 5.0, 10.0, 20.0, 50.0, 100.0, 256.0, 300.0, 400.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: Radius1 > 0

▷ **Radius2** (input_control) . . . . . number(-array) ⇝ *real* / integer
Shorter radius.
Default: 60.0
Suggested values: Radius2 ∈ {1.0, 2.0, 4.0, 5.0, 10.0, 20.0, 50.0, 100.0, 256.0, 300.0, 400.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: Radius2 > 0 && Radius2 <= Radius1

▷ **StartAngle** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
Start angle of the sector.
Default: 0.0
Suggested values: StartAngle ∈ {0.0, 0.785398, 1.5708, 2.35619, 3.14159, 3.92699, 4.71239, 5.49779, 6.28318}
Value range: 0 ≤ StartAngle ≤ 6.28318 (lin)

▷ **EndAngle** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
End angle of the sector.
Default: 3.14159
Suggested values: EndAngle ∈ {0.0, 0.785398, 1.5708, 2.35619, 3.14159, 3.92699, 4.71239, 5.49779, 6.28318}
Value range: 0 ≤ EndAngle ≤ 6.28318 (lin)

Example

```
read_image (Image, 'fabrik')
gen_ellipse_sector (EllipseSector, 200, 200, rad(30),\
                    150, 90, rad(45), rad(280))
reduce_domain (Image, EllipseSector, ImageReduced)
dev_clear_window ()
dev_display (ImageReduced)
```

Complexity

Runtime complexity: $O(\texttt{Radius1} * 2)$

Storage complexity (byte): $O(\texttt{Radius1} * 8)$

Result

If the parameter values are correct, the operator gen_ellipse returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system ('clip_region',<'true'/'false'>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

paint_region, reduce_domain

Alternatives

gen_circle, gen_circle_sector, gen_region_polygon_filled, draw_ellipse, gen_ellipse

See also

disp_ellipse, set_shape, smallest_circle, reduce_domain

Module

Foundation

gen_empty_region (: EmptyRegion : :)

Create an empty region.

The operator gen_empty_region creates an empty region. This means that the output parameter contains an object. Thus, count_obj returns 1. The area of the region is 0. Most of the shape features are undefined (0). It should be noted that an empty region must not be confused with the empty tuple.

Parameters

▷ **EmptyRegion** (output_object) ..... region ⇝ *object*
Empty region (no pixels).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

gen_grid_region (: RegionGrid : RowSteps, ColumnSteps, Type, Width, Height :)

Create a region from lines or pixels.

The operator gen_grid_region creates a grid constructed of lines (Type = 'lines') or pixels (Type = 'points'). In case of 'lines' continuous lines are returned, in case of 'points' only the intersections of the lines. Starting from the pixel (0,0) to the pixel (Height-1,Width-1) the grid is built up at stepping width RowSteps in row direction and ColumnSteps in column direction. The step widths have to be greater than *1*. Exceptions are in 'lines' mode RowSteps, where RowSteps or ColumnSteps can be set equal to *0*. In such a case, only columns, rows respectively, are created.

Attention

If a very small pattern is chosen (RowSteps $<$ 4 or ColumnSteps $<$ 4) the created region requires much storage.

In the 'points' mode RowSteps and ColumnSteps must not be set to zero.

Parameters

▷ **RegionGrid** (output_object) . . . . . region ⇝ *object*
Created lines/pixel region.

▷ **RowSteps** (input_control) . . . . . extent.y ⇝ *integer* / real
Step width in line direction or zero.
Default: 10
Suggested values: RowSteps ∈ {0, 2, 3, 4, 5, 7, 10, 15, 20, 30, 50, 100}
(lin)
Minimum increment: 1
Recommended increment: 10
Restriction: RowSteps > 1 || RowSteps == 0

▷ **ColumnSteps** (input_control) . . . . . extent.x ⇝ *integer* / real
Step width in column direction or zero.
Default: 10
Suggested values: ColumnSteps ∈ {0, 2, 3, 4, 5, 7, 10, 15, 20, 30, 50, 100}
(lin)
Minimum increment: 1
Recommended increment: 10
Restriction: ColumnSteps > 1 || ColumnSteps == 0

▷ **Type** (input_control) . . . . . string ⇝ *string*
Type of created pattern.
Default: 'lines'
List of values: Type ∈ {'lines', 'points'}

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Maximum width of pattern.
Default: 512
Suggested values: Width ∈ {128, 256, 512, 1024}
Value range: 1 ≤ Width (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Maximum height of pattern.
Default: 512
Suggested values: Height ∈ {128, 256, 512, 1024}
Value range: 1 ≤ Height (lin)
Minimum increment: 1
Recommended increment: 10

Example

```
read_image(Image,'fabrik')
gen_grid_region(Raster,10,10,'lines',512,512)
reduce_domain(Image,Raster,Mask)
sobel_amp(Mask,GridSobel,'sum_abs',3)
dev_display(GridSobel)
```

Complexity

The necessary storage (in bytes) for the region is:

$O((ImageWidth/ColumnSteps) * (ImageHeight/RowSteps))$

Result

If the parameter values are correct the operator gen_grid_region returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

reduce_domain, paint_region

Alternatives

gen_region_line, gen_region_polygon, gen_region_points, gen_region_runs

See also

gen_checker_region, reduce_domain

Module

Foundation

gen_random_region (: RegionRandom : Width, Height :)

Create a random region.

The operator gen_random_region returns a random region. During this process every pixel in the image area [0...Width-1] [0...Height-1] is adapted into the region with the probability 0.5. The created region can be imagined as the threshold formation in an image with noise.

This procedure is particularly important for the creation of uncorrelated binary patterns.

The random pattern is generated using the C function "nrand48()". See the parameter *'seed_rand'* of set_system for information on the used random seed.

Attention

If Width and Height are chosen large (> 100) the created region may require much storage space due to the internally used runlength coding. The gray values of the output region are undefined.

Parameters

▷ **RegionRandom** (output_object) ..... region ⇝ *object*
Created random region with expansion Width x Height.

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Maximum horizontal expansion of random region.
Default: 128
Suggested values: Width ∈ {16, 32, 50, 64, 100, 128, 256, 300, 400, 512}
(lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Width > 0

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Maximum vertical expansion of random region.
Default: 128
Suggested values: Height ∈ {16, 32, 50, 64, 100, 128, 256, 300, 400, 512}
(lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Height > 0

Complexity

The worst case for the storage complexity for the created region (in byte) is: $O(Width * Height * 2)$.

Result

If the parameter values are correct, the operator gen_random_region returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

paint_region, reduce_domain

gen_checker_region, add_noise_distribution, add_noise_white, reduce_domain

Module

Foundation

gen_random_regions (: Regions : Type, WidthMin, WidthMax, HeightMin, HeightMax, PhiMin, PhiMax, NumRegions, Width, Height :)

Create random regions like circles, rectangles and ellipses.

The operator gen_random_regions generates regions, whose parameters are determined at random within the given limits, and returns them in Regions.

The parameter NumRegions determines how many regions are created.

The position is always random and cannot be determined by parameters, but the center of every region lies in the pixel area [0...Width-1] [0...Height-1].

The parameter Type defines the type of the regions. The meaning of the lower and upper limits depends on Type:

- *'rectangle1'*: Minimum/maximum width/height.
  PhiMin and PhiMax are without further significance.
- *'rectangle2'*: Minimum/maximum half edge lengths, minimum/maximum rotation angle. Thereby the larger value is used for the first half edge length. The parameters correspond to the parameters Length1, Length2, and Phi of gen_rectangle2.
- *'circle'*: WidthMin and WidthMax determine the minimum and maximum radii. The parameters correspond to the parameter Radius in gen_circle.
  HeightMin and HeightMax as well as PhiMin and PhiMax are without further significance.
- *'ellipse'*: Minimum/maximum half-radii and minimal/maximum rotation angle. Thereby the larger value is used for the first half-radius. The parameters correspond to the parameters Radius1, Radius2, and Phi in gen_ellipse.
- *'ring'*: Minimum/maximum radii, whereby the larger one determines the radius of the larger circle and the smaller one the radius of the hole.
  PhiMin and PhiMax are without further significance.

The random parameters are generated using the C function "nrand48()". See the parameter *'seed_rand'* of set_system for information on the used random seed.

Parameters

▷ **Regions** (output_object) ..... region-array ⇝ *object*
Created regions.

▷ **Type** (input_control) ..... string ⇝ *string*
Type of regions to be created.
Default: 'circle'
List of values: Type ∈ {'circle', 'ring', 'ellipse', 'rectangle1', 'rectangle2'}

▷ **WidthMin** (input_control) ..... number ⇝ *real* / integer
Minimum object characteristic, depending on type and value.
Default: 10.0
Suggested values: WidthMin ∈ {1.0, 3.0, 5.0, 10.0, 20.0, 40.0, 80.0}
Value range: 0 ≤ WidthMin (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **WidthMax** (input_control) . . . . . number ⇝ *real* / integer
Maximum object characteristic, depending on type and value.
Default: 20.0
Suggested values: WidthMax ∈ {1.0, 3.0, 5.0, 10.0, 20.0, 40.0, 80.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: WidthMin <= WidthMax

▷ **HeightMin** (input_control) . . . . . number ⇝ *real* / integer
Minimum object characteristic, depending on type and value.
Default: 10.0
Suggested values: HeightMin ∈ {1.0, 3.0, 5.0, 10.0, 20.0, 40.0, 80.0}
Value range: 0 ≤ HeightMin (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **HeightMax** (input_control) . . . . . number ⇝ *real* / integer
Maximum object characteristic, depending on type and value.
Default: 30.0
Suggested values: HeightMax ∈ {1.0, 3.0, 5.0, 10.0, 20.0, 40.0, 80.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: HeightMin <= HeightMax

▷ **PhiMin** (input_control) . . . . . number ⇝ *real* / integer
Minimum rotation angle of the region.
Default: -0.7854
Suggested values: PhiMin ∈ {0.0, 0.1, 0.3, 0.6, 0.9, 1.2, 1.5}
Value range: 0.0 ≤ PhiMin ≤ 6.28 (lin)
Restriction: PhiMin > 0

▷ **PhiMax** (input_control) . . . . . number ⇝ *real* / integer
Maximum rotation angle of the region.
Default: 0.7854
Suggested values: PhiMax ∈ {0.0, 0.1, 0.3, 0.6, 0.9, 1.2, 1.5}
Value range: 0.0 ≤ PhiMax ≤ 6.28 (lin)
Restriction: PhiMax > 0

▷ **NumRegions** (input_control) . . . . . integer ⇝ *integer*
Number of regions.
Default: 100
Suggested values: NumRegions ∈ {1, 5, 20, 100, 200, 500, 1000, 2000}
Value range: 1 ≤ NumRegions (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Width** (input_control) . . . . . integer ⇝ *integer*
Maximum horizontal expansion of the centers.
Default: 512
Suggested values: Width ∈ {128, 256, 512, 1024}
Value range: 1 ≤ Width (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Height** (input_control) . . . . . integer ⇝ *integer*
Maximum vertical expansion of the centers.
Default: 512
Suggested values: Height ∈ {128, 256, 512, 1024}
Value range: 1 ≤ Height (lin)
Minimum increment: 1
Recommended increment: 10

Result

If the parameter values are correct gen_random_regions returns the value 2 (H_MSG_TRUE). Otherwise

an exception is raised. The clipping according to the current image format is determined by the operator `set_system('clip_region',<'true'/'false'>)`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`paint_region`

Module

Foundation

gen_rectangle1 (: Rectangle : Row1, Column1, Row2, Column2 :)

Create a rectangle parallel to the coordinate axes.

The operator `gen_rectangle1` generates one or more rectangles parallel to the coordinate axes which are described by the upper left corner (`Row1`, `Column1`) and the lower right corner (`Row2`, `Column2`). More than one region can be created by passing a tuple of corner points. The coordinate system runs from (0,0) (upper left corner) to (Width-1,Height-1). See `get_system` and `reset_obj_db` in this context.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **Rectangle** (output_object) . . . . . region(-array) ⇝ *object*
Created rectangle.

▷ **Row1** (input_control) . . . . . rectangle.origin.y(-array) ⇝ *real* / integer
Line of upper left corner point.
Default: 30.0
Suggested values: `Row1` ∈ {0.0, 10.0, 20.0, 50.0, 100.0, 200.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Column1** (input_control) . . . . . rectangle.origin.x(-array) ⇝ *real* / integer
Column of upper left corner point.
Default: 20.0
Suggested values: `Column1` ∈ {0.0, 10.0, 20.0, 50.0, 100.0, 200.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Row2** (input_control) . . . . . rectangle.corner.y(-array) ⇝ *real* / integer
Line of lower right corner point.
Default: 100.0
Suggested values: `Row2` ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0, 511.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: Row2 >= Row1

▷ **Column2** (input_control) . . . . . rectangle.corner.x(-array) ⇝ *real* / integer
Column of lower right corner point.
Default: 200.0
Suggested values: Column2 ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0, 511.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0
Restriction: Column2 >= Column1

Example

```
* Contrast improvement in a rectangular region of interest
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
read_image(Image,'mreut')
dev_display (Image)
draw_rectangle1(WindowHandle,Row1,Column1,Row2,Column2)
gen_rectangle1(Rectangle,Row1,Column1,Row2,Column2)
reduce_domain(Image,Rectangle,Mask)
emphasize(Mask,Emphasize,9,9,1.0)
dev_display (Emphasize)
```

Result

If the parameter values are correct, the operator gen_rectangle1 returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

gen_rectangle2, gen_region_polygon, fill_up, gen_region_runs, gen_region_points, gen_region_line

See also

draw_rectangle1, reduce_domain, smallest_rectangle1

Module

Foundation

gen_rectangle2 (: Rectangle : Row, Column, Phi, Length1, Length2 :)

Create a rectangle of any orientation.

The operator gen_rectangle2 generates one or more rectangles with the center (Row, Column) , the orientation Phi and the half edge lengths Length1 and Length2. The orientation is given in arc measure and indicates the angle between the horizontal axis and the edge (with Length1) (mathematically positive). The coordinate system runs from (0,0) (upper left corner) to (Width-1,Height-1). See get_system and reset_obj_db in this context. More than one region can be created by passing one tuple of corner points.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Attention

The gray values of the output objects are undefined. For speed reasons, the resulting region may contain additional

pixels at the border and some individual pixels at the border may be missing. This may lead to an inconsistency between the operators smallest_rectangle2 and gen_rectangle2.

Parameters

▷ **Rectangle** (output_object) . . . . . region(-array) ⇝ *object*
Created rectangle.

▷ **Row** (input_control) . . . . . rectangle2.center.y(-array) ⇝ *real* / integer
Line index of the center.
Default: 300.0
Suggested values: Row ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Column** (input_control) . . . . . rectangle2.center.x(-array) ⇝ *real* / integer
Column index of the center.
Default: 200.0
Suggested values: Column ∈ {10.0, 20.0, 50.0, 100.0, 200.0, 300.0, 400.0, 500.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Phi** (input_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real* / integer
Angle of the first edge to the horizontal (in radians).
Default: 0.0
Suggested values: Phi ∈ {-1.178097, -0.785398, -0.392699, 0.0, 0.392699, 0.785398, 1.178097}
(lin)
Restriction: - pi / 2 < Phi && Phi <= pi / 2

▷ **Length1** (input_control) . . . . . rectangle2.hwidth(-array) ⇝ *real* / integer
Half width.
Default: 100.0
Suggested values: Length1 ∈ {3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0, 300.0, 500.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Length2** (input_control) . . . . . rectangle2.hheight(-array) ⇝ *real* / integer
Half height.
Default: 20.0
Suggested values: Length2 ∈ {1.0, 2.0, 3.0, 5.0, 10.0, 15.0, 20.0, 50.0, 100.0, 200.0}
(lin)
Minimum increment: 1.0
Recommended increment: 10.0

Result

If the parameter values are correct the operator gen_rectangle2 returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

gen_region_contour_xld (Contour : Region : Mode :)

Create a region from an XLD contour.

gen_region_contour_xld creates a region Region from a subpixel XLD contour Contour. The contour is sampled according to the Bresenham algorithm and influenced by the parameter *'neighborhood'* of the operator set_system. Open contours are closed before converting them to regions. Finally, the parameter Mode defines whether the region is filled up (*'filled'*) or returned by its contour (*'margin'*).

Please note that the coordinates of the contour points are rounded to their nearest integer pixel coordinates during the conversion. This may lead to unexpected results when passing the contour obtained by the operator gen_contour_region_xld to gen_region_contour_xld: When setting Mode of gen_contour_region_xld to *'border'*, the input region of gen_contour_region_xld and the output region of gen_region_contour_xld differ. For example, let us assume that the input region of gen_contour_region_xld consists of the single pixel (1,1). Then, the resulting contour that is obtained when calling gen_contour_region_xld with Mode set to *'border'* consists of the five points (0.5,0.5), (0.5,1.5), (1.5,1.5), (1.5,0.5), and (0.5,0.5). Consequently, when passing this contour again to gen_region_contour_xld, the resulting region consists of the points (1,1), (1,2), (2,2), and (2,1).

Parameters

▷ **Contour** (input_object) ..... xld_cont(-array) ⇝ *object*
Input contour(s).

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Created region(s).

▷ **Mode** (input_control) ..... string ⇝ *string*
Fill mode of the region(s).
Default: 'filled'
Suggested values: Mode ∈ {'filled', 'margin'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_system

Module

Foundation

gen_region_histo (: Region : Histogram, Row, Column, Scale :)

Convert a histogram into a region.

gen_region_histo converts a histogram created with gray_histo, gray_histo_range ,or tuple_histo_range into a region. Row and Column define the position of the center of the graphic. Scale allows scaling of the graphic, whereby *1* means displaying all 256 values, *2* means displaying 128 values, *3* means displaying only 64 values, etc.

Parameters

▷ **Region** (output_object) . . . . . region ⇝ *object*
Region containing the histogram.

▷ **Histogram** (input_control) . . . . . histogram-array ⇝ *integer*
Input histogram.

▷ **Row** (input_control) . . . . . point.y ⇝ *integer*
Row coordinate of the center of the histogram.
Default: 255
Suggested values: Row ∈ {100, 200, 255, 300, 400}
Value range: 0 ≤ Row ≤ 511

▷ **Column** (input_control) . . . . . point.x ⇝ *integer*
Column coordinate of the center of the histogram.
Default: 255
Suggested values: Column ∈ {100, 200, 255, 300, 400}
Value range: 0 ≤ Column ≤ 511

▷ **Scale** (input_control) . . . . . integer ⇝ *integer*
Scale factor for the histogram.
Default: 1
Suggested values: Scale ∈ {1, 2, 3, 4, 5, 6, 7}
Value range: 1 ≤ Scale ≤ 10 (lin)
Minimum increment: 1
Recommended increment: 1

Result

gen_region_histo returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

gen_region_hline (: Regions : Orientation, Distance :)

Store input lines described in Hesse normal form as regions.

The operator gen_region_hline stores the lines described in Hesse normal form as regions. A line is determined by the distance from the line to the origin (Distance, corresponds to the length of the normal vector) and the direction of the normal vector (Orientation, corresponds to the orientation of the line $\pm\pi/2$). The directions were defined in such a way that at Orientation = 0 the normal vector lies in the direction of the X axis, which corresponds to a vertical line. At Orientation = $\pi/2$ the normal vector points in the direction of the Y axis, i.e. a horizontal line is described.

Attention

The lines are clipped to the current maximum image format.

Parameters

▷ **Regions** (output_object) . . . . . region(-array) ⇝ *object*
Created regions (one for every line), clipped to maximum image format.
Number of elements: Regions == Distance

▷ **Orientation** (input_control) . . . . . hesseline.angle.rad(-array) ⇝ *real* / integer
Orientation of the normal vector in radians.
Number of elements: Orientation == Distance
Default: 0.0
Suggested values: Orientation ∈ {-0.78, 0.0, 0.78, 1.57}
(lin)
Recommended increment: 0.02

▷ **Distance** (input_control) . . . . . hesseline.distance(-array) ⇝ *real* / integer
Distance from the line to the coordinate origin (0.0).
Default: 200
Suggested values: Distance ∈ {10, 50, 100, 200, 300, 400}
(lin)
Recommended increment: 1

Result

The operator gen_region_hline always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

gen_region_line

hough_lines

Module

Foundation

gen_region_line (: RegionLines : BeginRow, BeginCol, EndRow, EndCol :)

Store input lines as regions.

The operator gen_region_line stores the given lines (with starting point [BeginRow,BeginCol] and ending point [EndRow, EndCol]) as region.

Parameters

▷ **RegionLines** (output_object) . . . . . region(-array) ⇝ *object*
Created regions.

▷ **BeginRow** (input_control) . . . . . line.begin.y(-array) ⇝ *integer* / real
Line coordinates of the starting points of the input lines.
Default: 100
Suggested values: BeginRow ∈ {10, 50, 100, 200, 300, 400}
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **BeginCol** (input_control) . . . . . line.begin.x(-array) ⇝ *integer* / real
Column coordinates of the starting points of the input lines.
Default: 50
Suggested values: BeginCol ∈ {10, 50, 100, 200, 300, 400}
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **EndRow** (input_control) . . . . . line.end.y(-array) ⇝ *integer* / real
Line coordinates of the ending points of the input lines.
Default: 150
Suggested values: EndRow ∈ {50, 100, 200, 300, 400, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **EndCol** (input_control) . . . . . line.end.x(-array) ⇝ *integer* / real
Column coordinates of the ending points of the input lines.
Default: 250
Suggested values: EndCol ∈ {50, 100, 200, 300, 400, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

Result

The operator gen_region_line always returns the value 2 (H_MSG_TRUE). The clipping according to the current image format is determined by the operator set_system('clip_region',<'true'/'false'>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

split_skeleton_lines

Alternatives

gen_region_hline

Module

Foundation

gen_region_points (: Region : Rows, Columns :)

Store individual pixels as image region.

The operator gen_region_points creates a region described by a number of pixels. The pixels do not have to be stored in a fixed order, but the best runtime behavior is obtained when the pixels are stored in ascending order. The order is as follows:

$$(l_1, c_1) \leq (l_2, c_2) := (l_1 < l_2) \quad \vee \quad (l_1 = l_2) \wedge (c_1 \leq c_2)$$

The indicated coordinates stand for two consecutive pixels in the tuple.

Parameters

▷ **Region** (output_object) . . . . . region ⇝ *object*
Created region.

▷ **Rows** (input_control) . . . . . coordinates.y(-array) ⇝ *integer* / real
Lines of the pixels in the region.
Default: 100
Suggested values: Rows ∈ {0, 10, 30, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Columns** (input_control) . . . . . coordinates.x(-array) ⇝ *integer / real*
Columns of the pixels in the region.
Number of elements: Columns == Rows
Default: 100
Suggested values: Columns ∈ {0, 10, 30, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

Complexity

F shall be the number of pixels. If the pixels are sorted in ascending order the runtime complexity is: $O(F)$, otherwise $O(log(F) * F)$.

Result

The operator gen_region_points returns the value 2 (H_MSG_TRUE) if the pixels are located within the image format. Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>). If an empty region is created (by the clipping or by an empty input) the operator set_system('store_empty_region',<'true'/'false'>) determines whether the region is returned or an empty object tuple.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

Foundation

gen_region_polygon (: Region : Rows, Columns :)

Store a polygon as a region.

The operator gen_region_polygon creates a region from a polygon row described by a series of line and column coordinates. The created region consists of the pixels of the routes defined thereby, wherein it is linearly interpolated between the base points.

Attention

The region is not automatically closed and not filled.

Parameters

▷ **Region** (output_object) . . . . . region ⇝ *object*
Created region.

▷ **Rows** (input_control) . . . . . polygon.y-array ⇝ *integer*
Line indices of the base points of the region contour.
Default: 100
Suggested values: Rows ∈ {0, 10, 30, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Columns** (input_control) . . . . . polygon.x-array ⇝ *integer*
Column indices of the base points of the region contour.
Number of elements: Columns == Rows
Default: 100
Suggested values: Columns ∈ {0, 10, 30, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

Example

```
* Polygon-approximation
get_region_polygon(Region,7,Row,Column)
* store it as a region
gen_region_polygon(Pol,Row,Column)
* fill up the hole
fill_up(Pol,Filled)
```

Result

If the base points are correct the operator gen_region_polygon returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>). If an empty region is created (by the clipping or by an empty input) the operator set_system('store_empty_region',<'true'/'false'>) determines whether the region is returned or an empty object tuple.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

See also

fill_up, reduce_domain, get_region_polygon, draw_polygon

Module

Foundation

gen_region_polygon_filled (: Region : Rows, Columns :)

Store a polygon as a "filled" region.

The operator gen_region_polygon_filled creates a region from a polygon containing the corner points of the region (line and column coordinates) either clockwise or anti-clockwise. Contrary to gen_region_polygon a "filled" region is returned here. Note that for subpixel coordinates Rows and Columns the coordinates are rounded before the polygon containing the corner points is determined. Therefore there might be pixels in the Region which do not lie on the orignial (subpixel) polygon. An simple alternative in the case of polygons without holes would be to use the operators gen_region_polygon and fill_up.

Parameters

▷ **Region** (output_object) . . . . . region ⇝ *object*
Created region.

▷ **Rows** (input_control) . . . . . polygon.y-array ⇝ *integer* / real
Line indices of the base points of the region contour.
Default: 100
Suggested values: Rows ∈ {0, 10, 30, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

▷ **Columns** (input_control) . . . . . polygon.x-array ⇝ *integer* / real
Column indices of the base points of the region contour.
Number of elements: Columns == Rows
Default: 100
Suggested values: Columns ∈ {0, 10, 30, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 1

Example

```
/* Polygon approximation */
T_get_region_polygon(Region,7,&Row,&Column);
T_gen_region_polygon_filled(&Pol,Row,Column);
/* fill up with original gray value */
reduce_domain(Image,Pol,&New);
```

Result

If the base points are correct the operator gen_region_polygon_filled returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system('clip_region',<'true'/'false'>). If an empty region is created (by the clipping or by an empty input) the operator set_system('store_empty_region',<'true'/'false'>) determines whether the region is returned or an empty object tuple.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_region_polygon_xld (Polygon : Region : Mode :)

Create a region from an XLD polygon.

gen_region_polygon_xld creates a region Region from a subpixel XLD polygon Polygon. The polygon is sampled according to the Bresenham algorithm and influenced by the parameter *'neighborhood'* of the operator set_system. Open polygons are closed before converting them to regions. Finally, the parameter Mode defines whether the region is filled up (*'filled'*) or returned by its contour (*'margin'*).

Parameters

▷ **Polygon** (input_object) . . . . . xld_poly(-array) ⇝ *object*
Input polygon(s).

▷ **Region** (output_object) . . . . . region(-array) ⇝ *object*
Created region(s).

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Fill mode of the region(s).
Default: 'filled'
Suggested values: Mode ∈ {'filled', 'margin'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_system

Module

Foundation

gen_region_runs (: Region : Row, ColumnBegin, ColumnEnd :)

Create a region from a runlength coding.

The operator gen_region_runs creates a region described by the input runlength structure. The runlength representation is created by examining a region line by line with ascending line number (= from "top" to "bottom"). Every line runs through from left to right (ascending column number). All starting and ending points being stored by region segments (=runs). Thus a region can be described by a sequence of runs, a run being defined by line number as well as starting and ending points (column number).

The storing is fastest when the runs are sorted. The order is as follows:

$$(l_1, b_1, e_1) \leq (l_2, b_2, e_2) := (l_1 < l_2) \quad \vee \quad (l_1 = l_2) \wedge (b_1 \leq b_2)$$

.

Attention

For runtime reasons, it is not checked whether the restriction ColumnEnd >= ColumnBegin is fulfilled. Note that if this restriction is violated, subsequent operations will likely lead to errors or unexpected behavior.

Parameters

▷ **Region** (output_object) . . . . . region ⇝ *object*
Created region.

▷ **Row** (input_control) . . . . . chord.y(-array) ⇝ *integer*
Lines of the runs.
Default: 100
Suggested values: Row ∈ {0, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 10

▷ **ColumnBegin** (input_control) . . . . . chord.x1(-array) ⇝ *integer*
Columns of the starting points of the runs.
Number of elements: ColumnBegin == Row
Default: 50
Suggested values: ColumnBegin ∈ {0, 50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 10

▷ **ColumnEnd** (input_control) . . . . . chord.x2(-array) ⇝ *integer*
Columns of the ending points of the runs.
Number of elements: ColumnEnd == Row
Default: 200
Suggested values: ColumnEnd ∈ {50, 100, 200, 300, 500}
(lin)
Minimum increment: 1
Recommended increment: 10
Restriction: ColumnEnd >= ColumnBegin

Complexity

F shall be the number of pixels. If the pixels are sorted in ascending order the runtime complexity is: $O(F)$, otherwise it is $O(log(F) * F)$.

Result

If the data is correct the operator gen_region_runs returns the value 2 (H_MSG_TRUE), otherwise an exception is raised. The clipping according to the current image format is set via the operator set_system ('clip_region',<'true'/'false'>). If an empty region is created (by the clipping or by an empty input) the operator set_system('store_empty_region',<'true'/'false'>) determines whether the region is returned or an empty object tuple.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

label_to_region (LabelImage : Regions : :)

Extract regions with equal gray values from an image.

label_to_region segments an image into regions of equal gray value. One output region is generated for each gray value occurring in the image. This is similar to calling threshold multiple times, and accumulating the results with concat_obj. Another related operator is regiongrowing. However, label_to_region does not perform a connection operation on the resulting regions, i.e., they may be disconnected. A typical application of label_to_region is the segmentation of label images, hence its name.

The number of output regions is limited by the system parameter *'max_outp_obj_par'*, which can be read via get_system(::'max_outp_obj_par':<number>).

Attention

`label_to_region` is not implemented for images of type `real`. The input images must not contain negative gray values.

Parameters

▷ **`LabelImage`** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / int2 / int4 / int8
Label image.

▷ **`Regions`** (output_object) . . . . . region-array ⇝ *object*
Regions having a constant gray value.

Complexity

Let $x1$ be the minimum x-coordinate, $x2$ the maximum x-coordinate, $y1$ be the minimum y-coordinate, and $y2$ the maximum y-coordinate of a particular gray value. Furthermore, let N be the number of different gray values in the image. Then the runtime complexity is $O(N * (x2 - x1 + 1) * (y2 - y1 + 1))$

Result

`label_to_region` returns 2 (`H_MSG_TRUE`) if the gray values lie within a correct range. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

23.3 Features

This chapter contains operators that allow you to access the different features of regions.

List of Features

In the following, the available features are illustrated.

'area': Area of the object

'row': Row index of the center

'column': Column index of the center

'row1': Row index of upper left corner

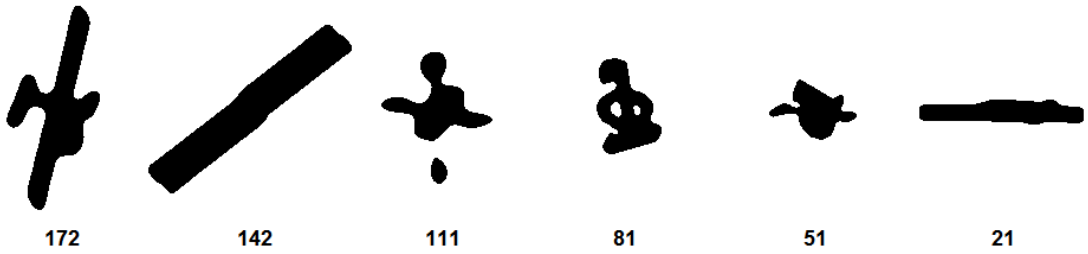
'column1': Column index of upper left corner

'row2': Row index of lower right corner

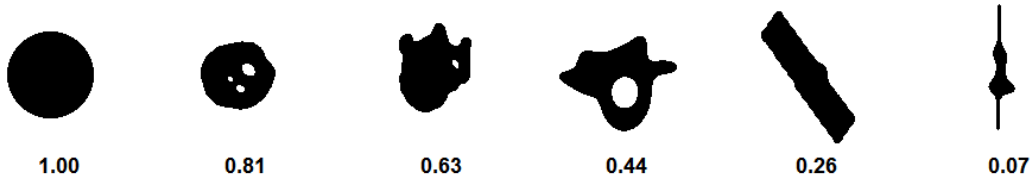
'column2': Column index of lower right corner

'width': Width of the region (parallel to the coordinate axis)

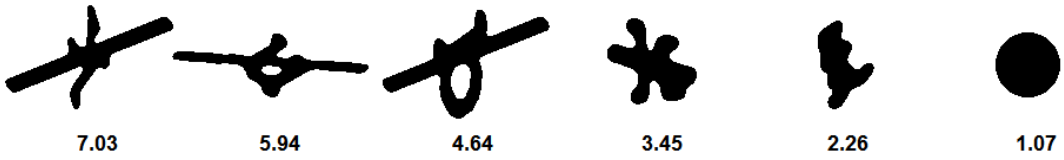
'height': Height of the region (parallel to the coordinate axis)



'circularity': Circularity (see `circularity`)

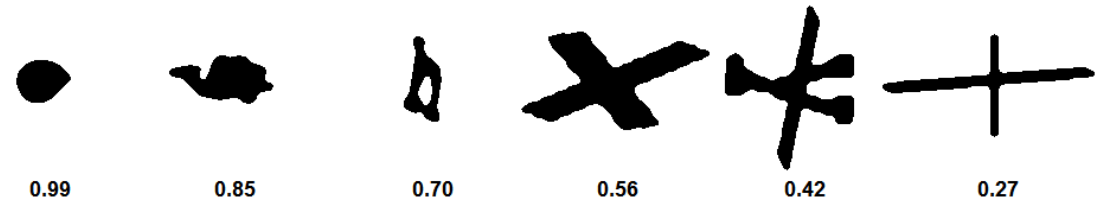


'compactness': Compactness (see `compactness`)



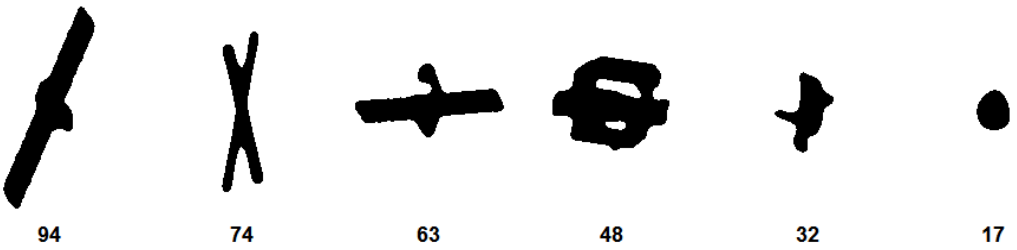
'contlength': Total length of contour (see operator `contlength`)

'convexity': Convexity (see `convexity`)

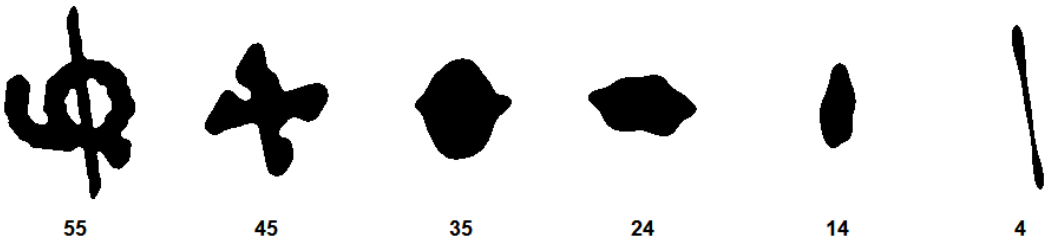


'rectangularity': Rectangularity (see `rectangularity`)

'ra': Main radius of the equivalent ellipse (see `elliptic_axis`)

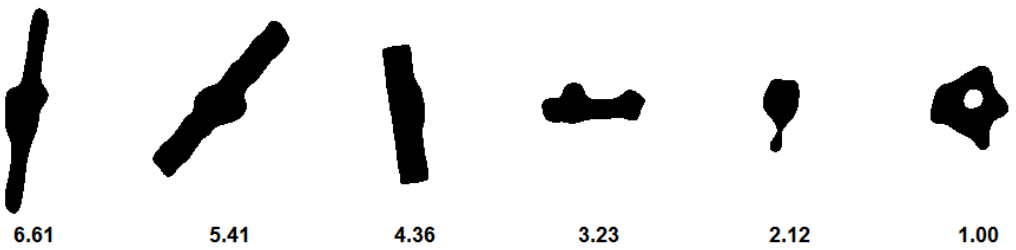


'rb': Secondary radius of the equivalent ellipse (see `elliptic_axis`)

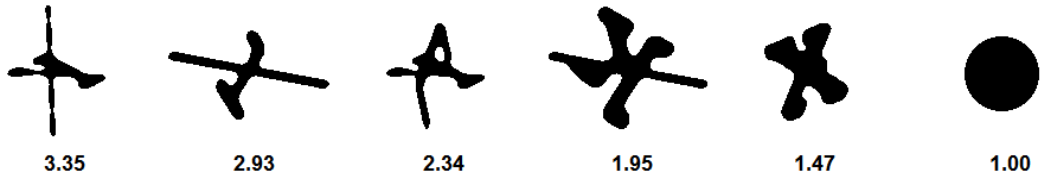


'phi': Orientation of the equivalent ellipse see `elliptic_axis`)

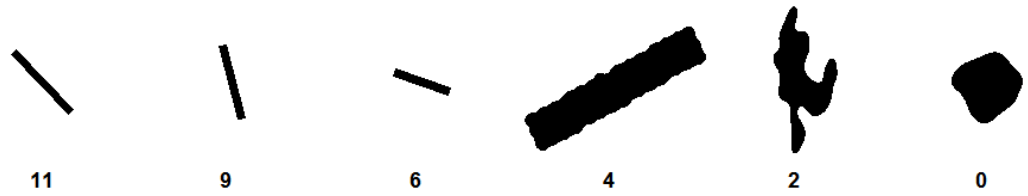
'anisometry': Anisometry (see `eccentricity`)



'bulkiness': Bulkiness (see operator `eccentricity`)



'struct_factor': Structure Factor (see operator `eccentricity`)



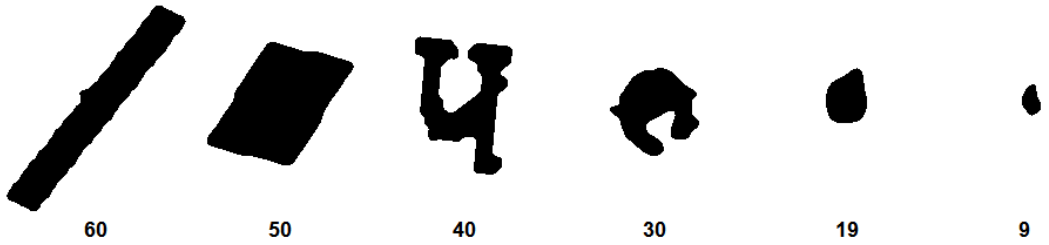
'outer_radius': Radius of smallest surrounding circle (see `smallest_circle`)

'inner_radius': Radius of largest inner circle (see `inner_circle`)

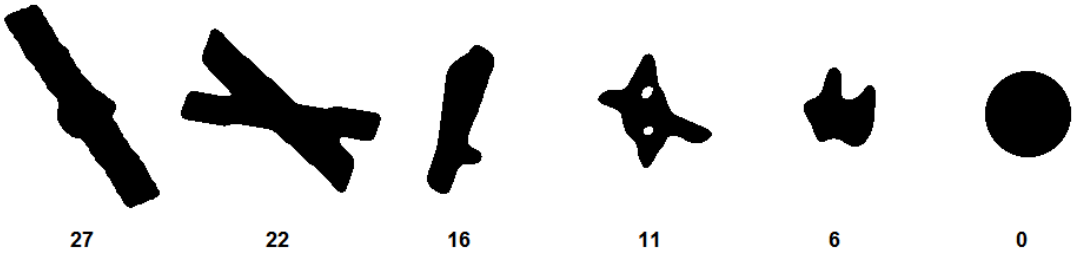
'inner_width': Width of the largest axis-parallel rectangle that fits into the region (see `inner_rectangle1`)

'inner_height': Height of the largest axis-parallel rectangle that fits into the region (see `inner_rectangle1`)

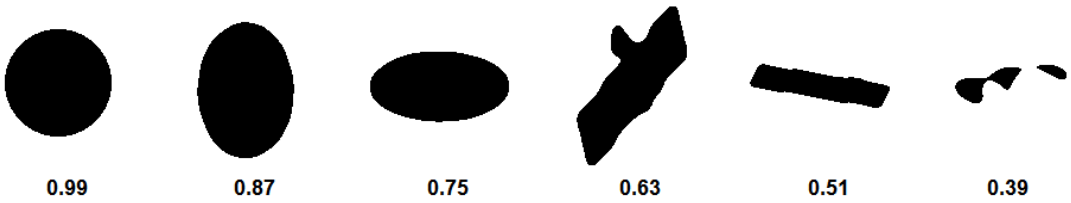
'dist_mean': Mean distance from the region border to the center (see operator `roundness`)



'dist_deviation': Deviation of the distance from the region border to the center (see operator `roundness`)



'roundness': Roundness (see operator `roundness`)



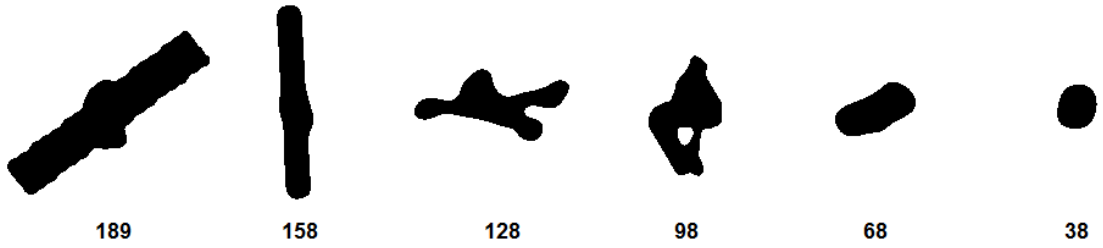
'num_sides': Number of polygon sides (see operator `roundness`)

'connect_num': Number of connection components (see operator `connect_and_holes`)

'holes_num': Number of holes (see operator `connect_and_holes`)

'area_holes': Area of the holes of the object (see operator `area_holes`)

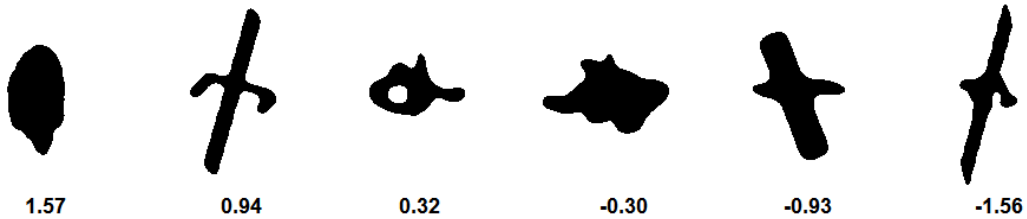
'max_diameter': Maximum diameter of the region (see operator `diameter_region`)



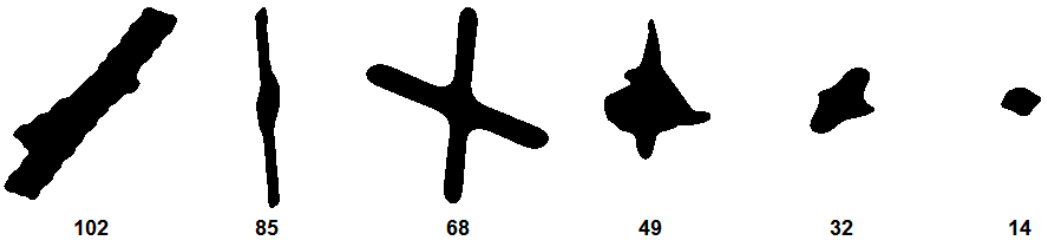
'orientation': Orientation of the region (see operator `orientation_region`)

'euler_number': Euler number (see operator `euler_number`)

'rect2_phi': Orientation of the smallest surrounding rectangle (see operator `smallest_rectangle2`)



'rect2_len1': Half the length of the smallest surrounding rectangle (see operator `smallest_rectangle2`)



'rect2_len2': Half the width of the smallest surrounding rectangle (see operator smallest_rectangle2)

'moments_m11': Geometric moments of the region (see operator moments_region_2nd)

'moments_m20': Geometric moments of the region (see operator moments_region_2nd)

'moments_m02': Geometric moments of the region (see operator moments_region_2nd)

'moments_ia': Geometric moments of the region (see operator moments_region_2nd)

'moments_ib': Geometric moments of the region (see operator moments_region_2nd)

'moments_m11_invar': Geometric moments of the region (see operator moments_region_2nd_invar)

'moments_m20_invar': Geometric moments of the region (see operator moments_region_2nd_invar)

'moments_m02_invar': Geometric moments of the region (see operator moments_region_2nd_invar)

'moments_phi1': Geometric moments of the region (see operator moments_region_2nd_rel_invar)

'moments_phi2': Geometric moments of the region (see operator moments_region_2nd_rel_invar)

'moments_m21': Geometric moments of the region (see operator moments_region_3rd)

'moments_m12': Geometric moments of the region (see operator moments_region_3rd)

'moments_m03': Geometric moments of the region (see operator moments_region_3rd)

'moments_m30': Geometric moments of the region (see operator moments_region_3rd)

'moments_m21_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_m12_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_m03_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_m30_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_i1': Geometric moments of the region (see operator moments_region_central)

'moments_i2': Geometric moments of the region (see operator moments_region_central)

'moments_i3': Geometric moments of the region (see operator moments_region_central)

'moments_i4': Geometric moments of the region (see operator moments_region_central)

'moments_psi1': Geometric moments of the region (see operator moments_region_central_invar)

'moments_psi2': Geometric moments of the region (see operator moments_region_central_invar)

'moments_psi3': Geometric moments of the region (see operator moments_region_central_invar)

'moments_psi4': Geometric moments of the region (see operator moments_region_central_invar)

area_center (Regions : : : Area, Row, Column)

Area and center of regions.

The operator area_center calculates the area and the center of the input regions. The area is defined as the number of pixels of a region. The center is calculated as the mean value of the line or column coordinates, respectively, of all pixels.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their area.

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of the input region. In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system).

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Region(s) to be examined.
- ▷ **Area** (output_control) ..... integer(-array) ⇝ *integer*
  Area of the region.
- ▷ **Row** (output_control) ..... point.y(-array) ⇝ *real*
  Line index of the center.
- ▷ **Column** (output_control) ..... point.x(-array) ⇝ *real*
  Column index of the center.

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

main()
{
  Tuple   area, row, column;

  HImage   img ("monkey");
  HWindow  w;

  img.Display (w);
  w.Click ();

  HRegionArray   reg = (img >= 164).Connection ();

  reg.Display (w);
  w.Click ();

  area = reg.AreaCenter (&row, &column);

  for (int i = 0; i < reg.Num (); i++)
  {
    cout << "Row    [" << i << "]" << "= " << row[i].D ();
    cout << "\t\tColumn [" << i << "]" << "= " << column[i].D () << endl;
  }

  cout << "Total number of regions: " << reg.Num () << endl;
  return(0);
}
```

Complexity

If F is the area of a region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator `area_center` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`

See also

`select_shape`

Module

Foundation

area_holes (Regions : : : Area)

Compute the area of holes of regions.

The operator `area_holes` calculates the area of the holes in the input regions. The area is defined as the number of pixels contained in the holes. If a region has more than one hole the sum of the areas of all holes in this region are returned. The neighborhood type is set via `set_system('neighborhood',<4/8>)` (default: 8-neighborhood).

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in the area of their holes.

If more than one region is passed the results are stored in tuples with the index of a value in the tuple corresponding to the index of the input region. In case of an empty region the area has the value 0.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Area** (output_control) ..... integer(-array) ⇝ *integer*
Area(s) of holes of the region(s).

Example

```
read_image(Image,'modules/modules_01')
threshold(Image,Region,50,250)
area_holes(Region,Area)
```

Result

The operator `area_holes` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, regiongrowing, connection

See also

area_center, fill_up

Module

Foundation

circularity (Regions : : : Circularity)

Shape factor for the circularity (similarity to a circle) of a region.

The operator circularity calculates the similarity of the input region with a circle.

Calculation: If F is the area of the region and max is the maximum distance from the center to all contour pixels, the shape factor C is defined as:

$$C' = \frac{F}{(max^2 * \pi)}$$

$$C = \min(1.0, C')$$

The shape factor C of a circle is 1. If the region is long or has holes, C is smaller than 1. The operator circularity especially responds to large bulges, holes and unconnected regions. The value of C is clipped to 1.0, because the pixel area of a region can only be an approximation of a real circle's area. This approximation error is bigger for small regions than for large regions.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their circularity.

In case of an empty region the operator circularity returns the value 0 (if no other behavior was set (see set_system)). If more than one region is passed the numerical values of the shape factor are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Circularity** (output_control) ..... real(-array) ⇝ *real*
Circularity of the input region(s).
Assertion: 0 <= Circularity && Circularity <= 1.0

Example

```
* Comparison between shape factors of rectangle, circle and ellipse:
gen_rectangle1(R1,10,10,20,20)
gen_rectangle2(R2,100,100,0.0,100,20)
gen_ellipse(E100,100,100,0.0,100,20)
gen_circle(C,100,100,20)
circularity(R1,M_R1)
circularity(R2,M_R2)
circularity(E100,M_E)
circularity(C,M_C)
fwrite_string(FileId,['quadrate:  ',M_R1])
fnew_line(FileId)
fwrite_string(FileId,['rectangle: ',M_R2])
fnew_line(FileId)
fwrite_string(FileId,['ellipse:   ',M_E])
fnew_line(FileId)
fwrite_string(FileId,['circle:    ',M_C])
fnew_line(FileId)
```

Result

The operator circularity returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Foundation

compactness (Regions : : : Compactness)

Shape factor for the compactness of a region.

The operator compactness calculates the compactness of the input regions.

Calculation: If L is the length of the contour (see contlength) and F the area of the region the shape factor C is defined as:

$$C' = \frac{L^2}{4F\pi}$$

$$C = \max(1, C')$$

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their compactness.

The shape factor C of a circle is 1. If the region is long or has holes C is larger than 1. The operator compactness responds to the course of the contour (roughness) and to holes. The value of C is clipped to 1.0, because the pixel area of a region can only be an approximation of a real circle's area. This approximation error is bigger for small regions than for large regions.

In case of an empty region the operator compactness returns the value 0 if no other behavior was set (see set_system). If more than one region is passed the numerical values of the shape factor are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Compactness** (output_control) ..... real(-array) ⇝ *real*
Compactness of the input region(s).
Assertion: Compactness >= 1.0 || Compactness == 0

Result

The operator compactness returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

Alternatives

convexity, eccentricity

contlength, area_center, select_shape

Module

Foundation

connect_and_holes (Regions : : : NumConnected, NumHoles)

Number of connection components and holes

The operator connect_and_holes calculates the number of connection components and the number of holes of each region of Regions.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in the number of their connection components and the number of their holes.

If more than one region is passed the numerical values of the output control parameters NumConnected and NumHoles are each stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **NumConnected** (output_control) ..... integer(-array) ⇝ *integer*
Number of connection components of a region.

▷ **NumHoles** (output_control) ..... integer(-array) ⇝ *integer*
Number of holes of a region.

Result

The operator connect_and_holes returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

Alternatives

euler_number

See also

connection, fill_up, fill_up_shape, union1

Module

Foundation

contlength (Regions : : : ContLength)

Contour length of a region.

The operator contlength calculates the total length of the contour (sum of all connection components of the region) for each region of Regions. The distance between two neighboring contour points parallel to the coordinate axes is rated 1, the distance in the diagonal is rated $\sqrt{2}$.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in the length of their contours.

If more than one region is passed the numerical values of the contour length are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple. In case of an empty region the operator contlength returns the value 0.

Attention

The contour of holes is not calculated.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **ContLength** (output_control) ..... real(-array) ⇝ *real*
Contour length of the input region(s).
Assertion: ContLength >= 0

Example

```
#include "HalconCpp.h"
#include <iostream>
using namespace HalconCpp;

int main (int argc, char *argv[])
{
  HWindow        w(10,10,512,512);
  HRegion        reg;
  int            NumOfElements = 3;

  std::cout << "Draw " << NumOfElements << " regions " << std::endl;
  GenEmptyObj(&reg);
  for (int i=0; i < NumOfElements; i++)
  {
    reg = reg.ConcatObj(w.DrawRegion());
  }

  HTuple circ = reg.Circularity ();
  HTuple cont = reg.Contlength ();

  for (int i = 0; i < NumOfElements; i++)
  {
    std::cout << "region " << i+1 << ": \tcircularity = " << circ[i].D() <<
                 "\tcontour length =" << cont[i].D() << std::endl;
  }
  std::cout << "Click into the graphics window to end." << std::endl;
  w.Click ();
  return(0);
}
```

Result

The operator contlength returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

area_center, get_region_contour

Module

Foundation

convexity (Regions : : : Convexity)

Shape factor for the convexity of a region.

The operator convexity calculates the convexity of each input region of Regions.

Calculation: If F_c is the area of the convex hull and F_o the original area of the region the shape factor C is defined as:

$$C = \frac{F_o}{F_c}$$

The shape factor C is 1 if the region is convex (e.g., rectangle, circle etc.). If there are indentations or holes C is smaller than 1.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their convexity.

In case of an empty region the operator convexity returns the value 0 (if no other behavior was set (see set_system)). If more than one region is passed the numerical values of the contour length are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Convexity** (output_control) ..... real(-array) ⇝ *real*
Convexity of the input region(s).
Assertion: Convexity <= 1

Result

The operator convexity returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

See also

select_shape, area_center, shape_trans

Module

Foundation

diameter_region (Regions : : : Row1, Column1, Row2, Column2, Diameter)

Maximal distance between two boundary points of a region.

The operator diameter_region calculates the maximal distance between two boundary points of a region. The coordinates of these two extremes and the distance between them will be returned.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their diameter.

Attention

If the region is empty, the results of Row1, Column1, Row2 and Column2 (all of them = 0) may lead to confusion.

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Row1** (output_control) ..... line.begin.y(-array) ⇝ *integer*
  Row index of the first extreme point.
- ▷ **Column1** (output_control) ..... line.begin.x(-array) ⇝ *integer*
  Column index of the first extreme point.
- ▷ **Row2** (output_control) ..... line.end.y(-array) ⇝ *integer*
  Row index of the second extreme point.
- ▷ **Column2** (output_control) ..... line.end.x(-array) ⇝ *integer*
  Column index of the second extreme point.
- ▷ **Diameter** (output_control) ..... number(-array) ⇝ *real*
  Distance of the two extreme points.

Complexity

If F is the area of a region, the runtime complexity amounts to $O(sqrt(F))$ on average.

Result

The operator diameter_region returns the value 2 (H_MSG_TRUE), if the input is not empty. The reaction to empty input (no input regions are available) may be determined with the help of the operator set_system ('no_object_result',<Result>). The reaction concerning an empty region (region is the empty set) will be determined by the operator set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

disp_line

Alternatives

smallest_rectangle2

Module

Foundation

eccentricity (Regions : : : Anisometry, Bulkiness, StructureFactor)

Shape features derived from the ellipse parameters.

The operator eccentricity calculates the three shape features Anisometry, Bulkiness, and StructureFactor for the given Regions:

$$\begin{aligned} \texttt{Anisometry} &= \frac{Ra}{Rb} \\ \texttt{Bulkiness} &= \frac{\pi \cdot Ra \cdot Rb}{A} \\ \texttt{StructureFactor} &= \texttt{Anisometry} \cdot \texttt{Bulkiness} - 1 \end{aligned}$$

where Ra and Rb denote the ellipse radii (see elliptic_axis) and A denotes the area of the region (see area_center).

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their anisometry, bulkiness and structure factor.

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system).

Attention

It should be noted that, like for all region-moments-based operators, the region's pixels are regarded as mathematical, infinitely small points that are represented by the center of the pixels (see the documentation of elliptic_axis). This can lead to non-empty regions that have Rb = *0*. In these cases, the output features that require a division by Rb are set to *0*. In particular, regions that contain a single point or regions whose points lie exactly on a straight line (e.g., one pixel high horizontal regions or one pixel wide vertical regions) have an anisometry of *0*.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Anisometry** (output_control) ..... real(-array) ⇝ *real*
Shape feature (in case of a circle = 1.0).
Assertion: Anisometry >= 1.0

▷ **Bulkiness** (output_control) ..... real(-array) ⇝ *real*
Calculated shape feature.

▷ **StructureFactor** (output_control) ..... real(-array) ⇝ *real*
Calculated shape feature.

Complexity

If F is the area of the region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator eccentricity returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

elliptic_axis, moments_region_2nd, select_shape, area_center

Module

Foundation

elliptic_axis (Regions : : : Ra, Rb, Phi)

Calculate the parameters of the equivalent ellipse.

The operator elliptic_axis calculates the radii Ra and Rb and the orientation Phi of the ellipse having the same orientation and the same aspect ratio as the input region in Regions. Several input regions can be passed as tuples. Ra represents the main radius of the ellipse whereas the radius Rb represents the secondary radius of the ellipse. The orientation of the main axis with regard to the x-axis is returned in Phi which is represented in radians. The principle axis of the ellipse is equivalent to the principle axis of the inertia moment of the input region.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their Phi, Ra and Rb.

Calculation:

If the moments M_{20}, M_{02} and M_{11} are normalized and passed to the area (see moments_region_2nd), the radii Ra and Rb are calculated as:

$$\mathtt{Ra} = \frac{\sqrt{8(M_{20} + M_{02} + \sqrt{(M_{20} - M_{02})^2 + 4M_{11}^2})}}{2}$$

$$\mathtt{Rb} = \frac{\sqrt{8(M_{20} + M_{02} - \sqrt{(M_{20} - M_{02})^2 + 4M_{11}^2})}}{2}$$

The orientation Phi is defined by:

$$\mathtt{Phi} = -0.5 atan2(2M_{11}, M_{02} - M_{20})$$

If more than one region is passed, the results are stored in tuples. The index of an resulting tuple element corresponds to the index of the respective input region.

If an empty region is passed, all parameters have the value 0.0 if no other behavior was set (see set_system ('no_object_result',<Result>)).

Attention

It should be noted that, like for all region-moments-based operators, the region's pixels are regarded as mathematical, infinitely small points that are represented by the center of the pixels. This means that Ra and Rb can assume the value *0*. In particular, for an empty region and a region containing a single point Ra = Rb = *0* is returned. Furthermore, for regions whose points lie exactly on a straight line (e.g., one pixel high horizontal regions or one pixel wide vertical regions), Rb = *0* is returned.

Parameters

- ▷ **Regions** (input_object) . . . region(-array) ⇝ *object*
  Input regions.
- ▷ **Ra** (output_control) . . . real(-array) ⇝ *real*
  Main radius (normalized to the area).
  Assertion: Ra >= 0.0
- ▷ **Rb** (output_control) . . . real(-array) ⇝ *real*
  Secondary radius (normalized to the area).
  Assertion: Rb >= 0.0 && Rb <= Ra
- ▷ **Phi** (output_control) . . . angle.rad(-array) ⇝ *real*
  Angle between main radius and x-axis in radians.
  Assertion: - pi / 2 < Phi && Phi <= pi / 2

Example

```
read_image(Image,'fabrik')
regiongrowing(Image,Seg,5,5,6,100)
elliptic_axis(Seg,Ra,Rb,Phi)
area_center(Seg,_,Row,Column)
gen_ellipse(Ellipses,Row,Column,Phi,Ra,Rb)
dev_set_draw('margin')
dev_display(Ellipses)
```

Complexity

If F is the area of a region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator `elliptic_axis` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

euler_number (Regions : : : EulerNumber)

Calculate the Euler number.

The operator `euler_number` calculates the Euler number, i.e., the difference between the number of connection components and the number of holes.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their Euler number.

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **EulerNumber** (output_control) ..... integer(-array) ⇝ *integer*
Calculated Euler number.

Result

The operator euler_number returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

find_neighbors (Regions1, Regions2 : : MaxDistance : RegionIndex1, RegionIndex2)

Search direct neighbors.

The operator find_neighbors determines neighboring regions with Regions1 and Regions2 containing the regions to be examined. Regions1 can have three different states:

- Regions1 is empty:
  In this case all regions in Regions2 are permutatively checked for neighborhood.
- Regions1 consists of one region:
  The regions of Regions1 are compared to all regions in Regions2.
- Regions1 consists of the same number of regions as Regions2:
  Here all regions at the n-th position in Regions1 and Regions2 are checked for the neighboring relation.

The operator find_neighbors uses the chessboard distance between neighboring regions. It can be specified by the parameter MaxDistance. Neighboring regions are located at the n-th position in RegionIndex1 and RegionIndex2, i.e., the region with index RegionIndex1[n] from Regions1 is the neighbor of the region with index RegionIndex2[n] from Regions2.

Attention

Covered regions are not found!

Parameters

▷ **Regions1** (input_object) . . . . . region(-array) ⇝ *object*
Starting regions.

▷ **Regions2** (input_object) . . . . . region(-array) ⇝ *object*
Comparative regions.

▷ **MaxDistance** (input_control) . . . . . integer ⇝ *integer*
Maximal distance of regions.
Default: 1
Suggested values: MaxDistance ∈ {1, 2, 3, 4, 5, 6, 7, 8, 10, 15, 20, 50}
Value range: 1 ≤ MaxDistance ≤ 255
Minimum increment: 1
Recommended increment: 1

▷ **RegionIndex1** (output_control) . . . . . integer-array ⇝ *integer*
Indices of the found regions from Regions1.

▷ **RegionIndex2** (output_control) . . . . . integer-array ⇝ *integer*
Indices of the found regions from Regions2.

Result

The operator find_neighbors returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_region_index (Regions : : Row, Column : Index)

Index of all regions containing a given pixel.

The operator get_region_index returns the index of all regions in Regions (range of values: 1 to n) containing the test pixel (Row,Column), i.e.:

$$|\texttt{Regions}[n] \cap \{(\texttt{Row}, \texttt{Column})\}| \neq \emptyset$$

The returned indices can be used, e.g., in select_obj to select the regions containing the test pixel.

Attention

If the regions overlap more than one region might contain the pixel. In this case all these regions are returned. If no region contains the indicated pixel the empty tuple (= no region) is returned.

Parameters

▷ **Regions** (input_object) . . . . . region-array ⇝ *object*
Regions to be examined.

▷ **Row** (input_control) . . . . . point.y ⇝ *integer*
Line index of the test pixel.
Default: 100
(lin)

▷ **Column** (input_control) . . . . . point.x ⇝ *integer*
Column index of the test pixel.
Default: 100
(lin)

▷ **Index** (output_control) . . . . . integer(-array) ⇝ *integer*
Index of the regions containing the test pixel.

Complexity

If F is the area of the region and N is the number of regions the mean runtime complexity is $O(ln(sqrt(F)) * N)$.

Result

The operator get_region_index returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_region_thickness (Region : : : Thickness, Histogramm)

Access the thickness of a region along the main axis.

The operator get_region_thickness calculates the thickness of the regions along the main axis (see elliptic_axis) for each pixel of the section. The thickness at one point on the main axis is defined as the distance between the intersections of the contour with the plumb on the main axis in the respective point which are the furthest apart. Additionally the operator get_region_thickness returns the Histogramm of the thicknesses of the region. The length of the histogram corresponds to the largest occurring thickness in the observed region.

Attention

Only one region may be passed. If the region has several connection components, only the first one is investigated. All other components are ignored.

Parameters

▷ **Region** (input_object) ..... region ⇝ *object*
Region to be analyzed.

▷ **Thickness** (output_control) ..... integer-array ⇝ *integer*
Thickness of the region along its main axis.

▷ **Histogramm** (output_control) ..... integer-array ⇝ *integer*
Histogram of the thickness of the region along its main axis.

Result

The operator get_region_thickness returns the value 2 (H_MSG_TRUE) if exactly one region is passed. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

hamming_distance (Regions1, Regions2 : : : Distance, Similarity)

Hamming distance between two regions.

The operator hamming_distance returns the hamming distance between two regions, i.e., the number of pixels of the regions which are different (Distance), i.e., the number of pixels contained in one region but not in the other:

$$\texttt{Distance} = |\texttt{Regions1} \cap \overline{\texttt{Regions2}}| + |\texttt{Regions2} \cap \overline{\texttt{Regions1}}|$$

The parameter Similarity describes the similarity between the two regions based on the hamming distance Distance:

$$\texttt{Similarity} = 1 - \frac{\texttt{Distance}}{|\texttt{Regions1}| + |\texttt{Regions2}|}$$

If both regions are empty Similarity is set to 0. The regions with the same index from both input parameters are always compared.

Attention

In both input parameters the same number of regions must be passed.

Parameters

- ▷ **Regions1** (input_object) . . . . . region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Regions2** (input_object) . . . . . region(-array) ⇝ *object*
  Comparative regions.
- ▷ **Distance** (output_control) . . . . . integer(-array) ⇝ *integer*
  Hamming distance of two regions.
  Assertion: Distance >= 0
- ▷ **Similarity** (output_control) . . . . . real(-array) ⇝ *real*
  Similarity of two regions.
  Assertion: 0 <= Similarity && Similarity <= 1

Complexity

If F is the area of a region the mean runtime complexity is $O(sqrt(F))$.

Result

hamming_distance returns the value 2 (H_MSG_TRUE) if the number of objects in both parameters is the same and is not 0. The behavior in case of empty input (no input objects available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

hamming_change_region

Module

Foundation

hamming_distance_norm (Regions1, Regions2 : : Norm : Distance, Similarity)

Hamming distance between two regions using normalization.

The operator hamming_distance_norm returns the hamming distance between two regions, i.e., the number of pixels of the regions which are different (Distance). Before calculating the difference the region in Regions1 is normalized onto the regions in Regions2. The result is the number of pixels contained in one region but not in the other:

$$\texttt{Distance} = |Norm(\texttt{Regions1}) \cap \overline{\texttt{Regions2}}| + |\texttt{Regions2} \cap \overline{Norm(\texttt{Regions1})}|$$

The parameter Similarity describes the similarity between the two regions based on the hamming distance Distance:

$$\texttt{Similarity} = 1 - \frac{\texttt{Distance}}{|Norm(\texttt{Regions1})| + |\texttt{Regions2}|}$$

The following types of normalization are available:

'center': The region is moved so that both regions have the save center of gravity.

If both regions are empty Similarity is set to 0. The regions with the same index from both input parameters are always compared.

Attention

In both input parameters the same number of regions must be passed.

Parameters

- ▷ **Regions1** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Regions2** (input_object) ..... region(-array) ⇝ *object*
  Comparative regions.
- ▷ **Norm** (input_control) ..... string(-array) ⇝ *string*
  Type of normalization.
  Default: 'center'
  List of values: Norm ∈ {'center'}
- ▷ **Distance** (output_control) ..... integer(-array) ⇝ *integer*
  Hamming distance of two regions.
  Assertion: Distance >= 0
- ▷ **Similarity** (output_control) ..... real(-array) ⇝ *real*
  Similarity of two regions.
  Assertion: 0 <= Similarity && Similarity <= 1

Complexity

If F is the area of a region the mean runtime complexity is $O(sqrt(F))$.

Result

hamming_distance_norm returns the value 2 (H_MSG_TRUE) if the number of objects in both parameters is the same and is not 0. The behavior in case of empty input (no input objects available) is set via the operator set_system('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Foundation

height_width_ratio (Regions : : : Height, Width, Ratio)

Compute the width, height, and aspect ratio of the surrounding rectangle parallel to the coordinate axes.

The operator height_width_ratio calculates the surrounding rectangle of all input regions (parallel to the coordinate axes). The surrounding rectangle is described by the coordinates of the corner pixels (Row1,Column1,Row2,Column2) (see smallest_rectangle1). Based on these values, height_width_ratio computes the width, height, and aspect ratio of the smallest surrounding rectangle as follows:

$$\begin{aligned} \texttt{Width} &= \texttt{Column2} - \texttt{Column1} + 1 \\ \texttt{Height} &= \texttt{Row2} - \texttt{Row1} + 1 \\ \texttt{Ratio} &= \texttt{Height}/\texttt{Width} \end{aligned}$$

If more than one region is passed in Regions, the results are stored in tuples in the same order as the respective regions in the Regions. In case of empty regions, all parameters have the value 0 if no other behavior was set (see set_system).

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Height** (output_control) ..... extent.y(-array) ⇝ *integer*
  Height of the surrounding rectangle of the region.
- ▷ **Width** (output_control) ..... extent.x(-array) ⇝ *integer*
  Width of the surrounding rectangle of the region.
- ▷ **Ratio** (output_control) ..... real(-array) ⇝ *real*
  Aspect ratio of the surrounding rectangle of the region.

Complexity

If F is the area of the region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator height_width_ratio returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, runlength_features

Alternatives

smallest_rectangle1, smallest_rectangle2, region_features

See also

select_shape, smallest_circle, elliptic_axis, area_center

Module

Foundation

inner_circle (Regions : : : Row, Column, Radius)

Largest inner circle of a region.

The operator inner_circle determines the largest inner circle of a region. This is the biggest discrete circle region that completely fits into the region. For this circle the center (Row, Column) and the radius (Radius) are calculated. If the position of the circle is ambiguous, the "first possible" position (as far upper left as possible) is returned.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions with varying inner circles.

The output of the operator is chosen in such a way that it can be used as an input for the operators disp_circle, gen_circle, and gen_ellipse_contour_xld.

If several regions are passed in Regions corresponding tuples are returned as output parameters. In case of an empty input region all parameters have the value *0.0* if no other behavior was set with set_system.

Attention

If several inner circles are present at a region only the most upper left solution is returned.

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Row** (output_control) ..... circle.center.y(-array) ⇝ *real*
  Line index of the center.
- ▷ **Column** (output_control) ..... circle.center.x(-array) ⇝ *real*
  Column index of the center.
- ▷ **Radius** (output_control) ..... circle.radius(-array) ⇝ *real*
  Radius of the inner circle.
  Assertion: Radius >= 0

Example

```
read_image(Image,'fabrik')
regiongrowing(Image,Seg,5,5,6,100)
select_shape(Seg,H,'area','and',100,2000)
inner_circle(H,Row,Column,Radius)
gen_circle(Circles,Row,Column,Radius)
dev_set_draw('margin')
dev_display(Circles)
```

Complexity

If F is the area of the region and R is the radius of the inner circle the runtime complexity is $O(sqrt(F) * R)$.

Result

The operator inner_circle returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>), the behavior in case of empty region is set via set_system ('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

inner_rectangle1 (Regions : : : Row1, Column1, Row2, Column2)

Largest inner rectangle of a region.

The operator inner_rectangle1 determines the largest axis-parallel rectangle that fits into a region. The rectangle is described by the coordinates of the corner pixels (Row1, Column1, Row2, Column2).

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in the width and height of their inner rectangle.

If more than one region is passed in Regions the results are stored in tuples, the index of a value in the tuple corresponding to the index of the input region. For empty regions all parameters have the value 0 if no other behavior was set (see set_system).

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Region to be examined.
- ▷ **Row1** (output_control) ..... rectangle.origin.y(-array) ⇝ *integer*
  Row coordinate of the upper left corner point.
- ▷ **Column1** (output_control) ..... rectangle.origin.x(-array) ⇝ *integer*
  Column coordinate of the upper left corner point.
- ▷ **Row2** (output_control) ..... rectangle.corner.y(-array) ⇝ *integer*
  Row coordinate of the lower right corner point.
- ▷ **Column2** (output_control) ..... rectangle.corner.x(-array) ⇝ *integer*
  Column coordinate of the lower right corner point.

Result

The operator inner_rectangle1 returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Module

Foundation

moments_region_2nd (Regions : : : M11, M20, M02, Ia, Ib)

Calculate the geometric moments of regions.

moments_region_2nd calculates the geometric moments M11, M20 and M02 of the input regions in Regions. Furthermore the major and minor axis of the input regions are calculated and returned in Ia and Ib.

The covariance matrix is given by:

$$\begin{bmatrix} M20 & M11 \\ M11 & M02 \end{bmatrix}$$

The row-dependent moment of 2nd order is returned in `M20` and the column-dependent moment of 2nd order is returned in `M02`. The moment `M11` represents the covariance between the row and column coordinates of the region points.

Calculation: r_0 and c_0 are the coordinates of the center of gravity of a region R. Then the moments M_{ij} are defined by:

$$M_{ij} = \sum_{(r,c) \in R} (r_0 - r)^i (c_0 - c)^j$$

wherein r and c run over all pixels of the region R.

Furthermore the length of the major and minor axes are defined by:

$$Ia = h + \sqrt{h^2 - M20 * M02 + M11^2}$$

$$Ib = h - \sqrt{h^2 - M20 * M02 + M11^2}$$

wherein h is defined by:

$$h = \frac{M20 + M02}{2}$$

The equation for the major and minor axes can be derived from the definition of the moments by diagonalizing the covariance matrix and reforming the resulting formula.

If more than one region is passed, the results are returned in tuples. The index of a tuple element corresponds to the index of the respective input region.

If an empty region is passed, 0.0 is returned for all parameters, if no other behavior was set (see `set_system`).

Parameters

- ▷ **`Regions`** (input_object) ..... region(-array) ⇝ *object*
  Input regions.
- ▷ **`M11`** (output_control) ..... real(-array) ⇝ *real*
  Product of inertia of the axes through the center parallel to the coordinate axes.
- ▷ **`M20`** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order (row-dependent).
- ▷ **`M02`** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order (column-dependent).
- ▷ **`Ia`** (output_control) ..... real(-array) ⇝ *real*
  Length of the major axis of the input region.
- ▷ **`Ib`** (output_control) ..... real(-array) ⇝ *real*
  Length of the minor axis of the input region.

Complexity

If F is the area of the region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator `moments_region_2nd` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system ('no_object_result',<Result>)`. The behavior in case of empty region (region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on tuple level.

moments_region_2nd_invar (Regions : : : M11, M20, M02)

Geometric moments of regions.

The operator moments_region_2nd_invar calculates the scaled moments (M20, M02) and the product of inertia of the axes through the center parallel to the coordinate axes (M11).

Calculation: Z_0 and S_0 are the coordinates of the center of a region R with the area F. Then the moments M_{ij} are defined by:

$$M_{ij} = \frac{1}{F^2} \sum_{(Z,S) \in R} (Z_0 - Z)^i (S_0 - S)^j$$

,

wherein Z and S run through all pixels of the region R.

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system).

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **M11** (output_control) ..... real(-array) ⇝ *real*
  Product of inertia of the axes through the center parallel to the coordinate axes.
- ▷ **M20** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order (line-dependent).
- ▷ **M02** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order (column-dependent).

Complexity

If F is the area of the region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator moments_region_2nd_invar returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

moments_region_2nd_rel_invar (Regions : : : PHI1, PHI2)

Geometric moments of regions.

The operator moments_region_2nd_rel_invar calculates the scaled relative moments (PHI1, PHI2).

Calculation: The moments PHI_1 and PHI_2 are defined by:

$$PHI_1 = M_{20} + M_{02}$$

$$PHI_2 = (M_{20} - M_{02})^2 + 4M_{11}^2$$

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system).

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **PHI1** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order.
- ▷ **PHI2** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order.

Result

The operator moments_region_2nd_rel_invar returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

moments_region_3rd (Regions : : : M21, M12, M03, M30)

Geometric moments of regions.

The operator moments_region_3rd calculates the translation-invariant central moments (M21, M12, M03, M30) of order $(p + q)$.

Calculation: x and y are the coordinates of the center of a region R with the area Z.
Then the moments M_{pq} are defined by:

$$M_{pq} = \sum_{i=1} MZ(x_i, y_i)(x_i - x)^p (y_i - y)^q$$

,
wherein are $x = \frac{m_{10}}{m_{00}}$ and $y = \frac{m_{01}}{m_{00}}$.

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system).

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **M21** (output_control) ..... real(-array) ⇝ *real*
  Moment of 3rd order (line-dependent).
- ▷ **M12** (output_control) ..... real(-array) ⇝ *real*
  Moment of 3rd order (column-dependent).
- ▷ **M03** (output_control) ..... real(-array) ⇝ *real*
  Moment of 3rd order (column-dependent).
- ▷ **M30** (output_control) ..... real(-array) ⇝ *real*
  Moment of 3rd order (line-dependent).

Complexity

If Z is the area of the region the mean runtime complexity is $O(sqrt(Z))$.

Result

The operator moments_region_3rd returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

moments_region_central (Regions : : : I1, I2, I3, I4)

Geometric moments of regions.

The operator moments_region_central calculates the central moments (I1, I2, I3, I4).

Calculation: Then the moments I_i are defined by:

$$
\begin{aligned}
I_1 &= \mu_{20}\mu_{02} - \mu_{11}^2 \\
I_2 &= (\mu_{30}\mu_{03} - \mu_{21}\mu_{12})^2 - 4(\mu_{30}\mu_{12} - \mu_{21}^2)(\mu_{21}\mu_{03} - \mu_{12}^2) \\
I_3 &= \mu_{20}(\mu_{21}\mu_{03} - \mu_{12}^2) - \mu_{11}(\mu_{30}\mu_{03} - \mu_{21}\mu_{12}) + \mu_{02}(\mu_{30}\mu_{12} - \mu_{21}^2) \\
I_4 &= \mu_{30}^2\mu_{02}^3 - 6\mu_{30}\mu_{21}\mu_{11}\mu_{02}^2 + 6\mu_{30}\mu_{12}\mu_{02}(2\mu_{11}^2 - \mu_{20}\mu_{02}) \\
&\quad +\mu_{30}\mu_{03}(6\mu_{20}\mu_{11}\mu_{02} - 8\mu_{11}^3) + 9\mu_{21}^2\mu_{20}\mu_{02}^2 - 18\mu_{21}\mu_{12}\mu_{20}\mu_{11}\mu_{02} \\
&\quad +6\mu_{21}\mu_{03}\mu_{20}(2\mu_{11}^2 - \mu_{20}\mu_{02}) + 9\mu_{12}^2\mu_{20}^2\mu_{02} - 6\mu_{12}\mu_{03}\mu_{11}\mu_{20}^2 + \mu_{03}^2\mu_{20}^3
\end{aligned}
$$

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

In case of empty region all parameters have the value 0.0 if no other behavior was set (see `set_system`).

Parameters

- ▷ **`Regions`** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **`I1`** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order.
- ▷ **`I2`** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order.
- ▷ **`I3`** (output_control) ..... real(-array) ⇝ *real*
  Moment of 2nd order.
- ▷ **`I4`** (output_control) ..... real(-array) ⇝ *real*
  Moment of 3rd order.

Complexity

If Z is the area of the region the mean runtime complexity is $O(sqrt(Z))$.

Result

The operator `moments_region_central` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system ('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Module

Foundation

`orientation_region` (Regions : : : Phi)

Orientation of a region.

The operator orientation_region calculates the orientation of the region. The operator is based on elliptic_axis. In addition the point on the contour with maximal distance to the center of gravity is calculated. If, in the rotated coordinate system, the column coordinate of this point is less than the column coordinate of the center of gravity, the value of π is added to the angle.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their orientation.

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system ('no_object_result',<Result>)).

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Phi** (output_control) ..... angle.rad(-array) ⇝ *real*
Orientation of region (arc measure).
Assertion: - pi <= Phi && Phi < pi

Complexity

If F is the area of a region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator orientation_region returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

rectangularity (Regions : : : Rectangularity)

Shape factor for the rectangularity of a region.

The operator rectangularity calculates the rectangularity of the input regions.

To determine the rectangularity, first a rectangle is computed that has the same first and second order moments as the input region. The computation of the rectangularity measure is finally based on the area of the difference between the computed rectangle and the input region normalized with respect to the area of the rectangle.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their rectangularity.

For rectangles rectangularity returns the value 1. The more the input region deviates from a perfect rectangle, the less the returned value for Rectangularity will be.

In case of an empty region the operator rectangularity returns the value 0 (if no other behavior was set (see set_system)). If more than one region is passed the numerical values of the rectangularity are stored in a tuple, the position of a value in the tuple corresponding to the position of the region in the input tuple.

Attention

For input regions which orientation cannot be computed by using second order moments (as it is the case for square regions, for example), the returned Rectangularity is underestimated by up to 10% depending on the orientation of the input region.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Rectangularity** (output_control) ..... real(-array) ⇝ *real*
Rectangularity of the input region(s).
Assertion: 0 <= Rectangularity && Rectangularity <= 1.0

Result

The operator rectangularity returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

region_features (Regions : : Features : Value)

Calculate shape features of regions.

The operator region_features calculates for each input region from Regions the indicated features (Features).

For an illustration of these features, please refer to the documentation of this chapter (Regions / Features).

Possible values for Features:

'area': Area of the object

'row': Row index of the center

'column': Column index of the center

'row1': Row index of upper left corner

'column1': Column index of upper left corner

'row2': Row index of lower right corner

'column2': Column index of lower right corner
'width': Width of the region (parallel to the coordinate axes)
'height': Height of the region (parallel to the coordinate axes)
'ratio': Ratio of the height and the width of the region (parallel to the coordinate axes)
'circularity': Circularity (see `circularity`)
'compactness': Compactness (see `compactness`)
'contlength': Total length of contour (see operator `contlength`)
'convexity': Convexity (see `convexity`)
'rectangularity': Rectangularity (see `rectangularity`)
'ra': Main radius of the equivalent ellipse (see `elliptic_axis`)
'rb': Secondary radius of the equivalent ellipse (see `elliptic_axis`)
'phi': Orientation of the equivalent ellipse (see `elliptic_axis`)
'anisometry': Anisometry (see `eccentricity`)
'bulkiness': Bulkiness (see operator `eccentricity`)
'struct_factor': Structure Factor (see operator `eccentricity`)
'outer_radius': Radius of smallest surrounding circle (see `smallest_circle`)
'inner_radius': Radius of largest inner circle (see `inner_circle`)
'inner_width': Width of the largest axis-parallel rectangle that fits into the region (see `inner_rectangle1`)
'inner_height': Height of the largest axis-parallel rectangle that fits into the region (see `inner_rectangle1`)
'dist_mean': Mean distance from the region border to the center (see operator `roundness`)
'dist_deviation': Deviation of the distance from the region border to the center (see operator `roundness`)
'roundness': Roundness (see operator `roundness`)
'num_sides': Number of polygon sides (see operator `roundness`)
'connect_num': Number of connection components (see operator `connect_and_holes`)
'holes_num': Number of holes (see operator `connect_and_holes`)
'area_holes': Area of the holes of the object (see operator `area_holes`)
'max_diameter': Maximum diameter of the region (see operator `diameter_region`)
'orientation': Orientation of the region (see operator `orientation_region`)
'euler_number': Euler number (see operator `euler_number`)
'rect2_phi': Orientation of the smallest surrounding rectangle (see operator `smallest_rectangle2`)
'rect2_len1': Half the length of the smallest surrounding rectangle (see operator `smallest_rectangle2`)
'rect2_len2': Half the width of the smallest surrounding rectangle (see operator `smallest_rectangle2`)
'moments_m11': Geometric moments of the region (see operator `moments_region_2nd`)
'moments_m20': Geometric moments of the region (see operator `moments_region_2nd`)
'moments_m02': Geometric moments of the region (see operator `moments_region_2nd`)
'moments_ia': Geometric moments of the region (see operator `moments_region_2nd`)
'moments_ib': Geometric moments of the region (see operator `moments_region_2nd`)
'moments_m11_invar': Geometric moments of the region (see operator `moments_region_2nd_invar`)
'moments_m20_invar': Geometric moments of the region (see operator `moments_region_2nd_invar`)
'moments_m02_invar': Geometric moments of the region (see operator `moments_region_2nd_invar`)
'moments_phi1': Geometric moments of the region (see operator `moments_region_2nd_rel_invar`)
'moments_phi2': Geometric moments of the region (see operator `moments_region_2nd_rel_invar`)
'moments_m21': Geometric moments of the region (see operator `moments_region_3rd`)
'moments_m12': Geometric moments of the region (see operator `moments_region_3rd`)
'moments_m03': Geometric moments of the region (see operator `moments_region_3rd`)

'moments_m30': Geometric moments of the region (see operator moments_region_3rd)

'moments_m21_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_m12_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_m03_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_m30_invar': Geometric moments of the region (see operator moments_region_3rd_invar)

'moments_i1': Geometric moments of the region (see operator moments_region_central)

'moments_i2': Geometric moments of the region (see operator moments_region_central)

'moments_i3': Geometric moments of the region (see operator moments_region_central)

'moments_i4': Geometric moments of the region (see operator moments_region_central)

'moments_psi1': Geometric moments of the region (see operator moments_region_central_invar)

'moments_psi2': Geometric moments of the region (see operator moments_region_central_invar)

'moments_psi3': Geometric moments of the region (see operator moments_region_central_invar)

'moments_psi4': Geometric moments of the region (see operator moments_region_central_invar)

Several features are processed in the sequence in which they are entered.

Parameters

▷ **Regions** (input_object) ..... region-array ⇝ *object*
Regions to be examined.

▷ **Features** (input_control) ..... string(-array) ⇝ *string*
Shape features to be calculated.
Default: 'area'
List of values: Features ∈ {'area', 'row', 'column', 'width', 'height', 'ratio', 'row1', 'column1', 'row2', 'column2', 'circularity', 'compactness', 'contlength', 'convexity', 'rectangularity', 'ra', 'rb', 'phi', 'anisometry', 'bulkiness', 'struct_factor', 'outer_radius', 'inner_radius', 'inner_width', 'inner_height', 'max_diameter', 'dist_mean', 'dist_deviation', 'roundness', 'num_sides', 'orientation', 'connect_num', 'holes_num', 'area_holes', 'euler_number', 'rect2_phi', 'rect2_len1', 'rect2_len2', 'moments_m11', 'moments_m20', 'moments_m02', 'moments_ia', 'moments_ib', 'moments_m11_invar', 'moments_m20_invar', 'moments_m02_invar', 'moments_phi1', 'moments_phi2', 'moments_m21', 'moments_m12', 'moments_m03', 'moments_m30', 'moments_m21_invar', 'moments_m12_invar', 'moments_m03_invar', 'moments_m30_invar', 'moments_i1', 'moments_i2', 'moments_i3', 'moments_i4', 'moments_psi1', 'moments_psi2', 'moments_psi3', 'moments_psi4'}

▷ **Value** (output_control) ..... real(-array) ⇝ *real*
The calculated features.

Example

```
read_image(Image,'monkey')
threshold(Image,S1,160,255)
connection(S1,S2)
region_features(S2,['area','anisometry'],Value)
```

Result

The operator region_features returns the value 2 (H_MSG_TRUE) if the input is not empty. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, runlength_features

Module

Foundation

roundness (Regions : : : Distance, Sigma, Roundness, Sides)

Shape factors from contour.

The operator roundness examines the distance between the contour and the center of the area. In particular the mean distance (Distance), the deviation from the mean distance (Sigma) and two shape features derived therefrom are determined. Roundness is the relation between mean value and standard deviation, and Sides indicates the number of polygon pieces if a regular polygon is concerned.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in their mean distance, distance deviation, roundness and number of polygon pieces.

The contour for calculating the features is determined depending on the global neighborhood (see set_system).

Calculation:

If p is the center of the area, p_i the pixels and F the area of the contour.

$$\texttt{Distance} = \frac{1}{F} \sum ||p - p_i||$$

$$\texttt{Sigma}^2 = \frac{1}{F} \sum (||p - p_i|| - \texttt{Distance})^2$$

$$\texttt{Roundness} = 1 - \frac{\texttt{Sigma}}{\texttt{Distance}}$$

$$\texttt{Sides} = 1.4111 \left(\frac{\texttt{Distance}}{\texttt{Sigma}} \right)^{0.4724}$$

If more than one region is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input.

In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system).

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Distance** (output_control) ..... real(-array) ⇝ *real*
Mean distance from the center.
Assertion: Distance >= 0.0

▷ **Sigma** (output_control) ..... real(-array) ⇝ *real*
Standard deviation of Distance.
Assertion: Sigma >= 0.0

▷ **Roundness** (output_control) . . . . . real(-array) ⇝ *real*
Shape factor for roundness.
Assertion: Roundness <= 1.0

▷ **Sides** (output_control) . . . . . real(-array) ⇝ *real*
Number of polygon sides.
Assertion: Sides >= 0

Complexity

If F is the area of a region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator `roundness` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system ('no_object_result',<Result>)`, the behavior in case of empty region is set via `set_system ('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

runlength_distribution (Region : : : Foreground, Background)

Distribution of runs needed for runlength encoding of a region.

The operator `runlength_distribution` calculates the distribution of the runs of a region of the fore- and background. The frequency of the occurrence of a certain length is calculated. Runs of infinite length are not counted. Therefore the background are the holes of the region. As many values are passed as set by the maximum length of fore- or background, respectively. The length of both tuples usually differs. The first entry of the tuples is always 0 (no runs of the length 0). If there are no blanks the empty tuple is passed at `Background`. Analogously the empty tuple is passed in case of an empty region at `Foreground`.

Parameters

▷ **Region** (input_object) . . . . . region ⇝ *object*
Region to be examined.

▷ **Foreground** (output_control) . . . . . integer-array ⇝ *integer*
Length distribution of the region (foreground).

▷ **Background** (output_control) . . . . . integer-array ⇝ *integer*
Length distribution of the background.

Complexity

If n is the number of runs of the region the runtime complexity is $O(n)$.

Result

The operator `runlength_distribution` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system ('no_object_result',<Result>)`. If more than one region is passed an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`runlength_features`

Module

Foundation

runlength_features (Regions : : : NumRuns, KFactor, LFactor, MeanLength, Bytes)

Characteristic values for runlength coding of regions.

The operator `runlength_features` calculates for every input region from `Regions` the number of runs necessary for storing this region with the aid of runlength coding. Furthermore the so-called "K-factor" is determined, which indicates by how much the number of runs differs from the ideal of the square in which this value is 1.0.

The K-factor (`KFactor`) is calculated according to the formula:

$$\texttt{KFactor} = \frac{\texttt{NumRuns}}{\sqrt{Area}}$$

wherein $Area$ indicates the area of the region. It should be noted that the K-factor can be smaller than 1.0 (in case of long horizontal regions).

The L-factor (`LFactor`) indicates the mean number of runs for each line index occurring in the region.

`MeanLength` indicates the mean length of the runs. The parameter `Bytes` indicates how many bytes are necessary for coding the region with runlengths.

Attention

All features calculated by the operator `runlength_features` are not rotation invariant because the runlength coding depends on the direction. The operator `runlength_features` does not serve for calculating shape features but for controlling and analyzing the efficiency of the runlength coding.

Parameters

▷ **Regions** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be examined.

▷ **NumRuns** (output_control) . . . . . integer(-array) ⇝ *integer*
Number of runs.
Assertion: 0 <= NumRuns

▷ **KFactor** (output_control) . . . . . real(-array) ⇝ *real*
Storing factor in relation to a square.
Assertion: 0 <= KFactor

▷ **LFactor** (output_control) . . . . . real(-array) ⇝ *real*
Mean number of runs per line.
Assertion: 0 <= LFactor

▷ **MeanLength** (output_control) . . . . . real(-array) ⇝ *real*
Mean length of runs.
Assertion: 0 <= MeanLength

▷ **Bytes** (output_control) ..... integer(-array) ⇝ *integer*
Number of bytes necessary for coding the region.
Assertion: 0 <= Bytes

Complexity

The mean runtime complexity is $O(1)$.

Result

The operator `runlength_features` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`

See also

`runlength_distribution`

Module

Foundation

select_region_point (Regions : DestRegions : Row, Column :)

Choose all regions containing a given pixel.

The operator `select_region_point` selects all regions from `Regions` containing the test pixel (`Row`,`Column`), i.e.:

$$|\texttt{Regions}[n] \cap \{(\texttt{Row}, \texttt{Column})\}| = 1$$

Attention

If the regions overlap more than one region might contain the pixel. In this case all these regions are returned. If no region contains the indicated pixel the empty tuple (= no region) is returned.

Parameters

▷ **Regions** (input_object) ..... region-array ⇝ *object*
Regions to be examined.

▷ **DestRegions** (output_object) ..... region-array ⇝ *object*
All regions containing the test pixel.

▷ **Row** (input_control) ..... point.y ⇝ *integer*
Line index of the test pixel.
Default: 100

▷ **Column** (input_control) ..... point.x ⇝ *integer*
Column index of the test pixel.
Default: 100

Example

```
read_image(Image,'fabrik')
regiongrowing(Image,Seg,3,3,5,0)
dev_set_color('red')
dev_set_draw('margin')
Button := 1
while (Button == 1)
  get_mbutton(WindowHandle,Row,Column,Button)
```

```
  select_region_point(Seg,Single,Row,Column)
  dev_display(Image)
  dev_display(Single)
endwhile
```

Complexity

If F is the area of the region and N is the number of regions, the mean runtime complexity is $O(ln(sqrt(F)) * N)$.

Result

The operator `select_region_point` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. The behavior in case of empty input (no input regions available) is set via the operator `set_system ('no_object_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`

Alternatives

`test_region_point`

`get_mbutton`, `get_mposition`

Module

Foundation

select_region_spatial (Regions1, Regions2 : : Direction : RegionIndex1, RegionIndex2)

Pose relation of regions.

The operator `select_region_spatial` chooses the regions from `Regions2` which are sufficient for the neighboring relation `Direction`. The regions to be examined have to be passed in `Regions1` or `Regions2`, respectively. `Regions1` can have three different states:

- `Regions1` is empty:
  In this case all regions in `Regions2` are permutatively checked for neighborhood.
- `Regions1` consists of one region:
  The regions of `Regions1` are compared to all regions in `Regions2`.
- `Regions1` consists of the same number of regions as `Regions2`:
  The regions at the n-th position in `Regions1` and `Regions2` are each checked for a neighboring relation.

Possible values for `Direction` are:

'left': `Regions2` is left of `Regions1`

'right': `Regions2` is right of `Regions1`

'above': `Regions2` is above `Regions1`

'below': `Regions2` is below `Regions1`

The operator `select_region_spatial` calculates the centers of the regions to be compared and decides according to the angle between the center straight lines and the x axis whether the direction relation is fulfilled. The relation is fulfilled within the area of -45 degree to +45 degree around the coordinate axes. Thus, the direction relation can be understood in such a way that the center of the second region must be located left (or right, above, below) of the center of the first region. The indices of the regions fulfilling the direction relation are located at the

n-th position in RegionIndex1 and RegionIndex2, i.e., the region with the index RegionIndex2[n] has the indicated relation with the region with the index RegionIndex1[n]. Access to regions via the index can be obtained via the operator copy_obj.

Parameters

▷ **Regions1** (input_object) ..... region(-array) ⇝ *object*
Starting regions

▷ **Regions2** (input_object) ..... region(-array) ⇝ *object*
Comparative regions

▷ **Direction** (input_control) ..... string ⇝ *string*
Desired neighboring relation.
Default: 'left'
List of values: Direction ∈ {'left', 'right', 'above', 'below'}

▷ **RegionIndex1** (output_control) ..... integer-array ⇝ *integer*
Indices in the input tuples (Regions1 or Regions2), respectively.

▷ **RegionIndex2** (output_control) ..... integer-array ⇝ *integer*
Indices in the input tuples (Regions1 or Regions2), respectively.

Result

The operator select_region_spatial returns the value 2 (H_MSG_TRUE) if Regions2 is not empty. The behavior in case of empty parameter Regions2 (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

select_shape (Regions : SelectedRegions : Features, Operation, Min, Max :)

Choose regions with the aid of shape features.

The operator select_shape chooses regions according to shape. For each input region from Regions the indicated features (Features) are calculated. If each (Operation = *'and'*) or at least one (Operation = *'or'*) of the calculated features is within the default limits (Min,Max) the region is adapted into the output (duplicated). The parameters Min and Max can be set to *'min'* or *'max'* in order to leave bottom and top limits, respectively, open.

Condition: $Min_i \leq Feature_i(Object) \leq Max_i$

For an illustration of these features, please refer to the documentation of this chapter (Regions / Features).

Possible values for Features:

'area': Area of the object

'row': Row index of the center

'column': Column index of the center

'width': Width of the region (parallel to the coordinate axes; see height_width_ratio)
'height': Height of the region (parallel to the coordinate axes; see height_width_ratio)
'ratio': Ratio of the height and width of the region (parallel to the coordinate axes; see height_width_ratio)
'row1': Row index of upper left corner
'column1': Column index of upper left corner
'row2': Row index of lower right corner
'column2': Column index of lower right corner
'circularity': Circularity (see circularity)
'compactness': Compactness (see compactness)
'contlength': Total length of contour (see operator contlength)
'convexity': Convexity (see convexity)
'rectangularity': Rectangularity (see rectangularity)
'ra': Main radius of the equivalent ellipse (see elliptic_axis)
'rb': Secondary radius of the equivalent ellipse (see elliptic_axis)
'phi': Orientation of the equivalent ellipse (see elliptic_axis)
'anisometry': Anisometry (see eccentricity)
'bulkiness': Bulkiness (see operator eccentricity)
'struct_factor': Structure Factor (see operator eccentricity)
'outer_radius': Radius of smallest surrounding circle (see smallest_circle)
'inner_radius': Radius of largest inner circle (see inner_circle)
'inner_width': Width of the largest axis-parallel rectangle that fits into the region (see inner_rectangle1)
'inner_height': Height of the largest axis-parallel rectangle that fits into the region (see inner_rectangle1)
'dist_mean': Mean distance from the region border to the center (see operator roundness)
'dist_deviation': Deviation of the distance from the region border from the center (see operator roundness)
'roundness': Roundness (see operator roundness)
'num_sides': Number of polygon sides (see operator roundness)
'connect_num': Number of connection components (see operator connect_and_holes)
'holes_num': Number of holes (see operator connect_and_holes)
'area_holes': Area of the holes of the object (see operator area_holes)
'max_diameter': Maximum diameter of the region (see operator diameter_region)
'orientation': Orientation of the region (see operator orientation_region)
'euler_number': Euler number (see operator euler_number)
'rect2_phi': Orientation of the smallest surrounding rectangle (see operator smallest_rectangle2)
'rect2_len1': Half the length of the smallest surrounding rectangle (see operator smallest_rectangle2)
'rect2_len2': Half the width of the smallest surrounding rectangle (see operator smallest_rectangle2)
'moments_m11': Geometric moments of the region (see operator moments_region_2nd)
'moments_m20': Geometric moments of the region (see operator moments_region_2nd)
'moments_m02': Geometric moments of the region (see operator moments_region_2nd)
'moments_ia': Geometric moments of the region (see operator moments_region_2nd)
'moments_ib': Geometric moments of the region (see operator moments_region_2nd)
'moments_m11_invar': Geometric moments of the region (see operator moments_region_2nd_invar)
'moments_m20_invar': Geometric moments of the region (see operator moments_region_2nd_invar)
'moments_m02_invar': Geometric moments of the region (see operator moments_region_2nd_invar)
'moments_phi1': Geometric moments of the region (see operator moments_region_2nd_rel_invar)
'moments_phi2': Geometric moments of the region (see operator moments_region_2nd_rel_invar)

'moments_m21': Geometric moments of the region (see operator `moments_region_3rd`)
'moments_m12': Geometric moments of the region (see operator `moments_region_3rd`)
'moments_m03': Geometric moments of the region (see operator `moments_region_3rd`)
'moments_m30': Geometric moments of the region (see operator `moments_region_3rd`)
'moments_m21_invar': Geometric moments of the region (see operator `moments_region_3rd_invar`)
'moments_m12_invar': Geometric moments of the region (see operator `moments_region_3rd_invar`)
'moments_m03_invar': Geometric moments of the region (see operator `moments_region_3rd_invar`)
'moments_m30_invar': Geometric moments of the region (see operator `moments_region_3rd_invar`)
'moments_i1': Geometric moments of the region (see operator `moments_region_central`)
'moments_i2': Geometric moments of the region (see operator `moments_region_central`)
'moments_i3': Geometric moments of the region (see operator `moments_region_central`)
'moments_i4': Geometric moments of the region (see operator `moments_region_central`)
'moments_psi1': Geometric moments of the region (see operator `moments_region_central_invar`)
'moments_psi2': Geometric moments of the region (see operator `moments_region_central_invar`)
'moments_psi3': Geometric moments of the region (see operator `moments_region_central_invar`)
'moments_psi4': Geometric moments of the region (see operator `moments_region_central_invar`)

If only one feature (`Features`) is used the value of `Operation` is meaningless. Several features are processed in the sequence in which they are entered.

Parameters

▷ **`Regions`** (input_object) ..... region-array ⇝ *object*
Regions to be examined.

▷ **`SelectedRegions`** (output_object) ..... region-array ⇝ *object*
Regions fulfilling the condition.

▷ **`Features`** (input_control) ..... string(-array) ⇝ *string*
Shape features to be checked.
Default: 'area'
List of values: `Features` ∈ {'area', 'row', 'column', 'width', 'height', 'ratio', 'row1', 'column1', 'row2', 'column2', 'circularity', 'compactness', 'contlength', 'convexity', 'rectangularity', 'ra', 'rb', 'phi', 'anisometry', 'bulkiness', 'struct_factor', 'outer_radius', 'inner_radius', 'inner_width', 'inner_height', 'max_diameter', 'dist_mean', 'dist_deviation', 'roundness', 'num_sides', 'orientation', 'connect_num', 'holes_num', 'area_holes', 'euler_number', 'rect2_phi', 'rect2_len1', 'rect2_len2', 'moments_m11', 'moments_m20', 'moments_m02', 'moments_ia', 'moments_ib', 'moments_m11_invar', 'moments_m20_invar', 'moments_m02_invar', 'moments_phi1', 'moments_phi2', 'moments_m21', 'moments_m12', 'moments_m03', 'moments_m30', 'moments_m21_invar', 'moments_m12_invar', 'moments_m03_invar', 'moments_m30_invar', 'moments_i1', 'moments_i2', 'moments_i3', 'moments_i4', 'moments_psi1', 'moments_psi2', 'moments_psi3', 'moments_psi4'}

▷ **`Operation`** (input_control) ..... string ⇝ *string*
Linkage type of the individual features.
Default: 'and'
List of values: `Operation` ∈ {'and', 'or'}

▷ **`Min`** (input_control) ..... real(-array) ⇝ *real* / integer / string
Lower limits of the features or 'min'.
Default: 150.0
Value range: 0.0 ≤ `Min` ≤ 99999.0
Minimum increment: 0.001
Recommended increment: 1.0

▷ **`Max`** (input_control) ..... real(-array) ⇝ *real* / integer / string
Upper limits of the features or 'max'.
Default: 99999.0
Value range: 0.0 ≤ `Max` ≤ 99999.0
Minimum increment: 0.001
Recommended increment: 1.0
Restriction: Max >= Min

Example

```
* Where are the eyes of the Mandrill?
read_image(Image,'monkey')
threshold(Image,Region,128,255)
connection(Region,ConnectedRegions)
select_shape(ConnectedRegions,Eyes,['area','max_diameter'],\
             'and',[500,30.0],[1000,50.0])
dev_display(Eyes)
```

Result

The operator select_shape returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input objects available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection, runlength_features

select_shape_proto (Regions, Pattern : SelectedRegions : Feature, Min, Max :)

Choose regions having a certain relation to each other.

The operator select_shape_proto selects regions based on certain relations between the regions. Every region from Regions is compared to the union of regions from Pattern. The limits (Min and Max) are specified absolutely or in percent (0..100), depending on the feature. Possible values for Feature are:

'distance_dilate' The minimum distance in the maximum norm from the edge of Pattern to the edge of every region from Regions is determined (see distance_rr_min_dil).

'distance_contour' The minimum Euclidean distance from the edge of Pattern to the edge of every region from Regions is determined. (see distance_rr_min).

'distance_center' The Euclidean distance from the center of Pattern to the center of every region from Regions is determined.

'covers' It is examined how well the region `Pattern` fits into the regions from `Regions`. If there is no shift so that `Pattern` is a subset of `Regions` the overlap is 0. If `Pattern` corresponds to the region after a corresponding shift the overlap is 100. Otherwise the area of the opening of `Regions` with `Pattern` is put into relation with the area of `Regions` (in percent).

'fits' It is examined whether `Pattern` can be shifted in such a way that it fits in `Regions`. If this is possible the corresponding region is copied from `Regions`. The parameters `Min` and `Max` are ignored.

'overlaps_abs' The area of the intersection of `Pattern` and every region in `Regions` is computed.

'overlaps_rel' The area of the intersection of `Pattern` and every region in `Regions` is computed. The relative overlap is the ratio of the area of the intersection, and the area of the respective region in `Regions` (in percent).

Parameters

▷ **`Regions`** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be examined.

▷ **`Pattern`** (input_object) . . . . . region(-array) ⇝ *object*
Region compared to `Regions`.

▷ **`SelectedRegions`** (output_object) . . . . . region(-array) ⇝ *object*
Regions fulfilling the condition.

▷ **`Feature`** (input_control) . . . . . string(-array) ⇝ *string*
Shape features to be checked.
Default: 'covers'
List of values: `Feature` ∈ {'distance_center', 'distance_dilate', 'distance_contour', 'covers', 'fits', 'overlaps_abs', 'overlaps_rel'}

▷ **`Min`** (input_control) . . . . . number ⇝ *real* / integer
Lower border of feature.
Default: 50.0
Suggested values: `Min` ∈ {0.0, 1.0, 5.0, 10.0, 20.0, 30.0, 50.0, 60.0, 70.0, 80.0, 90.0, 95.0, 99.0, 100.0, 200.0, 400.0}
Value range: 0.0 ≤ Min
Minimum increment: 0.001
Recommended increment: 5.0

▷ **`Max`** (input_control) . . . . . number ⇝ *real* / integer
Upper border of the feature.
Default: 100.0
Suggested values: `Max` ∈ {0.0, 10.0, 20.0, 30.0, 50.0, 60.0, 70.0, 80.0, 90.0, 95.0, 99.0, 100.0, 200.0, 300.0, 400.0}
Value range: 0.0 ≤ Max
Minimum increment: 0.001
Recommended increment: 5.0

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  if (argc < 2)
  {
    cout << "Usage: " << argv[0] << " <radius of circle>" << endl;
    exit (1);
  }
```

```
  double   rad = atof (argv[1]);
  HImage   img ("monkey");
  HWindow  w;

  img.Display (w);

  HRegion       circ = HRegion::GenCircle (100, 100, rad);
  HRegionArray  reg  = img.Regiongrowing (3, 3, 5, 0);
  HRegionArray  seg  = reg.SelectShapeProto (circ, "fits", 0, 0);

  w.SetColor  ("red");
  seg.Display (w);
  w.Click ();
  return(0);
}
```

Result

The operator `select_shape_proto` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

select_shape_std (Regions : SelectedRegions : Shape, Percent :)

Select regions of a given shape.

The operator `select_shape_std` compares the shape of the given regions with default shapes. If the region has a similar shape it is adopted into the output. Possible values for `Shape` are:

'max_area' The largest region is selected.

'rectangle1' The surrounding rectangle parallel to the coordinate axes is determined via the operator `smallest_rectangle1`. If the area difference in percent is larger than `Percent` the region is adopted.

'rectangle2' The smallest surrounding rectangle with any orientation is determined via the operator `smallest_rectangle2`. If the area difference in percent is larger than `Percent` the region is adopted. Note that as a more robust alternative the operator `select_shape` with `Feature` set to *'rectangularity'* can be used instead.

Parameters

▷ **Regions** (input_object) . . . . . region(-array) ⇝ *object*
Input regions to be selected.

▷ **SelectedRegions** (output_object) . . . . . region(-array) ⇝ *object*
Regions with desired shape.

▷ **Shape** (input_control) . . . . . string ⇝ *string*
Shape features to be checked.
Default: 'max_area'
List of values: `Shape` ∈ {'max_area', 'rectangle1', 'rectangle2'}

▷ **Percent** (input_control) . . . . . real ⇝ *real*
Similarity measure.
Default: 70.0
Suggested values: `Percent` ∈ {10.0, 30.0, 50.0, 60.0, 70.0, 80.0, 90.0, 95.0, 100.0}
Value range: 0.0 ≤ `Percent` ≤ 100.0 (lin)
Minimum increment: 0.1
Recommended increment: 10.0

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Foundation

smallest_circle (Regions : : : Row, Column, Radius)

Smallest surrounding circle of a region.

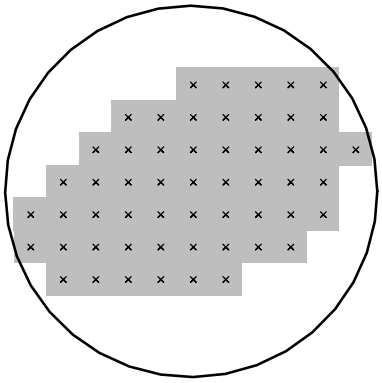
The operator `smallest_circle` determines the smallest surrounding circle of a region, i.e., the circle with the smallest area of all circles containing the region. For this circle the center (`Row`,`Column`) and the radius (`Radius`) are calculated. The operator is applied when, for example, the location and size of circular objects (e.g., coins) which, however, are not homogeneous inside or have broken edges due to bad segmentation, has to be determined. The output of the operator is selected in such a way that it can be used as input for the operators `disp_circle` and `gen_circle`.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions with varying outer and inner radii.

If several regions are passed in `Regions` corresponding tuples are returned as output parameter. In case of empty region all parameters have the value 0.0 if no other behavior was set (see `set_system`).

Attention

Internally, the calculation is based on the center coordinates of the region pixels. To take into account that pixels are not just infinitely small points but have a certain area, the calculated radius is enlarged by 0.5 before it is returned in `Radius`. This, in most cases, gives acceptable results. However, in the worst case (pixel diagonal) this enlargement is not sufficient. If one wants to ensure that the border of the input region completely lies within the circle, one had to enlarge the radius by $1/\sqrt{2}$ instead of 0.5. Consequently, the value returned in `Radius` must be corrected by $1/\sqrt{2} - 0.5$. However, this would also be only an upper bound, i.e., the circle with the corrected radius would be slightly too big in most cases.



The smallest surrounding circle of a region. Note that the calculation is based on the center coordinates of the region pixels and that 0.5 is added to the resulting radius.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Regions to be examined.

▷ **Row** (output_control) ..... circle.center.y(-array) ⇝ *real*
Line index of the center.

▷ **Column** (output_control) ..... circle.center.x(-array) ⇝ *real*
Column index of the center.

▷ **Radius** (output_control) ..... circle.radius(-array) ⇝ *real*
Radius of the surrounding circle.
Assertion: Radius >= 0

Example

```
read_image(Image,'fabrik')
regiongrowing(Image,Regions,5,5,6,100)
select_shape(Regions,SelectedRegions,'area','and',100,2000)
smallest_circle(SelectedRegions,Row,Column,Radius)
gen_circle(Circles,Row,Column,Radius)
dev_display (Circles)
```

Complexity

If F is the area of the region, then the mean runtime complexity is $O(sqrt(F)$.

Result

The operator `smallest_circle` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`, `runlength_features`

Possible Successors

`gen_circle`, `disp_circle`

Alternatives

set_shape, select_shape, inner_circle

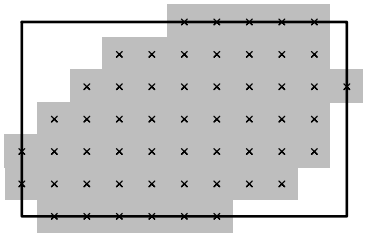
Module

Foundation

smallest_rectangle1 (Regions : : : Row1, Column1, Row2, Column2)

Surrounding rectangle parallel to the coordinate axes.

The operator smallest_rectangle1 calculates the surrounding rectangle of all input regions (parallel to the coordinate axes). The surrounding rectangle is described by the coordinates of the corner pixels (Row1,Column1,Row2,Column2). The calculation of the rectangle is based on the center coordinates of the region pixels.



The smallest axis aligned surrounding rectangle of a region. Note that the calculation is based on the center coordinates of the region pixels.

If more than one region is passed in Regions, the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input. In case of empty region all parameters have the value 0 if no other behavior was set (see set_system).

Attention

In case of empty region the result of Row1,Column1, Row2 and Column2 (all are 0) can lead to confusion.

Parameters

- ▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Row1** (output_control) ..... rectangle.origin.y(-array) ⇝ *integer*
  Line index of upper left corner point.
- ▷ **Column1** (output_control) ..... rectangle.origin.x(-array) ⇝ *integer*
  Column index of upper left corner point.
- ▷ **Row2** (output_control) ..... rectangle.corner.y(-array) ⇝ *integer*
  Line index of lower right corner point.
- ▷ **Column2** (output_control) ..... rectangle.corner.x(-array) ⇝ *integer*
  Column index of lower right corner point.

Complexity

If F is the area of the region the mean runtime complexity is $O(sqrt(F))$.

Result

The operator smallest_rectangle1 returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

select_shape

Module

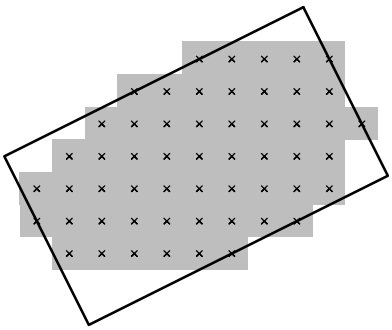
Foundation

smallest_rectangle2 (Regions : : : Row, Column, Phi, Length1, Length2)

Smallest surrounding rectangle with any orientation.

The operator smallest_rectangle2 determines the smallest surrounding rectangle of a region, i.e., the rectangle with the smallest area of all rectangles containing the region. For this rectangle the center, the inclination and the two radii are calculated. The calculation of the rectangle is based on the center coordinates of the region pixels.

In the documentation of this chapter (Regions / Features), you can find an image illustrating regions which vary in the length and phi of their smallest surrounding rectangle.



The smallest surrounding rectangle of a region. Note that the calculation is based on the center coordinates of the region pixels.

The operator is applied when, for example, the location of a scenery of several regions (e.g., printed text on a rectangular paper or in rectangular print (justified lines)) must be found. The parameters of smallest_rectangle2 are chosen in such a way that they can be used directly as input for the operators disp_rectangle2 and gen_rectangle2.

If more than one region is passed in Regions the results are stored in tuples, the index of a value in the tuple corresponding to the index of a region in the input. In case of empty region all parameters have the value 0.0 if no other behavior was set (see set_system).

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Regions to be examined.

▷ **Row** (output_control) ..... rectangle2.center.y(-array) ⇝ *real*
Line index of the center.

▷ **Column** (output_control) ..... rectangle2.center.x(-array) ⇝ *real*
Column index of the center.

▷ **Phi** (output_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real*
Orientation of the surrounding rectangle (arc measure)
Assertion: - pi / 2 < Phi && Phi <= pi / 2

▷ **Length1** (output_control) . . . . . rectangle2.hwidth(-array) ⇝ *real*
First radius (half length) of the surrounding rectangle.
Assertion: Length1 >= 0.0

▷ **Length2** (output_control) . . . . . rectangle2.hheight(-array) ⇝ *real*
Second radius (half width) of the surrounding rectangle.
Assertion: Length2 >= 0.0 && Length2 <= Length1

Example

```
read_image(Image,'fabrik')
regiongrowing(Image,Regions,5,5,6,100)
smallest_rectangle2(Regions,Row,Column,Phi,Length1,Length2)
gen_rectangle2(Rectangle,Row,Column,Phi,Length1,Length2)
dev_set_draw ('margin')
dev_display(Rectangle)
```

Complexity

If F is the area of the region and N is the number of supporting points of the convex hull, the runtime complexity is $O(sqrt(F) + N^2)$.

Result

The operator `smallest_rectangle2` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system('no_object_result',<Result>)`. The behavior in case of empty region (the region is the empty set) is set via `set_system('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`, `runlength_features`

spatial_relation (Regions1, Regions2 : : Percent : RegionIndex1, RegionIndex2, Relation1, Relation2)

Pose relation of regions with regard to the coordinate axes.

The operator `spatial_relation` selects regions located by `Percent` percent “left”, “right”, “above” or “below” other regions. `Regions1` and `Regions2` contain the regions to be compared. `Regions1` can have three states:

- `Regions1` contains an empty object tuple, i.e., `count_obj` returns *0*:
  In this case all regions in `Regions2` are permutatively checked for neighborhood.

- Regions1 consists of one region:
  The regions of Regions1 are compared to all regions in Regions2.
- Regions1 consists of the same number of regions as Regions2:
  Regions1 and Regions2 are checked for a neighboring relation.

The percentage Percent is interpreted in such a way that the area of the second region has to be located really left/right or above/below the region margins of the first region by at least Percent percent. The indices of the regions that fulfill at least one of these conditions are then located at the n-th position in the output parameters RegionIndex1 and RegionIndex2. Additionally the output parameters Relation1 and Relation2 contain at the n-th position the type of relation of the region pair (RegionIndex1[n], RegionIndex2[n]), i.e., region with index RegionIndex2[n] has the relation Relation1[n] and Relation2[n] with region with index RegionIndex1[n].

Possible values for Relation1 and Relation2 are:

- Relation1: *'above'*, *'below'* or *''*
- Relation2: *'left'*, *'right'* or *''*

In RegionIndex1 and RegionIndex2 the indices of the regions in the tuples of the input regions (Regions1 or Regions2), respectively, are entered as image identifiers. Access to chosen regions via the index can be obtained by the operator copy_obj.

Parameters

▷ **Regions1** (input_object) . . . . . region(-array) ⇝ *object*
Starting regions.

▷ **Regions2** (input_object) . . . . . region(-array) ⇝ *object*
Comparative regions.

▷ **Percent** (input_control) . . . . . integer ⇝ *integer*
Percentage of the area of the comparative region which must be located left/right or above/below the region margins of the starting region.
Default: 50
Suggested values: Percent ∈ {0, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100}
Value range: 0 ≤ Percent ≤ 100 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **RegionIndex1** (output_control) . . . . . integer-array ⇝ *integer*
Indices of the regions in the tuple of the input regions which fulfill the pose relation.

▷ **RegionIndex2** (output_control) . . . . . integer-array ⇝ *integer*
Indices of the regions in the tuple of the input regions which fulfill the pose relation.

▷ **Relation1** (output_control) . . . . . string-array ⇝ *string*
Vertical pose relation in which RegionIndex2[n] stands with RegionIndex1[n].

▷ **Relation2** (output_control) . . . . . string-array ⇝ *string*
Horizontal pose relation in which RegionIndex2[n] stands with RegionIndex1[n].

Result

The operator spatial_relation returns the value 2 (H_MSG_TRUE) if Regions2 is not empty and Percent is correctly chosen. The behavior in case of empty parameter Regions2 (no input regions available) is set via the operator set_system('no_object_result',<Result>). The behavior in case of empty region (the region is the empty set) is set via set_system('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

23.4 Geometric Transformations

affine_trans_region (Region : RegionAffineTrans : HomMat2D, Interpolate :)

Apply an arbitrary affine 2D transformation to regions.

affine_trans_region applies an arbitrary affine 2D transformation, i.e., scaling, rotation, translation, and slant (skewing), to the regions given in Region and returns the transformed regions in RegionAffineTrans. The affine transformation is described by the homogeneous transformation matrix given in HomMat2D, which can be created using the operators hom_mat2d_identity, hom_mat2d_scale, hom_mat2d_rotate, hom_mat2d_translate, etc., or be the result of operators like vector_angle_to_rigid.

The components of the homogeneous transformation matrix are interpreted as follows: The *row* coordinate of the image corresponds to x and the *column* coordinate corresponds to y of the coordinate system in which the transformation matrix was defined. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

The parameter Interpolate determines whether the transformation is to be done by using interpolation internally. The interpolation modes *'nearest_neighbor'* and *'constant'*, which are described in detail for affine_trans_image, can be used. An interpolation can lead to smoother region boundaries, especially if regions are enlarged. However, the runtime increases drastically.

Attention

affine_trans_region in general is not reversible (clipping and discretization during rotation and scaling).

affine_trans_region does not use the HALCON standard coordinate system (with the origin in the center of the upper left pixel), but instead uses the same coordinate system as in affine_trans_pixel, i.e., the origin lies in the upper left corner of the upper left pixel. Therefore, applying affine_trans_region corresponds to a chain of transformations (see affine_trans_pixel), which is applied to each point of the region (input and output pixels as homogeneous vectors). As an effect, you might get unexpected results when creating affine transformations based on coordinates that are derived from the region, e.g., by operators like area_center. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric region and then rotate the region around this point using hom_mat2d_rotate, the resulting region will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to HomMat2D before using it in affine_trans_region:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
affine_trans_region(Region, RegionAffineTrans, HomMat2DAdapted,
'nearest_neighbor')
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Region(s) to be rotated and scaled.

▷ **RegionAffineTrans** (output_object) . . . . . region(-array) ⇝ *object*
Transformed output region(s).
Number of elements: RegionAffineTrans == Region

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Interpolate** (input_control) . . . . . string ⇝ *string*
Should the transformation be done using interpolation?
Default: 'nearest_neighbor'
List of values: `Interpolate` ∈ {'constant', 'nearest_neighbor'}

Result

If the matrix `HomMat2D` represents an affine transformation (i.e., not a projective transformation), `affine_trans_region` returns 2 (`H_MSG_TRUE`). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)`, the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`, and the behavior in case of an empty result region via `set_system('store_empty_region',<'true'/'false'>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Module

Foundation

mirror_region (Region : RegionMirror : Mode, WidthHeight :)

Reflect a region about an axis.

`mirror_region` reflects a region about one of three possible axes. If `Mode` is set to *'row'*, it is reflected about the horizontal axis, if `Mode` is set to *'column'*, about the vertical axis, and if `Mode` is set to *'diagonal'*, about the main diagonal $x = y$.

For `Mode` = *'row'* or *'column'* the parameter `WidthHeight` specifies two times the coordinate of the axis of symmetry. Hence, if `Region` has been extracted from an image and should be mirrored in a way such as if it had been extracted from a mirrored version of this image, `WidthHeight` corresponds to one of the dimensions of this image (according to `Mode`). If `Mode` = *'diagonal'*, the parameter `WidthHeight` is not used.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Region(s) to be reflected.

▷ **RegionMirror** (output_object) ..... region(-array) ⇝ *object*
Reflected region(s).
Number of elements: RegionMirror == Region

▷ **Mode** (input_control) ..... string ⇝ *string*
Axis of symmetry.
Default: 'row'
List of values: Mode ∈ {'column', 'row', 'diagonal'}

▷ **WidthHeight** (input_control) ..... integer ⇝ *integer*
Twice the coordinate of the axis of symmetry.
Default: 512
Suggested values: WidthHeight ∈ {128, 256, 512, 525, 768, 1024}
Value range: 1 ≤ WidthHeight ≤ 1024 (lin)
Minimum increment: 1
Recommended increment: 1
Restriction: WidthHeight > 0

Example

```
read_image(&Image,"monkey");
threshold(Image,&Seg,128.0,255.0);
mirror_region(Seg,&Mirror,"row",512);
disp_region(Mirror,WindowHandle);
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

move_region (Region : RegionMoved : Row, Column :)

Translate a region.

move_region translates the input regions by the vector given by (Row, Column). If necessary, the resulting regions are clipped with the current image format.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be moved.

▷ **RegionMoved** (output_object) ..... region(-array) ⇝ *object*
Translated region(s).
Number of elements: RegionMoved == Region

▷ **Row** (input_control) . . . . . point.y ⇝ *integer*
Row coordinate of the vector by which the region is to be moved.
Default: 30
Suggested values: Row ∈ {-128, -64, -32, -16, -10, -8, -4, -2, -1, 0, 1, 2, 4, 5, 8, 10, 16, 32, 64, 128}
Value range: -512 ≤ Row ≤ 512 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Column** (input_control) . . . . . point.x ⇝ *integer*
Row coordinate of the vector by which the region is to be moved.
Default: 30
Suggested values: Column ∈ {-128, -64, -32, -16, -10, -8, -4, -2, -1, 0, 1, 2, 4, 5, 8, 10, 16, 32, 64, 128}
Value range: -512 ≤ Column ≤ 512 (lin)
Minimum increment: 1
Recommended increment: 10

Complexity

Let F be the area of the input region. Then the runtime complexity is $O(F)$.

Result

move_region always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>), the behavior in case of an empty input region via set_system('empty_region_result',<Result>), and the behavior in case of an empty result region via set_system('store_empty_region',<'true'/'false'>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

polar_trans_region (Region : PolarTransRegion : Row, Column, AngleStart, AngleEnd, RadiusStart, RadiusEnd, Width, Height, Interpolation :)

Transform a region within an annular arc to polar coordinates.

polar_trans_region transforms a Region within the annular arc specified by the center point (Row, Column), the radii RadiusStart and RadiusEnd and the angles AngleStart and AngleEnd to its polar coordinate version in a virtual image of the dimensions Width × Height.

The polar transformation is a change of the coordinate system. Instead of a row and a column coordinate, each point's position is expressed by its radius r (i.e. the distance to the center point Row, Column) and the angle phi between the column axis (through the center point) and the line from the center point towards the point. Note that this transformation is not affine.

The coordinate $(0, 0)$ in the output region always corresponds to the point in the input region that is specified by RadiusStart and AngleStart. Analogously, the coordinate $(\text{Height} - 1, \text{Width} - 1)$ corresponds to the point in the input region that is specified by RadiusEnd and AngleEnd. In the usual mode (AngleStart < AngleEnd and RadiusStart < RadiusEnd), the polar transformation is performed in the mathematically positive orientation (counterclockwise). Furthermore, points with smaller radii lie in the upper part of the

output region. By suitably exchanging the values of these parameters (e.g., AngleStart > AngleEnd or RadiusStart > RadiusEnd), any desired orientation of the output region can be achieved.

The angles can be chosen from all real numbers. Center point and radii can be real as well. However, if they are both integers and the difference of RadiusEnd and RadiusStart equals Height − 1, calculation will be sped up through an optimized routine.

The radii and angles are inclusive, which means that the first row of the virtual target image contains the circle with radius RadiusStart and the last row contains the circle with radius RadiusEnd. For complete circles, where the difference between AngleStart and AngleEnd equals 2π (360 degrees), this also means that the first column of the target image will be the same as the last.

To avoid this, do not make this difference 2π, but $2\pi(1 - \frac{1}{\text{Width}})$ degrees instead.

The parameter Interpolation is used to select the interpolation method *'bilinear'* or *'nearest_neighbor'*. Setting Interpolation to *'bilinear'* leads to smoother region boundaries, especially if regions are enlarged. However, the runtime increases significantly.

If more than one region is passed in Region, their polar transformations are computed individually and stored as a tuple in PolarTransRegion. Please note that the indices of an input region and its transformation only correspond if the system variable *'store_empty_regions'* is set to *'true'* (see set_system). Otherwise empty output regions are discarded and the length of the input tuple Region is most likely not equal to the length of the output tuple PolarTransRegion.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

If Width or Height are chosen greater than the dimensions of the current image, the system variable *'clip_region'* should be set to *'false'* (see set_system). Otherwise, an output region that does not lie within the dimensions of the current image can produce an error message.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Input region.

▷ **PolarTransRegion** (output_object) . . . . . region(-array) ⇝ *object*
Output region.

▷ **Row** (input_control) . . . . . number ⇝ *real* / integer
Row coordinate of the center of the arc.
Default: 256
Suggested values: Row ∈ {0, 16, 32, 64, 128, 240, 256, 480, 512}

▷ **Column** (input_control) . . . . . number ⇝ *real* / integer
Column coordinate of the center of the arc.
Default: 256
Suggested values: Column ∈ {0, 16, 32, 64, 128, 256, 320, 512, 640}

▷ **AngleStart** (input_control) . . . . . angle.rad ⇝ *real*
Angle of the ray to be mapped to column coordinate *0* of PolarTransRegion.
Default: 0.0
Suggested values: AngleStart ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853, 12.566370616}
Value range: -6.2831853 ≤ AngleStart ≤ 6.2831853

▷ **AngleEnd** (input_control) . . . . . angle.rad ⇝ *real*
Angle of the ray to be mapped to column coordinate Width − 1 of PolarTransRegion.
Default: 6.2831853
Suggested values: AngleEnd ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853, 12.566370616}
Value range: -6.2831853 ≤ AngleEnd ≤ 6.2831853

▷ **RadiusStart** (input_control) . . . . . number ⇝ *real* / integer
Radius of the circle to be mapped to row coordinate *0* of PolarTransRegion.
Default: 0
Suggested values: RadiusStart ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusStart ≤ 32767

▷ **RadiusEnd** (input_control) ..... number ⇝ *real / integer*
Radius of the circle to be mapped to row coordinate Height − 1 of PolarTransRegion.
Default: 100
Suggested values: RadiusEnd ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusEnd ≤ 32767

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the virtual output image.
Default: 512
Suggested values: Width ∈ {256, 320, 512, 640, 800, 1024}
Value range: 2 ≤ Width ≤ 32767

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the virtual output image.
Default: 512
Suggested values: Height ∈ {240, 256, 480, 512, 600, 1024}
Value range: 2 ≤ Height ≤ 32767

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Interpolation method for the transformation.
Default: 'nearest_neighbor'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

Module

Foundation

polar_trans_region_inv (PolarRegion : XYTransRegion : Row, Column, AngleStart, AngleEnd, RadiusStart, RadiusEnd, WidthIn, HeightIn, Width, Height, Interpolation :)

Transform a region in polar coordinates back to Cartesian coordinates.

polar_trans_region_inv transforms the polar coordinate representation of a region, stored in PolarRegion, back onto an annular arc in Cartesian coordinates, described by the radii RadiusStart and RadiusEnd and the angles AngleStart and AngleEnd with the center point located at (Row, Column). All of these values can be chosen as real numbers. In addition, the dimensions of the virtual image containing the region PolarRegion must be given in WidthIn and HeightIn. WidthIn − 1 is the column coordinate corresponding to AngleEnd and HeightIn − 1 is the row coordinate corresponding to RadiusEnd. AngleStart and RadiusStart correspond to column and row coordinate *0*. Furthermore, the dimensions Width and Height of the virtual output image containing the transformed region XYTransRegion are required.

The angles and radii are inclusive, which means that the row coordinate *0* in PolarRegion will be mapped onto a a circle with a distance of RadiusStart pixels from the specified center and the row with the coordinate HeightIn − 1 will be mapped onto a circle of radius RadiusEnd. This applies to AngleStart, AngleEnd, and WidthIn in an analogous way. If the width of the input region PolarRegion corresponds to an angle interval greater than $2pi$, the region is cropped such that length of this interval is $2pi$.

The parameter Interpolation is used to select the interpolation method *'bilinear'* or *'nearest_neighbor'*. Setting Interpolation to *'bilinear'* leads to smoother region boundaries, especially if regions are enlarged. However, the runtime increases significantly.

polar_trans_region_inv is the inverse function of polar_trans_region.

The call sequence:

```
polar_trans_region(Region, PolarRegion, Row, Column, rad(360)
polar_trans_region_inv(PolarRegion, XYTransRegion, Row,
Column, rad(360), 0, 0, Radius, Width, Height, Width, Height,
'nearest_neighbor')
```

returns the region Region, restricted to the circle around (Row, Column) with radius Radius, as its output region XYTransRegion.

If more than one region is passed in PolarRegion, their Cartesian transformations are computed individually and stored as a tuple in XYTransRegion. Please note that the indices of an input region and its transformation only correspond if the system variable *'store_empty_regions'* is set to *'false'* (see set_system). Otherwise empty output regions are discarded and the length of the input tuple PolarRegion is most likely not equal to the length of the output tuple XYTransRegion.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

If Width or Height are chosen greater than the dimensions of the current image, the system variable *'clip_region'* should be set to *'false'* (see set_system). Otherwise, an output region that does not lie within the dimensions of the current image can produce an error message.

Parameters

- ▷ **PolarRegion** (input_object) ..... region(-array) ⇝ *object*
  Input region.
- ▷ **XYTransRegion** (output_object) ..... region(-array) ⇝ *object*
  Output region.
- ▷ **Row** (input_control) ..... number ⇝ *real* / integer
  Row coordinate of the center of the arc.
  Default: 256
  Suggested values: Row ∈ {0, 16, 32, 64, 128, 240, 256, 480, 512}
  Value range: -131068 ≤ Row ≤ 131068
- ▷ **Column** (input_control) ..... number ⇝ *real* / integer
  Column coordinate of the center of the arc.
  Default: 256
  Suggested values: Column ∈ {0, 16, 32, 64, 128, 256, 320, 512, 640}
  Value range: -131068 ≤ Column ≤ 131068
- ▷ **AngleStart** (input_control) ..... angle.rad ⇝ *real*
  Angle of the ray to map the column coordinate *0* of PolarRegion to.
  Default: 0.0
  Suggested values: AngleStart ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853}
  Value range: -6.2831853 ≤ AngleStart ≤ 6.2831853
- ▷ **AngleEnd** (input_control) ..... angle.rad ⇝ *real*
  Angle of the ray to map the column coordinate WidthIn − 1 of PolarRegion to.
  Default: 6.2831853
  Suggested values: AngleEnd ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853}
  Value range: -6.2831853 ≤ AngleEnd ≤ 6.2831853
- ▷ **RadiusStart** (input_control) ..... number ⇝ *real* / integer
  Radius of the circle to map the row coordinate *0* of PolarRegion to.
  Default: 0
  Suggested values: RadiusStart ∈ {0, 16, 32, 64, 100, 128, 256, 512}
  Value range: 0 ≤ RadiusStart ≤ 32767
- ▷ **RadiusEnd** (input_control) ..... number ⇝ *real* / integer
  Radius of the circle to map the row coordinate HeightIn − 1 of PolarRegion to.
  Default: 100
  Suggested values: RadiusEnd ∈ {0, 16, 32, 64, 100, 128, 256, 512}
  Value range: 0 ≤ RadiusEnd ≤ 32767

▷ **WidthIn** (input_control) ..... extent.x ⇝ *integer*
Width of the virtual input image.
Default: 512
Suggested values: WidthIn ∈ {256, 320, 512, 640, 800, 1024}
Value range: 2 ≤ WidthIn ≤ 32767

▷ **HeightIn** (input_control) ..... extent.y ⇝ *integer*
Height of the virtual input image.
Default: 512
Suggested values: HeightIn ∈ {240, 256, 480, 512, 600, 1024}
Value range: 2 ≤ HeightIn ≤ 32767

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the virtual output image.
Default: 512
Suggested values: Width ∈ {256, 320, 512, 640, 800, 1024}
Value range: 1 ≤ Width ≤ 32767

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the virtual output image.
Default: 512
Suggested values: Height ∈ {240, 256, 480, 512, 600, 1024}
Value range: 1 ≤ Height ≤ 32767

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Interpolation method for the transformation.
Default: 'nearest_neighbor'
List of values: Interpolation ∈ {'nearest_neighbor', 'bilinear'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Foundation

projective_trans_region (Regions : TransRegions : HomMat2D, Interpolation :)

Apply a projective transformation to a region.

projective_trans_region applies the projective transformation specified by the homogeneous matrix HomMat2D on the regions in Regions and returns the transformed regions in TransRegions.

For creation and interpretation details of this matrix see also projective_trans_image.

If *'clip_region'* is set to its default value *'true'* by set_system('clip_region', 'true') or if the transformation is degenerated and thus produces infinite regions, the output region is clipped by the rectangle with upper left corner (0, 0) and lower right corner (*'width'*, *'height'*), where *'width'* and *'height'* are system variables (see also get_system). If *'clip_region'* is *'false'*, the output region is not clipped except by the maximum supported coordinate size. See the "Installation Guide" for further information about coordinate range limitations. This may result in extremely memory and time intensive computations, so use with care.

Attention

The used coordinate system is the same as in affine_trans_pixel. This means that in fact not HomMat2D is applied but a modified version. Therefore, applying projective_trans_region corresponds to the following chain of transformations, which is applied to each point (Row_i, Col_i) of the region (input and output pixels as homogeneous vectors):

$$\begin{pmatrix} RowTrans_i \\ ColTrans_i \\ 1 \end{pmatrix} = \begin{bmatrix} 1 & 0 & -0.5 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D} \cdot \begin{bmatrix} 1 & 0 & +0.5 \\ 0 & 1 & +0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} Row_i \\ Col_i \\ 1 \end{pmatrix}$$

As an effect, you might get unexpected results when creating projective transformations based on coordinates that are derived from the region, e.g., by operators like `area_center`. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric region and then rotate the region around this point using `hom_mat2d_rotate`, the resulting region will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to `HomMat2D` before using it in `projective_trans_region`:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
projective_trans_region(Region, TransRegion, HomMat2DAdapted,
'bilinear')
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

▷ **Regions** (input_object) ..... region(-array) ⇝ *object*
Input regions.

▷ **TransRegions** (output_object) ..... region(-array) ⇝ *object*
Output regions.

▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
Homogeneous projective transformation matrix.

▷ **Interpolation** (input_control) ..... string ⇝ *string*
Interpolation method for the transformation.
Default: 'bilinear'
List of values: `Interpolation` ∈ {'nearest_neighbor', 'bilinear'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

transpose_region (Region : Transposed : Row, Column :)

Reflect a region about a point.

`transpose_region` reflects a region about a point. The fixed point is given by `Column` and `Row`. The image P' of a point P is determined by the following requirement:

If $P = S$, then $P' = S$, i.e., the point S is the fixed point of the mapping. If $P \neq S$, S is the center point of a line segment connecting P and P'. Therefore, the following equations result:

$$\begin{aligned} \texttt{Column} &= \frac{x + x'}{2} \\ \texttt{Row} &= \frac{y + y'}{2}. \end{aligned}$$

If `Row` and `Column` are set to the origin, the in morphology often used transposition results. Hence `transpose_region` is often used to reflect (transpose) a structuring element.

Parameters

▷ **`Region`** (input_object) . . . . . region(-array) ⇝ *object*
Region to be reflected.

▷ **`Transposed`** (output_object) . . . . . region(-array) ⇝ *object*
Transposed region.

▷ **`Row`** (input_control) . . . . . point.y ⇝ *integer*
Row coordinate of the reference point.
Default: 0
Suggested values: `Row` ∈ {0, 64, 128, 256, 512}
Value range: 0 ≤ `Row` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **`Column`** (input_control) . . . . . point.x ⇝ *integer*
Column coordinate of the reference point.
Default: 0
Suggested values: `Column` ∈ {0, 64, 128, 256, 512}
Value range: 0 ≤ `Column` ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let F be the area of the input region. Then the runtime complexity for one region is

$$O(\sqrt{F}) \ .$$

Result

`transpose_region` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty or no input region can be set via:

- no region: `set_system('no_object_result',<RegionResult>)`
- empty region: `set_system('empty_region_result',<RegionResult>)`

Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

zoom_region (Region : RegionZoom : ScaleWidth, ScaleHeight :)

Zoom a region.

zoom_region enlarges or reduces the regions given in Region in the x- and y-direction by the given scale factors ScaleWidth and ScaleHeight.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be zoomed.

▷ **RegionZoom** (output_object) ..... region(-array) ⇝ *object*
Zoomed region(s).
Number of elements: RegionZoom == Region

▷ **ScaleWidth** (input_control) ..... extent.x ⇝ *real*
Scale factor in x-direction.
Default: 2.0
Suggested values: ScaleWidth ∈ {0.25, 0.5, 1.0, 2.0, 3.0}
Value range: 0.0 ≤ ScaleWidth ≤ 100.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.5

▷ **ScaleHeight** (input_control) ..... extent.y ⇝ *real*
Scale factor in y-direction.
Default: 2.0
Suggested values: ScaleHeight ∈ {0.25, 0.5, 1.0, 2.0, 3.0}
Value range: 0.0 ≤ ScaleHeight ≤ 100.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.5

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

23.5 Sets

complement (Region : RegionComplement : :)

Return the complement of a region.

complement determines the complement of the input region(s).

If the system flag *'clip_region'* is *'true'*, which is the default, the difference of the largest image processed so far (see reset_obj_db) and the input region is returned.

If the system flag *'clip_region'* is *'false'* (see set_system), the resulting region would be infinitely large. To avoid this, the complement is done only virtually by setting the complement flag of Region to TRUE. For succeeding operations the de Morgan laws are applied while calculating results. Using complement with *'clip_region'*

set to *'false'* makes sense only to avoid fringe effects, e.g., if the area of interest is bigger or smaller than the image. For the latter case, the clipping would be set explicitly. If there is no reason to use the operator with *'clip_region'='false'* but you need the flag for other operations of your program, it is recommended to temporarily set the system flag to*'true'* and change it back to *'false'* after applying `complement`. Otherwise, negative regions may result from succeeding operations.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Input region(s).

▷ **RegionComplement** (output_object) . . . . . region(-array) ⇝ *object*
Complemented regions.
Number of elements: RegionComplement == Region

Result

`complement` always returns the value 2 (`H_MSG_TRUE`). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)` and the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`threshold`, `connection`, `regiongrowing`, `pouring`, `class_ndim_norm`

Possible Successors

`select_shape`

See also

`difference`, `union1`, `union2`, `intersection`, `reset_obj_db`, `set_system`

Module

Foundation

difference (Region, Sub : RegionDifference : :)

Calculate the difference of two regions.

`difference` calculates the set-theoretic difference of two regions:

(Regions in `Region`) − (Regions in `Sub`)

The resulting region is defined as the input region (`Region`) with all points from `Sub` removed. Note that, internally, all regions of `Sub` are united to a single region before the differences between the individual regions of `Region` and the united region are calculated.

Attention

Empty regions are valid for both parameters. On output, empty regions may result. The value of the system flag *'store_empty_region'* determines the behavior in this case.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be processed.

▷ **Sub** (input_object) . . . . . region(-array) ⇝ *object*
The union of these regions is subtracted from Region.

▷ **RegionDifference** (output_object) . . . . . region(-array) ⇝ *object*
Resulting region.

Example

```
* provides the region X without the points in Y
difference(X,Y,RegionDifference)
```

Complexity

Let N be the number of regions, F_1 be their average area, and F_2 be the total area of all regions in `Sub`. Then the runtime complexity is $O(F_1 * \log(F_1) + N * (\sqrt{F_1} + \sqrt{F_2}))$.

Result

`difference` always returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)` and the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`threshold`, `connection`, `regiongrowing`, `pouring`, `class_ndim_norm`

Possible Successors

`select_shape`, `disp_region`

See also

`intersection`, `union1`, `union2`, `complement`, `symm_difference`

Module

Foundation

intersection (Region1, Region2 : RegionIntersection : :)

Calculate the intersection of two regions.

`intersection` calculates the intersection of the regions in `Region1` with the regions in `Region2`. Each region in `Region1` is intersected with all regions in `Region2`. That is, internally all regions of `Region2` are united to a single region before the individual regions of `Region1` are intersected with the united region. The order of regions in `RegionIntersection` is identical to the order of regions in `Region1`.

Attention

Empty input regions are permitted. Because empty result regions are possible, the system flag *'store_empty_region'* should be set appropriately.

Parameters

▷ **Region1** (input_object) ..... region(-array) ⇝ *object*
Regions to be intersected with all regions in Region2.

▷ **Region2** (input_object) ..... region(-array) ⇝ *object*
Regions with which Region1 is intersected.

▷ **RegionIntersection** (output_object) ..... region(-array) ⇝ *object*
Result of the intersection.
Number of elements: RegionIntersection <= Region1

Complexity

Let N be the number of regions in `Region1`, F_1 be their average area, and F_2 be the total area of all regions in `Region2`. Then the runtime complexity is $O(F_1 \log(F_1) + N * (\sqrt{F_1} + \sqrt{F_2}))$.

Result

`intersection` always returns `2` (`H_MSG_TRUE`). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)` and the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, connection, regiongrowing, pouring

Possible Successors

select_shape, disp_region

See also

union1, union2, complement

Module

Foundation

symm_difference (Region1, Region2 : RegionDifference : :)

Calculate the symmetric difference of two regions.

symm_difference calculates the symmetric difference of two regions. Note that, internally, all regions of Region2 are united to a single region before the symmetric differences between the individual regions of Region1 and the united region are calculated. Two possible definitions of the symmetric difference can be seen in the example below. A third definition is to regard the exclusive or of the two regions.

Attention

Empty regions are valid for both parameters. On output, empty regions may result. The value of the system flag *'store_empty_region'* determines the behavior in this case.

Parameters

▷ **Region1** (input_object) ..... region(-array) ⇝ *object*
Input region 1.

▷ **Region2** (input_object) ..... region(-array) ⇝ *object*
Input region 2.

▷ **RegionDifference** (output_object) ..... region(-array) ⇝ *object*
Resulting region.

Example

```
* Simulate the symmetric difference of Region1 and Region2 with
* difference and union:
difference(Region1, Region2, Diff1)
difference(Region2, Region1, Diff2)
union2(Diff1, Diff2, Difference)

* Simulate the symmetric difference of Region1 and Region2 with
* union, intersection, and difference:
union2(Region1, Region2, Union)
intersection(Region1, Region2, Intersection)
difference(Union, Intersection, Difference)
```

Result

symm_difference always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

select_shape, disp_region

intersection, union1, union2, complement, difference

Module

Foundation

union1 (Region : RegionUnion : :)

Return the union of all input regions.

union1 computes the union of all input regions and returns the result in RegionUnion.

Parameters

▷ **Region** (input_object) ..... region-array ⇝ *object*
Regions of which the union is to be computed.

▷ **RegionUnion** (output_object) ..... region ⇝ *object*
Union of all input regions.
Number of elements: RegionUnion <= Region

Example

```
* Union of segmentation results:
threshold(Image,Region1,128,255)
dyn_threshold(Image,Mean,Region2,5,'light')
concat_obj(Region1,Region2,Regions)
union1(Regions,RegionUnion)
```

Complexity

Let F be the sum of all areas of the input regions. Then the runtime complexity is $O(log(sqrt(F)) * sqrt(F))$.

Result

union1 always returns 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, connection, regiongrowing, pouring

Possible Successors

intersection, complement

Module

Foundation

union2 (Region1, Region2 : RegionUnion : :)

Return the union of two regions.

union2 computes the union of the region in Region1 with all regions in Region2. Internally, all regions of Region2 are united to a single region before the individual regions of Region1 are united with the already united region. This means that union2 is not commutative!

Parameters

- ▷ **Region1** (input_object) ..... region(-array) ⇝ *object*
  Region for which the union with all regions in Region2 is to be computed.
- ▷ **Region2** (input_object) ..... region(-array) ⇝ *object*
  Regions which should be added to Region1.
- ▷ **RegionUnion** (output_object) ..... region(-array) ⇝ *object*
  Resulting regions.
  Number of elements: RegionUnion == Region1

Complexity

Let F be the sum of all areas of the input regions. Then the runtime complexity is $O(log(sqrt(F)) * sqrt(F))$.

Result

union2 always returns 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

23.6 Tests

test_equal_region (Regions1, Regions2 : : : IsEqual)

Test whether the regions of two objects are identical.

The operator test_equal_region compares the regions of the two input parameters. The n-th element in Regions1 is compared to the n-th object in Regions2 (for all n). If all regions are equal and the number of regions is identical the operator IsEqual is set to TRUE, otherwise FALSE.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **Regions1** (input_object) . . . . . region(-array) ⇝ *object*
Test regions.

▷ **Regions2** (input_object) . . . . . region(-array) ⇝ *object*
Comparative regions.
Number of elements: Regions1 == Regions2

▷ **IsEqual** (output_control) . . . . . integer ⇝ *integer*
Boolean result value.

Complexity

If F is the area of a region the runtime complexity is $O(1)$ or $O(sqrt(F))$ if the result is TRUE, $O(sqrt(F))$ if the result is FALSE.

Result

The operator `test_equal_region` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. The behavior in case of empty input (no input objects available) is set via the operator `set_system(::'no_object_result',<Result>:)`. If the number of objects differs an exception is raised. Else `test_equal_region` returns the value `2` (`H_MSG_TRUE`)

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`intersection`, `complement`, `area_center`

See also

`test_equal_obj`

Module

Foundation

test_region_point (Regions : : Row, Column : IsInside)

Test if the region contains a given point.

If an array of regions and one test point is provided, `test_region_point` tests if at least one input region of `Regions` contains the single test point given in (`Row`,`Column`). If this is the case, `IsInside` is set to TRUE, else to FALSE. Alternatively, if a single region and several test points are provided, `test_region_point` tests if at least one of the test points (given in `Row`,`Column`) is contained in the input region given in `Regions`. If this is the case, `IsInside` is set to TRUE, otherwise it is set to FALSE. If (`Row`,`Column`) are real-valued, rounding is performed internally since regions are pixel precise.

To test, which points exactly are contained in a region, use the operator `test_region_points`.

Attention

The test pixel is not contained in an empty region (no pixel of the region corresponds to the pixel). If all regions are empty `IsInside` is set to FALSE.

In case of an empty input object (empty tuple) `Regions` and `set_system('no_object_result','true')`, an empty tuple is returned in `IsInside`. If `set_system('no_object_result','false')` was set, an exception is raised.

Parameters

▷ **Regions** (input_object) . . . . . region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Row** (input_control) . . . . . point.y(-array) ⇝ *integer* / real
Row index of the test pixel(s).
Default: 100

▷ **Column** (input_control) . . . . . point.x(-array) ⇝ *integer* / real
Column index of the test pixel(s).
Number of elements: Row == Column
Default: 100

▷ **IsInside** (output_control) . . . . . integer ⇝ *integer*
Boolean result value.

Complexity

If F is the area of one region, N is the number of regions, and M is the number of test points, the runtime complexity is $O(ln(sqrt(F)) * N)$ in the case of one test point and several regions and $O(ln(sqrt(F)) * M)$ in the case of one region and several test points.

Result

The operator `test_region_point` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. The behavior in case of an empty object is set via the operator `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`threshold`, `regiongrowing`, `connection`

Alternatives

`union1`, `intersection`, `area_center`, `test_region_points`

`select_region_point`, `test_region_points`

Module

Foundation

test_region_points (Regions : : Row, Column : IsInside)

Test if points are contained in regions.

`test_region_points` tests if points (`Row`,`Column`) are contained in the regions `Regions`.

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple or object array of length *1* or *N*. Parameters with length *1* will be repeated internally such that the number of computed tests is always *N*.

In all cases, for each performed test, `IsInside` is set to TRUE (*1*) if the point is contained in the region and to FALSE (*0*) otherwise.

If (`Row`,`Column`) are real-valued, rounding is performed internally since regions are pixel precise.

Attention

Test pixels are not contained in an empty region.

Parameters

▷ **Regions** (input_object) . . . . . region(-array) ⇝ *object*
Region(s) to be examined.

▷ **Row** (input_control) . . . . . point.y(-array) ⇝ *integer* / real
Row index of the test pixel(s).
Default: 100

▷ **Column** (input_control) . . . . . point.x(-array) ⇝ *integer* / real
Column index of the test pixel(s).
Number of elements: Row == Column
Default: 100

▷ **IsInside** (output_control) . . . . . integer(-array) ⇝ *integer*
Boolean result value.

Result

The operator test_region_points returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of an empty object is set via the operator set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

threshold, regiongrowing, connection

Alternatives

intersection, area_center, test_region_point

See also

select_region_point, test_region_point

Module

Foundation

test_subset_region (Region1, Region2 : : : IsSubset)

Test whether a region is contained in another region.

test_subset_region tests whether Region1 is a subset of Region2 and returns the result in IsSubset. If more than one region should be tested, Region1 and Region2 must have the same number of elements. In this case, a tuple that contains as many elements as Region1 and Region2 is returned in IsSubset.

For a short description of the iconic objects that are available in HALCON see the introduction of chapter Object.

Parameters

▷ **Region1** (input_object) . . . . . region(-array) ⇝ *object*
Test region.

▷ **Region2** (input_object) . . . . . region(-array) ⇝ *object*
Region for comparison.
Number of elements: Region1 == Region2

▷ **IsSubset** (output_control) . . . . . integer(-array) ⇝ *integer*
Is Region1 contained in Region2?

Result

test_subset_region returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input objects available) is set via the operator set_system(:: 'no_object_result',<Result>:). If the number of objects differs an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Alternatives

difference, area_center

23.7 Transformations

background_seg (Foreground : BackgroundRegions : :)

Determine the connected components of the background of given regions.

background_seg determines connected components of the background of the foreground regions given in Foreground. This operator is normally used after an edge operator in order to determine the regions enclosed by the extracted edges. The connected components are determined using 4-neighborhood.

Parameters

▷ **Foreground** (input_object) ..... region(-array) ⇝ *object*
Input regions.

▷ **BackgroundRegions** (output_object) ..... region-array ⇝ *object*
Connected components of the background.

Example

```
* Simulation of background_seg:
background_seg(Foreground,BackgroundRegions)
  complement(Foreground,Background)
  get_system('neighborhood',Save)
  set_system('neighborhood',4)
  connection(Background,BackgroundRegions)
  set_system('neighborhood',Save)

* Segmentation with edge filter:
read_image(Image,'fabrik')
sobel_dir(Image,Sobel,Dir,'sum_sqrt',3)
threshold(Sobel,Edges,20,255)
skeleton(Edges,Margins)
background_seg(Margins,Regions)
```

Complexity

Let F be the area of the background, H and W be the height and width of the image, and N be the number of resulting regions. Then the runtime complexity is $O(H + sqrt(F) * sqrt(N))$.

Result

background_seg always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, connection, regiongrowing, pouring, class_ndim_norm

Possible Successors

clip_region (Region : RegionClipped : Row1, Column1, Row2, Column2 :)

Clip a region to a rectangle.

clip_region clips the input regions to the rectangle given by the four control parameters. clip_region is more efficient than calling intersection with a rectangle generated by gen_rectangle1.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Region to be clipped.

▷ **RegionClipped** (output_object) . . . . . region(-array) ⇝ *object*
Clipped regions.

▷ **Row1** (input_control) . . . . . rectangle.origin.y ⇝ *integer*
Row coordinate of the upper left corner of the rectangle.
Default: 0
Suggested values: Row1 ∈ {0, 128, 200, 256}
(lin)

▷ **Column1** (input_control) . . . . . rectangle.origin.x ⇝ *integer*
Column coordinate of the upper left corner of the rectangle.
Default: 0
Suggested values: Column1 ∈ {0, 128, 200, 256}
(lin)

▷ **Row2** (input_control) . . . . . rectangle.corner.y ⇝ *integer*
Row coordinate of the lower right corner of the rectangle.
Default: 256
Suggested values: Row2 ∈ {128, 200, 256, 512}
Value range: 0 ≤ Row2 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Column2** (input_control) . . . . . rectangle.corner.x ⇝ *integer*
Column coordinate of the lower right corner of the rectangle.
Default: 256
Suggested values: Column2 ∈ {128, 200, 256, 512}
Value range: 0 ≤ Column2 ≤ 511 (lin)
Minimum increment: 1
Recommended increment: 10

Result

clip_region returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, connection, regiongrowing, pouring

Possible Successors

select_shape, disp_region

Alternatives

intersection, gen_rectangle1, clip_region_rel

Module

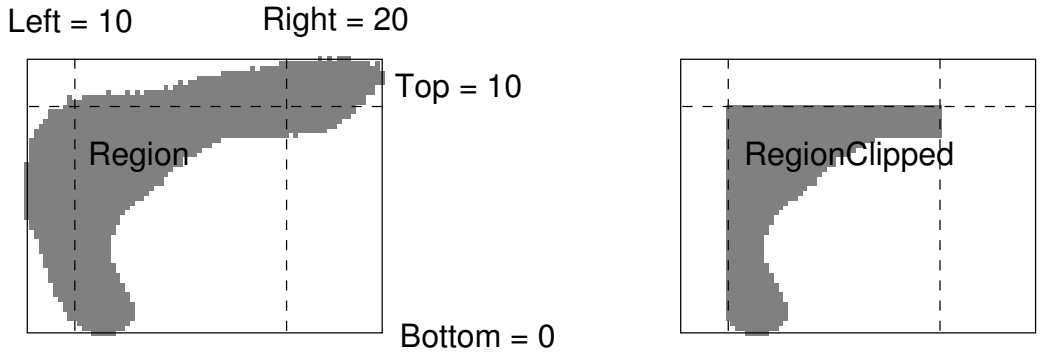
Foundation

clip_region_rel (Region : RegionClipped : Top, Bottom, Left, Right :)

Clip a region relative to its smallest surrounding rectangle.

clip_region_rel reduces the Region by eliminating parts close to the smallest surrounding rectangle of the Region. Specifically this means that the Region is clipped to a rectangle that is smaller than or equal to the smallest surrounding rectangle. The resulting clipped region is returned in RegionClipped.

The rectangle to which the Region is clipped is determined by reducing the smallest surrounding axis-parallel rectangle at the top, bottom, left, and right side by the values given in Top, Bottom, Left, and Right, respectively.



Region with smallest surrounding rectangle (1) and clipped region (2).

These four parameters must contain numbers larger or equal to zero. If all parameters are set to zero, the region remains unchanged.

Parameters

▷ **Region** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be clipped.

▷ **RegionClipped** (output_object) . . . . . region(-array) ⇝ *object*
Clipped regions.

▷ **Top** (input_control) . . . . . integer ⇝ *integer*
Number of rows clipped at the top.
Default: 1
Suggested values: Top ∈ {0, 1, 2, 3, 4, 5, 7, 10, 20, 30, 50}
Value range: 0 ≤ Top (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Bottom** (input_control) . . . . . integer ⇝ *integer*
Number of rows clipped at the bottom.
Default: 1
Suggested values: Bottom ∈ {0, 1, 2, 3, 4, 5, 7, 10, 20, 30, 50}
Value range: 0 ≤ Bottom (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Left** (input_control) . . . . . integer ⇝ *integer*
Number of columns clipped at the left.
Default: 1
Suggested values: Left ∈ {0, 1, 2, 3, 4, 5, 7, 10, 20, 30, 50}
Value range: 0 ≤ Left (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Right** (input_control) . . . . . integer ⇝ *integer*
Number of columns clipped at the right.
Default: 1
Suggested values: Right ∈ {0, 1, 2, 3, 4, 5, 7, 10, 20, 30, 50}
Value range: 0 ≤ Right (lin)
Minimum increment: 1
Recommended increment: 1

Result

clip_region_rel returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, connection, regiongrowing, pouring

Possible Successors

Alternatives

smallest_rectangle1, intersection, gen_rectangle1, clip_region

Module

Foundation

closest_point_transform (Region : Distances,
ClosestPoints : Metric, Foreground, ClosestPointMode, Width,
Height :)

Compute the closest-point transformation of a region.

closest_point_transform computes for every pixel of the input region Region (or its complement, respectively) the distance to the closest pixel outside the region (i.e., to the pixel on the outside border of the region) and returns this information in Distances. In addition to the distance, the corresponding closest pixel is returned in ClosestPoints.

The parameter Foreground determines whether the distances are calculated for all points within the region (Foreground = *'true'*) or for all points outside the region (Foreground = *'false'*). The distance is computed for every pixel of the output images Distances and ClosestPoints. The size of the images is specified by Width and Height. The input region is always clipped to the extent of the output image. If it is important that the distances within the entire region should be computed, the region should be moved (see move_region) so that it has only positive coordinates and the width and height of the output image should be large enough to contain the region. The extent of the input region can be obtained with smallest_rectangle1.

The parameter Metric determines which metric is used for the calculation of the distances. If Metric = *'city-block'*, the distance is calculated from the shortest path from the point to the border of the region, where only horizontal and vertical "movements" are allowed. They are weighted with a weight of 1. If Metric = *'chess-board'*, the distance is calculated from the shortest path to the border, where horizontal, vertical, and diagonal "movements" are allowed. They are weighted with a weight of 1. If Metric = *'octagonal'*, a combination of these approaches is used, which leads to diagonal paths receiving a higher weight. If Metric = *'chamfer-3-4'*, horizontal and vertical movements are weighted with a weight of 3, while diagonal movements are weighted with a weight of 4. To normalize the distances, the resulting distance image is divided by 3. Since this normalization step takes some time, and one usually is interested in the relative distances of the points, the normalization can be suppressed with Metric = *'chamfer-3-4-unnormalized'*. Finally, if Metric = *'euclidean'*, the computed distance is approximately Euclidean.

The parameter ClosestPointMode determines how the closest points are stored. For ClosestPointMode = *'absolute'*, absolute coordinates are stored in ClosestPoints. For ClosestPointMode = *'relative'*, the offset to the coordinate of the respective pixel is stored in ClosestPoints.

Attention

It should be noted that the closest points are usually not unique, i.e., for each pixel in the image Distances, there usually exist several points on the outer border of the region that have the respective distance to that pixel. For example, all points on the skeleton of the region in the chosen metric have the same distance to at least two distinct points on the outer border of the region. closest_point_transform returns one of these points that is determined by the implementation of the algorithm. In particular, invariances with respect to rotation or mirroring of the region should *not* be expected.

Furthermore, it should be noted that for Foreground = *'true'*, point coordinates that lie outside the image defined by Width and Height are returned if the input region Region touches the border of this image, since in this case the outside border of the region lies one pixel outside of the image. If the returned coordinates should be used for a direct access to an image, a suitable border treatment must be implemented.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Region for which the distance to the border is computed.
- ▷ **Distances** (output_object) ..... image ⇝ *object :* int4
  Image containing the distance information.
- ▷ **ClosestPoints** (output_object) ..... image ⇝ *object :* vector_field
  Image containing the coordinates of the closest points.
- ▷ **Metric** (input_control) ..... string ⇝ *string*
  Type of metric to be used for the closest-point transformation.
  Default: 'city-block'
  List of values: Metric ∈ {'city-block', 'chessboard', 'octagonal', 'chamfer-3-4', 'chamfer-3-4-unnormalized', 'euclidean'}
- ▷ **Foreground** (input_control) ..... string ⇝ *string*
  Compute the distance for pixels inside (*'true'*) or outside (*'false'*) the input region.
  Default: 'true'
  List of values: Foreground ∈ {'true', 'false'}
- ▷ **ClosestPointMode** (input_control) ..... string ⇝ *string*
  Mode in which the coordinates of the closest points are returned.
  Default: 'absolute'
  List of values: ClosestPointMode ∈ {'absolute', 'relative'}
- ▷ **Width** (input_control) ..... extent.x ⇝ *integer*
  Width of the output images.
  Default: 640
  Suggested values: Width ∈ {160, 192, 320, 384, 640, 768}
  Value range: 1 ≤ Width
- ▷ **Height** (input_control) ..... extent.y ⇝ *integer*
  Height of the output images.
  Default: 480
  Suggested values: Height ∈ {120, 144, 240, 288, 480, 576}
  Value range: 1 ≤ Height

Complexity

The runtime complexity is $O(\text{Width} * \text{Height})$.

Result

closest_point_transform returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, dyn_threshold, regiongrowing

Possible Successors

threshold, vector_field_to_real

Alternatives

distance_transform

Module

Foundation

connection (Region : ConnectedRegions : :)

Compute connected components of a region.

connection determines the connected components of the input regions given in Region. The neighborhood used for this can be set via set_system('neighborhood',<4/8>). The default is 8-neighborhood, which is useful for determining the connected components of the foreground. The maximum number of connected components that is returned by connection can be set via set_system('max_connection',<Num>). The default value of *0* causes all connected components to be returned. The inverse operator of connection is union1.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Input region.
- ▷ **ConnectedRegions** (output_object) ..... region-array ⇝ *object*
  Connected components.

Example

```
read_image(Image,'clip')
dev_set_colored(12)
threshold(Image,Dark,0,150)
count_obj(Dark,NumThresholded)
dev_display (Dark)
connection(Dark,ConnectedRegions)
count_obj(ConnectedRegions,NumConnected)
dev_display (ConnectedRegions)
```

Complexity

Let F be the area of the input region and N be the number of generated connected components. Then the runtime complexity is $O(sqrt(F) * sqrt(N))$.

Result

connection always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given)

can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

distance_transform (Region : DistanceImage : Metric, Foreground, Width, Height :)

Compute the distance transformation of a region.

distance_transform computes for every point of the input region Region (or its complement, respectively) the distance of the point to the border of the region. The parameter Foreground determines whether the distances are calculated for all points within the region (Foreground = *'true'*) or for all points outside the region (Foreground = *'false'*). The distance is computed for every point of the output image DistanceImage, which has the specified dimensions Width and Height. The input region is always clipped to the extent of the output image. If it is important that the distances within the entire region should be computed, the region should be moved (see move_region) so that it has only positive coordinates and the width and height of the output image should be large enough to contain the region. The extent of the input region can be obtained with smallest_rectangle1.

The parameter Metric determines which metric is used for the calculation of the distances. If Metric = *'city-block'*, the distance is calculated from the shortest path from the point to the border of the region, where only horizontal and vertical "movements" are allowed. They are weighted with a weight of 1. If Metric = *'chessboard'*, the distance is calculated from the shortest path to the border, where horizontal, vertical, and diagonal "movements" are allowed. They are weighted with a weight of 1. If Metric = *'octagonal'*, a combination of these approaches is used, which leads to diagonal paths receiving a higher weight. If Metric = *'chamfer-3-4'*, horizontal and vertical movements are weighted with a weight of 3, while diagonal movements are weighted with a weight of 4. To normalize the distances, the resulting distance image is divided by 3. Since this normalization step takes some time, and one usually is interested in the relative distances of the points, the normalization can be suppressed with Metric = *'chamfer-3-4-unnormalized'*. Finally, if Metric = *'euclidean'*, the computed distance is approximately Euclidean.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region for which the distance to the border is computed.

▷ **DistanceImage** (output_object) ..... image ⇝ *object :* int4
Image containing the distance information.

▷ **Metric** (input_control) ..... string ⇝ *string*
Type of metric to be used for the distance transformation.
Default: 'city-block'
List of values: Metric ∈ {'city-block', 'chessboard', 'octagonal', 'chamfer-3-4', 'chamfer-3-4-unnormalized', 'euclidean'}

▷ **Foreground** (input_control) ..... string ⇝ *string*
Compute the distance for pixels inside (*'true'*) or outside (*'false'*) the input region.
Default: 'true'
List of values: Foreground ∈ {'true', 'false'}

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the output image.
Default: 640
Suggested values: Width ∈ {160, 192, 320, 384, 640, 768}
Value range: 1 ≤ Width

▷ **Height** (input_control) ..... extent.y ⇝ *integer*
Height of the output image.
Default: 480
Suggested values: Height ∈ {120, 144, 240, 288, 480, 576}
Value range: 1 ≤ Height

Example

```
* Step towards extracting the medial axis of a shape:
gen_rectangle1 (Rectangle1, 0, 0, 200, 400)
gen_rectangle1 (Rectangle2, 200, 0, 400, 200)
union2 (Rectangle1, Rectangle2, Shape)
distance_transform (Shape, DistanceImage, 'chessboard', 'true', 640, 480)
```

Complexity

The runtime complexity is $O(\texttt{Width} * \texttt{Height})$.

Result

distance_transform returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

threshold, dyn_threshold, regiongrowing

Possible Successors

Foundation

eliminate_runs (Region : RegionClipped : ElimShorter, ElimLonger :)

Eliminate runs of a given length.

eliminate_runs eliminates all runs of the run length encoding of the input regions which are shorter than ElimShorter or longer as ElimLonger.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region to be clipped.

▷ **RegionClipped** (output_object) ..... region(-array) ⇝ *object*
Clipped regions.

▷ **ElimShorter** (input_control) ..... integer ⇝ *integer*
All runs which are shorter are eliminated.
Default: 3
Suggested values: ElimShorter ∈ {2, 3, 4, 5, 6, 8, 10, 12, 15}
Value range: 1 ≤ ElimShorter ≤ 500 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **ElimLonger** (input_control) ..... integer ⇝ *integer*
All runs which are longer are eliminated.
Default: 1000
Suggested values: ElimLonger ∈ {50, 100, 200, 500, 1000, 2000}
Value range: 1 ≤ ElimLonger ≤ 10000 (lin)
Minimum increment: 1
Recommended increment: 10

Result

eliminate_runs returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Alternatives

shape_trans

Module

Foundation

expand_region (Regions, ForbiddenArea : RegionExpanded : Iterations, Mode :)

Fill gaps between regions or split overlapping regions.

expand_region closes gaps between the input regions, which resulted from the suppression of small regions in a segmentation operator, for example, (mode *'image'*), or to separate overlapping regions (mode *'region'*). Both uses result from the expansion of regions. The operator works by adding or removing a one pixel wide "strip" to a region.

The expansion takes place only in regions that are designated as not "forbidden" (parameter ForbiddenArea). The number of iterations is determined by the parameter Iterations. By passing *'maximal'*, expand_region iterates until convergence, i.e., until no more changes occur. By passing 0 for this parameter, all non-overlapping regions are returned. The two modes of operation (*'image'* and *'region'*) are different in the following ways:

'image' The input regions are expanded iteratively until they touch another region or the image border. In this case, the image border is defined to be the rectangle ranging from (0,0) to (row_max,col_max). Here, (row_max,col_max) corresponds to the lower right corner of the smallest surrounding rectangle of all input regions (i.e., of all regions that are passed in `Regions` and `ForbiddenArea`). Because `expand_region` processes all regions simultaneously, gaps between regions are distributed evenly to all regions. Overlapping regions are split by distributing the area of overlap evenly to both regions.

'region' No expansion of the input regions is performed. Instead, only overlapping regions are split by distributing the area of overlap evenly to the respective regions. Because the intersection with the original region is computed after the shrinking operation gaps in the output regions may result, i.e., the segmentation is not complete. This can be prevented by calling `expand_region` a second time with the complement of the original regions as "forbidden area."

Parameters

▷ **`Regions`** (input_object) ..... region(-array) ⇝ *object*
Regions for which the gaps are to be closed, or which are to be separated.

▷ **`ForbiddenArea`** (input_object) ..... region ⇝ *object*
Regions in which no expansion takes place.

▷ **`RegionExpanded`** (output_object) ..... region(-array) ⇝ *object*
Expanded or separated regions.

▷ **`Iterations`** (input_control) ..... integer ⇝ *integer* / string
Number of iterations.
Default: 'maximal'
Suggested values: `Iterations` ∈ {'maximal', 0, 1, 2, 3, 5, 7, 10, 15, 20, 30, 50, 70, 100, 200}
Value range: 0 ≤ `Iterations` ≤ 1000 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **`Mode`** (input_control) ..... string ⇝ *string*
Expansion mode.
Default: 'image'
List of values: `Mode` ∈ {'image', 'region'}

Example

```
read_image(Image,'clip')
threshold(Image,Dark,0,150)
connection(Dark,ConnectedRegions)
gen_circle (Circle, 400, 400, 200.5)
expand_region (ConnectedRegions, Circle, RegionExpanded, 'maximal', 'image')
dev_display (RegionExpanded)
```

Result

`expand_region` always returns the value 2 (`H_MSG_TRUE`). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)`, the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`, and the behavior in case of an empty result region via `set_system('store_empty_region',<'true'/'false'>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fill_up (Region : RegionFillUp : :)

Fill up holes in regions.

fill_up fills up holes in regions. The number of regions remains unchanged. The neighborhood type is set via set_system('neighborhood',<4/8>) (default: 8-neighborhood).

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Input regions containing holes.
- ▷ **RegionFillUp** (output_object) ..... region(-array) ⇝ *object*
  Regions without holes.

Result

fill_up returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

fill_up_shape (Region : RegionFillUp : Feature, Min, Max :)

Fill up holes in regions having given shape features.

fill_up_shape fills up those holes in the input region Region having given shape features. The parameter Feature determines the shape feature to be used, while Min and Max determine the range the shape feature has to lie in in order for the hole to be filled up.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Input region(s).
- ▷ **RegionFillUp** (output_object) ..... region(-array) ⇝ *object*
  Output region(s) with filled holes.

▷ **Feature** (input_control) ..... string ⇝ *string*
Shape feature used.
Default: 'area'
List of values: Feature ∈ {'area', 'compactness', 'convexity', 'anisometry', 'phi', 'ra', 'rb', 'inner_circle', 'outer_circle'}

▷ **Min** (input_control) ..... number ⇝ *real* / integer
Minimum value for Feature.
Default: 1.0
Suggested values: Min ∈ {0.0, 1.0, 10.0, 50.0, 100.0, 500.0, 1000.0, 10000.0}
Value range: 0.0 ≤ Min

▷ **Max** (input_control) ..... number ⇝ *real* / integer
Maximum value for Feature.
Default: 100.0
Suggested values: Max ∈ {10.0, 50.0, 100.0, 500.0, 1000.0, 10000.0, 100000.0}
Value range: 0.0 ≤ Max

Example

```
read_image(&Image,"monkey");
threshold(Image,&Seg,120.0,255.0);
fill_up_shape(Seg,&Filled,"area",0.0,200.0);
```

Result

fill_up_shape returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

junctions_skeleton (Region : EndPoints, JuncPoints : :)

Find junctions and end points in a skeleton.

junctions_skeleton detects junctions and end points in a skeleton (see skeleton). The junctions in the input region Region are output as a region in JuncPoints, while the end points are output as a region in EndPoints.

To obtain reasonable results with junctions_skeleton the input region Region must not contain lines which are more than one pixel wide. Regions obtained by skeleton meet this condition, while regions obtained by morph_skeleton do not meet this condition in general.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Input skeletons.

▷ **EndPoints** (output_object) ..... region(-array) ⇝ *object*
Extracted end points.
Number of elements: EndPoints == Region

▷ **JuncPoints** (output_object) ..... region(-array) ⇝ *object*
Extracted junctions.
Number of elements: JuncPoints == Region

Example

```
* non-connected branches of a skeleton
skeleton(Region,Skeleton)
junctions_skeleton(Skeleton,EPoints,JPoints)
difference(Skeleton,JPoints,Rows)
set_system('neighborhood',4)
connection(Rows,Parts)
```

Complexity

Let F be the area of the input region. Then the runtime complexity is $O(F)$.

Result

`junctions_skeleton` always returns the value `2` (`H_MSG_TRUE`). The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)`, the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`, and the behavior in case of an empty result region via `set_system('store_empty_region',<'true'/'false'>)`. If necessary, an exception is raised.

Execution Information

merge_regions_line_scan (CurrRegions, PrevRegions : CurrMergedRegions, PrevMergedRegions : ImageHeight, MergeBorder, MaxImagesRegion :)

Merge regions from line scan images.

The operator `merge_regions_line_scan` connects adjacent regions, which were segmented from adjacent images with the height `ImageHeight`. This operator was especially designed to process regions that were extracted from images grabbed by a line scan camera. `CurrRegions` contains the regions from the current image and `PrevRegions` the regions from the previous one.

With the help of the parameter `MergeBorder` two cases can be distinguished: If the top (first) line of the current image touches the bottom (last) line of the previous image, `MergeBorder` must be set to *'top'*, otherwise set `MergeBorder` to *'bottom'*.

If the operator merge_regions_line_scan is used recursively, the parameter MaxImagesRegion determines the maximum number of images which are covered by a merged region. All older region parts are removed.

The operator merge_regions_line_scan returns two region arrays. PrevMergedRegions contains all those regions from the previous input regions PrevRegions, which could not be merged with a current region. CurrMergedRegions collects all current regions together with the merged parts from the previous images. Merged regions will exceed the original image, because the previous regions are moved upward (MergeBorder='top') or downward (MergeBorder='bottom') according to the image height. For this the system parameter *'clip_region'* (see also set_system) will internally be set to *'false'*.

Parameters

- ▷ **CurrRegions** (input_object) ..... region(-array) ⇝ *object*
  Current input regions.
- ▷ **PrevRegions** (input_object) ..... region(-array) ⇝ *object*
  Merged regions from the previous iteration.
- ▷ **CurrMergedRegions** (output_object) ..... region(-array) ⇝ *object*
  Current regions, merged with old ones where applicable.
- ▷ **PrevMergedRegions** (output_object) ..... region(-array) ⇝ *object*
  Regions from the previous iteration which could not be merged with the current ones.
- ▷ **ImageHeight** (input_control) ..... integer ⇝ *integer*
  Height of the line scan images.
  Default: 512
  Suggested values: ImageHeight ∈ {240, 480, 512, 1024}
- ▷ **MergeBorder** (input_control) ..... string ⇝ *string*
  Image line of the current image, which touches the previous image.
  Default: 'top'
  List of values: MergeBorder ∈ {'top', 'bottom'}
- ▷ **MaxImagesRegion** (input_control) ..... integer ⇝ *integer*
  Maximum number of images for a single region.
  Default: 3
  Suggested values: MaxImagesRegion ∈ {1, 2, 3, 4, 5}

Result

The operator merge_regions_line_scan returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

partition_dynamic (Region : Partitioned : Distance, Percent :)

Partition a region horizontally at positions of small vertical extent.

partition_dynamic partitions the input Region horizontally into regions that have an approximate width of Distance. The input region is split at positions where it has a relatively small vertical extent.

The positions where the input region is split are determined by the following approach: First, initial split positions are determined such that they are equally distributed over the horizontal extent of the input region, i.e., such that all the resulting parts would have the same width. For this, the number n of resulting parts is determined by dividing the width of the input region by Distance and rounding the result to the closest integer value. The distance between the initial split positions is now calculated by dividing the width of the input region by n. Note that the distance between these initial split positions is typically not identical to Distance. Then, the final split positions are determined in the neighborhood of the initial split positions such that the input region is split at positions where

it has the least vertical extent within this neighborhood. The maximum deviation of the final split position from the initial split position is Distance*Percent*0.01.

The resulting regions are returned in Partitioned. Note that the input region is only partitioned if its width is larger than 1.5 times Distance.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Region to be partitioned.
- ▷ **Partitioned** (output_object) ..... region-array ⇝ *object*
  Partitioned region.
- ▷ **Distance** (input_control) ..... real ⇝ *real*
  Approximate width of the resulting region parts.
- ▷ **Percent** (input_control) ..... real ⇝ *real*
  Maximum percental shift of the split position.
  Default: 20
  Suggested values: Percent ∈ {0.0, 10.0, 20.0, 30.0, 40.0, 50.0, 70.0, 90.0, 100.0}
  Value range: 0 ≤ Percent ≤ 100

Result

partition_dynamic returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>), the behavior in case of an empty input region via set_system('empty_region_result',<Result>), and the behavior in case of an empty result region via set_system('store_empty_region',<'true'/'false'>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, connection

Alternatives

partition_rectangle

See also

intersection, smallest_rectangle1, shape_trans, clip_region

Module

Foundation

partition_rectangle (Region : Partitioned : Width, Height :)

Partition a region into rectangles of approximately equal size.

partition_rectangle partitions the input region into rectangles having an extent of Width times Height. The rectangles are returned in Partitioned. The region is always split into rectangles of approximately equal size. If this is not possible with the requested rectangle size, then Width and Height are adapted so that the size of the resulting rectangles is approximately equal. If the region is smaller than the given size, its output remains unchanged. A partition is only done if the size of the region is at least 1.5 times the size of the rectangle given by the parameters.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Region to be partitioned.
- ▷ **Partitioned** (output_object) ..... region(-array) ⇝ *object*
  Partitioned region.

▷ **Width** (input_control) ..... extent.x ⇝ *real*
Width of the individual rectangles.

▷ **Height** (input_control) ..... extent.y ⇝ *real*
Height of the individual rectangles.

Result

`partition_rectangle` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)`, the behavior in case of an empty input region via `set_system('empty_region_result',<Result>)`, and the behavior in case of an empty result region via `set_system('store_empty_region',<'true'/'false'>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

rank_region (Region : RegionCount : Width, Height, Number :)

Rank operator for regions.

`rank_region` calculates the binary rank operator. A filter mask of size `Height` x `Width`) is used. In the process, for each point in the region the number of points of `Region` lying within the filter mask are counted. If this number is greater or equal to `Number`, the current point is added to the output region. If

$$\texttt{Number} = \frac{\texttt{Height} * \texttt{Width}}{2},$$

is chosen, the median operator is obtained.

Attention

For `Height` and `Width` only odd values > 3 are valid. If invalid parameters are chosen they are converted automatically (without raising an exception) to the next larger odd values.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region(s) to be transformed.

▷ **RegionCount** (output_object) ..... region(-array) ⇝ *object*
Resulting region(s).

▷ **Width** (input_control) ..... extent.x ⇝ *integer*
Width of the filter mask.
Default: 15
Suggested values: `Width` ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21}
Value range: $3 \leq$ `Width` ≤ 511 (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: Width >= 3 && odd(Width)

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the filter mask.
Default: 15
Suggested values: Height ∈ {3, 5, 7, 9, 11, 13, 15, 17, 19, 21}
Value range: 3 ≤ Height ≤ 511 (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: Height >= 3 && odd(Height)

▷ **Number** (input_control) . . . . . integer ⇝ *integer*
Minimum number of points lying within the filter mask.
Default: 70
Suggested values: Number ∈ {5, 10, 20, 40, 60, 80, 90, 120, 150, 200}
Value range: 1 ≤ Number ≤ 1000 (lin)
Minimum increment: 1
Recommended increment: 10
Restriction: Number > 0

Example

```
read_image(Image,'monkey')
mean_image(Image,Mean,5,5)
dyn_threshold(Image,Mean,Points,25,'light')
rank_region(Points,Textur,15,15,30)
gen_circle(Mask,10,10,3)
opening(Textur,Mask,Seg)
```

Complexity

Let F be the area of the input region. Then the runtime complexity is $O(F * 8)$.

Result

rank_region returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

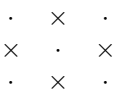
Foundation

remove_noise_region (InputRegion : OutputRegion : Type :)

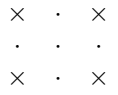
Remove noise from a region.

remove_noise_region removes noise from a region. Depending on Type one of the following structuring elements will be used:

'n_4' A structuring element consisting of the four 4-neighbors of a point is being used:



'n_8' A structuring element consisting of the four 8-neighbors of a point is being used:



'n_48' A structuring element consisting of the four 4-neighbors and the four 8-neighbors of a point is being used:

A dilation with this structuring element is performed and the intersection of the result and the input region is calculated. Thus, all pixels having no according neighbors are removed.

Parameters

▷ **InputRegion** (input_object) . . . . . region(-array) ⇝ *object*
Regions to be modified.

▷ **OutputRegion** (output_object) . . . . . region(-array) ⇝ *object*
Less noisy regions.

▷ **Type** (input_control) . . . . . string ⇝ *string*
Mode of noise removal.
Default: 'n_4'
List of values: `Type` ∈ {'n_4', 'n_8', 'n_48'}

Complexity

Let F be the area of the input region. Then the runtime complexity is $O(\sqrt{F} * 4)$.

Result

`remove_noise_region` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

shape_trans (Region : RegionTrans : Type :)

Transform the shape of a region.

`shape_trans` transforms the shape of the input regions depending on the parameter `Type`:

'convex' Convex hull.

'ellipse' Ellipse with the same moments and area as the input region.

'outer_circle' Smallest enclosing circle.

'inner_circle' Largest circle fitting into the region.

'rectangle1' Smallest enclosing rectangle parallel to the coordinate axes.

'rectangle2' Smallest enclosing rectangle.

'inner_rectangle1' Largest axis-parallel rectangle fitting into the region.

'inner_center' The point on the skeleton of the input region having the smallest distance to the center of gravity of the input region.

Attention

If `Type` = *'outer_circle'* is selected it might happen that the resulting circular region does not completely cover the input region. This is because internally the operators `smallest_circle` and `gen_circle` are used to compute the outer circle. As described in the documentation of `smallest_circle`, the calculated radius can be too small by up to $1/\sqrt{2} - 0.5$ pixels. Additionally, the circle that is generated by `gen_circle` is translated by up to 0.5 pixels in both directions, i.e., by up to $1/\sqrt{2}$ pixels. Consequently, when adding up both effects, the original region might protrude beyond the returned circular region by at most 1 pixel.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be transformed.

▷ **RegionTrans** (output_object) ..... region(-array) ⇝ *object*
Transformed regions.

▷ **Type** (input_control) ..... string ⇝ *string*
Type of transformation.
Default: 'convex'
List of values: `Type` ∈ {'convex', 'ellipse', 'outer_circle', 'inner_circle', 'rectangle1', 'rectangle2', 'inner_rectangle1', 'inner_center'}

Complexity

Let F be the area of the input region. Then the runtime complexity is $O(F)$.

Result

`shape_trans` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`connection`, `regiongrowing`

Possible Successors

Module

Foundation

skeleton (Region : Skeleton : :)

Compute the skeleton of a region.

skeleton computes the skeleton, i.e., the medial axis of the input regions. The skeleton is constructed in a way that each point on it can be seen as the center point of a circle with the largest radius possible while still being completely contained in the region.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Region to be thinned.

▷ **Skeleton** (output_object) ..... region(-array) ⇝ *object*
Resulting skeleton.
Number of elements: Skeleton == Region

Complexity

Let F be the area of the enclosing rectangle of the input region. Then the runtime complexity is $O(F)$ (per region).

Result

skeleton returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>) and the behavior in case of an empty input region via set_system('empty_region_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

sort_region (Regions : SortedRegions : SortMode, Order, RowOrCol :)

Sorting of regions with respect to their relative position.

The operator sort_region sorts the regions with respect to their relative position. All sorting methods with the exception of *'character'* use one point of the region. With the help of the parameter RowOrCol = *'row'* these points will be sorted according to their row and then according to their column. By using *'column'*, the column value will be used first. The following values are available for the parameter SortMode:

'character' The regions are treated like characters, which can be read horizontally or vertically. They are sorted according to the reading direction given by RowOrCol with the following specifications:

- *'row'*: Regarded as rows, the reading direction is firstly from left to right and then from top to bottom.
- *'column'*: Regarded as columns, the reading direction is firstly from top to bottom and then from left to right.

For SortMode *'character'*, a second numeric value can be passed to SortMode in addition to *'character'*. This value specifies the maximum percentage of overlap. This overlap depends on the parameter RowOrCol and is determined as follows:

- RowOrCol = *'row'*: overlap of row coordinates between two regions
- RowOrCol = *'column'*: overlap of column coordinates between two regions,

whereas the percentage of overlap is calculated using the smaller one of the overlapping regions (with respect to the specified axis). Regions that do not overlap in their coordinates or have an overlap of less than the set percentage are seen as being in different rows (or columns, respectively) and sorted accordingly. In case the overlap is larger, the regions are seen as being in the same row (or column) instead and therefore sorted within the row (or column). For example when this additional parameter is set to 0, all regions that overlap in their row (or column) coordinates are sorted within the same row (or column). The default value of this parameter is 15 which means that adjacent rows (or columns) can have an overlap of maximum 15% in order to be considered as different rows (or columns). Note that for Order = *'false'*, the characters are sorted in a reversed order to the one described above.

'first_point' The point with the lowest column value in the first row of the region.

'last_point' The point with the highest column value in the last row of the region.

'upper_left' Upper left corner of the surrounding rectangle.

'upper_right' Upper right corner of the surrounding rectangle.

'lower_left' Lower left corner of the surrounding rectangle.

'lower_right' Lower right corner of the surrounding rectangle.

The parameter Order determines whether the sorting order is increasing or decreasing: using *'true'* the order will be increasing, using *'false'* the order will be decreasing.

Parameters

▷ **Regions** (input_object) ..... region-array ⇝ *object*
Regions to be sorted.

▷ **SortedRegions** (output_object) ..... region-array ⇝ *object*
Sorted regions.

▷ **SortMode** (input_control) ..... tuple(-array) ⇝ *string* / integer / real
Kind of sorting.
Default: 'first_point'
List of values: SortMode ∈ {'character', 'first_point', 'last_point', 'upper_left', 'lower_left', 'upper_right', 'lower_right'}

▷ **Order** (input_control) ..... string ⇝ *string*
Increasing or decreasing sorting order.
Default: 'true'
List of values: Order ∈ {'true', 'false'}

▷ **RowOrCol** (input_control) ..... string ⇝ *string*
Sorting first with respect to row, then to column.
Default: 'row'
List of values: RowOrCol ∈ {'row', 'column'}

Result

If the parameters are correct, the operator sort_region returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

do_ocr_multi_class_mlp, do_ocr_single_class_mlp

Module

Foundation

split_skeleton_lines (SkeletonRegion : : MaxDistance : BeginRow, BeginCol, EndRow, EndCol)

Split lines represented by one pixel wide, non-branching lines.

split_skeleton_lines splits lines represented by one pixel wide, non-branching regions into shorter lines based on their curvature. A line is split if the maximum distance of a point on the line to the line segment connecting its end points is larger than MaxDistance (split & merge algorithm). The start and end points of the approximating line segments are returned in BeginRow, BeginCol, EndRow, and EndCol.

Attention

The input regions must represent non-branching lines, that is single branches of the skeleton.

Parameters

▷ **SkeletonRegion** (input_object) ..... region-array ⇝ *object*
Input lines (represented by 1 pixel wide, non-branching regions).

▷ **MaxDistance** (input_control) ..... integer ⇝ *integer*
Maximum distance of the line points to the line segment connecting both end points.
Default: 3
Suggested values: MaxDistance ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Value range: 1 ≤ MaxDistance ≤ 500 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **BeginRow** (output_control) ..... line.begin.y-array ⇝ *integer*
Row coordinates of the start points of the output lines.

▷ **BeginCol** (output_control) ..... line.begin.x-array ⇝ *integer*
Column coordinates of the start points of the output lines.

▷ **EndRow** (output_control) ..... line.end.y-array ⇝ *integer*
Row coordinates of the end points of the output lines.

▷ **EndCol** (output_control) ..... line.end.x-array ⇝ *integer*
Column coordinates of the end points of the output lines.

Example

```
read_image(Image,'fabrik')
edges_image (Image, ImaAmp, ImaDir, 'lanser2', 0.5, 'nms', 8, 16)
threshold (ImaAmp, RawEdges, 8, 255)
skeleton (RawEdges, Skeleton)
junctions_skeleton (Skeleton, EndPoints, JuncPoints)
difference (Skeleton, JuncPoints, SkelWithoutJunc)
connection (SkelWithoutJunc, SingleBranches)
select_shape (SingleBranches, SelectedBranches, 'area', 'and', 16, 99999)
split_skeleton_lines (SelectedBranches, 3, BeginRow, BeginCol, EndRow, \
                      EndCol)
```

Result

split_skeleton_lines always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>), the behavior in case of an empty input region via set_system('empty_region_result',<Result>), and the behavior in case of an empty result region via set_system('store_empty_region',<'true'/'false'>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

split_skeleton_region (
SkeletonRegion : RegionLines : MaxDistance :)

Split lines represented by one pixel wide, non-branching regions.

split_skeleton_region splits lines represented by one pixel wide, non-branching regions into shorter lines based on their curvature. A line is split if the maximum distance of a point on the line to the line segment connecting its end points is larger than MaxDistance (split & merge algorithm). However, not the approximating lines are returned, but rather the original lines split into several output regions.

Attention

The input regions must represent non-branching lines, that is single branches of the skeleton.

Parameters

▷ **SkeletonRegion** (input_object) ..... region(-array) ⇝ *object*
Input lines (represented by 1 pixel wide, non-branching regions).

▷ **RegionLines** (output_object) ..... region-array ⇝ *object*
Split lines.

▷ **MaxDistance** (input_control) ..... integer ⇝ *integer*
Maximum distance of the line points to the line segment connecting both end points.
Default: 3
Suggested values: MaxDistance ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Value range: 1 ≤ MaxDistance ≤ 500 (lin)
Minimum increment: 1
Recommended increment: 1

Example

```
read_image(Image,'fabrik')
edges_image (Image, ImaAmp, ImaDir, 'lanser2', 0.5, 'nms', 8, 16)
threshold (ImaAmp, RawEdges, 8, 255)

24.1 Classification

add_samples_image_class_gmm (Image, ClassRegions : : GMMHandle, Randomize :)

Add training samples from an image to the training data of a Gaussian Mixture Model.

add_samples_image_class_gmm adds training samples from the Image to the Gaussian Mixture Model (GMM) given by GMMHandle. add_samples_image_class_gmm is used to store the training samples before a classifier to be used for the pixel classification of multichannel images with classify_image_class_gmm is trained. add_samples_image_class_gmm works analogously to add_sample_class_gmm. The Image must have a number of channels equal to NumDim, as specified with create_class_gmm. The training regions for the NumClasses pixel classes are passed in ClassRegions. Hence, ClassRegions must be a tuple containing NumClasses regions. The order of the regions in ClassRegions determines the class of the pixels. If there are no samples for a particular class in Image an empty region must be passed at the position of the class in ClassRegions. With this mechanism it is possible to use multiple images to add training samples for all relevant classes to the GMM by calling add_samples_image_class_gmm multiple times with the different images and suitably chosen regions. The regions in ClassRegions should contain representative training samples for the respective classes. Hence, they need not cover the entire image. The regions in ClassRegions should not overlap each other, because this would lead to the fact that in the training data the samples from the overlapping areas would be assigned to multiple classes, which may lead to a lower classification performance. Image data of integer type can be particularly badly suited for modeling with a GMM. Randomize can be used to overcome this problem, as explained in add_sample_class_gmm.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Training image.

▷ **ClassRegions** (input_object) ..... region-array ⇝ *object*
Regions of the classes to be trained.

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **Randomize** (input_control) ..... real ⇝ *real*
Standard deviation of the Gaussian noise added to the training data.
Default: 0.0
Suggested values: Randomize ∈ {0.0, 1.5, 2.0}
Restriction: Randomize >= 0.0

Result

If the parameters are valid, the operator add_samples_image_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- GMMHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

add_samples_image_class_knn (Image, ClassRegions : : KNNHandle :)

Add training samples from an image to the training data of a k-Nearest-Neighbor classifier.

add_samples_image_class_knn adds training samples from the Image to the k-Nearest-Neighbor (k-NN) given by KNNHandle. add_samples_image_class_knn is used to store the training samples before a classifier is used for the pixel classification of multichannel images with classify_image_class_knn. add_samples_image_class_knn works analogously to add_sample_class_knn. The Image must have a number of channels equal to NumDim, as specified with create_class_knn. ClassRegions must be a tuple containing of at least 2 regions. The order of the regions in ClassRegions determines the class of the pixels. If there are no samples for a particular class in Image an empty region must be passed at the position of the class in ClassRegions. With this mechanism it is possible to use multiple images to add training samples for all relevant classes to the k-NN classifier by calling add_samples_image_class_knn multiple times with different images and suitably chosen regions. The regions in ClassRegions should contain representative training samples for the respective classes. Hence, they do not need to cover the entire image. The regions in ClassRegions should not overlap each other, as these samples from overlapping areas would be assigned to multiple classes in the training data, which may lead to a lower classification performance.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Training image.

▷ **ClassRegions** (input_object) ..... region-array ⇝ *object*
Regions of the classes to be trained.

▷ **KNNHandle** (input_control) ..... class_knn ⇝ *handle*
Handle of the k-NN classifier.

Result

If the parameters are valid, the operator add_samples_image_class_knn returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- KNNHandle

add_samples_image_class_mlp (Image, ClassRegions : : MLPHandle :)

Add training samples from an image to the training data of a multilayer perceptron.

add_samples_image_class_mlp adds training samples from the image Image to the multilayer perceptron (MLP) given by MLPHandle. add_samples_image_class_mlp is used to store the training samples before a classifier to be used for the pixel classification of multichannel images with classify_image_class_mlp is trained. add_samples_image_class_mlp works analogously to add_sample_class_mlp. Because here the MLP is always used for classification, OutputFunction = *'softmax'* must be specified when the MLP is created with create_class_mlp. The image Image must have a number of channels equal to NumInput, as specified with create_class_mlp. The training regions for the NumOutput pixel classes are passed in ClassRegions. Hence, ClassRegions must be a tuple containing NumOutput regions. The order of the regions in ClassRegions determines the class of the pixels. If there are no samples for a particular class in Image an empty region must be passed at the position of the class in ClassRegions. With this mechanism it is possible to use multiple images to add training samples for all relevant classes to the MLP by calling add_samples_image_class_mlp multiple times with the different images and suitably chosen regions. The regions in ClassRegions should contain representative training samples for the respective classes. Hence, they need not cover the entire image. The regions in ClassRegions should not overlap each other, because this would lead to the fact that in the training data the samples from the overlapping areas would be assigned to multiple classes, which may lead to slower convergence of the training and a lower classification performance.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Training image.

▷ **ClassRegions** (input_object) ..... region-array ⇝ *object*
Regions of the classes to be trained.

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

Result

If the parameters are valid, the operator add_samples_image_class_mlp returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

add_samples_image_class_svm (Image, ClassRegions : : SVMHandle :)

Add training samples from an image to the training data of a support vector machine.

add_samples_image_class_svm adds training samples from the image Image to the support vector machine (SVM) given by SVMHandle. add_samples_image_class_svm is used to store the training samples before training a classifier for the pixel classification of multichannel images with classify_image_class_svm. add_samples_image_class_svm works analogously to add_sample_class_svm.

The image Image must have a number of channels equal to NumFeatures, as specified with create_class_svm. The training regions for the NumClasses pixel classes are passed in ClassRegions. Hence, ClassRegions must be a tuple containing NumClasses regions. The order of the regions in ClassRegions determines the class of the pixels. If there are no samples for a particular class in Image, an empty region must be passed at the position of the class in ClassRegions. With this mechanism it is possible to use multiple images to add training samples for all relevant classes to the SVM by calling add_samples_image_class_svm multiple times with the different images and suitably chosen regions.

The regions in ClassRegions should contain representative training samples for the respective classes. Hence, they need not cover the entire image. The regions in ClassRegions should not overlap each other, because this would lead to the fact that in the training data the samples from the overlapping areas would be assigned to multiple classes, which may lead to slower convergence of the training and a lower classification performance.

A further application of this operator is the automatic novelty detection, where, e.g., anomalies in color or texture can be detected. For this mode a training set that defines a sample region (e.g., skin regions for skin detection or samples of the correct texture) is passed to the SVMHandle, which is created in the Mode *'novelty-detection'*. After training, regions that differ from the trained sample regions are detected (e.g., the rejection class for skin or errors in texture).

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Training image.

▷ **ClassRegions** (input_object) ..... region-array ⇝ *object*
Regions of the classes to be trained.

▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
SVM handle.

Result

If the parameters are valid `add_samples_image_class_svm` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SVMHandle

class_2dim_sup (ImageCol, ImageRow, FeatureSpace : RegionClass2Dim : :)

Segment an image using two-dimensional pixel classification.

`class_2dim_sup` classifies the points in two-channel images using a two-dimensional feature space. For each point, two gray values (one from each image) are used as features. The feature space is represented by the input region. The classification is done as follows:

A point from the input region of an image is accepted if the point (g_r, g_c), which is determined by the respective gray values, is contained in the region `FeatureSpace`. g_r is here a gray value from the image `ImageRow`, while g_c is the corresponding gray value from `ImageCol`.

Let P be a point with the coordinates $P = (R, C)$, g_r be the gray value at position (R, C) in the image `ImageRow`, and g_c be the gray value at position (R, C) in the image `ImageCol`. Then the point P is aggregated into the output region if

$$(g_r, g_c) \in \texttt{FeatureSpace}$$

g_r is interpreted as row coordinate and g_c as column coordinate.

For the generation of `FeatureSpace`, see `histo_2dim`. The feature space can be modified by applying region transformation operators, such as `rank_region`, `dilation1`, `shape_trans`, `elliptic_axis`, etc., before calling `class_2dim_sup`.

The parameters `ImageCol` and `ImageRow` must contain an equal number of images with the same size. The image points are taken from the intersection of the domains of both images (see `reduce_domain`).

Parameters

- ▷ **ImageCol** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1
  Input image (first channel).
- ▷ **ImageRow** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1
  Input image (second channel).
- ▷ **FeatureSpace** (input_object) . . . . . region(-array) ⇝ *object*
  Region defining the feature space.
- ▷ **RegionClass2Dim** (output_object) . . . . . region(-array) ⇝ *object*
  Classified regions.

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  if (argc != 2)
  {
    cout << "Usage : " << argv[0] << " 'image' " << endl;
    return (-1);
  }

  HRegion   feats, cd2reg;
  HImage    image (argv[1]),
            text1, text2,
            mean1, mean2,
            histo;

  HWindow   win;
  Hlong      nc;

  if ((nc = image.CountChannels ()) != 3)
  {
    cout << argv[1] << " is not a rgb-image " << endl;
    return (-2);
  }

  image.Display (win);

  win.SetColor ("green");
  cout << "Draw the region of interrest " << endl;

  HRegion  region = win.DrawRegion ();

  text1 = image.TextureLaws ("el", 2, 5);
  mean1 = text1.MeanImage (21, 21);
  text2 = mean1.TextureLaws ("es", 2, 5);
  mean2 = text2.MeanImage (21, 21);

  histo = region.Histo2dim (mean1, mean2);
  feats = histo.Threshold (1.0, 1000000.0);

  win.SetDraw ("fill");
  win.SetColor ("red");
```

```
  feats.Display (win);

  cout << "Charakteristics area in red" << endl;

  cd2reg = mean1.Class2dimSup (mean2, feats);

  win.SetColor ("blue");
  cd2reg.Display (win);

  cout << "Result of classification in blue " << endl;
  win.Click ();
  return (0);
}
```

Complexity

Let A be the area of the input region. Then the runtime complexity is $O(256^2 + A)$.

Result

`class_2dim_sup` returns `2` (`H_MSG_TRUE`). If all parameters are correct, the behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`histo_2dim`, `threshold`, `draw_region`, `dilation1`, `opening`, `shape_trans`

Possible Successors

class_2dim_unsup (Image1, Image2 : Classes : Threshold, NumClasses :)

Segment two images by clustering.

`class_2dim_unsup` performs a classification with two single-channel images. First, a two-dimensional histogram of the two images is computed (`histo_2dim`). In this histogram, the first maximum is extracted; it serves as the first cluster center. The histogram is computed with the intersection of the domains of both images (see `reduce_domain`). After this, all pixels in the images that are at most `Threshold` pixels from the cluster center in the maximum norm, are determined. These pixels form one output region. Next, the pixels thus classified are deleted from the histogram so that they are not taken into account for the next class. In this modified histogram, again the maximum is extracted; it again serves as a cluster center. The above steps are repeated `NumClasses` times; thus, `NumClasses` output regions result. Only pixels defined in both images are returned.

Attention

Both input images must have the same size.

Parameters

▷ **Image1** (input_object) ..... singlechannelimage ⇝ *object :* byte
First input image.

▷ **Image2** (input_object) ..... singlechannelimage ⇝ *object :* byte
Second input image.

▷ **Classes** (output_object) ..... region-array ⇝ *object*
Classification result.

▷ **Threshold** (input_control) ..... integer ⇝ *integer*
Threshold (maximum distance to the cluster's center).
Default: 15
Suggested values: `Threshold` ∈ {0, 2, 5, 8, 12, 17, 20, 30, 50, 70}

▷ **NumClasses** (input_control) ..... integer ⇝ *integer*
Number of classes (cluster centers).
Default: 5
Suggested values: `NumClasses` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 15, 20, 30, 40, 50}

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  if (argc != 2)
  {
    cout << "Usage : " << argv[0] << " 'image' " << endl;
    return (-1);
  }

  HImage   colimg (argv[1]),
           green, blue;

  HWindow  w;
  Hlong     nc;

  if ((nc = colimg.CountChannels ()) != 3)
  {
    cout << argv[1] << " is not a rgb-image " << endl;
    return (-2);
  }

  colimg.Display (w);

  HImage        red = colimg.Decompose3 (&green, &blue);
  HRegionArray  seg = red.Class2dimUnsup (green, 15, 5);

  w.SetDraw ("margin");
  w.SetColored (12);
  seg.Display (w);
  w.Click ();

  return (0);
}
```

Result

`class_2dim_unsup` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to

the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Possible Successors

select_shape, select_gray, connection

Alternatives

threshold, histo_2dim, class_2dim_sup, class_ndim_norm

Module

Foundation

class_ndim_norm (MultiChannelImage : Regions : Metric, SingleMultiple, Radius, Center :)

Classify pixels using hyper-spheres or hyper-cubes.

class_ndim_norm classifies the pixels of the multi-channel image given in MultiChannelImage. The result is returned in Regions as one region per classification object. The metric used (*'euclid'* or *'maximum'*) is determined by Metric. This parameter must be set to the same value used in learn_ndim_norm. The parameter SingleMultiple determines whether one region (*'single'*) or multiples regions (*'multiple'*) are generated for each cluster. Radius determines the radii or half edge length of the clusters, respectively. Center determines their centers.

Parameters

▷ **MultiChannelImage** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Multi channel input image.

▷ **Regions** (output_object) ..... region-array ⇝ *object*
Classification result.

▷ **Metric** (input_control) ..... string ⇝ *string*
Metric to be used.
Default: 'euclid'
List of values: Metric ∈ {'euclid', 'maximum'}

▷ **SingleMultiple** (input_control) ..... string ⇝ *string*
Return one region or one region for each cluster.
Default: 'single'
List of values: SingleMultiple ∈ {'single', 'multiple'}

▷ **Radius** (input_control) ..... number(-array) ⇝ *real* / integer
Cluster radii or half edge lengths (returned by learn_ndim_norm).

▷ **Center** (input_control) ..... number(-array) ⇝ *real* / integer
Coordinates of the cluster centers (returned by learn_ndim_norm).

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;
```

```
int main ()
{
  HImage   image ("meer"),
           t1, t2, t3,
           m1, m2, m3, m;

  HWindow  w;

  w.SetColor ("green");
  image.Display (w);

  cout << "Draw your region of interest " << endl;

  HRegion testreg = w.DrawRegion ();

  t1 = image.TextureLaws ("el", 2, 5);     m1 = t1.MeanImage (21, 21);
  t2 = image.TextureLaws ("es", 2, 5);     m2 = t2.MeanImage (21, 21);
  t3 = image.TextureLaws ("le", 2, 5);     m3 = t3.MeanImage (21, 21);

  m  = m1.Compose3 (m2, m3);

  Tuple Metric = "euclid";
  Tuple Radius = 20.0;
  Tuple MinNum = 5;
  Tuple NbrCha = 3;

  HRegion empty;
  Tuple cen, t;

  Radius = testreg.LearnNdimNorm (empty, m, Metric, Radius,
                                  MinNum, NbrCha, &cen, &t);
  Tuple RegMod = "multiple";

  HRegionArray reg = m.ClassNdimNorm (Metric, RegMod, Radius, cen, NbrCha);

  w.SetColored (12);
  reg.Display (w);
  cout << "Result of classification" << endl;
  return (0);
}
```

Complexity

Let N be the number of clusters and A be the area of the input region. Then the runtime complexity is $O(N, A)$.

Result

`class_ndim_norm` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

classify_image_class_gmm (Image : ClassRegions : GMMHandle, RejectionThreshold :)

Classify an image with a Gaussian Mixture Model.

classify_image_class_gmm performs a pixel classification with the Gaussian Mixture Model (GMM) GMMHandle on the multichannel image Image. Before calling classify_image_class_gmm the GMM must be trained with train_class_gmm. Image must have NumDim channels, as specified with create_class_gmm. On output, ClassRegions contains NumClasses regions as the result of the classification. Note that the order of the regions that are returned in ClassRegions corresponds to the order of the classes as defined by the training regions in add_samples_image_class_gmm. The parameter RejectionThreshold can be used to reject pixels that have an uncertain classification. RejectionThreshold represents a threshold on the K-sigma probability measure returned by the classification (see classify_class_gmm and evaluate_class_gmm). All pixels having a probability below RejectionThreshold are not assigned to any class.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Input image.

▷ **ClassRegions** (output_object) ..... region-array ⇝ *object*
Segmented classes.

▷ **GMMHandle** (input_control) ..... class_gmm ⇝ *handle*
GMM handle.

▷ **RejectionThreshold** (input_control) ..... real ⇝ *real*
Threshold for the rejection of the classification.
Default: 0.5
Suggested values: RejectionThreshold ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: RejectionThreshold >= 0.0 && RejectionThreshold <= 1.0

Example

```
read_image (Image, 'ic')
gen_rectangle1 (Board, 80, 320, 110, 350)
gen_rectangle1 (Capacitor, 359, 263, 371, 302)
gen_rectangle1 (Resistor, 200, 252, 290, 256)
gen_rectangle1 (IC, 180, 135, 216, 165)
concat_obj (Board, Capacitor, Classes)
concat_obj (Classes, Resistor, Classes)
concat_obj (Classes, IC, Classes)
create_class_gmm (3, 4, [1,30], 'full', 'none',0, 42, GMMHandle)
add_samples_image_class_gmm (Image, Classes, GMMHandle, 1.5)
get_sample_num_class_gmm (GMMHandle, NumSamples)
train_class_gmm (GMMHandle, 150, 1e-4, 'training', 1e-4, Centers, Iter)
classify_image_class_gmm (Image, ClassRegions, GMMHandle, 0.0001)
```

Result

If the parameters are valid, the operator classify_image_class_gmm returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).

classify_image_class_knn (Image : ClassRegions, DistanceImage : KNNHandle, RejectionThreshold :)

Classify an image with a k-Nearest-Neighbor classifier.

classify_image_class_knn performs a pixel classification with a k-Nearest-Neighbor classifier (k-NN) KNNHandle on the multichannel image Image. Before calling classify_image_class_knn the k-NN classifier must be trained with train_class_knn. Image must have NumDim channels, as specified with create_class_knn. On output, ClassRegions contains NumClasses regions as the result of the classification. Note that the order of the regions that are returned in ClassRegions corresponds to the order of the classes as defined by the training regions in add_samples_image_class_knn. The parameter RejectionThreshold can be used to reject pixels that have an uncertain classification. RejectionThreshold represents a threshold on the distance to the nearest neighbor returned by the classification. All pixels having a probability below RejectionThreshold are not assigned to any class. DistanceImage contains the distance of each pixel to its nearest neighbor.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Input image.

▷ **ClassRegions** (output_object) ..... region-array ⇝ *object :* real
Segmented classes.

▷ **DistanceImage** (output_object) ..... image ⇝ *object*
Distance of the pixel's nearest neighbor.

▷ **KNNHandle** (input_control) ..... class_knn ⇝ *handle*
Handle of the k-NN classifier.

▷ **RejectionThreshold** (input_control) ..... real ⇝ *real*
Threshold for the rejection of the classification.
Default: 0.5
Suggested values: RejectionThreshold ∈ {0.0, 0.1, 0.2, 0.3, 5.0, 10.0, 255.0}
Restriction: RejectionThreshold >= 0.0

Example

```
read_image (Image, 'ic')
gen_rectangle1 (Board, 80, 320, 110, 350)
gen_rectangle1 (Capacitor, 359, 263, 371, 302)
gen_rectangle1 (Resistor, 200, 252, 290, 256)
gen_rectangle1 (IC, 180, 135, 216, 165)
concat_obj (Board, Capacitor, Classes)
concat_obj (Classes, Resistor, Classes)
concat_obj (Classes, IC, Classes)
create_class_knn (3, KNNHandle)
add_samples_image_class_knn (Image, Classes, KNNHandle)
```

```
get_sample_num_class_knn (KNNHandle, NumSamples)
train_class_knn (KNNHandle, [], [])
classify_image_class_knn (Image, ClassRegions, DistanceImage, \
                          KNNHandle, 0.5)
dev_display (ClassRegions)
```

Result

If the parameters are valid, the operator `classify_image_class_knn` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

classify_image_class_lut (
Image : ClassRegions : ClassLUTHandle :)

Classify a byte image using a look-up table.

`classify_image_class_lut` performs a pixel classification on a multi-channel byte `Image` using a look-up table (LUT) `ClassLUTHandle`. The operator can replace `classify_image_class_gmm`, `classify_image_class_knn`, `classify_image_class_mlp` and `classify_image_class_svm`. The classification gets a major speed-up, because the estimation of the class in every image point is no longer necessary since every possible response of the GMM, KNN, MLP or SVM, respectively, is stored in the LUT. This LUT classifier must be created with the trained classifier in `create_class_lut_gmm`, `create_class_lut_knn`, `create_class_lut_mlp` or `create_class_lut_svm`, respectively, before `classify_image_class_lut` can be used. For the classification the parameters in `create_class_gmm`, `create_class_knn`, `create_class_mlp` and `create_class_svm`, respectively, are important: The byte `Image` must have the same number of channels as specified by `NumInput`, `NumFeatures` or `NumDim`, respectively. As result of the pixel classification `classify_image_class_lut` passes `NumOutput` or `NumClasses` regions in `ClassRegions`, respectively

Parameters

▷ **Image** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte
Input image.

▷ **ClassRegions** (output_object) . . . . . region-array ⇝ *object*
Segmented classes.

▷ **ClassLUTHandle** (input_control) . . . . . class_lut ⇝ *handle*
Handle of the LUT classifier.

Example

```
read_image (Image, 'patras')
gen_rectangle1 (Sea, 10, 10, 120, 270)
```

```
gen_rectangle2 (Deck, [170,400], [350,375], [-0.56192,-0.75139], \
                [64,104], [26,11])
union1 (Deck, Deck)
gen_rectangle1 (Walls, 355, 623, 420, 702)
gen_rectangle2 (Chimney, 286, 623, -0.56192, 64, 33)
concat_obj (Sea, Deck, Classes)
concat_obj (Classes, Walls, Classes)
concat_obj (Classes, Chimney, Classes)
*
* create MLP classifier and train it with sample classes
create_class_mlp (3, 3, 4, 'softmax', 'principal_components', 3, \
                  42, MLPHandle)
add_samples_image_class_mlp (Image, Classes, MLPHandle)
train_class_mlp (MLPHandle, 200, 1, 0.01, Error, ErrorLog)
*
* create the LUT classifier
create_class_lut_mlp (MLPHandle, [], [], ClassLUTHandle)
*
* classify the image with the LUT
classify_image_class_lut (Image, ClassRegions, ClassLUTHandle)
```

Result

If the parameters are valid, the operator `classify_image_class_lut` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

classify_image_class_mlp (Image : ClassRegions : MLPHandle, RejectionThreshold :)

Classify an image with a multilayer perceptron.

`classify_image_class_mlp` performs a pixel classification with the multilayer perceptron (MLP) `MLPHandle` on the multichannel image `Image`. Before calling `classify_image_class_mlp` the MLP must be trained with `train_class_mlp`. `Image` must have `NumInput` channels, as specified with `create_class_mlp`. On output, `ClassRegions` contains `NumOutput` regions as the result of the classification. Note that the order of the regions that are returned in `ClassRegions` corresponds to the order of the classes as defined by the training regions in `add_samples_image_class_mlp`. The parameter `RejectionThreshold` can be used to reject pixels that have an uncertain classification. `RejectionThreshold` represents a threshold on the probability measure returned by the classification (see `classify_class_mlp` and `evaluate_class_mlp`). All pixels having a probability below

RejectionThreshold are not assigned to any class. Because an MLP typically assigns pixels that lie outside the convex hull of the training data in the feature space to one of the classes with high probability (confidence), it is useful in many cases to explicitly train a rejection class, even if RejectionThreshold is used, by adding samples for the rejection class with add_samples_image_class_mlp and by re-training the MLP with train_class_mlp.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
Input image.

▷ **ClassRegions** (output_object) ..... region-array ⇝ *object*
Segmented classes.

▷ **MLPHandle** (input_control) ..... class_mlp ⇝ *handle*
MLP handle.

▷ **RejectionThreshold** (input_control) ..... real ⇝ *real*
Threshold for the rejection of the classification.
Default: 0.5
Suggested values: RejectionThreshold ∈ {0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0}
Restriction: RejectionThreshold >= 0.0 && RejectionThreshold <= 1.0

Example

```
read_image (Image, 'ic')
gen_rectangle1 (Board, 80, 320, 110, 350)
gen_rectangle1 (Capacitor, 359, 263, 371, 302)
gen_rectangle1 (Resistor, 200, 252, 290, 256)
gen_rectangle1 (IC, 180, 135, 216, 165)
concat_obj (Board, Capacitor, Classes)
concat_obj (Classes, Resistor, Classes)
concat_obj (Classes, IC, Classes)
create_class_mlp (3, 3, 4, 'softmax', 'principal_components', 3, 42, \
                  MLPHandle)
add_samples_image_class_mlp (Image, Classes, MLPHandle)
get_sample_num_class_mlp (MLPHandle, NumSamples)
train_class_mlp (MLPHandle, 200, 1, 0.01, Error, ErrorLog)
classify_image_class_mlp (Image, ClassRegions, MLPHandle, 0.5)
dev_display (ClassRegions)
```

Result

If the parameters are valid, the operator classify_image_class_mlp returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

classify_image_class_svm (Image : ClassRegions : SVMHandle :)

Classify an image with a support vector machine.

classify_image_class_svm performs a pixel classification with the support vector machine (SVM) SVMHandle on the multichannel image Image. Before calling classify_image_class_svm the SVM must be trained with train_class_svm. Image must have NumFeatures channels, as specified with create_class_svm. On output, ClassRegions contains NumClasses regions as the result of the classification. Note that the order of the regions that are returned in ClassRegions corresponds to the order of the classes as defined by the training regions in add_samples_image_class_svm.

To prevent that the SVM assigns pixels that lie outside the convex hull of the training data in the feature space to one of the classes, it is useful in many cases to explicitly train a rejection class by adding samples for the rejection class with add_samples_image_class_svm and by re-training the SVM with train_class_svm.

An alternative for explicitly defining a rejection class is to use an SVM in the mode *'novelty-detection'*. Please refer to the description in create_class_svm and add_samples_image_class_svm.

Parameters

- ▷ **Image** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic / direction / int1 / int2 / uint2 / int4 / real
  Input image.
- ▷ **ClassRegions** (output_object) ..... region-array ⇝ *object*
  Segmented classes.
- ▷ **SVMHandle** (input_control) ..... class_svm ⇝ *handle*
  SVM handle.

Example

```
read_image (Image, 'ic')
gen_rectangle1 (Board, 20, 270, 160, 420)
gen_rectangle1 (Capacitor, 359, 263, 371, 302)
gen_rectangle1 (Resistor, 200, 252, 290, 256)
gen_rectangle1 (IC, 180, 135, 216, 165)
concat_obj (Board, Capacitor, Classes)
concat_obj (Classes, Resistor, Classes)
concat_obj (Classes, IC, Classes)
create_class_svm (3, 'rbf', 0.01, 0.01, 4, 'one-versus-all', \
                  'normalization', 3, SVMHandle)
add_samples_image_class_svm (Image, Classes, SVMHandle)
train_class_svm (SVMHandle, 0.001, 'default')
reduce_class_svm (SVMHandle, 'bottom_up', 2, 0.01, SVMHandleReduced)
classify_image_class_svm (Image, ClassRegions, SVMHandleReduced)
dev_display (ClassRegions)
```

Result

If the parameters are valid the operator classify_image_class_svm returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

Foundation

learn_ndim_norm (Foreground, Background, Image : : Metric, Distance, MinNumberPercent : Radius, Center, Quality)

Construct classes for class_ndim_norm.

learn_ndim_norm generates classification clusters from the region Foreground and the corresponding gray values in the multi-channel image Image, which can be used in class_ndim_norm. Background determines a class of pixels not to be found in class_ndim_norm. This parameter may be empty (empty object).

The parameter Distance determines the maximum distance Radius of the clusters. It describes the minimum distance between two cluster centers. If the parameter Distance is small the (small) hyper-cubes or hyper-spheres can approximate the feature space well. Simultaneously the runtime during classification increases.

The ratio of the number of pixels in a cluster to the total number of pixels (in percent) must be larger than the value of MinNumberPercent, otherwise the cluster is not returned. MinNumberPercent serves to eliminate outliers in the training set. If it is chosen too large many clusters are suppressed.

Two different clustering procedures can be selected: The minimum Euclidean distance algorithm (n-dimensional hyper-spheres) and the maximum algorithm (n-dimensional hyper-cubes) for describing the pixels of the image to classify in the n-dimensional histogram (parameter Metric). The Euclidean metric usually yields the better results, but takes longer to compute. The parameter Quality returns the quality of the clustering. It is a measure of overlap between the rejection class and the classificator classes. Values larger than 0 denote the corresponding ratio of overlap. If no rejection region is given, its value is set to 1. The regions in Background do not influence on the clustering. They are merely used to check the results that can be expected.

From a user's point of view the key difference between learn_ndim_norm and learn_ndim_box is that in the latter case the rejection class affects the classification process itself. Here, a hyper plane is generated that separates Foreground and Background classes, so that no points in feature space are classified incorrectly. As for learn_ndim_norm, however, an overlap between Foreground and Background class is allowed. This has its effect on the return value Quality. The larger the overlap, the smaller this value.

Parameters

▷ **Foreground** (input_object) . . . . . region(-array) ⇝ *object*
Foreground pixels to be trained.

▷ **Background** (input_object) . . . . . region(-array) ⇝ *object*
Background pixels to be trained (rejection class).

▷ **Image** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte
Multi-channel training image.

▷ **Metric** (input_control) . . . . . string ⇝ *string*
Metric to be used.
Default: 'euclid'
List of values: Metric ∈ {'euclid', 'maximum'}

▷ **Distance** (input_control) . . . . . number ⇝ *real* / integer
Maximum cluster radius.
Default: 10.0
Suggested values: Distance ∈ {1.0, 2.0, 3.0, 4.0, 6.0, 8.0, 10.0, 13.0, 17.0, 24.0, 30.0, 40.0}
Value range: 1.0 ≤ Distance (lin)
Minimum increment: 0.01
Recommended increment: 1.0

▷ **MinNumberPercent** (input_control) . . . . . number ⇝ *real* / integer
The ratio of the number of pixels in a cluster to the total number of pixels (in percent) must be larger than

MinNumberPercent (otherwise the cluster is not output).
Default: 0.01
Suggested values: MinNumberPercent ∈ {0.001, 0.05, 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0}
Value range: 0.0 ≤ MinNumberPercent ≤ 100.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.1

▷ **Radius** (output_control) ..... real-array ⇝ *real*
Cluster radii or half edge lengths.

▷ **Center** (output_control) ..... real-array ⇝ *real*
Coordinates of all cluster centers.

▷ **Quality** (output_control) ..... real ⇝ *real*
Overlap of the rejection class with the classified objects (1: no overlap).
Assertion: 0 <= Quality && Quality <= 1

Result

learn_ndim_norm returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images can be determined by setting the values of the flags *'no_object_result'* and *'empty_region_result'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

24.2 Edges

detect_edge_segments (Image : : SobelSize, MinAmplitude, MaxDistance, MinLength : BeginRow, BeginCol, EndRow, EndCol)

Detect straight edge segments.

detect_edge_segments detects straight edge segments in the gray image Image. The extracted edge segments are returned as line segments with start point (BeginRow,BeginCol) and end point (EndRow,EndCol). Edge detection is based on the Sobel filter, using *'sum_abs'* as parameter and SobelSize as the filter mask size (see sobel_amp). Only pixels with a filter response larger than MinAmplitude are used as candidates for edge points. These thresholded edge points are thinned and split into straight segments. Due to technical reasons, edge points in which several edges meet are lost. Therefore, detect_edge_segments usually does not return closed object contours. The parameter MaxDistance controls the maximum allowed distance of an edge point to its approximating line. For efficiency reasons, the sum of the absolute values of the coordinate differences is used instead of the Euclidean distance. MinLength controls the minimum length of the line segments. Lines shorter than MinLength are not returned.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte
Input image.

▷ **SobelSize** (input_control) ..... integer ⇝ *integer*
Mask size of the Sobel operator.
Default: 5
List of values: SobelSize ∈ {3, 5, 7, 9, 11, 13}

▷ **MinAmplitude** (input_control) ..... integer ⇝ *integer*
Minimum edge strength.
Default: 32
Suggested values: MinAmplitude ∈ {10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 80, 90, 100, 110}
Value range: 1 ≤ MinAmplitude ≤ 255
Minimum increment: 1
Recommended increment: 1

▷ **MaxDistance** (input_control) ..... integer ⇝ *integer*
Maximum distance of the approximating line to its original edge.
Default: 3
Suggested values: MaxDistance ∈ {2, 3, 4, 5, 6, 7, 8}
Value range: 0 ≤ MaxDistance
Minimum increment: 1
Recommended increment: 1

▷ **MinLength** (input_control) ..... integer ⇝ *integer*
Minimum length of to resulting line segments.
Default: 10
Suggested values: MinLength ∈ {3, 5, 7, 9, 11, 13, 16, 20}
Value range: 1 ≤ MinLength
Minimum increment: 1
Recommended increment: 1

▷ **BeginRow** (output_control) ..... line.begin.y-array ⇝ *integer*
Row coordinate of the line segments' start points.

▷ **BeginCol** (output_control) ..... line.begin.x-array ⇝ *integer*
Column coordinate of the line segments' start points.

▷ **EndRow** (output_control) ..... line.end.y-array ⇝ *integer*
Row coordinate of the line segments' end points.

▷ **EndCol** (output_control) ..... line.end.x-array ⇝ *integer*
Column coordinate of the line segments' end points.

Example

```
Htuple  SobelSize,MinAmplitude,MaxDistance,MinLength;
Htuple  RowBegin,ColBegin,RowEnd,ColEnd;

create_tuple(&SobelSize,1);
set_i(SobelSize,5,0);
create_tuple(&MinAmplitude,1);
set_i(MinAmplitude,32,0);
create_tuple(&MaxDistance,1);
set_i(MaxDistance,3,0);
create_tuple(&MinLength,1);
set_i(MinLength,10,0);
T_detect_edge_segments(Image,SobelSize,MinAmplitude,MaxDistance,MinLength,
                       &RowBegin,&ColBegin,&RowEnd,&ColEnd);
```

Result

detect_edge_segments returns 2 (H_MSG_TRUE) if all parameters are correct. If the input is empty the

behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

`hysteresis_threshold` (`Image` : `RegionHysteresis` : `Low`, `High`, `MaxLength` :)

Perform a hysteresis threshold operation on an image.

`hysteresis_threshold` performs a hysteresis threshold operation (introduced by Canny) on an image. All points in the input image `Image` having a gray value larger than or equal to `High` are immediately accepted ("secure" points). Conversely, all points with gray values less than `Low` are immediately rejected. "Potential" points with gray values between both thresholds are accepted if they are connected to "secure" points by a path of "potential" points having a length of at most `MaxLength` points. This means that "secure" points influence their surroundings (hysteresis).

Attention

For images of type byte, uint2, or int4 the lower threshold must be `Low` > 0.

Parameters

▷ **`Image`** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4 / real
Input image.

▷ **`RegionHysteresis`** (output_object) ..... region(-array) ⇝ *object*
Segmented region.

▷ **`Low`** (input_control) ..... number ⇝ *integer* / real
Lower threshold for the gray values.
Default: 30
Suggested values: `Low` ∈ {5, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100}

▷ **`High`** (input_control) ..... number ⇝ *integer* / real
Upper threshold for the gray values.
Default: 60
Suggested values: `High` ∈ {5, 10, 15, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, 130}
Restriction: High >= Low

▷ **`MaxLength`** (input_control) ..... integer ⇝ *integer*
Maximum length of a path of "potential" points to reach a "secure" point.
Default: 10
Suggested values: `MaxLength` ∈ {1, 2, 3, 5, 7, 10, 12, 14, 17, 20, 25, 30, 35, 40, 50}
Value range: 1 ≤ MaxLength
Minimum increment: 1
Recommended increment: 5

Result

`hysteresis_threshold` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect

to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

`nonmax_suppression_amp` (ImgAmp : ImageResult : Mode :)

Suppress non-maximum points on an edge.

`nonmax_suppression_amp` suppresses all points in the regions of the image `ImgAmp` whose gray values are not local (directed) maxima. In contrast to `nonmax_suppression_dir`, a direction image is not needed. Two modes of operation can be selected:

'hvnms' A point is labeled as a local maximum if its gray value is larger than or equal to the gray values within a search space of pm 5 pixels, either horizontally or vertically. Non-maximum points are removed from the region, gray values remain unchanged.

'loc_max' A point is labeled as a local maximum if its gray value is larger than or equal to the gray values of its eight neighbors.

Parameters

▷ **`ImgAmp`** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Amplitude (gradient magnitude) image.

▷ **`ImageResult`** (output_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Image with thinned edge regions.

▷ **`Mode`** (input_control) . . . . . string ⇝ *string*
Select horizontal/vertical or undirected NMS.
Default: 'hvnms'
List of values: `Mode` ∈ {'hvnms', 'loc_max'}

Result

`nonmax_suppression_amp` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

nonmax_suppression_dir (ImgAmp, ImgDir : ImageResult : Mode :)

Suppress non-maximum points on an edge using a direction image.

nonmax_suppression_dir suppresses all points in the regions of the image ImgAmp whose gray values are not local (directed) maxima. ImgDir is a direction image giving the direction perpendicular to the local maximum (Unit: 2 degrees, i.e., 50 degrees are coded as 25 in the image). Such images are returned, for example, by edges_image. Two modes of operation can be selected:

'nms' Each point in the image is tested whether its gray value is a local maximum perpendicular to its direction. In this mode only the two neighbors closest to the given direction are examined. If one of the two gray values is greater than the gray value of the point to be tested, it is suppressed (i.e., removed from the input region. The corresponding gray value remains unchanged).

'inms' Like *'nms'*. However, the two gray values for the test are obtained by interpolation from four adjacent points.

Parameters

▷ **ImgAmp** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Amplitude (gradient magnitude) image.

▷ **ImgDir** (input_object) ..... singlechannelimage(-array) ⇝ *object :* direction
Direction image.

▷ **ImageResult** (output_object) ..... image(-array) ⇝ *object :* byte / uint2 / real
Image with thinned edge regions.

▷ **Mode** (input_control) ..... string ⇝ *string*
Select non-maximum-suppression or interpolating NMS.
Default: 'nms'
List of values: Mode ∈ {'nms', 'inms'}

Result

nonmax_suppression_dir returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

24.3 Maximally Stable Extremal Regions

```
segment_image_mser ( Image : MSERDark, MSERLight : Polarity,
    MinArea, MaxArea, Delta, GenParamName, GenParamValue : )
```

Segment image using Maximally Stable Extremal Regions (MSER).

segment_image_mser segments an image into regions of homogenous gray values using the approach of Maximally Stable Extremal Regions (MSER). The segmentation process determines if a region is homogenous by observing the local region surrounding. Therefore, the operator is particularly suited to robustly segment objects in front of inhomogeneous background or in applications with changing illumination.

Parameters

Polarity The Polarity determines the type of the regions that are extracted.

Value	Meaning
'dark'	Only MSERs that are darker than their surroundings are extracted
'light'	Only MSERs that are lighter than their surroundings are extracted
'both' (default)	Both types of MSERs are extracted

MinArea, MaxArea The values MinArea and MaxArea restrict the size of the returned MSERs.

Note that very small values of MinArea, e.g., values smaller than 5, can increase the runtime significantly, especially for noisy images.

If MaxArea is set to an empty tuple (default), the MSERs are restricted to be true subsets of the connected components of the input domain.

Delta The value of Delta influences the selectivity of the algorithm. Larger values lead to fewer MSERs. Smaller values lead to more MSERs.

Please read the description of the segmentation process below to help understand the effect of this parameter.

The following generic parameters can be used to fine-tune the segmentation of MSERs. The generic parameters can be set with GenParamName and GenParamValue.

'max_variation': The maximum variation of a component's area within the range of ± Delta thresholds. Larger values lead to more MSERs. Smaller values lead to fewer MSERs.

Please read the description of the segmentation process below for a definition of 'variation' and to help understand the effect of this generic parameter.

Suggested values: *0.1*, *0.2*, *0.5*, *1.0*, *2.0*, *5.0*

Default: *0.2*

Restriction: real values lager than or equal to *0.0*.

'min_diversity': The minimum relative difference of the sizes of two overlapping MSERs. Smaller values lead to more overlapping MSERs. Larger values lead to fewer overlapping MSERs.

Please read the description of the segmentation process below for a definition of 'diversity' and to help understand the effect of this generic parameter.

Setting *'min_diversity'* very close to *0.0* may increase the runtime.

Suggested values: *0.1*, *0.5*, *0.8*, *1.0*, *2.0*, *5.0*

Default: *0.8*

Restriction: real values larger than or equal to *0.0*.

'may_touch_border': Controls if regions that touch the border of the input domain are returned (*'true'*) or rejected (*'false'*).

List of values: *'false'*, *'true'*

Default: *'false'* if a full domain is used, *'true'* if the input domain is reduced.

'min_gray', *'max_gray'*: The values *'min_gray'* and *'max_gray'* reduce the input domain dynamically by applying a `threshold` to the input image. All pixels outside the specified gray value range are ignored in the segmentation process. This may reduce the runtime considerably.

Please note, that if `Image` has a full domain and the domain is reduced by the settings of *'min_gray'* or *'max_gray'*, the default behavior of *'may_touch_border'* may lead to more result regions than without restricted gray value range.

Default: *'min_gray'*: 0, *'max_gray'*: *255* for byte images, *65535* for uint2 images

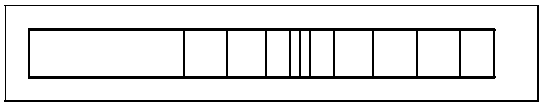
Restriction: integer values larger than or equal to *0*.

Segmentation Process

In a first step, the image is segmented with all threshold values t, from 0 to the maximal present gray value.

To illustrate this, the following example input image with twelve gray values (0...11) is used. On the right, the boundaries of the resulting threshold regions are shown.

Example input image with twelve gray values reaching from 0 (= black) to 11 (= white)



Boundaries of the threshold regions for all thresholds (t = 0...11)

The resulting threshold regions are split into their connected components (4-connected neighborhood) and the area increase of the individual components is monitored over the increasing thresholds. The area of each individual component increases monotonically with each (increasing) threshold. An MSER is a component whose area does not vary significantly within the range of $\pm$ `Delta` thresholds. To be accepted as an MSER, the variation of the component's area within the range of $\pm$ `Delta` thresholds must be a local minimum and it must be lower than *'max_variation'*. Furthermore, the diversity of overlapping MSERs must be greater than *'min_diversity'* (see below).

The variation of a component's area is defined by

$$Variation_t = \frac{area_{t+\Delta} - area_{t-\Delta}}{area_t}$$

where

$$\begin{aligned} area_{t-\Delta} &= area_0, \qquad t - \Delta < 0 \\ area_{t+\Delta} &= area_{t_{max}}, \qquad t + \Delta > t_{max} \end{aligned}$$

Decreasing the value of *'max_variation'* will reduce the number of accepted regions.

In our example, each threshold region consists of only one component. Therefore, the terms 'threshold region' and 'component' are used synonymously hereinafter. The following table shows the area of the threshold regions and their variations for `Delta` set to 1 and for `Delta` set to 2.

Threshold value t	Threshold region	Area of the threshold region	Variation of the area (for `Delta` = 1)	Variation of the area (for `Delta` = 2)
0		320	**0.28**	**0.53**
1		410	0.41	0.54
2		490	0.27	0.49
3		540	0.13	0.31
4		560	**0.07**	**0.25**
5		580	0.12	0.29
6		630	0.21	0.38
7		710	0.24	0.44
8		800	0.23	**0.41**
9		890	**0.18**	1.67
10		960	1.36	1.46
11		2200	**0.56**	**0.60**

The area of the threshold regions increases with the threshold value t. If `Delta` is set to 1, the local minima of the variation are obtained for the threshold values t = 0, t = 4, t = 9, and t = 11. Therefore, the threshold regions for t = 0, t = 4, t = 9, and t = 11 are MSER candidates. If `Delta` is set to 2, the MSER candidates correspond to the threshold regions for t = 0, t = 4, t = 8, t = 11.

Per default, the connected components of the image domain will not be returned as MSER. This behavior can be altered by explicitly setting `MaxArea` to a value larger than the area of the input domain and *'may_touch_border'* to *'true'*. In our example, the default behavior eliminates the MSER candidates that correspond to the threshold regions for t = 11.

The following figure shows the resulting MSER candidates for `Delta` = 1 and for `Delta` = 2 (with *'max_variation'* set to 1.0), overlaid over the input image.

MSER candidates for Delta = 1	MSER candidates for Delta = 2
	
corresponds to t = 0	corresponds to t = 0
	
corresponds to t = 4	corresponds to t = 4
	
corresponds to t = 9	corresponds to t = 8

The MSER segmentation does not divide the image into disjunct regions, but rather determines all MSERs within the input image. Hence for one image, multiple mutual overlapping regions may be returned as MSER candidates. Since the MSERs are calculated by continuously increasing the threshold t, two regions that overlap each other always consist of a larger region that completely contains the smaller one. The 'diversity' measures, how much the areas of two overlapping MSERs differ. It is calculated as the relative difference of the areas of the two MSER candidates:

$$diversity_i = \frac{area_{i+1} - area_i}{area_i}$$

where $area_i$: is the area of the currently examined MSER candidate and $area_{i+1}$: is the area of the MSER candidate that contains the currently examined MSER candidate.

If the diversity of an MSER candidate is smaller than *'min_diversity'*, it is discarded. Hence the parameter *'min_diversity'* is used to control the amount of overlapping regions. Higher values of *'min_diversity'* reduce the number of overlapping regions and lower values increase it. Note that the largest MSER candidates, i.e., those candidates that are not contained in another MSER candidate are always kept.

	MSER candidate index i	Threshold value t	Area of the threshold region	Diversity of the MSER candidate
Delta=1	0	0	320	0.75
	1	4	560	0.59
	2	9	890	N/A
Delta=2	0	0	320	0.75
	1	4	560	0.43
	2	8	800	N/A

First, the MSER candidate with the smallest diversity is eliminated if its diversity is less than *'min_diversity'*. In our example, the value for *'min_diversity'* is set to 0.5. For delta = 2, the MSER candidate with the diversity of 0.43 is eliminated. Then, the diversity is recalculated for the remaining MSER candidates. In our example, this yields a diversity of 1.5 for the MSER candidate 0. Now, all remaining MSER candidates have a diversity greater than 0.5 and are therefore accepted as MSERs.

The segmentation process calculates MSERs for each connected component of the input domain independently.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image.

▷ **MSERDark** (output_object) . . . . . region-array ⇝ *object*
Segmented dark MSERs.

▷ **MSERLight** (output_object) . . . . . region-array ⇝ *object*
Segmented light MSERs.

▷ **Polarity** (input_control) . . . . . string ⇝ *string*
The polarity of the returned MSERs.
Default: 'both'
List of values: `Polarity` ∈ {'dark', 'light', 'both'}

▷ **MinArea** (input_control) . . . . . number(-array) ⇝ *integer* / real
Minimal size of an MSER.
Default: 10
Suggested values: `MinArea` ∈ {1, 10, 100, 10000}
Value range: 1 ≤ MinArea

▷ **MaxArea** (input_control) . . . . . number(-array) ⇝ *integer* / real
Maximal size of an MSER.
Default: []
Suggested values: `MaxArea` ∈ {1, 10, 100, 10000}
Value range: 1 ≤ MaxArea

▷ **Delta** (input_control) . . . . . number ⇝ *integer* / real
Amount of thresholds for which a region needs to be stable.
Default: 15
Suggested values: `Delta` ∈ {5, 10, 20, 50}
Value range: 1 ≤ `Delta` ≤ 65535

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
List of generic parameter names.
Default: []
List of values: `GenParamName` ∈ {'max_variation', 'min_diversity', 'may_touch_border', 'min_gray', 'max_gray'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *string* / real / integer
List of generic parameter values.
Default: []
Suggested values: `GenParamValue` ∈ {0.5, 0.8, 'true', 'false', 30, 50, 200, 230}

Example

```
read_image (Image,'pellets')
segment_image_mser (Image, MSERDark, MSERLight, 'light',\
                    1000, 10000, 3, [],[])
```

Result

`segment_image_mser` returns 2 (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Successors

`select_shape`, `select_gray`

Alternatives

`auto_threshold`, `binary_threshold`, `char_threshold`, `local_threshold`, `watersheds`, `regiongrowing`

Module

Foundation

24.4 Region Growing

```
expand_gray ( Regions, Image,
    ForbiddenArea : RegionExpand : Iterations, Mode, Threshold : )
```

Fill gaps between regions (depending on gray value or color) or split overlapping regions.

`expand_gray` closes gaps between the input regions, which resulted from the suppression of small regions in a segmentation operator, (mode *'image'*), for example, or separates overlapping regions *'region'*). Both uses result from the expansion of regions. The operator works by adding a one pixel wide "strip" to a region, in which the gray values or color are different from the gray values or color of neighboring pixels on the region's border by at most `Threshold` (in each channel). For images of type *'cyclic'* (e.g., direction images), also points with a gray value difference of at least $255 - $ `Threshold` are added to the output region.

The expansion takes place only in regions, which are designated as not "forbidden" (parameter `ForbiddenArea`). The number of iterations is determined by the parameter `Iterations`. By passing *'maximal'*, `expand_gray` iterates until convergence, i.e., until no more changes occur. By passing 0 for this parameter, all non-overlapping regions are returned. The two modes of operation (*'image'* and *'region'*) are different in the following ways:

'image' The input regions are expanded iteratively until they touch another region or the image border, or the expansion stops because of too high gray value differences. Because `expand_gray` processes all regions simultaneously, gaps between regions are distributed evenly to all regions with a similar gray value. Overlapping regions are split by distributing the area of overlap evenly to both regions.

'region' No expansion of the input regions is performed. Instead, only overlapping regions are split by distributing the area of overlap evenly to regions having a matching gray value or color.

Attention

Because regions are only expanded into areas having a matching gray value or color, usually gaps will remain between the output regions, i.e., the segmentation is not complete.

Parameters

▷ **`Regions`** (input_object) ..... region(-array) ⇝ *object*
Regions for which the gaps are to be closed, or which are to be separated.

▷ **`Image`** (input_object) ..... (multichannel-)image ⇝ *object :* byte / cyclic
Image (possibly multi-channel) for gray value or color comparison.

▷ **`ForbiddenArea`** (input_object) ..... region ⇝ *object*
Regions in which no expansion takes place.

▷ **`RegionExpand`** (output_object) ..... region(-array) ⇝ *object*
Expanded or separated regions.

▷ **`Iterations`** (input_control) ..... string ⇝ *string* / integer
Number of iterations.
Default: 'maximal'
Suggested values: `Iterations` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 'maximal'}
Value range: $1 \leq$ `Iterations` ≤ 500 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **`Mode`** (input_control) ..... string ⇝ *string*
Expansion mode.
Default: 'image'
List of values: `Mode` ∈ {'image', 'region'}

▷ **Threshold** (input_control) . . . . . integer(-array) ⇝ *integer*
Maximum difference between the gray value or color at the region's border and a candidate for expansion.
Default: 32
Suggested values: Threshold ∈ {5, 10, 15, 20, 25, 30, 40, 50}
Value range: 1 ≤ Threshold ≤ 255 (lin)
Minimum increment: 1
Recommended increment: 5

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  HImage   image (argv[1]);
  HRegion  empty_region;
  HWindow  win;

  image.Display (win);

  HRegionArray seg = (image >= 100).Connection ();

  seg.Display (win);
  HRegionArray exp = seg.ExpandGray1 (image, empty_region,
                                      "maximal", "image", 32);
  win.SetDraw ("margin");
  win.SetColored (12);
  exp.Display (win);
  win.Click ();

  return (0);
}
```

Result

expand_gray always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>), the behavior in case of an empty input region via set_system('empty_region_result',<Result>), and the behavior in case of an empty result region via set_system('store_empty_region',<'true'/'false'>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

expand_gray_ref, expand_region

Module

Foundation

```
expand_gray_ref ( Regions, Image,
    ForbiddenArea : RegionExpand : Iterations, Mode, RefGray,
    Threshold : )
```

Fill gaps between regions (depending on gray value or color) or split overlapping regions.

`expand_gray_ref` closes gaps between the input regions, which resulted from the suppression of small regions in a segmentation operator, (mode *'image'*), for example, or separates overlapping regions *'region'*). Both uses result from the expansion of regions. The operator works by adding a one pixel wide "strip" to a region, in which the gray values or color are different from a reference gray value or color by at most `Threshold` (in each channel). For images of type *'cyclic'* (e.g., direction images), also points with a gray value difference of at least $255 - $ `Threshold` are added to the output region.

The expansion takes place only in regions, which are designated as not "forbidden" (parameter `ForbiddenArea`). The number of iterations is determined by the parameter `Iterations`. By passing *'maximal'*, `expand_gray_ref` iterates until convergence, i.e., until no more changes occur. By passing 0 for this parameter, all non-overlapping regions are returned. The two modes of operation (*'image'* and *'region'*) are different in the following ways:

'image' The input regions are expanded iteratively until they touch another region or the image border, or the expansion stops because of too high gray value differences. Because `expand_gray_ref` processes all regions simultaneously, gaps between regions are distributed evenly to all regions with a similar gray value. Overlapping regions are split by distributing the area of overlap evenly to both regions.

'region' No expansion of the input regions is performed. Instead, only overlapping regions are split by distributing the area of overlap evenly to regions having a matching gray value or color.

Attention

Because regions are only expanded into areas having a matching gray value or color, usually gaps will remain between the output regions, i.e., the segmentation is not complete.

Parameters

▷ **`Regions`** (input_object) . . . . . region(-array) ⇝ *object*
Regions for which the gaps are to be closed, or which are to be separated.

▷ **`Image`** (input_object) . . . . . (multichannel-)image ⇝ *object :* byte / cyclic
Image (possibly multi-channel) for gray value or color comparison.

▷ **`ForbiddenArea`** (input_object) . . . . . region ⇝ *object*
Regions in which no expansion takes place.

▷ **`RegionExpand`** (output_object) . . . . . region(-array) ⇝ *object*
Expanded or separated regions.

▷ **`Iterations`** (input_control) . . . . . string ⇝ *string* / integer
Number of iterations.
Default: 'maximal'
Suggested values: `Iterations` ∈ {'maximal', 1, 2, 3, 4, 5, 7, 10, 15, 20, 30, 50, 70, 100, 150, 200, 300, 500}
Value range: $1 \leq$ `Iterations` ≤ 500 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **`Mode`** (input_control) . . . . . string ⇝ *string*
Expansion mode.
Default: 'image'
List of values: `Mode` ∈ {'image', 'region'}

▷ **`RefGray`** (input_control) . . . . . integer(-array) ⇝ *integer*
Reference gray value or color for comparison.
Default: 128
Suggested values: `RefGray` ∈ {1, 10, 20, 50, 100, 128, 200, 255}
Value range: $1 \leq$ `RefGray` ≤ 255 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **Threshold** (input_control) . . . . . integer(-array) ⇝ *integer*
Maximum difference between the reference gray value or color and a candidate for expansion.
Default: 32
Suggested values: Threshold ∈ {4, 10, 15, 20, 25, 30, 40}
Value range: 1 ≤ Threshold ≤ 255 (lin)
Minimum increment: 1
Recommended increment: 5

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  HImage   image (argv[1]);
  HRegion  empty_region;
  HWindow  win;

  win.SetDraw ("margin");
  win.SetColored (12);

  image.Display (win);

  HRegionArray seg = (image >= 100).Connection ();
  seg.Display (win);

  Tuple iter = "maximal";
  Tuple mode = "image";
  Tuple refg = 128;
  Tuple thrs = 32;

  HRegionArray exp = seg.ExpandGrayRef (image, empty_region,
                                        iter, mode, refg, thrs);
  exp.Display (win);
  win.Click ();

  return (0);
}
```

Result

expand_gray_ref always returns the value 2 (H_MSG_TRUE). The behavior in case of empty input (no regions given) can be set via set_system('no_object_result',<Result>), the behavior in case of an empty input region via set_system('empty_region_result',<Result>), and the behavior in case of an empty result region via set_system('store_empty_region',<'true'/'false'>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

connection, regiongrowing, pouring, class_ndim_norm

Possible Successors

See also

expand_gray, expand_region

Module

Foundation

regiongrowing (Image : Regions : RasterHeight, RasterWidth, Tolerance, MinSize :)

Segment an image using regiongrowing.

regiongrowing segments images into regions of the same intensity - rastered into rectangles of size RasterHeight × RasterWidth. In order to decide whether two adjacent rectangles belong to the same region only the gray value of their center points is used. If the gray value difference is less then or equal to Tolerance the rectangles are merged into one region.

If g_1 and g_2 are two gray values to be examined, they are merged into the same region if:

$$|g_1 - g_2| < \texttt{Tolerance}$$

For images of type 'cyclic', the following formulas are used:

$$\begin{aligned} (|g_1 - g_2| < \texttt{Tolerance}) \quad &\wedge \quad (|g_1 - g_2| \leq 127) \\ (256 - |g_1 - g_2| < \texttt{Tolerance}) \quad &\wedge \quad (|g_1 - g_2| > 127) \end{aligned}$$

For rectangles larger than one pixel, usually the images should be smoothed with a lowpass filter with a size of at least RasterHeight × RasterWidth before calling regiongrowing (so that the gray values at the centers of the rectangles are "representative" for the whole rectangle). If the image contains little noise and the rectangles are small, the smoothing can be omitted in many cases.

The resulting regions are collections of rectangles of the chosen size RasterHeight × RasterWidth. Only regions containing at least MinSize points are returned.

Regiongrowing is a very fast operation, and thus suited for time-critical applications.

Attention

RasterWidth and RasterHeight are automatically converted to odd values if necessary.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / int4 / real

Input image.

▷ **Regions** (output_object) ..... region-array ⇝ *object*

Segmented regions.

▷ **RasterHeight** (input_control) ..... extent.y ⇝ *integer*

Vertical distance between tested pixels (height of the raster).
Default: 3
Suggested values: RasterHeight ∈ {1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21}
Value range: 1 ≤ RasterHeight ≤ 99 (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: RasterHeight >= 1 && odd(RasterHeight)

▷ **RasterWidth** (input_control) ..... extent.x ⇝ *integer*

Horizontal distance between tested pixels (height of the raster).
Default: 3
Suggested values: RasterWidth ∈ {1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21}
Value range: 1 ≤ RasterWidth ≤ 99 (lin)
Minimum increment: 2
Recommended increment: 2
Restriction: RasterWidth >= 1 && odd(RasterWidth)

▷ **Tolerance** (input_control) ..... number ⇝ *real* / integer
Points with a gray value difference less then or equal to tolerance are accumulated into the same object.
Default: 6.0
Suggested values: Tolerance ∈ {1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 12.0, 14.0, 18.0, 25.0}
Value range: 0 ≤ Tolerance (lin)
Minimum increment: 0.01
Recommended increment: 1.0

▷ **MinSize** (input_control) ..... integer ⇝ *integer*
Minimum size of the output regions.
Default: 100
Suggested values: MinSize ∈ {1, 5, 10, 20, 50, 100, 200, 500, 1000}
Value range: 1 ≤ MinSize
Minimum increment: 1
Recommended increment: 5

Example

```
read_image(Image,'fabrik')
mean_image(Image,Mean,RasterHeight,RasterWidth)
regiongrowing(Mean,Result,RasterHeight,RasterWidth,6.0,100)
```

Complexity

Let N be the number of found regions and M the number of points in one of these regions. Then the runtime complexity is $O(N * log(M) * M)$.

Result

regiongrowing returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

binomial_filter, mean_image, gauss_filter, smooth_image, median_image, anisotropic_diffusion

Possible Successors

select_shape, reduce_domain, select_gray

Alternatives

regiongrowing_n, regiongrowing_mean, label_to_region

Module

Foundation

regiongrowing_mean (Image : Regions : StartRows, StartColumns, Tolerance, MinSize :)

Perform a regiongrowing using mean gray values.

regiongrowing_mean performs a regiongrowing using the mean gray values of a region, starting from points given by StartRows and StartColumns. At any point in the process the mean gray value of the current region is calculated. Gray values at the boundary of the region are added to the region if they differ from the current mean by less than Tolerance. Regions smaller than MinSize are suppressed.

If no starting points are given (empty tuples), the expansion process starts at the upper leftmost point, and is continued with the first unprocessed point after a region has been created.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / int4
Input image.

▷ **Regions** (output_object) . . . . . region-array ⇝ *object*
Segmented regions.

▷ **StartRows** (input_control) . . . . . point.y(-array) ⇝ *integer*
Row coordinates of the starting points.
Default: []
Value range: 0 ≤ StartRows
Minimum increment: 1
Recommended increment: 1

▷ **StartColumns** (input_control) . . . . . point.x(-array) ⇝ *integer*
Column coordinates of the starting points.
Default: []
Value range: 0 ≤ StartColumns
Minimum increment: 1
Recommended increment: 1

▷ **Tolerance** (input_control) . . . . . number ⇝ *real*
Maximum deviation from the mean.
Default: 5.0
Suggested values: `Tolerance` ∈ {0.5, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 12.0, 15.0, 17.0, 20.0, 25.0, 30.0, 40.0}
Restriction: Tolerance > 0.0

▷ **MinSize** (input_control) . . . . . integer ⇝ *integer*
Minimum size of a region.
Default: 100
Suggested values: `MinSize` ∈ {0, 10, 30, 50, 100, 500, 1000, 2000}
Value range: 0 ≤ MinSize
Minimum increment: 1
Recommended increment: 100

Result

`regiongrowing_mean` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`binomial_filter`, `gauss_filter`, `sigma_image`, `anisotropic_diffusion`, `median_image`, `mean_image`

Possible Successors

`select_shape`, `reduce_domain`, `opening`, `expand_region`

Alternatives

`regiongrowing`, `regiongrowing_n`

Module

Foundation

regiongrowing_n (MultiChannelImage : Regions : Metric, MinTolerance, MaxTolerance, MinSize :)

Segment an image using regiongrowing for multi-channel images.

`regiongrowing_n` performs a multi-channel regiongrowing. The n channels give rise to an n-dimensional feature vector. Neighboring points are aggregated into the same region if the difference of their feature vectors with respect to the given metric lies in the interval [`MinTolerance`, `MaxTolerance`]. Only neighbors of the 4-neighborhood are examined. The following metrics can be used:

Let g_A denote the gray value in the feature vector A at point a of the image, and likewise be g_B the gray value in the feature vector B at point a neighboring point b. Let $g(d)$ be the gray value with index d. Furthermore, let $MinT$ denote `MinTolerance` and $MaxT$ denote `MaxTolerance`.

'1-norm': Sum of absolute values

$$MinT \leq \frac{1}{n} \sum |g_A - g_B| \leq MaxT$$

'2-norm': Euclidean distance

$$MinT \leq \sqrt{\frac{\sum (g_A - g_B)^2}{n}} \leq MaxT$$

'3-norm': p - Norm with p = 3

$$MinT \leq \sqrt[3]{\frac{\sum (g_A - g_B)^3}{n}} \leq MaxT$$

'4-norm': p - Norm with p = 4

$$MinT \leq \sqrt[4]{\frac{\sum (g_A - g_B)^4}{n}} \leq MaxT$$

'n-norm': Minkowski distance

$$MinT \leq \sqrt[n]{\frac{\sum (g_A - g_B)^n}{n}} \leq MaxT$$

'max-diff': Supremum distance

$$MinT \leq \max \{|g_A - g_B|\} \leq MaxT$$

'min-diff': Infimum distance

$$MinT \leq \min \{|g_A - g_B|\} \leq MaxT$$

'variance': Variance of gray value differences

$$MinT \leq Var(g_A - g_B) \leq MaxT$$

'dot-product': Dot product

$$MinT \leq \frac{1}{n} \sqrt{\sum (g_A g_B)} \leq MaxT$$

'correlation': Correlation

$$\begin{aligned} m_A &= \frac{1}{n} \sum g_A \\ Var_A &= \frac{1}{n} \sqrt{\sum (g_A - m_A)^2} \\ m_B &= \frac{1}{n} \sum g_B \\ Var_B &= \frac{1}{n} \sqrt{\sum (g_B - m_B)^2} \\ MinT &\leq \frac{1}{n^2} \sum \frac{(g_A - m_A)(g_B - m_B)}{(Var_A Var_B)} \leq MaxT \end{aligned}$$

'mean-diff': Difference of arithmetic means

$$\begin{aligned} a &= \frac{1}{n} \sum g_A \\ b &= \frac{1}{n} \sum g_B \\ MinT &\leq |a - b| \leq MaxT \end{aligned}$$

'mean-ratio': Ratio of arithmetic means

$$\begin{aligned} a &= \frac{1}{n}\sum g_A \\ b &= \frac{1}{n}\sum g_B \\ MinT &\leq \min\left\{\frac{a}{b},\frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'length-diff': Difference of the vector lengths

$$\begin{aligned} a &= \sqrt{\frac{\sum g_A^2}{n}} \\ b &= \sqrt{\frac{\sum g_B^2}{n}} \\ MinT &\leq |a-b| \leq MaxT \end{aligned}$$

'length-ratio': Ratio of the vector lengths

$$\begin{aligned} a &= \sqrt{\frac{\sum g_A^2}{n}} \\ b &= \sqrt{\frac{\sum g_B^2}{n}} \\ MinT &\leq \min\left\{\frac{a}{b},\frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'n-norm-ratio': Ratio of the vector lengths w.r.t the p-norm with $p = n$

$$\begin{aligned} a &= \sqrt[n]{\frac{\sum g_A^n}{n}} \\ b &= \sqrt[n]{\frac{\sum g_B^n}{n}} \\ MinT &\leq \min\left\{\frac{a}{b},\frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'gray-max-diff': Difference of the maximum gray values

$$\begin{aligned} a &= \max\{|g_A|\} \\ b &= \max\{|g_B|\} \\ MinT &\leq |a-b| \leq MaxT \end{aligned}$$

'gray-max-ratio': Ratio of the maximum gray values

$$\begin{aligned} a &= \max\{|g_A|\} \\ b &= \max\{|g_B|\} \\ MinT &\leq \min\left\{\frac{a}{b},\frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'gray-min-diff': Difference of the minimum gray values

$$\begin{aligned} a &= \min\{|g_A|\} \\ b &= \min\{|g_B|\} \\ MinT &\leq |a-b| \leq MaxT \end{aligned}$$

'gray-min-ratio': Ratio of the minimum gray values

$$\begin{aligned} a &= \min\{|g_A|\} \\ b &= \min\{|g_B|\} \\ MinT &\leq \min\left\{\frac{a}{b}, \frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'variance-diff': Difference of the variances over all gray values (channels)

$$MinT \leq |Var(g_A) - Var(g_B)| \leq MaxT$$

'variance-ratio': Ratio of the variances over all gray values (channels)

$$MinT \leq \frac{Var(g_B)}{Var(g_A)} \leq MaxT$$

'mean-abs-diff': Difference of the sum of absolute values over all gray values (channels)

$$\begin{aligned} a &= \sum_{d,k,k<d} |g_A(d) - g_A(k)| \\ b &= \sum_{d,k,k<d} |g_B(d) - g_B(k)| \\ MinT &\leq \frac{|a-b|}{\text{number of sums}} \leq MaxT \end{aligned}$$

'mean-abs-ratio': Ratio of the sum of absolute values over all gray values (channels)

$$\begin{aligned} a &= \sum_{d,k,k<d} |g_A(d) - g_A(k)| \\ b &= \sum_{d,k,k<d} |g_B(d) - g_B(k)| \\ MinT &\leq \min\left\{\frac{a}{b}, \frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'max-abs-diff': Difference of the maximum distance of the components

$$\begin{aligned} a &= \max\{g_A(d), g_A(k)\} \\ b &= \max\{g_B(d), g_B(k)\} \\ MinT &\leq \min\left\{\frac{a}{b}, \frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'max-abs-ratio': Ratio of the maximum distance of the components

$$\begin{aligned} a &= \max\{g_A(d), g_A(k)\} \\ b &= \max\{g_B(d), g_B(k)\} \\ MinT &\leq \min\left\{\frac{a}{b}, \frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'min-abs-diff': Difference of the minimum distance of the components

$$\begin{aligned} a &= \min\{g_A(d), g_A(k)\}, k < d \\ b &= \min\{g_B(d), g_B(k)\}, k < d \\ MinT &\leq |a-b| \leq MaxT \end{aligned}$$

'min-abs-ratio': Ratio of the minimum distance of the components

$$\begin{aligned} a &= \min\{g_A(d), g_A(k)\}, k < d \\ b &= \min\{g_B(d), g_B(k)\}, k < d \\ MinT &\leq \min\left\{\frac{a}{b}, \frac{b}{a}\right\} \leq MaxT \end{aligned}$$

'plane': The following has to hold for all d_1,$d_2 \in [1, n]$:

$$\begin{aligned} g_A(d_1) &> g_A(d_2) \Rightarrow g_B(d_1) > g_B(d_2) \\ g_A(d_1) &< g_A(d_2) \Rightarrow g_B(d_1) < g_B(d_2) \end{aligned}$$

Regions with an area less than `MinSize` are suppressed.

Parameters

▷ **`MultiChannelImage`** (input_object) . . . . . (multichannel-)image(-array) ⇝ *object :* byte
Input image.

▷ **`Regions`** (output_object) . . . . . region-array ⇝ *object*
Segmented regions.

▷ **`Metric`** (input_control) . . . . . string ⇝ *string*
Metric for the distance of the feature vectors.
Default: '2-norm'
List of values: `Metric` ∈ {'1-norm', '2-norm', '3-norm', '4-norm', 'n-norm', 'max-diff', 'min-diff', 'variance', 'dot-product', 'correlation', 'mean-diff', 'mean-ratio', 'length-diff', 'length-ratio', 'n-norm-ratio', 'gray-max-diff', 'gray-max-ratio', 'gray-min-diff', 'gray-min-ratio', 'variance-diff', 'variance-ratio', 'mean-abs-diff', 'mean-abs-ratio', 'max-abs-diff', 'max-abs-ratio', 'min-abs-diff', 'min-abs-ratio', 'plane'}

▷ **`MinTolerance`** (input_control) . . . . . number ⇝ *real* / integer
Lower threshold for the features' distance.
Default: 0.0
Suggested values: `MinTolerance` ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 12.0, 14.0, 16.0, 18.0, 20.0, 25.0, 30.0}

▷ **`MaxTolerance`** (input_control) . . . . . number ⇝ *real* / integer
Upper threshold for the features' distance.
Default: 20.0
Suggested values: `MaxTolerance` ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0, 9.0, 10.0, 12.0, 14.0, 16.0, 18.0, 20.0, 25.0, 30.0}

▷ **`MinSize`** (input_control) . . . . . integer ⇝ *integer*
Minimum size of the output regions.
Default: 30
Suggested values: `MinSize` ∈ {1, 10, 25, 50, 100, 200, 500, 1000}
Value range: 1 ≤ MinSize
Minimum increment: 1
Recommended increment: 5

Result

`regiongrowing_n` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

24.5 Threshold

This chapter describes threshold operators.

Concept of Threshold Operators

One way to perform a segmentation of an image is to use threshold operators. In doing so, regions that fulfill a certain threshold condition, depending on gray values, are determined within an image.

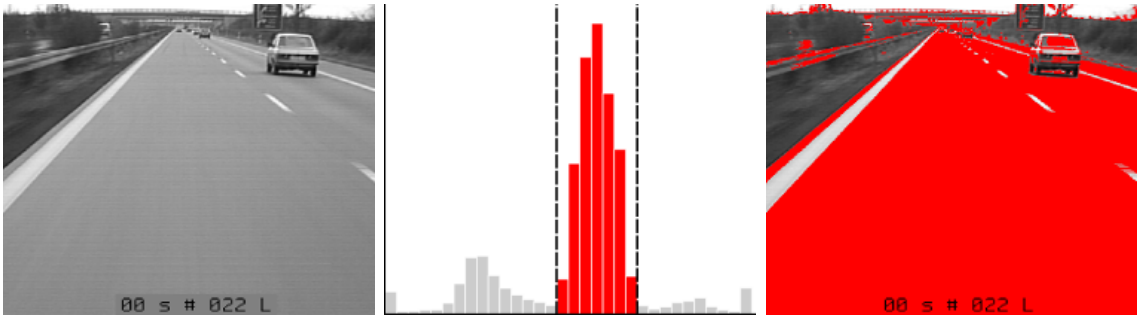
In order to fit different tasks and image properties there is a set of threshold operators provided.

The following paragraphs give an overview of the operators by differentiating them into histogram-based and local methods and having a closer look at the most important ones.

Histogram-based Threshold Operators

Histogram-based threshold segmentation does not take the position but only the pixel value into account. Therefore thresholds are determined by adjusting them to the histogram of an image.

Threshold By using threshold, you can select all pixels within user set gray value intervals.

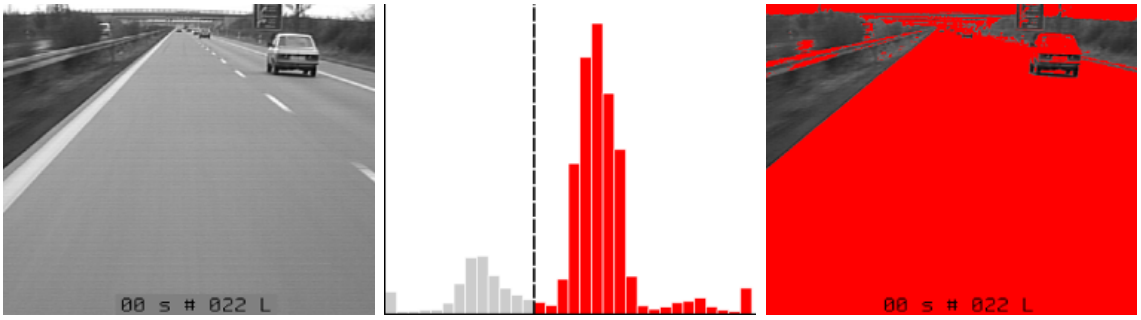


(1) (2) (3)

(1) Input image, (2) histogram of the input image with manually determined thresholds MinGray and MaxGray, (3) resulting segmentation of the input image.

The operator fast_threshold also works with two manually determined thresholds but uses another computing algorithm.

Binary Threshold To divide your image into light and dark regions, binary_threshold automatically computes a threshold to separate foreground from background.

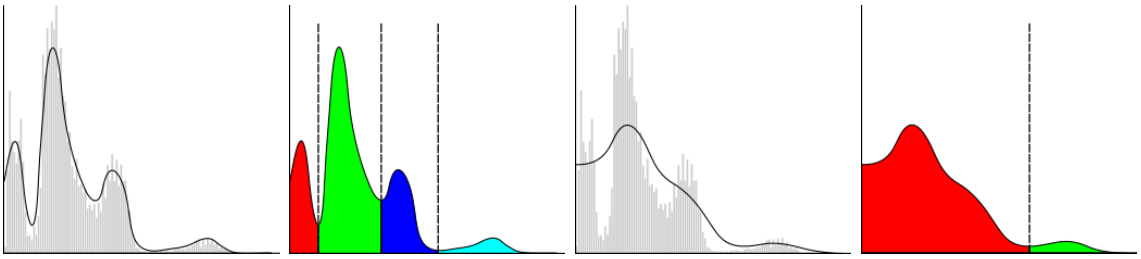


(1) (2) (3)

(1) Input image, (2) histogram of the input image with automatically determined binary threshold, (3) resulting segmentation of the input image.

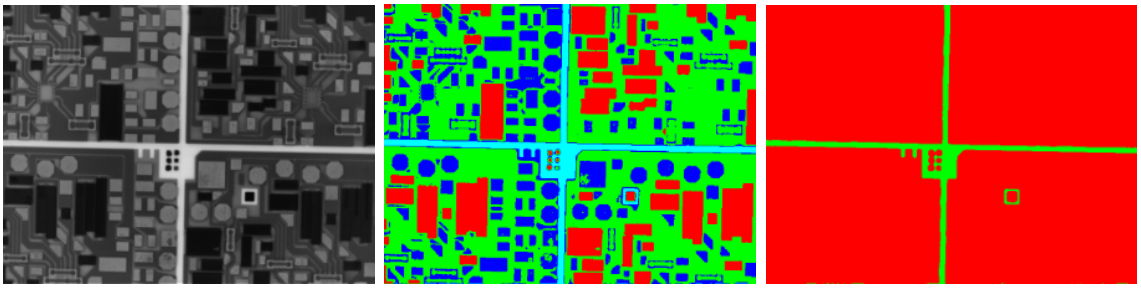
A segmentation using `threshold_sub_pix` also divides the image into foreground and background, but puts out the separating border with sub-pixel accuracy. The threshold has to be set manually.

Automatic Threshold `auto_threshold` computes local minima in the image histogram to determine thresholds. By smoothing the histogram you have influence on the number of classes found in the input image.



(1) (2) (3) (4)

(1) Slightly smoothed histogram, (2) results in higher number of local minima, (3) with further smoothing, (4) number of local minima decreases.

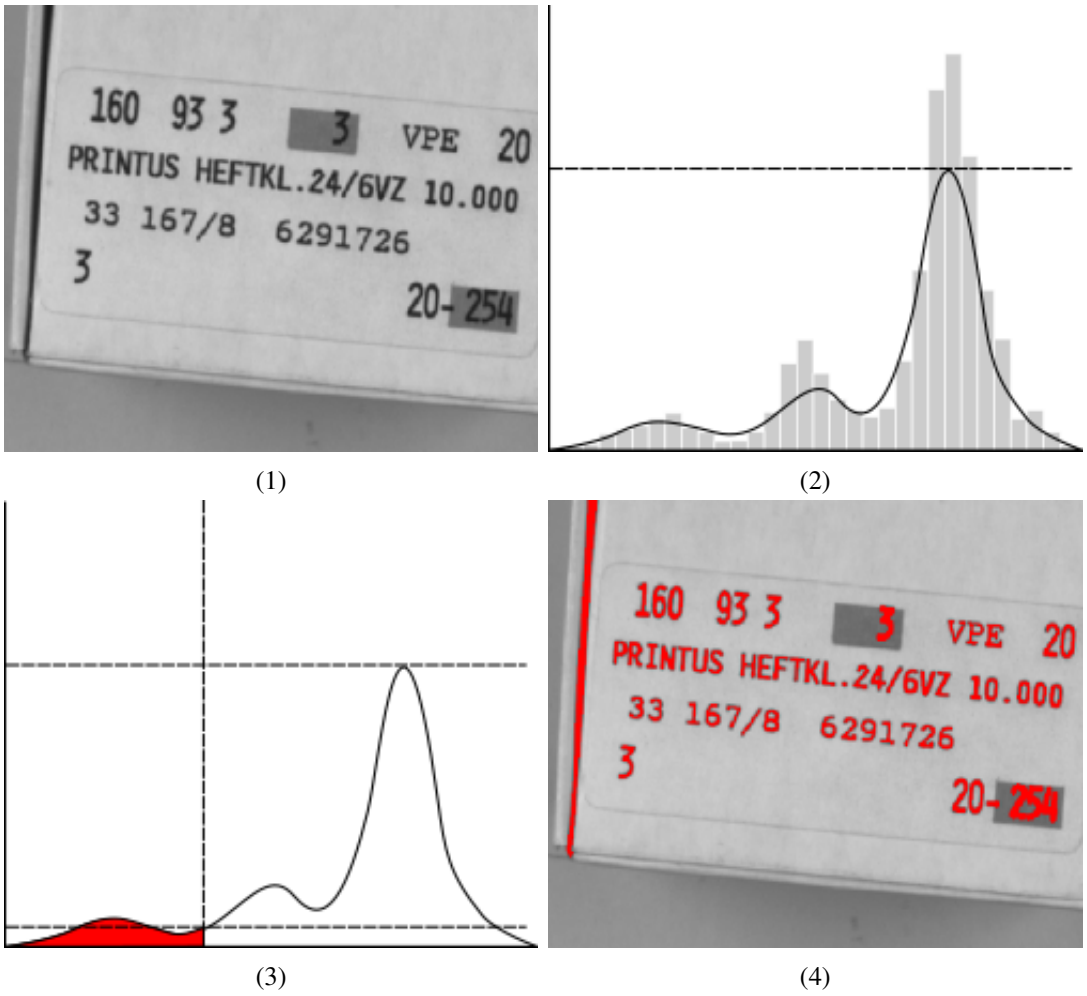


(1) (2) (3)

(1) Input image, (2) four classes are extracted from slightly smoothed histogram, (3) whereas in this case a further smoothed histogram results in two regions.

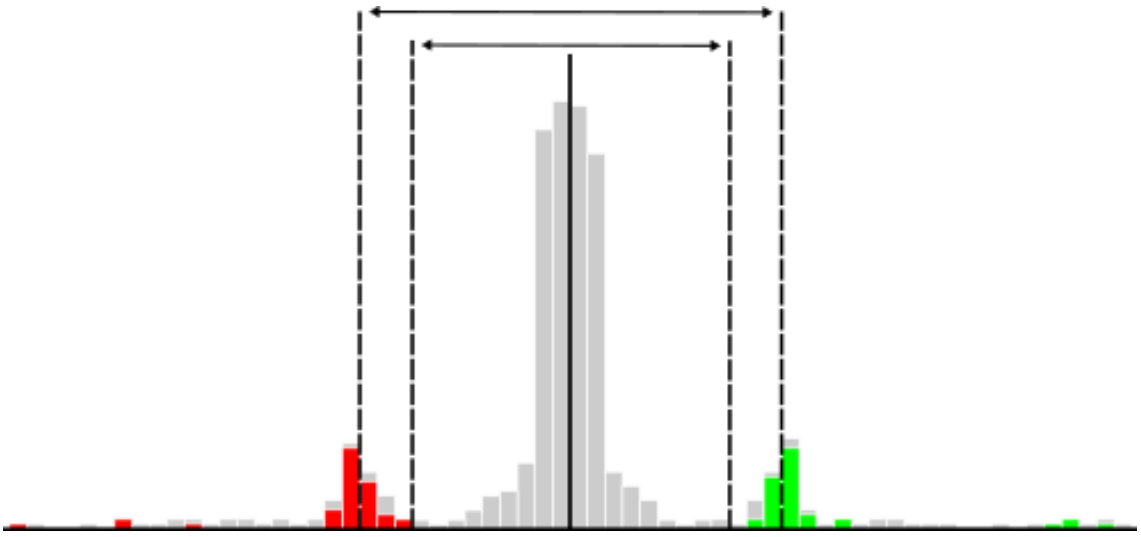
Use `histo_to_thresh` to get the gray values of local minima in the histogram.

Character Threshold To do a segmentation of dark text on light background, `char_threshold` is a useful tool. The maximum peak in the histogram corresponds to the light background. Assuming the text is darker than the background, you examine the smoothed histogram left of the maximum. The parameter `Percent` determines how far from the maximum the threshold is set, taking the frequencies of the gray values into account.

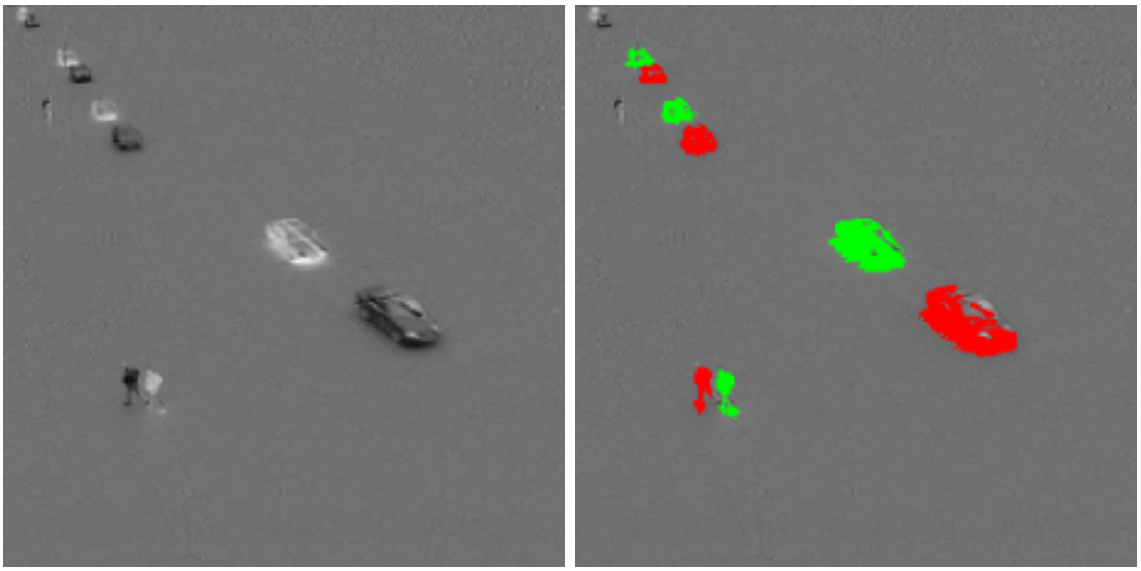


(1) Input image, (2) histogram is smoothed and global maximum is identified, (3) the parameter `Percent` determines threshold left of the maximum, (4) resulting image.

Dual-Threshold Subtracting an image from another or using an edge detecting operator like `laplace_of_gauss` usually leads to negative values in the resulting image. The operator `dual_threshold` is suited for the segmentation of signed images while also taking minimum region size into account.



Histogram of a signed image with `Threshold` (inner boundaries) and `MinGray`. Pixels are only selected if they fulfill the conditions regarding gray values and region size.



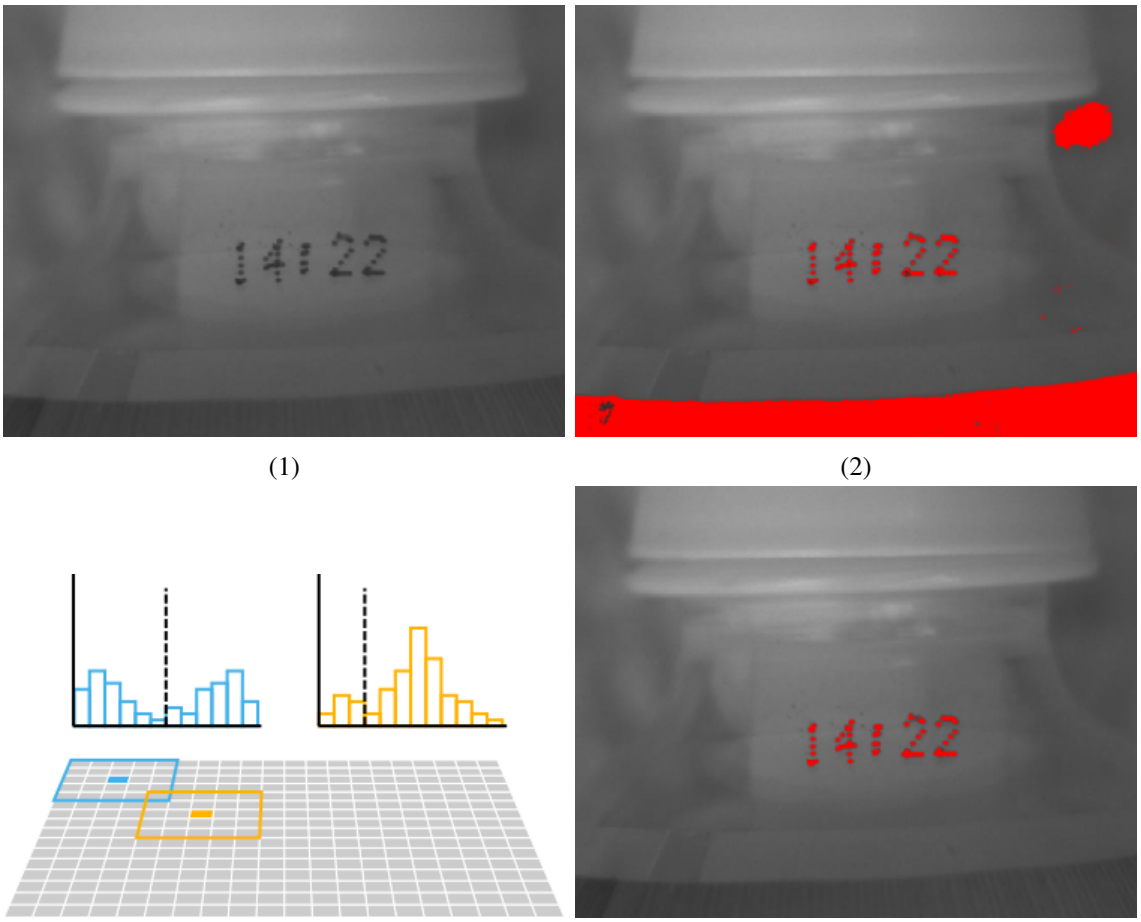
(1) (2)

(1) Signed input image (created with sub_image), (2) result after applying a dual threshold.

Local Threshold Operators

Unlike histogram-based threshold operators, a local threshold also takes position or neighborhood of pixels into account to assign them to the appropriate region. Instead of global thresholds that are applied to each pixel, it is sometimes be useful to adapt the threshold to local features of the image.

Local Threshold local_threshold takes the local mean and standard deviation into account and computes an individual threshold for each pixel. The size of the neighborhood is set by the user. This operator is especially suited for the segmentation of text, when lighting conditions or the background are not homogeneous.



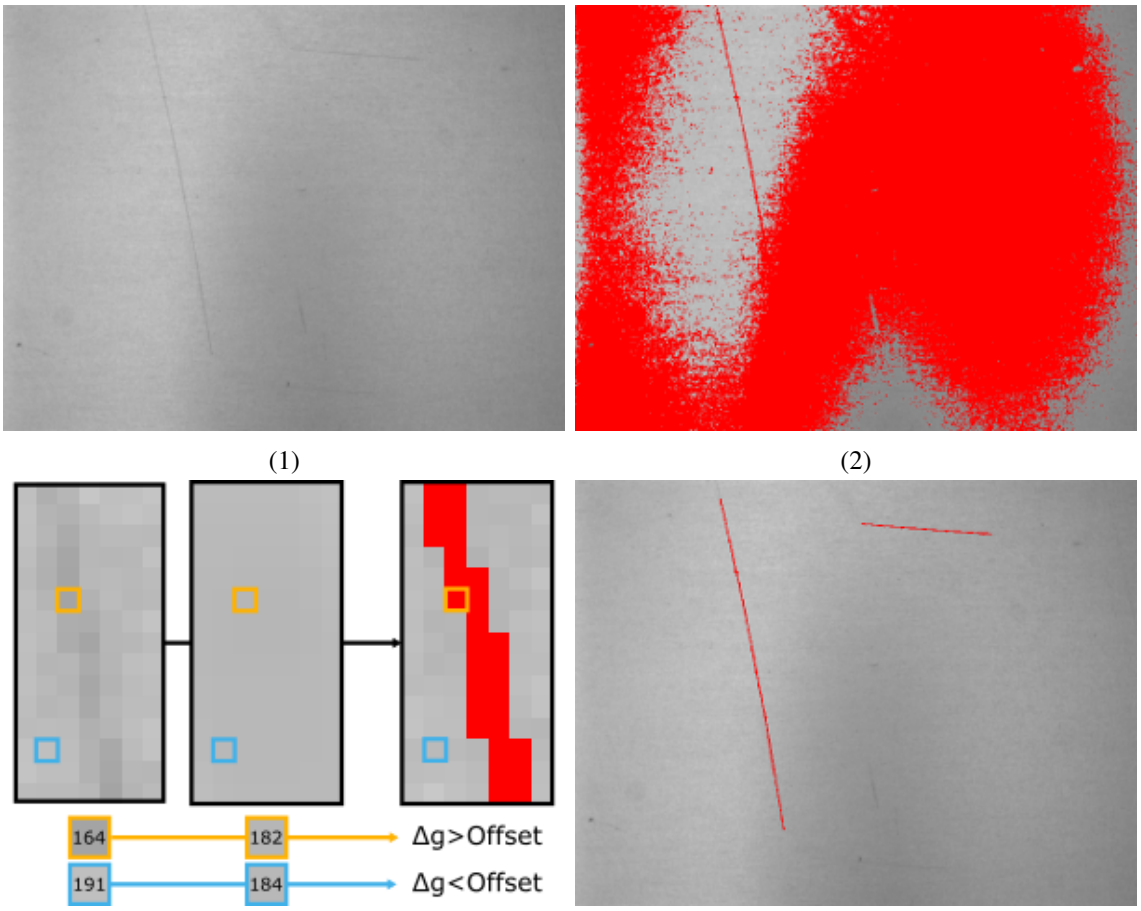
(1) (2)

(3) (4)

(1) Input image, (2) segmentation with global thresholds does not choose the desired text solely, (3) adapting the threshold to the neighborhood of each pixel individually, (4) segmentation of the text.

The operator `var_threshold` works in a similar way, except it selects those points of the image that fulfill specified conditions regarding their local standard deviation and brightness.

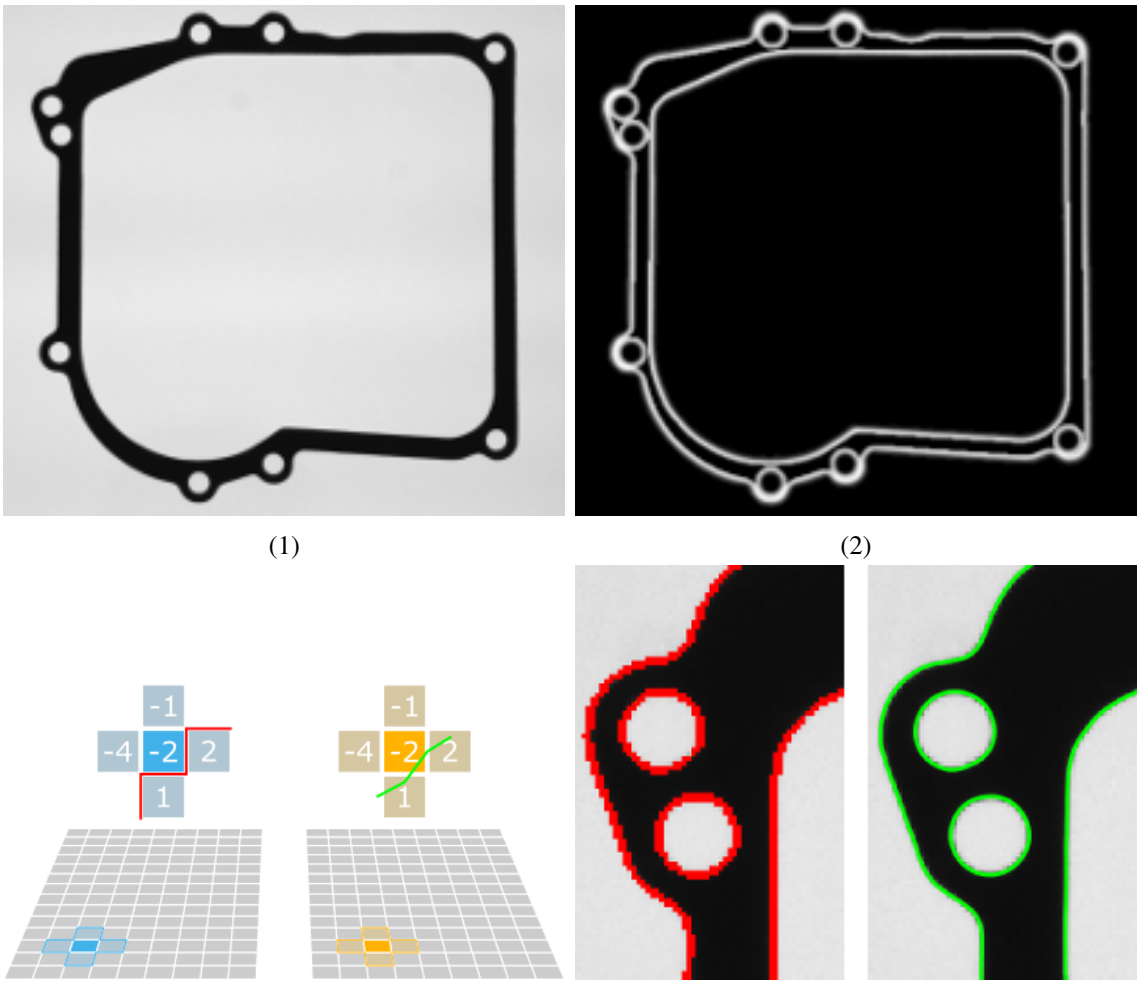
Dynamic Threshold With `dyn_threshold` you can inspect the differences between images. Usually the input image and a filtered version, e.g., the mean of the image, are compared pixel by pixel. The parameter `LightDark` is used to determine what kind of changes in the image are relevant. The sensitivity of the operator is controlled by the parameter `Offset`.



(1) Input image, (2) segmentation of scratches with global threshold is not possible due to inhomogeneous lighting conditions, (3) inspection of the gray value difference between the original image (left) and mean of the image (middle) pixel by pixel to segment regions (right) exceeding `Offset` (image detail), (4) result after selecting wanted regions. For more detail have a look at the example `surface_scratch.hdev`.

A similar operator is `check_difference`. The operator displays the absolute differences between two images. It is especially suited for change detection of consecutively acquired images.

Zero Crossing Threshold Operators like `laplace_of_gauss` that are used for edge detection return signed images, where edges are located at the zero crossings. `zero_crossing` and `zero_crossing_sub_pix` can be used to extract those edges, taking the individual 4-neighborhood into account.



(1) Input image, (2) domain is reduced and Laplace-of-Gaussian filter is applied, (3) the zero-crossing operators can detect edges with pixel (red) and sub-pixel accuracy (green), (4) image details of results using `zero_crossing` (red) and `zero_crossing_sub_pix` (green).

auto_threshold (Image : Regions : Sigma :)

Segment an image using thresholds determined from its histogram.

`auto_threshold` segments a single-channel image using multiple thresholding. First, the absolute histogram of the gray values is determined. Then, relevant minima are extracted from the histogram, which are used successively as parameters for a thresholding operation. The thresholds used for byte images are 0, 255, and all minima extracted from the histogram (after the histogram has been smoothed with a Gaussian filter with standard deviation `Sigma`). For each gray value interval *one* region is generated. Thus, the number of regions is the number of minima + 1. For uint2 images, the above procedure is used analogously. However, here the highest threshold is 65535. Furthermore, for uint2 images the value of `Sigma` (virtually) refers to a histogram with 256 values, although internally histograms with a higher resolution are used. This is done to facilitate switching between image types without having to change the parameter `Sigma`. For float images the thresholds are the minimum and maximum gray value in the image and all minima extracted from the histogram. Here, the scaling of the parameter `Sigma` refers to the original gray values of the image. The larger the value of `Sigma` is chosen, the fewer regions will be extracted. This operator is useful if the regions to be extracted exhibit similar gray values (homogeneous regions).

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **Regions** (output_object) . . . . . region-array ⇝ *object*
Regions with gray values within the automatically determined intervals.

▷ **Sigma** (input_control) . . . . . number ⇝ *real* / integer
Sigma for the Gaussian smoothing of the histogram.
Default: 2.0
Suggested values: Sigma ∈ {0.0, 0.5, 1.0, 2.0, 3.0, 4.0, 5.0}
(lin)
Minimum increment: 0.01
Recommended increment: 0.3

Example

```
read_image (Image, 'fabrik')
median_image (Image, Median, 'circle', 3, 'mirrored')
auto_threshold (Median, Seg, 2.0)
connection (Seg, Connected)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

binary_threshold (Image : Region : Method,
LightDark : UsedThreshold)

Segment an image using binary thresholding.

binary_threshold segments a single-channel Image using an automatically determined global threshold and returns the segmented region in Region. This is, e.g., useful for the segmentation of characters on a homogeneously illuminated background. binary_threshold also returns the used threshold in UsedThreshold.

The used threshold is determined by the method that is given in Method. Currently the operator provides the following two methods: *'max_separability'* and *'smooth_histo'*. Both methods should only be used for images that have a bimodal histogram.

The method *'smooth_histo'* provides the same functionality that has been provided by the operator bin_threshold. The method *'max_separability'* tends to determine smaller values for UsedThreshold. Furthermore, it is less sensitive to thin isolated peaks in the histogram that are far from the rest of the spectrum and often, it is faster than *'smooth_histo'*.

Maximize separability

By selecting Method = *'max_separability'*, automatic thresholding based on the gray-level histogram according to Otsu (see the paper in References) is invoked. The algorithm first calculates the histogram of the image and then uses statistical moments to find the optimal threshold T^* that divides the pixels into foreground and background and maximizes the separability between these two classes. This method is only available for byte and uint2 images.

- If LightDark = *'light'* all pixels with gray values greater or equal to T^* are selected.

- If LightDark = *'dark'* all pixels with gray values smaller than T^* are selected.

Histogram smoothing

By selecting Method = *'smooth_histo'* binary_threshold determines the threshold T^* in the following way: First, the relative histogram of the gray values is determined. Then, relevant minima are extracted from the histogram, which are used as parameters for a thresholding operation. In order to reduce the number of minima, the histogram is smoothed with a Gaussian, as in auto_threshold. The mask size is enlarged until there is only one minimum in the smoothed histogram. Then, the threshold T^* is set to the position of this minimum.

- If LightDark = *'light'* all pixels $p(r, c)$ with gray values greater or equal to T^* are selected.
- If LightDark = *'dark'* all pixels $p(r, c)$ with gray values smaller than T^* are selected.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2
Input Image.

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Segmented output region.

▷ **Method** (input_control) ..... string ⇝ *string*
Segmentation method.
Default: 'max_separability'
List of values: Method ∈ {'max_separability', 'smooth_histo'}

▷ **LightDark** (input_control) ..... string ⇝ *string*
Extract foreground or background?
Default: 'dark'
List of values: LightDark ∈ {'dark', 'light'}

▷ **UsedThreshold** (output_control) ..... number(-array) ⇝ *integer* / string
Used threshold.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

char_threshold (Image, HistoRegion : Characters : Sigma, Percent : Threshold)

Perform a threshold segmentation for extracting characters.

The main application of char_threshold is to segment single-channel images of dark characters on bright paper. The operator works as follows: First, a histogram of the gray values in the image Image is computed for the points in the region HistoRegion. To eliminate noise, the histogram is smoothed with the given Sigma

(Gaussian smoothing). In the histogram, the background (white paper) corresponds to a large peak at high gray values, while the characters form a small peak at low gray values. In contrast to the operator binary_threshold (with Method='*smooth_histo*'), which locates the minimum between the two peaks, here the threshold for the segmentation is determined in relation to the maximum of the histogram, i.e., the background, with the following condition:

$$histogram[\text{threshold}] * 100.0 < histogram[\text{maximum}] * (100.0 - \texttt{Percent})$$

For example, if you choose Percent = 95 the operator locates the gray value whose frequency is at most 5 percent of the maximum frequency. Because char_threshold assumes that the characters are darker than the background, the threshold is searched for "to the left" of the maximum.

In comparison to binary_threshold, this operator should be used if there is no clear minimum between the histogram peaks corresponding to the characters and the background, respectively, or if there is no peak corresponding to the characters at all. This may happen, e.g., if the image contains only few characters or in the case of a non-uniform illumination.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
  Input image.
- ▷ **HistoRegion** (input_object) ..... region ⇝ *object*
  Region in which the histogram is computed.
- ▷ **Characters** (output_object) ..... region(-array) ⇝ *object*
  Dark regions (characters).
- ▷ **Sigma** (input_control) ..... number ⇝ *real*
  Sigma for the Gaussian smoothing of the histogram.
  Default: 2.0
  Suggested values: Sigma ∈ {0.0, 0.5, 1.0, 2.0, 3.0, 4.0, 5.0}
  Value range: 0.0 ≤ Sigma ≤ 50.0 (lin)
  Minimum increment: 0.01
  Recommended increment: 0.2
- ▷ **Percent** (input_control) ..... number ⇝ *real* / integer
  Percentage for the gray value difference.
  Default: 95
  Suggested values: Percent ∈ {90, 92, 95, 96, 97, 98, 99, 99.5, 100}
  Value range: 0.0 ≤ Percent ≤ 100.0 (lin)
  Minimum increment: 0.1
  Recommended increment: 0.5
- ▷ **Threshold** (output_control) ..... integer(-array) ⇝ *integer*
  Calculated threshold.

Example

```
read_image (Image, 'letters')
char_threshold (Image, Image, Seg, 0.0, 5.0, Threshold)
connection (Seg, Connected)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

check_difference (Image, Pattern : Selected : Mode, DiffLowerBound, DiffUpperBound, GrayOffset, AddRow, AddCol :)

Compare two images pixel by pixel.

check_difference selects from the input image Image those pixels ($g_o = g_{\texttt{Image}}$), whose gray value difference to the corresponding pixels in Pattern is inside (outside) of the interval [DiffLowerBound, DiffUpperBound]. The pixels of Pattern are translated by (AddRow, AddCol) with respect to Image. Let g_p be the gray value from Pattern translated by (AddRow, AddCol) with respect to g_o.

If the selected mode Mode is *'diff_inside'*, a pixel g_o is selected if

$$g\_o - g\_p - \texttt{GrayOffset} \geq \texttt{DiffLowerBound} \quad \text{and}$$
$$g\_o - g\_p - \texttt{GrayOffset} \leq \texttt{DiffUpperBound}.$$

If the mode is set to *'diff_outside'*, a pixel g_o is selected if

$$g\_o - g\_p - \texttt{GrayOffset} < \texttt{DiffLowerBound} \quad \text{or}$$
$$g\_o - g\_p - \texttt{GrayOffset} > \texttt{DiffUpperBound}.$$

This test is performed for all points of the domain (region) of Image, intersected with the domain of the translated Pattern. All points fulfilling the above condition are aggregated in the output region. The two images may be of different size. Typically, Pattern is smaller than Image.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
Input image.

▷ **Pattern** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte
Comparison image.

▷ **Selected** (output_object) ..... region(-array) ⇝ *object*
Points in which the two images are similar/different.

▷ **Mode** (input_control) ..... string ⇝ *string*
Mode: return similar or different pixels.
Default: 'diff_outside'
Suggested values: Mode ∈ {'diff_inside', 'diff_outside'}

▷ **DiffLowerBound** (input_control) ..... number ⇝ *integer*
Lower bound of the tolerated gray value difference.
Default: -5
Suggested values: DiffLowerBound ∈ {0, -1, -2, -3, -5, -7, -10, -12, -15, -17, -20, -25, -30}
Value range: -255 ≤ DiffLowerBound ≤ 255 (lin)
Minimum increment: 1
Recommended increment: 2

▷ **DiffUpperBound** (input_control) ..... number ⇝ *integer*
Upper bound of the tolerated gray value difference.
Default: 5
Suggested values: DiffUpperBound ∈ {0, 1, 2, 3, 5, 7, 10, 12, 15, 17, 20, 25, 30}
Value range: -255 ≤ DiffUpperBound ≤ 255 (lin)
Minimum increment: 1
Recommended increment: 2

▷ **GrayOffset** (input_control) ..... number ⇝ *integer*
Offset gray value subtracted from the input image.
Default: 0
Suggested values: GrayOffset ∈ {-30, -25, -20, -17, -15, -12, -10, -7, -5, -3, -2, -1, 0, 1, 2, 3, 5, 7, 10, 12, 15, 17, 20, 25, 30}
Value range: -255 ≤ GrayOffset ≤ 255 (lin)
Minimum increment: 1
Recommended increment: 2

▷ **AddRow** (input_control) ..... point.y ⇝ *integer*
Row coordinate by which the comparison image is translated.
Default: 0
Suggested values: AddRow ∈ {-200, -100, -20, -10, 0, 10, 20, 100, 200}
Value range: -32000 ≤ AddRow ≤ 32000 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **AddCol** (input_control) ..... point.x ⇝ *integer*
Column coordinate by which the comparison image is translated.
Default: 0
Suggested values: AddCol ∈ {-200, -100, -20, -10, 0, 10, 20, 100, 200}
Value range: -32000 ≤ AddCol ≤ 32000 (lin)
Minimum increment: 1
Recommended increment: 1

Complexity

Let A be the number of valid pixels. Then the runtime complexity is $O(A)$.

Result

check_difference returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Successors

connection, select_shape, reduce_domain, select_gray, rank_region, dilation1, opening

Alternatives

sub_image, dyn_threshold

Module

dual_threshold (Image : RegionCrossings : MinSize, MinGray, Threshold :)

Threshold operator for signed images.

dual_threshold segments the input image into a region with gray values ≥Threshold ("positive" regions) and a region with gray values ≤ −Threshold ("negative" regions). Only "positive" or "negative" regions having a size larger than MinSize are taken into account. And regions whose maximum gray value is less than MinGray in absolute value are suppressed.

The segmentation performed is not complete, i.e., the "positive" and "negative" regions together do not necessarily cover the entire image: Areas with a gray value between −Threshold and Threshold, −MinGray and MinGray, respectively, are not taken into account.

dual_threshold is usually called after applying a Laplace operator (laplace, laplace_of_gauss, derivate_gauss or diff_of_gauss) to an image or with the difference of two images (sub_image).

The zero crossings of a Laplace image correspond to edges in an image, and are the separating regions of the "positive" and "negative" regions in the Laplace image. They can be determined by calling dual_threshold with Threshold = 1 and then creating the complement regions with complement. The parameter MinGray determines the noise invariance, while MinSize determines the resolution of the edge detection.

Using byte images, only the positive part of the operator is applied. Therefore dual_threshold behaves like a standard threshold operator (threshold) with successive connection and select_gray.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / int1 / int2 / int4 / real
Input image.

▷ **RegionCrossings** (output_object) ..... region-array ⇝ *object*
Positive and negative regions.

▷ **MinSize** (input_control) ..... integer ⇝ *integer*
Regions smaller than MinSize are suppressed.
Default: 20
Suggested values: MinSize ∈ {0, 10, 20, 50, 100, 200, 500, 1000}
Value range: 0 ≤ MinSize ≤ 10000 (lin)
Minimum increment: 1
Recommended increment: 10

▷ **MinGray** (input_control) ..... real ⇝ *real*
Regions whose maximum absolute gray value is smaller than MinGray are suppressed.
Default: 5.0
Suggested values: MinGray ∈ {1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 20.0}
Value range: 0 ≤ MinGray (lin)
Minimum increment: 1.0
Recommended increment: 10.0

▷ **Threshold** (input_control) ..... real ⇝ *real*
Regions that have a gray value smaller than Threshold (or larger than -Threshold) are suppressed.
Default: 2.0
Suggested values: Threshold ∈ {1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 9.0, 11.0, 15.0, 20.0}
Value range: 0 ≤ Threshold (lin)
Minimum increment: 1.0
Recommended increment: 10.0

Example

```
* Edge detection with the Laplace operator (and edge thinning)
diff_of_gauss(Image,Laplace,2.0,1.6)
* find "`positive"' and "`negative"' regions:
dual_threshold(Laplace,Region,20,2,1)
* The zero runnings are the complement to these image section:
complement(Region,ZeroCrossings)

* Simulation of dual_threshold
dual_threshold(Laplace,Result,MinS,MinG,Threshold)
threshold(Laplace,Tmp1,Threshold,999999)
connection(Tmp1,Tmp2)
select_shape(Tmp2,Tmp3,'area','and',MinS,999999)
select_gray(Laplace,Tmp3,Tmp4,'max','and',MinG,999999)
threshold(Laplace,Tmp5,-999999,-Threshold)
connection(Tmp5,Tmp6)
select_shape(Tmp6,Tmp7,'area','and',MinS,999999)
select_gray(Laplace,Tmp7,Tmp8,'min','and',-999999,-MinG)
concat_obj(Tmp4,Tmp8,Result)
```

Result

dual_threshold returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to

the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

dyn_threshold (OrigImage, ThresholdImage : RegionDynThresh : Offset, LightDark :)

Segment an image using a local threshold.

dyn_threshold selects from the input image those regions in which the pixels fulfill a threshold condition. Let $g_o = g_$OrigImage, and $g_t = g_$ThresholdImage. Then the condition for LightDark = *'light'* is:

$$g_o \geq g_t + \texttt{Offset}$$

For LightDark = *'dark'* the condition is:

$$g_o \leq g_t - \texttt{Offset}$$

For LightDark = *'equal'* it is:

$$g_t - \texttt{Offset} \leq g_o \leq g_t + \texttt{Offset}$$

Finally, for LightDark = *'not_equal'* it is:

$$g_t - \texttt{Offset} > g_o \vee g_o > g_t + \texttt{Offset}$$

Typically, the threshold images are smoothed versions of the original image (e.g., by applying mean_image, binomial_filter, gauss_filter, etc.). Then the effect of dyn_threshold is similar to applying threshold to a highpass-filtered version of the original image (see highpass_image).

With dyn_threshold, contours of an object can be extracted, where the objects' size (diameter) is determined by the mask size of the lowpass filter and the amplitude of the objects' edges:

The larger the mask size is chosen, the larger the found regions become. As a rule of thumb, the mask size should be about twice the diameter of the objects to be extracted. It is important not to set the parameter Offset to zero because in this case too many small regions will be found (noise). Values between 5 and 40 are a useful choice. The larger Offset is chosen, the smaller the extracted regions become.

All points of the input image fulfilling the above condition are stored jointly in one region. If necessary, the connected components can be obtained by calling connection.

Attention

If `Offset` is chosen from -1 to 1 usually a very noisy region is generated, requiring large storage. If `Offset` is chosen too large (> 60, say) it may happen that no points fulfill the threshold condition (i.e., an empty region is returned). If `Offset` is chosen too small ($<$ -60, say) it may happen that all points fulfill the threshold condition (i.e., a full region is returned).

Parameters

- ▷ **`OrigImage`** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
  Input image.
- ▷ **`ThresholdImage`** (input_object) . . . . singlechannelimage(-array) ⇝ *object :* byte / int2 / uint2 / int4 / real
  Image containing the local thresholds.
- ▷ **`RegionDynThresh`** (output_object) . . . . . region(-array) ⇝ *object*
  Segmented regions.
- ▷ **`Offset`** (input_control) . . . . . number ⇝ *real* / integer
  Offset applied to ThresholdImage.
  Default: 5.0
  Suggested values: `Offset` ∈ {1.0, 3.0, 5.0, 7.0, 10.0, 20.0, 30.0}
  Value range: -255.0 ≤ `Offset` ≤ 255.0 (lin)
  Minimum increment: 0.01
  Recommended increment: 5
- ▷ **`LightDark`** (input_control) . . . . . string ⇝ *string*
  Extract light, dark or similar areas?
  Default: 'light'
  List of values: `LightDark` ∈ {'dark', 'light', 'equal', 'not_equal'}

Example

```
* Looking for regions with the diameter D
mean_image(Image,Mean,D*2+1,D*2+1)
dyn_threshold(Image,Mean,Seg,5,'light')
connection(Seg,Regions)
```

Complexity

Let A be the area of the input region. Then the runtime complexity is $O(A)$.

Result

`dyn_threshold` returns `2` (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

fast_threshold (Image : Region : MinGray, MaxGray, MinSize :)

Fast thresholding of images using global thresholds.

fast_threshold selects the pixels from the input image whose gray values g fulfill the following condition:

$$\texttt{MinGray} \leq g \leq \texttt{MaxGray} \ .$$

To reduce the processing time, the selection is done in two steps: At first, all points lying on selected horizontal lines that are specified by their distance MinSize are processed. In the next step the neighborhood (size $(2 * MinSize + 1) \times (2 * MinSize + 1)$) of all previously selected points are processed.

Attention

On multi-core computers supporting the SSE2 instruction set, threshold is most likely faster than fast_threshold. fast_threshold may only be preferred to threshold if those features are not available, e.g., on embedded platforms.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2 / direction / cyclic / real
Input image.

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Segmented regions.

▷ **MinGray** (input_control) ..... number ⇝ *real* / integer
Lower threshold for the gray values.
Default: 128
Suggested values: MinGray ∈ {0.0, 10.0, 30.0, 64.0, 128.0, 200.0, 220.0, 255.0}
Value range: 0.0 ≤ MinGray ≤ 255.0 (lin)
Minimum increment: 1
Recommended increment: 5.0

▷ **MaxGray** (input_control) ..... number ⇝ *real* / integer
Upper threshold for the gray values.
Default: 255.0
Suggested values: MaxGray ∈ {0.0, 10.0, 30.0, 64.0, 128.0, 200.0, 220.0, 255.0}
Value range: 0.0 ≤ MaxGray ≤ 255.0 (lin)
Minimum increment: 1
Recommended increment: 5.0

▷ **MinSize** (input_control) ..... number ⇝ *integer*
Minimum size of objects to be extracted.
Default: 20
Suggested values: MinSize ∈ {5, 10, 15, 20, 25, 30, 40, 50, 60, 70, 100}
Value range: 2 ≤ MinSize ≤ 200 (lin)
Minimum increment: 1
Recommended increment: 2

Complexity

Let A be the area of the output region and $height$ the height of Image. Then the runtime complexity is $O(A + height/\texttt{MinSize})$.

Result

fast_threshold returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

histo_to_thresh (: : Histogramm, Sigma : MinThresh, MaxThresh)

Determine gray value thresholds from a histogram.

histo_to_thresh determines gray value thresholds from a histogram for a segmentation of an image using threshold. The thresholds returned are 0, the maximum gray value in the histogram, and all minima extracted from the histogram. Before the thresholds are determined, the histogram is smoothed with a Gaussian smoothing function.

histo_to_thresh can process the absolute and relative histograms that are returned by gray_histo. Note, however, that here only byte images should be used, because otherwise the returned thresholds cannot easily be transformed to the thresholds for the actual image. For images of type uint2, the histograms should be computed with gray_histo_abs since this facilitates a simple transformation of the thresholds by simply multiplying the thresholds with the quantization selected in gray_histo_abs. For uint2 images, it is important to ensure that the quantization must be chosen in such a manner that the histogram still contains salient information. For example, a 640×480 image with 16 bits per pixel gray value resolution contains on average only $307200/65536 = 4.7$ entries per histogram bin, i.e., the histogram is too sparsely populated to derive any useful statistics from it. To be able to extract useful thresholds from such a histogram, Sigma would have to be set to an extremely large value, which would lead to very high run times and numerical problems. The quantization in gray_histo_abs should therefore normally be chosen such that the histogram contains a maximum of 1024 entries. Hence, for images with more than 10 bits per pixel, the quantization must be chosen greater than 1. The histogram returned by gray_histo_abs should furthermore be restricted to the parts that contain salient information. For example, for an image with 12 bits per pixel, the quantization should be set to 4. Only the first 1024 entries of the computed histogram (which contains 16384 entries in this example) should be passed to histo_to_thresh. Finally, MinThresh must be multiplied by 4 (i.e., the quantization), while MaxThresh must be multiplied by 4 and increased by 3 (i.e., the quantization minus 1).

Parameters

▷ **Histogramm** (input_control) ..... histogram-array ⇝ *integer / real*
Gray value histogram.

▷ **Sigma** (input_control) ..... number ⇝ *real*
Sigma for the Gaussian smoothing of the histogram.
Default: 2.0
Suggested values: Sigma ∈ {0.5, 1.0, 2.0, 3.0, 4.0, 5.0}
Value range: 0.5 ≤ Sigma ≤ 30.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.2

▷ **MinThresh** (output_control) ..... integer-array ⇝ *integer*
Minimum thresholds.

▷ **MaxThresh** (output_control) ..... integer-array ⇝ *integer*
Maximum thresholds.

Example

```
* Calculate thresholds from a byte image and threshold the image.
gray_histo (Image, Image, AbsoluteHisto, RelativeHisto)
histo_to_thresh (AbsoluteHisto, 4, MinThresh, MaxThresh)
threshold (Image, Region, MinThresh, MaxThresh)

* Calculate thresholds from a 12 bit uint2 image and threshold the image.
gray_histo_abs (Image, Image, 4, AbsoluteHisto)
AbsoluteHisto := AbsoluteHisto[0:1023]
histo_to_thresh (AbsoluteHisto, 16, MinThresh, MaxThresh)
MinThresh := MinThresh*4
MaxThresh := MaxThresh*4+3
threshold (Image, Region, MinThresh, MaxThresh)
```

Execution Information

local_threshold (Image : Region : Method, LightDark, GenParamName, GenParamValue :)

Segment an image using local thresholding.

local_threshold segments a single-channel image Image using the thresholding method given in Method and returns the segmented region in Region. Currently the operator offers only the Method *'adapted_std_deviation'*. This algorithm is a text binarization technique and provides good results for document images.

Adaptive Thresholding

By selecting Method = *'adapted_std_deviation'*, a locally adaptive thresholding based on local mean and standard deviation according to Sauvola (see the paper in References) is invoked. The algorithm is able to segment document images even if they are degraded, e.g., due to inhomogeneous illumination or noise. It enables text binarization on an inhomogeneous background by taking into account the local contrast.

For a segmentation of the dark foreground (see parameter LightDark), for a pixel at position (r, c), a local threshold $T(r, c)$ is calculated within a window of size *'mask_size'*×*'mask_size'* (see the generic parameter *'mask_size'*) as follows:

$$T(r,c) = \mu(r,c)\left(1 + k\left(\frac{\sigma(r,c)}{R} - 1\right)\right)$$

where $\mu(r, c)$ is the local mean value within the window and $\sigma(r, c)$ denotes the corresponding standard deviation. The parameter R (see *'range'*) is the assumed maximum value of the standard deviation (R= 128 for byte images) and k (see *'scale'*) a parameter that controls how much the threshold value $T(r, c)$ differs from the mean value $\mu(r, c)$. If there is high contrast in the neighborhood of a point (r, c) the standard deviation $\sigma(r, c)$ has a value close to R which yields a threshold value $T(r, c)$ close to the local mean $\mu(r, c)$. If the contrast is low, the local threshold is below the local mean value. For dark text on light background containing also darker regions, this lower threshold enables the segmentation of the text even in darker areas.

The parameter LightDark controls, whether light or dark structures are segmented.

- If LightDark = *'dark'*, dark structures on a light background are segmented. Every pixel $p(r, c)$ whose gray value is smaller than the calculated local threshold $T(r, c)$ is selected.
- If LightDark = *'light'*, light structures on a dark background are segmented. The result is essentially the same as if the image would have been inverted and then, LightDark was set to *'dark'*.

By setting GenParamName to one of the following values, additional parameters specific for the *'adapted_std_deviation'* method can be set with GenParamValue:

'mask_size': specifies the mask size, i.e., the size of the neighborhood in which the local threshold is calculated. The smaller the window size the thinner the segmented strokes. *'mask_size'* must be set to a value that is larger than the stroke width of the characters or structures to be segmented. If *'mask_size'* is even, the next larger odd value is used.

Suggested values: *15*, *21*, *31*.

Default: *15*.

'scale': sets the parameter k ($0 \leq k$), that controls how much the threshold value differs from the local mean value. Use smaller values for *'scale'* to also segment structures with a lower contrast to their background. Use larger values to suppress clutter.

Suggested values: *0.2*, *0.3*, *0.5*.

Default: *0.2*.

'range': sets the maximum assumed value of standard deviation R. This parameter should be adapted based on the expected gray value range. As a rule of thumb, the value for *'range'* can be set to $range = 0.5 \cdot (MaxGray - MinGray)$, where MinGray and MaxGray are the minimum and maximum gray values in the image, which can be determined with min_max_gray.

Suggested values: *128*, *32767.5*.

Default: *128* (for byte images), *32767.5* (for uint2 images).

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / uint2
Input Image.

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Segmented output region.

▷ **Method** (input_control) ..... string ⇝ *string*
Segmentation method.
Default: 'adapted_std_deviation'
List of values: Method ∈ {'adapted_std_deviation'}

▷ **LightDark** (input_control) ..... string ⇝ *string*
Extract foreground or background?
Default: 'dark'
List of values: LightDark ∈ {'dark', 'light'}

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
List of generic parameter names.
Default: []
List of values: GenParamName ∈ {'mask_size', 'scale', 'range'}

▷ **GenParamValue** (input_control) ..... attribute.value(-array) ⇝ *integer* / real
List of generic parameter values.
Default: []
Suggested values: GenParamValue ∈ {0.2, 15, 30, 128.0}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

- Automatically parallelized on internal data level.

Possible Successors

threshold (Image : Region : MinGray, MaxGray :)

Segment an image using global threshold.

threshold selects the pixels from the input image whose gray values g fulfill the following condition:

$$\texttt{MinGray} \leq g \leq \texttt{MaxGray} \ .$$

All points of an image fulfilling the condition are returned as one region. If more than one gray value interval is passed (tuples for MinGray and MaxGray), one separate region is returned for each interval. For vector field images, the threshold is not applied to gray values but to the lengths of the vectors. The parameters MinGray and MaxGray can be set to *'min'* or *'max'* in order to leave bottom and top limits, respectively, open.

Attention

The usage of MinGray and MaxGray can be affected by the input image type.

For images of type integer, floating point values in MinGray and MaxGray are truncated. For images of type real or vector field, floating point precision will be used for MinGray and MaxGray, if they are of type double.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / vector_field
Input image.

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Segmented region.

▷ **MinGray** (input_control) ..... number(-array) ⇝ *real* / integer / string
Lower threshold for the gray values or *'min'*.
Default: 128.0
Suggested values: MinGray ∈ {0.0, 10.0, 30.0, 64.0, 128.0, 200.0, 220.0, 255.0, 'min'}

▷ **MaxGray** (input_control) ..... number(-array) ⇝ *real* / integer / string
Upper threshold for the gray values or *'max'*.
Default: 255.0
Suggested values: MaxGray ∈ {0.0, 10.0, 30.0, 64.0, 128.0, 200.0, 220.0, 255.0, 'max'}
Restriction: MaxGray >= MinGray

Example

```
read_image(Image,'fabrik')
sobel_dir(Image,EdgeAmp,EdgeDir,'sum_abs',3)
threshold(EdgeAmp,Seg,50,255)
skeleton(Seg,Rand)
connection(Rand,Lines)
select_shape(Lines,Edges,'area','and',10,1000000)
```

Complexity

Let A be the area of the input region. Then the runtime complexity is $O(A)$.

Result

`threshold` returns 2 (`H_MSG_TRUE`) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on internal data level.

`threshold_sub_pix` (Image : Border : Threshold :)

Extract level crossings from an image with subpixel accuracy.

`threshold_sub_pix` extracts the level crossings at the level `Threshold` of the input image `Image` with subpixel accuracy. The extracted level crossings are returned as XLD-contours in `Border`. In contrast to the operator `threshold`, `threshold_sub_pix` does not return regions, but the lines that separate regions with a gray value less than `Threshold` from regions with a gray value greater than `Threshold`.

For the extraction, the input image is regarded as a surface, in which the gray values are interpolated bilinearly between the centers of the individual pixels. Consistent with the surface thus defined, level crossing lines are extracted for each pixel and linked into topologically sound contours. This means that the level crossing contours are correctly split at junction points. If the image contains extended areas of constant gray value `Threshold`, only the border of such areas is returned as level crossings.

Parameters

▷ **`Image`** (input_object) ..... singlechannelimage ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
Input image.

▷ **`Border`** (output_object) ..... xld_cont-array ⇝ *object*
Extracted level crossings.

▷ **`Threshold`** (input_control) ..... number ⇝ *real* / integer
Threshold for the level crossings.
Default: 128
Suggested values: `Threshold` ∈ {0.0, 10.0, 30.0, 64.0, 128.0, 200.0, 220.0, 255.0}

Example

```
read_image(Image,'fabrik')
threshold_sub_pix(Image,Border,35)
dev_display(Border)
```

Result

`threshold_sub_pix` usually returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

2D Metrology

var_threshold (Image : Region : MaskWidth, MaskHeight, StdDevScale, AbsThreshold, LightDark :)

Threshold an image by local mean and standard deviation analysis.

With `var_threshold`, it's possible to select the pixels of the input `Image` which

- have a high local standard deviation (for a positive `StdDevScale`), or a low local standard deviation (for a negative `StdDevScale`)

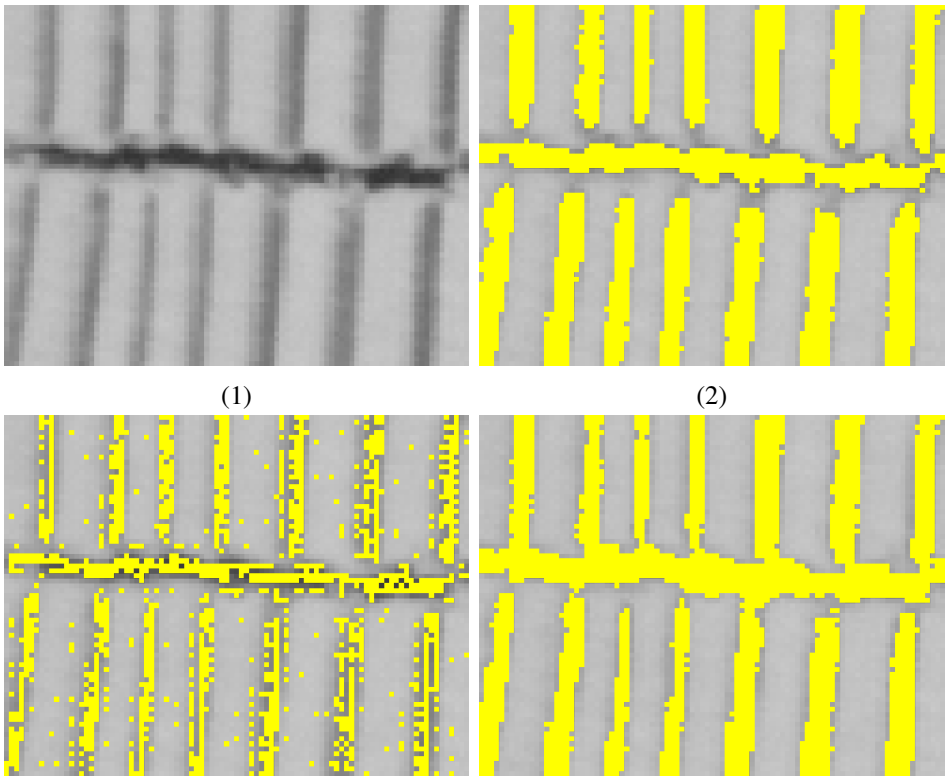
and

- are locally bright or dark, according to `LightDark`.

Thus, it is possible to segment regions on inhomogeneous, noisy, or unevenly illuminated backgrounds.

Hints for the input parameters

`MaskWidth`, `MaskHeight` The size of the filter mask defined by `MaskWidth` and `MaskHeight` determines the maximum size of the objects to be segmented. However, if the mask is chosen too large, objects that are very close might be merged.



(1) (2)

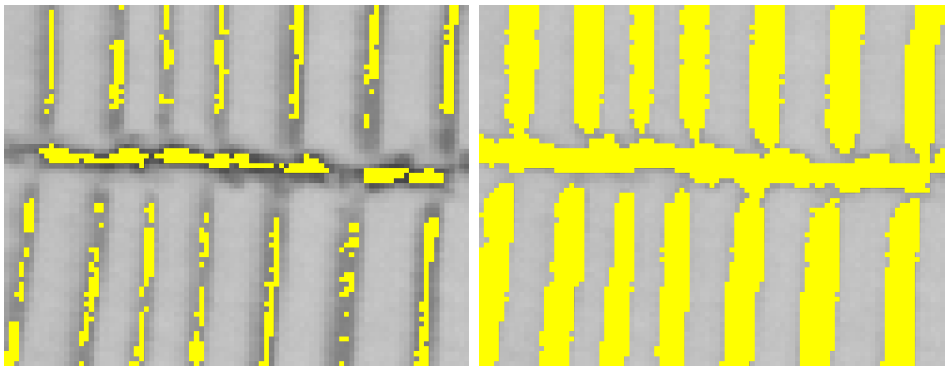
(3) (4)

(1) Original image; the goal is to count the vertical lines. (2) `MaskWidth` := *12*, `MaskHeight` := *12*, `StdDevScale` := *0.1*, all vertical lines are segmented correctly. (3) If the mask size is chosen too low (*3*), the desired regions are not selected properly. (4) If the mask size is too high (*40*), objects that are very close might be merged.

If `MaskWidth` or `MaskHeight` is even, the next larger odd value is used. Altogether, a value of *3* can be considered the minimum sensible value.

`StdDevScale` The local standard deviation is used as a measure of noise in the image. It can be scaled by `StdDevScale` to reflect the desired sensitivity. A higher value means that only pixels that are very different from their surrounding are selected.

For the parameter `StdDevScale` values between -1.0 and 1.0 are sensible choices, with 0.2 as a suggested value. If the parameter is too high or too low, an empty or full region may be returned.



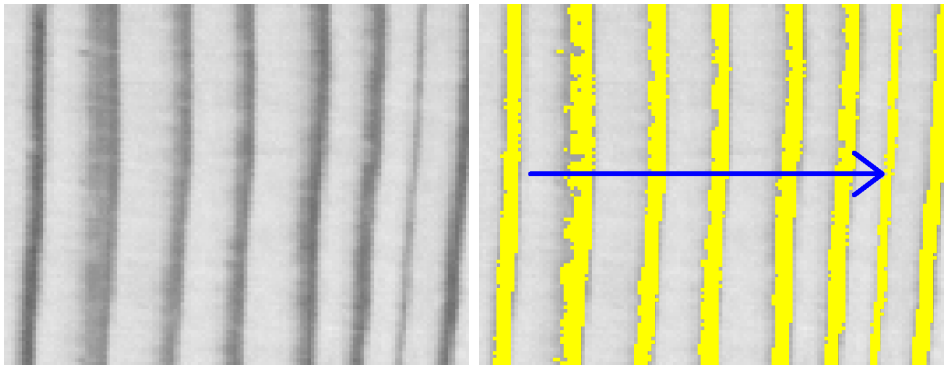
(1) (2)

(1) If `StdDevScale` is too high (*1.3*), the operator is 'picky'; only pixels that are very similar to their surrounding are selected. (2) If `StdDevScale` is too low (*-0.3*), too many pixels that are somewhat similar to their surrounding are incorrectly selected.

`AbsThreshold` In homogeneous areas of an image, the standard deviation is low; thus, the influence of single gray values is high. To reduce the sensitivity of the operator in homogeneous areas, it's possible to adjust `AbsThreshold`. Thus, small gray value changes in homogeneous surroundings can be ignored. Note that for negative values of `StdDevScale`, `AbsThreshold` should also be chosen negative.

LightDark *'light'* or *'dark'* returns all pixels that are lighter or darker than their surrounding, respectively. *'equal'* returns all pixels that are not selected by either option, i.e. the pixels that are relatively equal to their surrounding. *'not_equal'* returns the combined results of *'light'* and *'dark'*, i.e., all pixels that differ from their surrounding.

The calculation



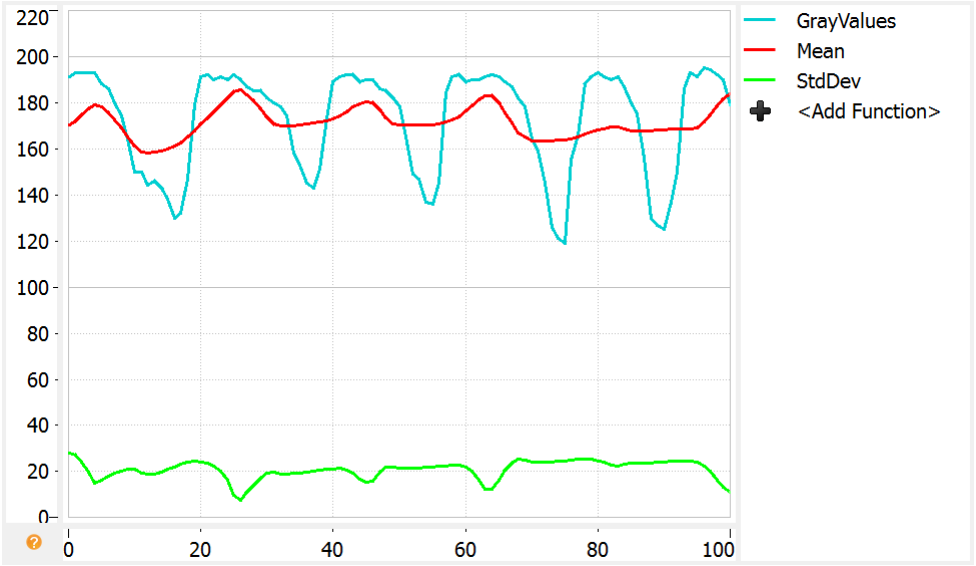
(1) (2)

(1) Initial image. (2) Thresholded image (StdDevScale := *0.6*, MaskWidth := *15*, MaskHeight := *15*, AbsThreshold := *10*). The following images visualize exemplary how the result along the blue arrow came to be.

var_threshold selects from the input image Image those regions Region in which the pixels fulfill a threshold condition. The threshold is calculated from the mean gray value and the standard deviation in a local mask of size MaskWidth x MaskHeight around each pixel (x, y).

Let

- $g(x, y)$ be the gray value at position (x, y) in the input Image,
- $m(x, y)$ the corresponding mean gray value, and
- $d(x, y)$ the corresponding standard deviation in the mask around that pixel.



The original gray values, the corresponding mean gray values, and the corresponding standard deviation in the mask around these pixels.

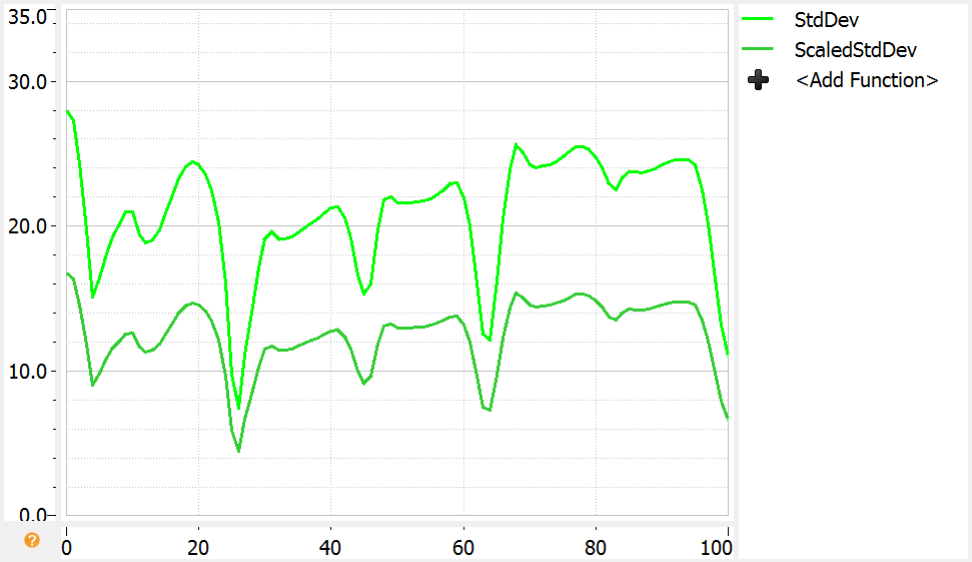
Then, the variable threshold $v(x, y)$ is defined as

$v(x, y) = max(\text{StdDevScale} * d(x, y), \text{AbsThreshold})$ for $\text{StdDevScale} \geq 0$

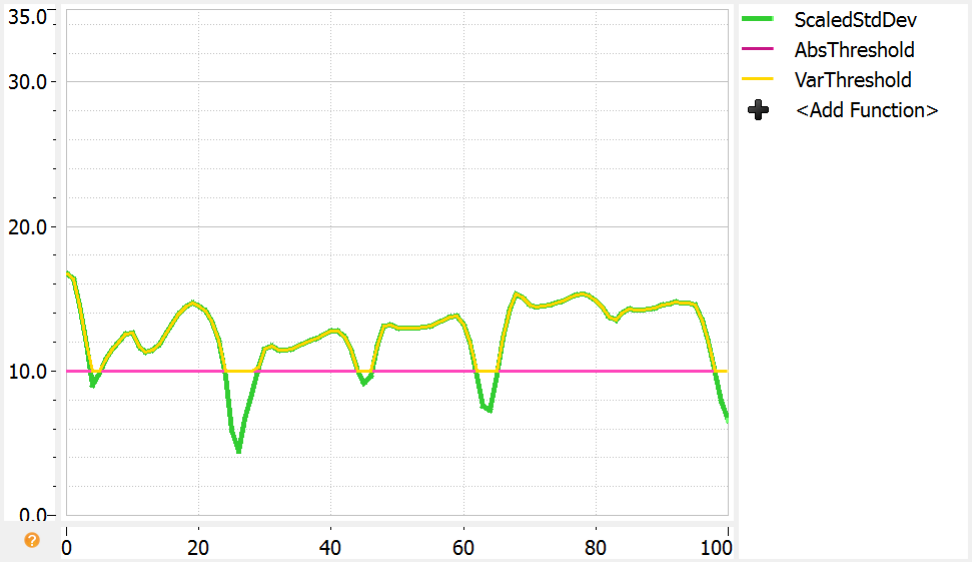
or

$v(x, y) = min(\text{StdDevScale} * d(x, y), \text{AbsThreshold})$ for $\text{StdDevScale} < 0$.

Interpretation: For a positive StdDevScale, each pixel is analyzed. It is determined whether the user-defined AbsThreshold or the scaled standard deviation is greater. The bigger value is chosen as variable threshold $v(x, y)$. For a negative StdDevScale, the corresponding smaller value is chosen.



The standard deviation can be scaled with StdDevScale.

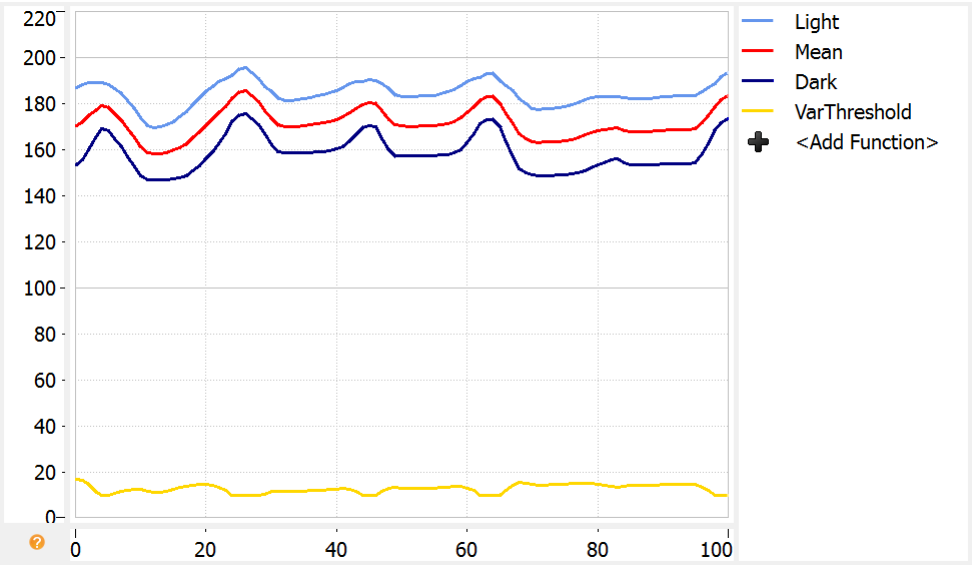


The variable threshold is chosen based on the scaled standard deviation and AbsThreshold.

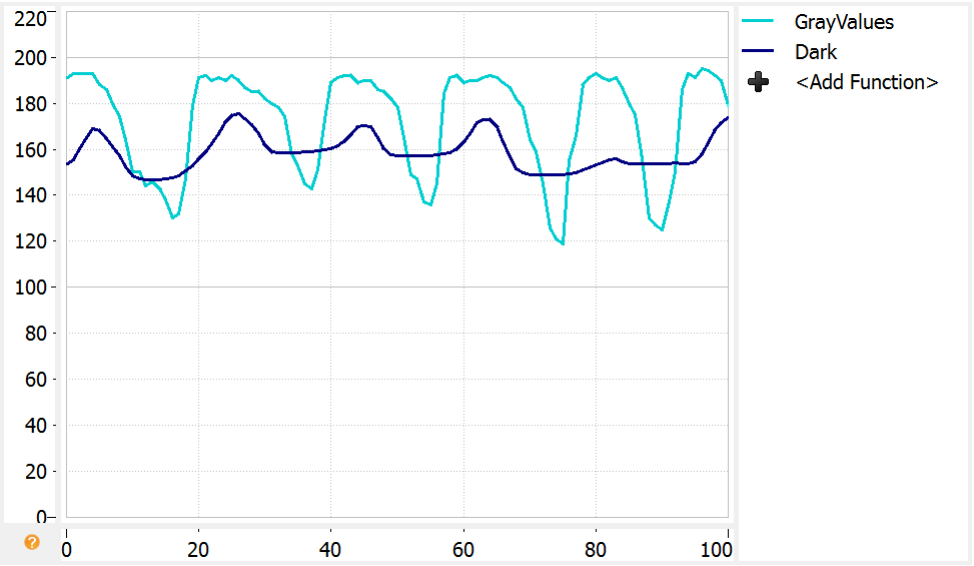
Which pixels are chosen based on the variable threshold is defined by the parameter LightDark:

- *'light'*:
  $g(x, y) \geq m(x, y) + v(x, y)$.
  Interpretation: If the pixel is brighter by $v(x, y)$ than its surrounding, it is selected.
- *'dark'*:
  $g(x, y) \leq m(x, y) - v(x, y)$.
  Interpretation: If the pixel is darker by $v(x, y)$ than its surrounding, it is selected.
  LightDark = *'equal'*:
  $m(x, y) - v(x, y) \leq g(x, y) \leq m(x, y) + v(x, y)$.
  Interpretation: Select exactly those pixels that are not selected by *'light'* and *'dark'*, i.e., the pixels that are relatively equal to their surrounding.

- *'not_equal'*:
  $m(x,y) - v(x,y) > g(x,y) \quad \vee \quad g(x,y) > m(x,y) + v(x,y)$.
  Interpretation: Select all pixels of *'light'* and *'dark'*, i.e., all pixels that differ by $v(x,y)$ from their surrounding.



'light' and *'dark'* are calculated based on the corresponding mean gray value and the variable threshold.



For example, if *'dark'* is selected, all pixels where the 'Dark' curve is above the 'GrayValues' curve would be selected.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / int2 / int4 / uint2 / real
Input image.

▷ **`Region`** (output_object) . . . . . region(-array) ⇝ *object*
Segmented regions.

▷ **`MaskWidth`** (input_control) . . . . . extent.x ⇝ *integer*
Mask width for mean and deviation calculation.
Default: 15
Suggested values: `MaskWidth` ∈ {9, 11, 13, 15}
Restriction: MaskWidth >= 1

▷ **MaskHeight** (input_control) . . . . . extent.y ⇝ *integer*
Mask height for mean and deviation calculation.
Default: 15
Suggested values: MaskHeight ∈ {9, 11, 13, 15}
Restriction: MaskHeight >= 1

▷ **StdDevScale** (input_control) . . . . . number ⇝ *real* / integer
Factor for the standard deviation of the gray values.
Default: 0.2
Suggested values: StdDevScale ∈ {-0.2, -0.1, 0.1, 0.2}

▷ **AbsThreshold** (input_control) . . . . . number ⇝ *real* / integer
Minimum gray value difference from the mean.
Default: 2
Suggested values: AbsThreshold ∈ {-2, -1, 0, 1, 2}

▷ **LightDark** (input_control) . . . . . string ⇝ *string*
Threshold type.
Default: 'dark'
List of values: LightDark ∈ {'dark', 'light', 'equal', 'not_equal'}

Complexity

Let A be the area of the input region, then the runtime is $O(A)$.

Result

var_threshold returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Module

Foundation

zero_crossing (Image : RegionCrossing : :)

Extract zero crossings from an image.

zero_crossing returns the zero crossings of the input image as a region. A pixel is accepted as a zero crossing if its gray value (in Image) is zero, or if at least one of its neighbors of the 4-neighborhood has a different sign.

This operator is intended to be used after edge operators returning the second derivative of the image (e.g., laplace_of_gauss), which were possibly followed by a smoothing operator. In this case, the zero crossings are (candidates for) edges.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* int1 / int2 / int4 / real
Input image.

▷ **RegionCrossing** (output_object) . . . . . region(-array) ⇝ *object*
Zero crossings.

Result

`zero_crossing` usually returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.
- Automatically parallelized on domain level.

zero_crossing_sub_pix (Image : ZeroCrossings : :)

Extract zero crossings from an image with subpixel accuracy.

`zero_crossing_sub_pix` extracts the zero crossings of the input image `Image` with subpixel accuracy. The extracted zero crossings are returned as XLD-contours in `ZeroCrossings`. Thus, `zero_crossing_sub_pix` can be used as a sub-pixel precise edge extractor if the input image is a Laplace-filtered image (see `laplace`, `laplace_of_gauss`, `derivate_gauss`).

For the extraction, the input image is regarded as a surface, in which the gray values are interpolated bilinearly between the centers of the individual pixels. Consistent with the surface thus defined, zero crossing lines are extracted for each pixel and linked into topologically sound contours. This means that the zero crossing contours are correctly split at junction points. If the image contains extended areas of constant gray value 0, only the border of such areas is returned as zero crossings.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* int1 / int2 / int4 / real
Input image.

▷ **ZeroCrossings** (output_object) ..... xld_cont-array ⇝ *object*
Extracted zero crossings.

Example

```
* Detection zero crossings of the Laplacian-of-Gaussian
* of an aerial image
read_image(Image,'mreut')
derivate_gauss(Image,Laplace,3,'laplace')
zero_crossing_sub_pix(Laplace,ZeroCrossings)
dev_display(ZeroCrossings)

* Detection of edges, i.e, zero crossings of the Laplacian-of-Gaussian
* that have a large gradient magnitude, in an aerial image
read_image(Image,'mreut')
Sigma := 1.5
* Compensate the threshold for the fact that derivate_gauss(...,'gradient')
* calculates a Gaussian-smoothed gradient, in which the edge amplitudes
* are too small because of the Gaussian smoothing, to correspond to a true
* edge amplitude of 20.
```

```
Threshold := 20/(Sigma*sqrt(2*3.1415926))
derivate_gauss(Image,Gradient,Sigma,'gradient')
threshold(Gradient,Region,Threshold,255)
reduce_domain(Image,Region,ImageReduced)
derivate_gauss(ImageReduced,Laplace,Sigma,'laplace')
zero_crossing_sub_pix(Laplace,Edges)
dev_display(Edges)
```

Result

`zero_crossing_sub_pix` usually returns the value 2 (`H_MSG_TRUE`). If necessary, an exception is raised.

24.6 Topography

`critical_points_sub_pix` (`Image` : : `Filter`, `Sigma`, `Threshold` : `RowMin`, `ColumnMin`, `RowMax`, `ColumnMax`, `RowSaddle`, `ColumnSaddle`)

Subpixel precise detection of critical points in an image.

`critical_points_sub_pix` extracts critical points, i.e., local maxima, local minima, and saddle points, from the image `Image` with subpixel precision. To do so, in each point the input image is approximated by a quadratic polynomial in x and y and subsequently the polynomial is examined for extremal values and saddle points. The partial derivatives, which are necessary for setting up the polynomial, are calculated either with various Gaussian derivatives or using the facet model, depending on `Filter`. In the first case, `Sigma` determines the size of the Gaussian kernels, while in the second case, before being processed the input image is smoothed by a Gaussian whose size is determined by `Sigma`. Therefore, *'facet'* results in a faster extraction at the expense of slightly less accurate results. A point is accepted to be a critical point if the absolute values of both eigenvalues of the Hessian matrix are greater than `Threshold`. The eigenvalues correspond to the curvature of the gray value surface. If both eigenvalues are negative, the point is a local maximum, if both are positive, a local minimum, and if they have different signs, a saddle point.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **`Image`** (input_object) ..... singlechannelimage ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
Input image.

▷ **`Filter`** (input_control) ..... string ⇝ *string*
Method for the calculation of the partial derivatives.
Default: 'facet'
List of values: `Filter` ∈ {'facet', 'gauss'}

▷ **Sigma** (input_control) ..... real ⇝ *real*
Sigma of the Gaussian. If Filter is 'facet', Sigma may be 0.0 to avoid the smoothing of the input image.
Suggested values: Sigma ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
Restriction: Sigma >= 0.0

▷ **Threshold** (input_control) ..... real ⇝ *real*
Minimum absolute value of the eigenvalues of the Hessian matrix.
Default: 5.0
Suggested values: Threshold ∈ {2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0}
Restriction: Threshold >= 0.0

▷ **RowMin** (output_control) ..... point.y-array ⇝ *real*
Row coordinates of the detected minima.

▷ **ColumnMin** (output_control) ..... point.x-array ⇝ *real*
Column coordinates of the detected minima.

▷ **RowMax** (output_control) ..... point.y-array ⇝ *real*
Row coordinates of the detected maxima.

▷ **ColumnMax** (output_control) ..... point.x-array ⇝ *real*
Column coordinates of the detected maxima.

▷ **RowSaddle** (output_control) ..... point.y-array ⇝ *real*
Row coordinates of the detected saddle points.

▷ **ColumnSaddle** (output_control) ..... point.x-array ⇝ *real*
Column coordinates of the detected saddle points.

Result

critical_points_sub_pix returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during the execution. If the input is empty the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Successors

gen_cross_contour_xld, disp_cross

Alternatives

local_min_sub_pix, local_max_sub_pix, saddle_points_sub_pix

Module

Foundation

local_max (Image : LocalMaxima : :)

Detect all local maxima in an image.

local_max extracts all points from Image having a gray value larger than the gray value of all its neighbors and returns them in LocalMaxima. The neighborhood used can be set by set_system(::'neighborhood',<4/8>).

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Input image.

▷ **LocalMaxima** (output_object) ..... region(-array) ⇝ *object*
Extracted local maxima as a region.
Number of elements: LocalMaxima == Image

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  using namespace Halcon;
  if (argc != 2)
  {
    cout << "Usage : " << argv[0] << " <name of image>" << endl;
    return (-1);
  }

  HImage   image (argv[1]);
  HWindow  win;

  image.Display (win);

  HImage       cres = image.CornerResponse (5, 0.04);
  HRegionArray maxi = cres.LocalMax ();

  win.SetColored (12);
  maxi.Display (win);
  win.Click ();

  return (0);
}
```

Execution Information

local_max_sub_pix (Image : : Filter, Sigma, Threshold : Row, Column)

Subpixel precise detection of local maxima in an image.

local_max_sub_pix extracts local maxima from the image Image with subpixel precision. To do so, in each point the input image is approximated by a quadratic polynomial in x and y and subsequently the polynomial is examined for local maxima. The partial derivatives, which are necessary for setting up the polynomial, are calculated either with various Gaussian derivatives or using the facet model, depending on Filter. In the first case, Sigma determines the size of the Gaussian kernels, while in the second case, before being processed the input image is smoothed by a Gaussian whose size is determined by Sigma. Therefore, *'facet'* results in a faster extraction at the expense of slightly less accurate results. A point is accepted to be a local maximum if both eigenvalues of the Hessian matrix are smaller than -Threshold. The eigenvalues correspond to the curvature of the gray value surface.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
  Input image.
- ▷ **Filter** (input_control) ..... string ⇝ *string*
  Method for the calculation of the partial derivatives.
  Default: 'facet'
  List of values: Filter ∈ {'facet', 'gauss'}
- ▷ **Sigma** (input_control) ..... real ⇝ *real*
  Sigma of the Gaussian. If Filter is 'facet', Sigma may be 0.0 to avoid the smoothing of the input image.
  Suggested values: Sigma ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
  Restriction: Sigma >= 0.0
- ▷ **Threshold** (input_control) ..... real ⇝ *real*
  Minimum absolute value of the eigenvalues of the Hessian matrix.
  Default: 5.0
  Suggested values: Threshold ∈ {2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0}
  Restriction: Threshold >= 0.0
- ▷ **Row** (output_control) ..... point.y-array ⇝ *real*
  Row coordinates of the detected maxima.
- ▷ **Column** (output_control) ..... point.x-array ⇝ *real*
  Column coordinates of the detected maxima.

Result

local_max_sub_pix returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during the execution. If the input is empty the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised.

local_min (Image : LocalMinima : :)

Detect all local minima in an image.

local_min extracts all points from Image having a gray value smaller than the gray value of all its neighbors and returns them in LocalMinima. The neighborhood used can be set by set_system('neighborhood',<4/8>).

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Image to be processed.

▷ **LocalMinima** (output_object) ..... region(-array) ⇝ *object*
Extracted local minima as regions.
Number of elements: LocalMinima == Image

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])

Module

Foundation

lowlands (Image : Lowlands : :)

Detect all gray value lowlands.

lowlands extracts all points from Image with a gray value less or equal to the gray value of its neighbors (8-neighborhood) and returns them in Lowlands. Each lowland is returned as a separate region.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Image to be processed.

▷ **Lowlands** (output_object) ..... region-array ⇝ *object*
Extracted lowlands as regions (one region for each lowland).

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  if (argc != 2)
  {
    cout << "Usage : " << argv[0] << " <name of image>" << endl;
    return (-1);
  }

  HImage   image (argv[1]);
  HWindow  win;

  image.Display (win);

  HImage       cres = image.CornerResponse (5, 0.04);
  HRegionArray mins = cres.Lowlands ();

  win.SetColored (12);
  mins.Display (win);
  win.Click ();

  return (0);
}
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

Possible Successors

area_center, get_region_points, select_shape

Alternatives

lowlands_center, gray_skeleton, local_min

See also

monotony, topographic_sketch, corner_response, texture_laws

Module

Foundation

lowlands_center (Image : Lowlands : :)

Detect the centers of all gray value lowlands.

lowlands_center extracts all points from Image with a gray value less or equal to the gray value of its neighbors (8-neighborhood) and returns them in Lowlands. If more than one of these points are connected (lowland), their center of gravity is returned. Each lowland is returned as a separate region.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

Image to be processed.

▷ **Lowlands** (output_object) ..... region-array ⇝ *object*

Centers of gravity of the extracted lowlands as regions (one region for each lowland).

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  if (argc != 2)
  {
    cout << "Usage : " << argv[0] << " <name of image>" << endl;
    return (-1);
  }

  HImage   image (argv[1]);
  HWindow  win;

  image.Display (win);

  HImage       cres = image.CornerResponse (5, 0.04);
  HRegionArray mins = cres.LowlandsCenter ();

  win.SetColored (12);
  mins.Display (win);
  win.Click ();

  return (0);
}
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

plateaus (Image : Plateaus : :)

Detect all gray value plateaus.

plateaus extracts all points from Image with a gray value greater or equal to the gray value of its neighbors (8-neighborhood) and returns them in Plateaus. Each maximum is returned as a separate region.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real
Input image.

▷ **Plateaus** (output_object) ..... region-array ⇝ *object*
Extracted plateaus as regions (one region for each plateau).

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  if (argc != 2)
  {
    cout << "Usage : " << argv[0] << " <name of image>" << endl;
    return (-1);
  }

  HImage   image (argv[1]);
  HWindow  win;

  image.Display (win);

  HImage       cres = image.CornerResponse (5, 0.04);
  HRegionArray maxi = cres.Plateaus ();
```

```
  win.SetColored (12);
  maxi.Display (win);
  win.Click ();

  return (0);
}
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

plateaus_center (Image : Plateaus : :)

Detect the centers of all gray value plateaus.

plateaus_center extracts all points from Image with a gray value greater or equal to the gray value of its neighbors (8-neighborhood) and returns them in Plateaus. If more than one of these points are connected (plateau), their center of gravity is returned. Each plateau center is returned as a separate region.

Parameters

▷ **Image** (input_object) ..... singlechannelimage(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real

Input image.

▷ **Plateaus** (output_object) ..... region-array ⇝ *object*

Centers of gravity of the extracted plateaus as regions (one region for each plateau).

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;

int main (int argc, char *argv[])
{
  if (argc != 2)
  {
    cout << "Usage : " << argv[0] << " <name of image>" << endl;
    return (-1);
  }
```

```
  HImage   image (argv[1]);
  HWindow  win;

  image.Display (win);

  HImage       cres = image.CornerResponse (5, 0.04);
  HRegionArray maxi = cres.PlateausCenter ();

  win.SetColored (12);
  maxi.Display (win);
  win.Click ();

  return (0);
}
```

Execution Information

pouring (Image : Regions : Mode, MinGray, MaxGray :)

Segment an image by "pouring water" over it.

pouring regards the input image as a "mountain range." Larger gray values correspond to mountain peaks, while smaller gray values correspond to valley bottoms. pouring segments the input image in several steps. First, the local maxima are extracted, i.e., pixels which either alone or in the form of an extended plateau have larger gray values than their immediate neighbors (in 4-neighborhood). In the next step, the maxima thus found are the starting points for an expansion until "valley bottoms" are reached. The expansion is done as long as there are chains of pixels in which the gray value becomes smaller (like water running downhill from the maxima in all directions). Again, the 4-neighborhood is used, but with a weaker condition (smaller or equal). This means that points at valley bottoms may belong to more than one maximum. These areas are at first not assigned to a region, but rather are split among all competing segments in the last step. The split is done by a uniform expansion of all involved segments, until all ambiguous pixels were assigned. The parameter Mode determines which steps are executed. The following values are possible:

'all' This is the normal mode of operation. All steps of the segmentation are performed. The regions are assigned to maxima, and overlapping regions are split.

'maxima' The segmentation only extracts the local maxima of the input image. No corresponding regions are extracted.

'regions' The segmentation extracts the local maxima of the input image and the corresponding regions, which are uniquely determined. Areas that were assigned to more than one maximum are not split.

In order to prevent the algorithm from splitting a uniform background that is different from the rest of the image, the parameters MinGray and MaxGray determine gray value thresholds for regions in the image that should be regarded as background. All parts of the image having a gray value smaller than MinGray or larger than MaxGray are disregarded for the extraction of the maxima as well as for the assignment of regions. For a complete segmentation of the image, MinGray = 0 and MaxGray = 255 should be selected. MinGray < MaxGray must be observed.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object : byte*
  Input image.
- ▷ **Regions** (output_object) ..... region-array ⇝ *object*
  Segmented regions.
- ▷ **Mode** (input_control) ..... string ⇝ *string*
  Mode of operation.
  Default: 'all'
  List of values: Mode ∈ {'all', 'maxima', 'regions'}
- ▷ **MinGray** (input_control) ..... integer ⇝ *integer*
  All gray values smaller than this threshold are disregarded.
  Default: 0
  Suggested values: MinGray ∈ {0, 10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110}
  Value range: 0 ≤ MinGray ≤ 254 (lin)
  Minimum increment: 1
  Recommended increment: 10
- ▷ **MaxGray** (input_control) ..... integer ⇝ *integer*
  All gray values larger than this threshold are disregarded.
  Default: 255
  Suggested values: MaxGray ∈ {100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, 210, 220, 230, 240, 250, 255}
  Value range: 1 ≤ MaxGray ≤ 255 (lin)
  Minimum increment: 1
  Recommended increment: 10
  Restriction: MaxGray > MinGray

Example

```
* Segment a filtered image
read_image(Image,'particle')
mean_image(Image,Mean,11,11)
pouring(Mean,Seg,'all',0,255)
dev_display(Mean)
dev_set_colored(12)
dev_display(Seg)

* Segment an image while masking the dark background
read_image(Image,'particle')
mean_image(Image,ImageMean,15,15)
pouring(Mean,Seg,'all',90,255)
dev_display(Mean)
dev_set_colored(12)
dev_display(Seg)
```

Complexity

Let N be the number of pixels in the input image and M be the number of found segments, where the enclosing rectangle of the segment i contains m_i pixels. Furthermore, let K_i be the number of chords in segment i. Then the runtime complexity is

$$O(3 * N + sum_M(3 * m_i) + sum_M(K_i)) \ .$$

Result

pouring usually returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: mutually exclusive (runs in parallel with other non-exclusive operators, but not with itself).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

binomial_filter, gauss_filter, smooth_image, mean_image

saddle_points_sub_pix (Image : : Filter, Sigma, Threshold : Row, Column)

Subpixel precise detection of saddle points in an image.

saddle_points_sub_pix extracts saddle points from the image Image with subpixel precision, i.e., points where along one direction the image intensity is minimal while at the same time along a different direction the image intensity is maximal. To do so, in each point the input image is approximated by a quadratic polynomial in x and y and subsequently the polynomial is examined for saddle points. The partial derivatives, which are necessary for setting up the polynomial, are calculated either with various Gaussian derivatives or using the facet model, depending on Filter. In the first case, Sigma determines the size of the Gaussian kernels, while in the second case, before being processed the input image is smoothed by a Gaussian whose size is determined by Sigma. Therefore, *'facet'* results in a faster extraction at the expense of slightly less accurate results. A point is accepted to be a saddle point if the absolute values of both eigenvalues of the Hessian matrix are greater than Threshold but their signs differ. The eigenvalues correspond to the curvature of the gray value surface.

saddle_points_sub_pix is especially useful for the detection of corners, where fields of different intensity join together like the black and white fields of a chess board. Their high contrast and shape facilitate the location and the determination of the precise position of such corners.

Attention

Note that filter operators may return unexpected results if an image with a reduced domain is used as input. Please refer to the chapter Filters.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / int1 / int2 / uint2 / int4 / real
Input image.

▷ **Filter** (input_control) ..... string ⇝ *string*
Method for the calculation of the partial derivatives.
Default: 'facet'
List of values: Filter ∈ {'facet', 'gauss'}

▷ **Sigma** (input_control) ..... real ⇝ *real*
Sigma of the Gaussian. If Filter is 'facet', Sigma may be 0.0 to avoid the smoothing of the input image.
Suggested values: Sigma ∈ {0.7, 0.8, 0.9, 1.0, 1.2, 1.5, 2.0, 3.0}
Restriction: Sigma >= 0.0

▷ **Threshold** (input_control) ..... real ⇝ *real*
Minimum absolute value of the eigenvalues of the Hessian matrix.
Default: 5.0
Suggested values: Threshold ∈ {2.0, 3.0, 4.0, 5.0, 6.0, 7.0, 8.0}
Restriction: Threshold >= 0.0

▷ **Row** (output_control) ..... point.y-array ⇝ *real*
Row coordinates of the detected saddle points.

▷ **Column** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinates of the detected saddle points.

Result

`saddle_points_sub_pix` returns `2` (`H_MSG_TRUE`) if all parameters are correct and no error occurs during the execution. If the input is empty the behavior can be set via `set_system ('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Successors

`gen_cross_contour_xld`, `disp_cross`

Alternatives

`critical_points_sub_pix`, `local_min_sub_pix`, `local_max_sub_pix`

Module

Foundation

watersheds (Image : Basins, Watersheds : :)

Extract watersheds and basins from an image.

`watersheds` segments an image based on the topology of the gray values. The image is interpreted as a "mountain range." Higher gray values correspond to "mountains," while lower gray values correspond to "valleys." In the resulting mountain range watersheds are extracted. These correspond to the bright ridges between dark basins. On output, the parameter `Basins` contains these basins, while `Watersheds` contains the watersheds, which are at most one pixel wide. `Watersheds` always is a single region per input image, while `Basins` contains a separate region for each basin.

It is advisable to apply a smoothing operator (e.g., `binomial_filter` or `gauss_filter`) to the input image before calling `watersheds` in order to reduce the number of output regions. A more sophisticated way to reduce the number of output regions is to merge neighboring basins based on a threshold criterion by using `watersheds_threshold` instead (for more details please refer to the documentation of `watersheds_threshold`).

Attention

If the image contains many fine structures or is noisy, many output regions result, and thus the runtime increases considerably.

Parameters

▷ **Image** (input_object) . . . . . singlechannelimage(-array) ⇝ *object :* byte / uint2 / real
Input image.

▷ **Basins** (output_object) . . . . . region-array ⇝ *object*
Segmented basins.

▷ **Watersheds** (output_object) . . . . . region(-array) ⇝ *object*
Watersheds between the basins.

Example

```
#include "HIOStream.h"
#if !defined(USE_IOSTREAM_H)
using namespace std;
#endif
#include "HalconCpp.h"
using namespace Halcon;
```

```
int main (int argc, char *argv[])
{
  HImage   image (argv[1]), gauss;
  HWindow  win;

  cout << "Gauss of original " << endl;
  gauss  = image.GaussImage (9);
  image.Display (win);

  HRegion        watersheds;
  HRegionArray   basins = gauss.Watersheds (&watersheds);

  win.SetColored (12);
  basins.Display (win);
  win.Click ();

  return (0);
}
```

Result

`watersheds` always returns `2` (`H_MSG_TRUE`). The behavior with respect to the input images and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with `set_system`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

`binomial_filter`, `gauss_filter`, `smooth_image`, `invert_image`

Possible Successors

`expand_region`, `select_shape`, `reduce_domain`, `opening`

Alternatives

`watersheds_threshold`, `pouring`, `watersheds_marker`

Foundation

watersheds_marker (Image, Markers : Basins : :)

Extract watersheds and combine basins based on markers.

`watersheds_marker` segments an image based on the topology of the gray values and returns the resulting regions in `Basins`. The image is interpreted as a "mountain range". Higher gray values correspond to "mountains", while lower gray values correspond to "valleys". The image, interpreted in this particular way, is flooded, starting with the regions defined in `Markers`, until the entire image is filled. Thus, each pixel is assigned to the marker to which it has the path with the lowest maximum height. If this is the case for multiple markers, the pixel is assigned to either of them.

The resulting basins, one per input region in `Markers`, are returned in `Basins`. Note that some of those regions might be empty. This can happen if, for example, two marker regions are in the same watershed basin. If a pixel is contained in multiple marker regions, only the last marker region is used as seed for that pixel. It is advised that the marker regions do not overlap.

The flooding is performed only for the domain of Image. Parts of the marker regions outside the domain of Image are ignored.

It is advisable to apply a smoothing operator (e.g., binomial_filter or gauss_filter) to the input image before calling watersheds_marker. To segment an image, it is also often reasonable to run an edge extractor (such as edges_image or edges_color) on the image, and pass the resulting amplitude image to watersheds_marker.

Attention

If the image contains many fine structures or is noisy, many watershed regions need to be processed internally, and thus the runtime increases considerably.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
  Input image.
- ▷ **Markers** (input_object) ..... region-array ⇝ *object*
  Initial markers from which to flood the image.
- ▷ **Basins** (output_object) ..... region-array ⇝ *object*
  Basins for all markers.

Example

```
read_image (Image, 'printer_chip/printer_chip_01')
edges_image (Image, ImaAmp, ImaDir, 'canny', 1, 'nms', 20, 40)

* Compute background marker
full_domain (ImaAmp, ImageFull)
erosion_circle (Image, RegionErosion, 2.5)
difference (Image, RegionErosion, Boundary)

* Compute foreground markers
threshold (Image, Region, 200, 255)
erosion_circle (Region, RegionErosion1, 7.5)
connection (RegionErosion1, ConnectedRegions)
select_shape (ConnectedRegions, SelectedRegions, 'area', 'and', 1500, 99999)

* Apply marker-based watersheds
concat_obj (Boundary, SelectedRegions, MarkerRegions)
watersheds_marker (ImageFull, MarkerRegions, Basins)

* Display results
dev_display (Image)
dev_set_color (['#FF000055', '#00FF0055', '#0000FF55', '#FF00FF55', \
               '#FFFF0055', '#00FFFF55', '#80FF0055', '#0080FF55'])
dev_display (MarkerRegions)
dev_set_draw ('fill')
dev_display (Basins)
```

Result

If all input parameters are valid, watersheds_marker returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

binomial_filter, gauss_filter, smooth_image, invert_image, edges_image

Possible Successors

expand_region, select_shape, reduce_domain, opening

Alternatives

watersheds, pouring, watersheds_threshold

Module

Foundation

watersheds_threshold (Image : Basins : Threshold :)

Extract watershed basins from an image using a threshold.

The operator watersheds_threshold segments regions (basins) that are separated from each other by a watershed that has a height of at least Threshold.

In the first step, watersheds_threshold computes the watersheds without applying a threshold, resulting in the same basins that would be obtained when calling watersheds (for more details please refer to the description of watersheds). In the second step, the basins are successively merged if they are separated by a watershed that is smaller than Threshold. Let B_1 and B_2 be the minimum gray values of two neighboring basins and W the minimum gray value of the watershed that separates the two basins. The watershed is eliminated and the two basins are merged if

$$\max\{W - B_1, W - B_2\} < \texttt{Threshold}.$$

The thus obtained basins are returned in Basins.

If Threshold is set to *0*, watersheds_threshold is comparable to watersheds except that no watersheds but only expanded basins are returned. If Threshold is set to the maximum gray value range of Image then no two basins are separated by a watershed exceeding Threshold, and hence, Basins will contain only one region.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
  Image to be segmented.
- ▷ **Basins** (output_object) ..... region-array ⇝ *object*
  Segments found (dark basins).
- ▷ **Threshold** (input_control) ..... number ⇝ *integer* / real
  Threshold for the watersheds.
  Default: 10
  Suggested values: Threshold ∈ {0, 5, 10, 20, 30, 50}
  Restriction: Threshold >= 0

Result

watersheds always returns 2 (H_MSG_TRUE). The behavior with respect to the input image and output regions can be determined by setting the values of the flags *'no_object_result'*, *'empty_region_result'*, and *'store_empty_region'* with set_system. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

binomial_filter, gauss_filter, smooth_image, invert_image

Possible Successors

expand_region, select_shape, reduce_domain, opening

Alternatives

Chapter 25

System

25.1 Compute Devices

activate_compute_device (: : DeviceHandle :)

Activate a compute device.

activate_compute_device activates the compute device DeviceHandle for the current HALCON thread. All subsequent HALCON operators called in this thread are executed on DeviceHandle if they provide an implementation (see get_operator_info) for this device. Use deactivate_compute_device to deactivate DeviceHandle.

Currently, only one compute device can be active for a HALCON thread. If a different device is active before activate_compute_device is called, this device is deactivated automatically.

Parameters

▷ **DeviceHandle** (input_control) ..... compute_device ⇝ *handle*
Compute device handle.

Example

```
open_compute_device (DeviceIdentifier, DeviceHandle)
read_image (Image, 'rings_and_nuts')
*
* Gaussian convolution on a compute device
activate_compute_device (DeviceHandle)
derivate_gauss (Image, DerivGauss, 5, 'none')
*
* Gaussian convolution on the CPU
deactivate_compute_device (DeviceHandle)
derivate_gauss (Image, DerivGauss, 5, 'none')
```

Result

activate_compute_device returns the value 2 (H_MSG_TRUE) if DeviceHandle is valid. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Possible Predecessors

deactivate_compute_device, deactivate_all_compute_devices

Module

Foundation

deactivate_all_compute_devices (: : :)

Deactivate all compute devices.

deactivate_all_compute_devices deactivates all compute devices for the current HALCON thread.

Result

deactivate_all_compute_devices returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

activate_compute_device, deactivate_compute_device

Module

Foundation

deactivate_compute_device (: : DeviceHandle :)

Deactivate a compute device.

deactivate_compute_device deactivates the compute device DeviceHandle for the current HALCON thread. Use activate_compute_device to reactivate the device.

Parameters

▷ **DeviceHandle** (input_control) ..... compute_device ⇝ *handle*
Compute device handle.

Result

deactivate_compute_device returns the value 2 (H_MSG_TRUE) if DeviceHandle is valid. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

get_compute_device_info (: : DeviceIdentifier, InfoName : Info)

Get information on a compute device.

The operator get_compute_device_info returns information on a compute device. In contrast to get_compute_device_param, only static information is queried, so that the device does not have to be opened (see open_compute_device) and activated (see activate_compute_device).

The following information can be queried:

'vendor' Vendor of the compute device.

'name' Name of the compute device.

'platform_version' Version of the compute device platform. E.g., OpenCL version in the case of OpenCL devices.

'driver_version' Version of the device driver.

'extensions' Supported OpenCL extensions.

'image_support' *'true'* if the device supports image objects.

'image2d_max_width' Maximum width of OpenCL image objects.

'image2d_max_height' Maximum height of OpenCL image objects.

'max_mem_alloc_size' Maximum size (in bytes) of an OpenCL memory block.

Parameters

▷ **DeviceIdentifier** (input_control) ..... integer ⇝ *integer*
Compute device handle.

▷ **InfoName** (input_control) ..... string ⇝ *string*
Name of Information to query.
Default: 'name'
List of values: InfoName ∈ {'driver_version', 'extensions', 'image_support', 'image2d_max_width', 'image2d_max_height', 'max_mem_alloc_size', 'name', 'platform_version', 'vendor'}

▷ **Info** (output_control) ..... string(-array) ⇝ *string* / integer / real
Returned information.

Result

The operator get_compute_device_info returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

query_available_compute_devices

Possible Successors

activate_compute_device

Module

Foundation

get_compute_device_param (: : DeviceHandle, GenParamName : GenParamValue)

Query compute device parameters.

get_compute_device_param returns parameters of the compute device DeviceHandle for the current HALCON thread in GenParamValue.

The following parameters can be queried (for more information see set_compute_device_param) by setting them for GenParamName:

'alloc_pinned' If *'true'*, the output image matrices of all operators are created in page locked (so called 'pinned') memory.

'asynchronous_execution' If *'true'*, operators executed on the compute device do not wait for the device computations to finish but return after initiation the computations.

'buffer_cache_capacity' Maximum size (in bytes) of the compute device buffer cache.

'buffer_cache_used' Current size (in bytes) of the compute device buffer cache.

'image_cache_capacity' Maximum size (in bytes) of the compute device image cache.

'image_cache_used' Current size (in bytes) of the compute device image cache.

'pinned_mem_cache_capacity' Maximum size (in bytes) of the page locked (pinned) memory cache.

'pinned_mem_cache_used' Current size (in bytes) of the page locked (pinned) memory cache.

Parameters

▷ **DeviceHandle** (input_control) . . . . . compute_device ⇝ *handle*
Compute device handle.

▷ **GenParamName** (input_control) . . . . . string ⇝ *string*
Name of the parameter to query.
Default: 'buffer_cache_capacity'
List of values: GenParamName ∈ {'alloc_pinned', 'asynchronous_execution', 'buffer_cache_capacity', 'buffer_cache_used', 'image_cache_capacity', 'image_cache_used', 'pinned_mem_cache_capacity', 'pinned_mem_cache_used'}

▷ **GenParamValue** (output_control) . . . . . string(-array) ⇝ *string* / integer / real
Value of the parameter.

Result

The operator get_compute_device_param returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Possible Predecessors

activate_compute_device

set_compute_device_param, get_compute_device_info

Module

Foundation

init_compute_device (: : DeviceHandle, Operators :)

Initialize a compute device.

init_compute_device initializes a compute device and prepares a list of operators given in Operators for the execution on this device. Further the device is activated for the current thread. If init_compute_device is not called or operators other than those in Operators are used on the device, the initialization is performed on demand.

Use get_operator_info to test if an operator qualifies for execution on the compute device.

Attention

Be aware that the execution time of init_compute_device depends on the number of Operators and may last up to several seconds.

Parameters

▷ **DeviceHandle** (input_control) . . . . . compute_device ⇝ *handle*
Compute device handle.

▷ **Operators** (input_control) . . . . . string-array ⇝ *string*
List of operators to prepare.
Default: 'all'
List of values: Operators ∈ {'all', 'derivate_gauss', 'sobel_amp'}

Result

The operator init_compute_device returns the value 2 (H_MSG_TRUE) if the initialization was successful. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Possible Predecessors

query_available_compute_devices, open_compute_device

Possible Successors

activate_compute_device

Module

Foundation

open_compute_device (: : DeviceIdentifier : DeviceHandle)

Open a compute device.

open_compute_device opens the compute device referenced by DeviceIdentifier and returns DeviceHandle. Enable computation on DeviceHandle via activate_compute_device.

DeviceIdentifier must be obtained by query_available_compute_devices.

Parameters

▷ **DeviceIdentifier** (input_control) . . . . . integer ⇝ *integer*
Compute device Identifier.

▷ **DeviceHandle** (output_control) . . . . . compute_device ⇝ *handle*
Compute device handle.

Result

open_compute_device returns the value 2 (H_MSG_TRUE) if DeviceIdentifier is valid. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

query_available_compute_devices

Possible Successors

activate_compute_device, init_compute_device

Module

Foundation

query_available_compute_devices (: : : DeviceIdentifier)

Get the list of available compute devices.

Returns the list of available compute devices. Use get_compute_device_info to query information on a specific device. Use open_compute_device to open a device in HALCON.

At present, HALCON only supports OpenCL compatible GPUs supporting the OpenCL extension cl_khr_byte_addressable_store and image objects. If you are not sure whether a certain device is supported, please refer to the manufacturer.

Be aware that currently it is not possible to use OpenCL via the Windows Remote Desktop, because Windows Remote Desktop does not allow access to the graphics driver. You may use a VNC solution to use OpenCL on a remote computer. Of course you can use OpenCL via ssh on a Linux machine.

It is recommended to install the latest graphics drivers available for your GPU. To access the GPU on a Linux system you should be member of the 'video' group.

Parameters

▷ **DeviceIdentifier** (output_control) ..... integer-array ⇝ *integer*
List of available compute devices.

Example

```
query_available_compute_devices (DeviceIdentifiers)
for Index := 0 to |DeviceIdentifiers|-1 by 1
  get_compute_device_info (DeviceIdentifiers[Index], 'name', DeviceName)
  get_compute_device_info (DeviceIdentifiers[Index], 'vendor', DeviceVendor)
  if (DeviceVendor == 'NVIDIA Corporation' and \
    DeviceName == 'GeForce 8800 Ultra')
    open_compute_device (DeviceIdentifiers[Index], DeviceHandle)
    break
  endif
endfor
*
init_compute_device (DeviceHandle, 'derivate_gauss')
read_image (Image, 'rings_and_nuts')
*
* Gaussian convolution on a compute device
activate_compute_device (DeviceHandle)
derivate_gauss (Image, DerivGauss, 5, 'none')
*
* Gaussian convolution on the CPU
deactivate_compute_device (DeviceHandle)
derivate_gauss (Image, DerivGauss, 5, 'none')
```

Result

query_available_compute_devices returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: mutually exclusive (runs in parallel with other non-exclusive operators, but not with itself).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_compute_device_info, open_compute_device

Module

Foundation

release_all_compute_devices (: : :)

Close all compute devices.

release_all_compute_devices must not be used in HDevelop!

release_all_compute_devices closes all compute devices for the current HALCON thread and frees all associated resources. release_all_compute_devices is solely for the purpose of freeing all device related resources before unloading the HALCON library, if the library was loaded using a mechanism like LoadLibrary or dlopen. In all other cases you must not use release_all_compute_devices.

Result

release_all_compute_devices returns the value 2 (H_MSG_TRUE) if all devices were closed successfully. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_compute_device_param (: : DeviceHandle, GenParamName, GenParamValue :)

Set parameters of an compute device.

set_compute_device_param sets parameters of the compute device DeviceHandle for the current HALCON thread.

The following parameters can be set:

'alloc_pinned' If *'true'*, the output image matrices of all operators (executed on the compute device or not) called in the current HALCON thread are created in page locked (so called 'pinned') memory. This accelerates the transfer between host and device memory. However, too excessive usage of page locked memory may have a negative impact on overall system performance. You should activate page locked memory allocation if the output image of of the next operator call is to be transferred to the device. Page locked memory allocation should be deactivated for all operator calls whose output images are not required on the compute device (see example).

List of values: *'true'*, *'false'*.

Default: *'true'*.

'asynchronous_execution' If *'true'*, operators executed on the compute device do not wait for the device computations to finish but return after initiating the computations. All device computations are synchronized as soon as the output of a compute device operation is used on the CPU (e.g., by disp_image).

List of values: *'true'*, *'false'*.

Default: *'true'*.

'buffer_cache_capacity' Maximum size (in bytes) of the compute device buffer cache.

Default: 1/3 of the available device memory

'image_cache_capacity' Maximum size (in bytes) of the compute device image cache.

Default: 1/3 of the available device memory

'pinned_mem_cache_capacity' Maximum size (in bytes) of the page locked (pinned) memory cache.

Default: *32000000* (32MByte)

Parameters

▷ **DeviceHandle** (input_control) . . . . . compute_device ⇝ *handle*
Compute device handle.

▷ **GenParamName** (input_control) . . . . . string ⇝ *string*
Name of the parameter to set.
Default: 'buffer_cache_capacity'
List of values: GenParamName ∈ {'alloc_pinned', 'asynchronous_execution', 'buffer_cache_capacity', 'image_cache_capacity', 'pinned_mem_cache_capacity'}

▷ **GenParamValue** (input_control) . . . . . string(-array) ⇝ *string* / integer / real
New parameter value.

Example

```
activate_compute_device (DeviceHandle)
read_image (Image, 'fuse')
set_compute_device_param (DeviceHandle, 'alloc_pinned', 'true')
* filter on compute device, output image is page locked
derivate_gauss (Image, DerivGauss, 3, 'gradient')
* filter result on the CPU, output image should not be page locked
set_compute_device_param (DeviceHandle, 'alloc_pinned', 'false')
median_image (DerivGauss, ImageMedian, 'circle', 1, 'mirrored')
```

Result

The operator `set_compute_device_param` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Module

Foundation

25.2 Database

`count_relation` (: : `RelationName` : `NumOfTuples`)

Number of entries in the HALCON database.

`count_relation` returns the number of entries `NumOfTuples` in the relation `RelationName` of the HALCON database since the database was switched on with the `set_system` parameter *'database'*. If the database is disabled, `NumOfTuples` is 0 and in addition a warning is raised if *'do_low_error'* is set with `set_system`. The state of the database can be queried by the parameter *'database'* of `get_system`.

The HALCON database is organized in five tables called relations. The entries in this relations are called tuples (not to mix up with HALCON tuples naming object arrays). If enabled, the HALCON database contains the basic relations for region data, image matrices, and XLDs, as well as the container relations for HALCON objects and HALCON tuples (i.e., object arrays). The HALCON objects region and image are constructed from elements from the region-data relations and the image-matrix relations. A region consists of a pointer to a tuple in the region-data relation. An image consists of a pointer to a tuple in the region-data relation and additionally of one or more pointers to tuples in the matrix relation. Multi-channel images have multiple matrix pointers.

Both regions and images are called objects. A region can be considered as the special case of an iconic object having no image matrices. For reasons of an efficient memory management, the tuples of the region-data relation and the image-matrix relation will be used by different objects together. Therefore there may be more images than image matrices. Only the three low-level relations *'image'*, *'region'*, and *'XLD'* are of relevance to the memory consumption. Image objects (regions as well as images) consist only of references on region and matrix data and therefore only need a couple of bytes of memory.

Possible values for `RelationName`:

'image': Image matrices. One matrix may be the component of multiple images (no redundant storage).

'region': Regions and image domains. One region may be the component of multiple image objects (no redundant storage).

'XLD': eXtended Line Description: Contours, polygons, parallels, lines, etc. XLD data types don't have gray values and are stored with subpixel accuracy.

'object': Iconic objects. Composed of a region (see *'region'*) and optionally image matrices (see *'image'*).

'tuple': In the compact mode, tuples of iconic objects are stored as a surrogate in this relation. Instead of working with the individual object keys, only this tuple key is used. It depends on the host language, whether the objects are passed individually (e.g., C++) or as tuples (e.g., C).

Certain database objects will be created already by the operator reset_obj_db and therefore have to be available all the time (the undefined gray value component, the objects 'full' (FULL_REGION in HALCON/C) and 'empty' (EMPTY_REGION in HALCON/C) as well as the herein included empty and full region). By calling get_channel_info, the operator therefore appears correspondingly also as 'creator' of the full and empty region. The operator can be used for example to check the completeness of the clear_obj operation.

Attention

Collecting database information is not thread-safe when passing iconic objects between threads, meaning when deleting objects in a different thread than generating them.

Parameters

▷ **RelationName** (input_control) ..... string ⇝ *string*
Relation of interest of the HALCON database.
Default: 'object'
List of values: RelationName ∈ {'image', 'region', 'XLD', 'object', 'tuple'}

▷ **NumOfTuples** (output_control) ..... integer ⇝ *integer*
Number of tuples in the relation.

Example

```
* Close the graphics window in order to close the graphics stack,
* which would influence the measurement.
dev_close_window ()
* Enable the measurement.
set_system ('database','true')
*
count_relation ('image', I1)
count_relation ('region', R1)
count_relation ('XLD', X1)
count_relation ('object', O1)
count_relation ('tuple', T1)
*
* Result:
* I1 = 0
* R1 = 0
* X1 = 0
* O1 = 0
* T1 = 0
*
read_image (Patras, 'patras')
*
count_relation ('image', I2)
count_relation ('region', R2)
count_relation ('XLD', X2)
count_relation ('object', O2)
count_relation ('tuple', T2)
*
* I2 = 3  (three channels of the rgb image 'patras')
* R2 = 1  (the image domain of the image 'patras')
* X2 = 0  (no XLD data)
* O2 = 1  (the iconic object holding the channels and the domain)
* T2 = 0  (no empty object or object array )
```

Result

If the parameter is correct, the operator count_relation returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_modules (: : : UsedModules, ModuleKey)

Query of used modules and the module key.

get_modules returns the modules UsedModules that were used up to this point in the HALCON session. Based on the used modules, a key is generated that is returned in ModuleKey. Each operator belongs to exactly one module. The information which modules where used can be reset by calling set_system with the *'reset_used_modules'* parameter.

Parameters

▷ **UsedModules** (output_control) . . . . . string-array ⇝ *string*
Names of used modules.

▷ **ModuleKey** (output_control) . . . . . integer ⇝ *integer*
Key for license manager.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

reset_obj_db (: : DefaultImageWidth, DefaultImageHeight, DefaultChannels :)

Reset the HALCON system for iconic objects.

The operator reset_obj_db reinitializes the HALCON system for iconic objects (which was set up during the HALCON initialization process). With this operator the five relations (gray value objects, region objects, XLD objects, image objects and object tuples) which are used for image processing with HALCON will be installed (see also count_relation). In case the HALCON database was enabled (set_system ('database','true')) and the relations already exist, all data entries listed in the relations will get deallocated!

The parameters DefaultImageWidth and DefaultImageHeight provide the initial values for the global maximum image size. If the first created object is an image, (e.g., read_image), the set values will only be overruled, if they are smaller than the size of the created object. If on the other hand the first object to be created is a region, the values will only be adjusted in case the new image is larger than the set values. This is not only the case for the first image which is created or read: the global image size will always be enlarged, if larger images are created.

The global image size is of consequence for the opening of windows (open_window) and the memory estimate and clipping of regions. Whenever the clip mode is activated, regions will be clipped according to the global

image size (set_system('clip_region','true')). This can lead to problems if images of various sizes are used. In this case only the fact that a region is smaller or of the same size as the largest image can be guaranteed.

The parameter DefaultChannels returns the most frequent number of channels of an image object. This value can be set to 0 if for the most part regions are used. If more channels than those having been set at the initialization are necessary for one image, the number will be enlarged dynamically for this image. If less channels than those having been set at the initialization are necessary for the image, the superfluous channels will be set as undefined. For the user this will seem as if they were non existent, however, memory is allocated unnecessarily.

The parameter values can be queried using the operator get_system.

Attention

If the operator reset_obj_db is not called at the beginning of a HALCON session, HALCON will be initialized automatically by the operator reset_obj_db(128,128,0) causing side effects on region clipping, accordingly. When the database was enabled by the parameter value *'database'* of the operator set_system, calling reset_obj_db will deallocate all iconic objects.

Parameters

▷ **DefaultImageWidth** (input_control) ..... integer ⇝ *integer*
Default image width (in pixels).
Default: 128
Suggested values: DefaultImageWidth ∈ {64, 128, 320, 640, 800, 1280}

▷ **DefaultImageHeight** (input_control) ..... integer ⇝ *integer*
Default image height (in pixels).
Default: 128
Suggested values: DefaultImageHeight ∈ {64, 128, 240, 480, 600, 1024}

▷ **DefaultChannels** (input_control) ..... integer ⇝ *integer*
Usual number of channels.
Default: 0
Suggested values: DefaultChannels ∈ {0, 1, 2, 3, 4, 5, 6, 7}

Result

The operator reset_obj_db returns the value 2 (H_MSG_TRUE) if the parameter values are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

25.3 Encrypted Item

read_encrypted_item (: : FileName : EncryptedItemHandle)

Read an encrypted item from a file.

The operator read_encrypted_item reads the file FileName and creates a new encrypted item in EncryptedItemHandle that is an identical copy of the saved item. The file FileName must have been created by the operator write_encrypted_item.

The default HALCON file extension for encrypted item is '.henc'.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
Name of the file.
Default: 'encrypted_item.henc'
File extension: .bin

▷ **EncryptedItemHandle** (output_control) . . . . . encrypted_item ⇝ *handle*
Handle of the encrypted item.

Result

The operator read_encrypted_item returns the value 2 (H_MSG_TRUE) if the named file was found and correctly read. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

decrypt_serialized_item

write_encrypted_item, encrypt_serialized_item

Module

Foundation

write_encrypted_item (: : EncryptedItemHandle, FileName :)

Write an encrypted item to a file.

The operator write_encrypted_item writes the encrypted item EncryptedItemHandle to the file FileName. The item can be read again with read_encrypted_item.

The default HALCON file extension for encrypted item is '.henc'.

Parameters

▷ **EncryptedItemHandle** (input_control) . . . . . encrypted_item ⇝ *handle*
Handle of the encrypted item.

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of the file.
Default: 'encrypted_item.henc'
File extension: .bin

Result

The operator write_encrypted_item returns the value 2 (H_MSG_TRUE) if the passed handle is valid and if the encrypted item can be written into the named file. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

25.4 Error Handling

get_check (: : : Check)

State of the HALCON control modes.

Executing the operator get_check the user can inquire what kind of control modes are currently activated and which are not. Check gives the tuple containing the names of the control modes (see also set_check) which are preceded by a tilde (~, e.g., '~data'), if the corresponding control is deactivated.

Parameters

▷ **Check** (output_control) ..... string-array ⇝ *string*
Tuple of the currently activated control modes.

Result

get_check always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

set_check

See also

set_check

Module

Foundation

get_error_text (: : ErrorCode : ErrorMessage)

Inquiry after the error text of a HALCON error number.

The operator get_error_text returns the error message for the corresponding HALCON error code. This is indeed the same text which will be given during an exception. The operator get_error_text is especially useful if the error treatment is programmed by the users themselves (see also set_check('~give_error')).

Attention

Unknown error codes will trigger a standard message.

Parameters

▷ **ErrorCode** (input_control) ..... integer ⇝ *integer*
HALCON error code.
Restriction: 1 <= ErrorCode && ErrorCode <= 36000

▷ **ErrorMessage** (output_control) ..... string ⇝ *string*
Corresponding error message.

Example

```
Herror   err;
char       message[MAX_STRING];

set_check("~give_error");
err = send_region(region,socket);
set_check("give_error");
if (err != H_MSG_TRUE) {
```

```
get_error_text((Hlong)err,message);
  fprintf(stderr,"my error message: %s\n",message);
  exit(1);
}
```

Result

The operator get_error_text returns the value 2 (H_MSG_TRUE), if the parameters are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

set_check

See also

set_check

Module

none

get_extended_error_info (: : : OperatorName, ErrorCode, ErrorMessage)

Returns the extended error information for the calling thread's last HALCON error.

get_extended_error_info returns the last error code that occurred in the calling thread. OperatorName contains the operator name of the HALCON operator that has set this error code. ErrorCode holds the actual error code and ErrorMessage the corresponding error message. If no error code has been set so far or a HALCON error comes with no extended error information, OperatorName and ErrorMessage contain an empty string and ErrorCode is set to *0*. Please refer to 'Result' slot of the particular operator reference to determine whether and on which occasion an operator provides extended error information.

get_extended_error_info is thread-local, i.e., the extended error information is maintained on a per thread basis. Setting an extended error code in one thread does not affect the extended error information in any other thread. This also implies that an error code can only be retrieved within the thread that was calling the operator setting the extended error. A thread-local extended error will be cleared (and set again when applicable) as soon as an error occurs in any other successive operator call within the same thread, if get_system is called from within the same thread with the *'tsp_clear_extended_error'* parameter, or the thread terminates.

Parameters

▷ **OperatorName** (output_control) ..... string ⇝ *string*
Operator that set the error code.

▷ **ErrorCode** (output_control) ..... integer ⇝ *integer*
Extended error code.

▷ **ErrorMessage** (output_control) ..... string ⇝ *string*
Extended error message.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_error_text

Module

none

get_spy (: : Class : Value)

Current configuration of the HALCON debugging-tool.

The operator get_spy returns the current configuration of spy, the HALCON debugging tool. The available control modes (possible choices for Class) as well as the corresponding tuning possibilities (possible values for Value) can be called up by using the operator query_spy. You will find a more detailed description under set_spy.

Parameters

▷ **Class** (input_control) . . . . . string ⇝ *string*
Control mode
Default: 'mode'
List of values: Class ∈ {'db', 'error', 'input_control', 'internal', 'log_file', 'mode', 'operator', 'output_control', 'parameter_values', 'time'}

▷ **Value** (output_control) . . . . . string ⇝ *string* / integer / real
State of the control mode.

Result

The operator get_spy returns the value 2 (H_MSG_TRUE) if the parameter Class is correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

reset_obj_db

set_spy, query_spy

Module

Foundation

query_spy (: : : Classes, Values)

Inquiring for possible settings of the HALCON debugging tool.

The operator query_spy returns all possible settings of spy, the HALCON debugging tool, i.e. all the available control modes (Classes) as well as the corresponding possible ways of setting (Values). For a more detailed description of spy see operator set_spy.

Attention

The values of Values cannot be used as direct input for set_spy, as they are transmitted as a symbolic constant.

Parameters

▷ **Classes** (output_control) . . . . . string-array ⇝ *string*
Available control modes (see also set_spy).

▷ **Values** (output_control) . . . . . string-array ⇝ *string*
Corresponding state of the control modes.

Result

query_spy always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Predecessors

reset_obj_db

set_spy, get_spy

Module

Foundation

set_check (: : Check :)

Activating and deactivating of HALCON control modes.

With the help of the operator set_check different control modes of the HALCON system can be activated or deactivated. If a certain control mode is activated, parameters etc., will be checked at runtime. Whenever an inconsistency is hereby detected, the program will be interrupted by an exception.

It is recommendable to activate the control modes during the development of a program and to deactivate them only after a successfully concluded test run. For if the control mode is deactivated and an error occurs, the system may react in an unpredictable way.

The HALCON system provides various possible control modes which can be activated and deactivated independently. By calling the operator set_check with the name (Check) of the desired control mode, this control mode is activated; the control mode is deactivated by passing its name prefixed with a tilde (~, e.g., '~data').

Except for the control mode *'memory'* that is set exclusively for the whole system, all control modes are set thread-specific by default. When preceding the name of these control modes with a *'ref_'* prefix, only the reference value of the particular mode is set. The reference value is used to initialize the respective mode when starting a new user thread.

Available control modes:

'color': If this control mode is activated, only colors may be used which are supported by the display for the currently active window. Otherwise an error message is displayed.

In case of deactivated control mode and non existent colors, the em nearest color is used (see also set_color, set_gray, set_rgb).

'text': If this control mode is activated, it will check the coordinates during the setting of the text cursor as well as during the display of strings (write_string) to the effect whether a part of a sign would lie outside the window frame (a fact which is not forbidden in principle by the system).

If the control mode is deactivated, the text will be clipped at the window frame.

'data': (For program development)

Checks the consistency of image objects (regions and gray value components.

'interface': If this control mode is activated, the interface between the host language and the HALCON procedures will be checked in course (e.g., typifying and counting of the values).

'database': This is a consistency check of objects (e.g., checks whether an object which shall be canceled does indeed exist or not.)

'give_error': Determines whether errors shall trigger exceptions or not. If this control modes is deactivated, the application program must provide a suitable error treatment itself. Please note that errors which are not reported usually lead to undefined output parameters which may cause an unpredictable reaction of the program. Details about how to handle exceptions in the different HALCON language interfaces can be found in the HALCON "Programmer's Guide" and the "HDevelop User's Guide".

'father': If this control mode is activated when calling the operators open_window, HALCON allows only the usage of the number of another HALCON window as the father window of the new window; otherwise it allows also the usage of IDs of operating system windows as the father window. This control mode is only relevant for windows of type 'WIN32-Window' and 'X-Window'.

'region': (For program development)

Checks the consistency of chords (this may lead to a notable speed reduction of routines).

'clear': Normally, if a list of objects shall be canceled by using clear_obj, an exception will be raised, in case individual objects do not or no longer exist. If the *'clear'* mode is activated, such objects will be ignored.

'memory': (For program development)
Checks the memory blocks freed by the HALCON memory management on consistency and overwriting of memory borders.

'all': Activates all control modes.

'none': Deactivates all control modes.

'default': Default settings: ['give_error','database']

Parameters

▷ **Check** (input_control) ..... string(-array) ⇝ *string*
Desired control mode.
Default: 'default'
List of values: Check ∈ {'color', 'text', 'database', 'data', 'interface', 'give_error', 'father', 'region', 'clear', 'memory', 'all', 'none', 'default'}

Result

The operator set_check returns the value 2 (H_MSG_TRUE), if the parameters are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_check, set_color, set_rgb, set_hsi, write_string

Module

none

set_spy (: : Class, Value :)

Control of the HALCON Debugging Tools.

The operator set_spy is the HALCON debugging tool. This tool allows the flexible control of the input and output data of HALCON-operators - in graphical as well as in textual form. The data control is activated by using

```
set_spy(::'mode','on':),
```

and deactivated by using

```
set_spy(::'mode','off':).
```

The debugging tool can further be activated with the help of the environment variable HALCONSPY. The definition of this variable corresponds to calling up *'mode'* and *'on'*.

The following control modes (Class) can be tuned using Value:

Class = *'operator'*
When a routine is called, its name and the names of its parameters will be given (in TRIAS notation).
Value: *'on'* or *'off'*.
Default: 'off'.

Class = *'input_control'*
When a routine is called, the names and values of the input control parameters will be given.
Value: *'on'* or *'off'*.
Default: 'off'.

Class = *'output_control'*
When a routine is called, the names and values of the output control parameters are given.
Value: *'on'* or *'off'*.
Default: 'off'.

Class = *'parameter_values'*
Additional information on *'input_control'* and *'output_control'*: indicates how many values per parameter shall be displayed at most (maximum tuple length of the output).
Value: tuple length (integer)
Default: 4

Class = *'db'*
Information concerning the 4 relations in the HALCON-database. This is especially valuable in looking for forgotten clear_obj.
Value: *'on'* or *'off'*.
Default: 'off'.

Class = *'time'*
Processing time of the operator
Value: *'on'* or *'off'*.
Default: 'off'.

Class = *'log_file'*
Spy can hereby divert the text output into a file having been opened with open_file.
Value: a file handle (see open_file)

Class = *'error'*
If *'error'* is activated and an internal error occurs, spy will show the internal procedures (file/line) concerned.
Value: *'on'* or *'off'*.
Default: 'off'.

Class = *'internal'*
If *'internal'* is activated, spy will display the internal procedures and their parameters (file/line) while an HALCON-operator is processed.
Value: *'on'* or *'off'*.
Default: 'off'.

Each output starts with the thread handle, followed by a global counter that marks the order of the outputs. In multi-threaded applications, this information can be used to assign the output to individual user threads and to reconstruct the chronological sequence.

Attention

Note that under Windows the output on stdout works only in combination with a console application.

Parameters

▷ **Class** (input_control) . . . . . string ⇝ *string*
Control mode
Default: 'mode'
List of values: Class ∈ {'db', 'error', 'input_control', 'internal', 'log_file', 'mode', 'operator', 'output_control', 'parameter_values', 'time'}

▷ **Value** (input_control) . . . . . string ⇝ *string* / integer / real
State of the control mode to be set.
Default: 'on'
Suggested values: Value ∈ {'on', 'off', 1, 2, 3, 4, 5, 10, 50, 0.0, 1.0, 2.0, 5.0, 10.0}

Example

```
/* init spy: Setting of the wished control modi */
set_spy("mode","on");
set_spy("operator","on");
set_spy("input_control","on");
set_spy("output_control","on");
/* calling of program section, that will be examined */
set_spy("mode","off");
```

Result

The operator `set_spy` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

25.5 I/O Devices

`close_io_channel` (: : `IOChannelHandle` :)

Close I/O channels.

The operator `close_io_channel` closes transmission channels opened by `open_io_channel`. The references to the channels are passed in `IOChannelHandle`. In particular, allocated memory and reserved device resources are released.

Parameters

▷ **`IOChannelHandle`** (input_control) . . . . . io_channel(-array) ⇝ *handle*
Handles of the opened I/O channels.

Result

If the parameters are valid, the operator `close_io_channel` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator `get_extended_error_info`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- IOChannelHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`open_io_channel`

Possible Successors

`close_io_device`

Module

Foundation

close_io_device (: : IODeviceHandle :)

Close the specified I/O device.

The operator close_io_device closes the I/O device specified by IODeviceHandle. In particular, all associated channels are closed (i.e., close_io_channel is called implicitly on all channels that had been opened for this device) and allocated memory for data buffers is released.

Parameters

▷ **IODeviceHandle** (input_control) ..... io_device ⇝ *handle*
Handle of the opened I/O device.

Result

If the parameters are valid, the operator close_io_device returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

control_io_channel (: : IOChannelHandle, Action,
Argument : Result)

Perform an action on I/O channels.

control_io_channel performs an action on the specified I/O channels. The supported parameters are interface-specific and listed in the corresponding documentation of the used I/O interface that can be found in the directory doc/html/reference/io.

Parameters

▷ **IOChannelHandle** (input_control) ..... io_channel(-array) ⇝ *handle*
Handles of the opened I/O channels.

▷ **Action** (input_control) ..... string ⇝ *string*
Name of the action to perform.

▷ **Argument** (input_control) ..... string-array ⇝ *string* / integer / real
List of arguments for the action.
Default: []

▷ **Result** (output_control) ..... string-array ⇝ *string* / integer / real
List of values returned by the action.

Result

If the parameters are valid, the operator control_io_channel returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case an extended error information may be set and can be queried with the operator get_extended_error_info.

Execution Information

control_io_device (: : IODeviceHandle, Action, Argument : Result)

Perform an action on the I/O device.

control_io_device performs an action on the I/O device. The supported parameters are interface-specific and listed in the corresponding documentation of the used I/O interface that can be found in the directory doc/html/reference/io.

Parameters

▷ **IODeviceHandle** (input_control) ..... io_device ⇝ *handle*
Handle of the opened I/O device.

▷ **Action** (input_control) ..... string ⇝ *string*
Name of the action to perform.

▷ **Argument** (input_control) ..... string(-array) ⇝ *string* / integer / real
List of arguments for the action.
Default: []

▷ **Result** (output_control) ..... string-array ⇝ *string* / integer / real
List of result values returned by the action.

Result

If the parameters are valid, the operator control_io_device returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case an extended error information may be set and can be queried with the operator get_extended_error_info.

- Processed without parallelization.

Possible Predecessors

open_io_device

Module

Foundation

control_io_interface (: : IOInterfaceName, Action, Argument : Result)

Perform an action on the I/O interface.

control_io_interface performs an action on the I/O interface. The supported parameters are interface-specific and listed in the corresponding documentation of the used I/O interface that can be found in the directory doc/html/reference/io.

The special value *'keep_open'* for Action is used to control when the interface should be unloaded. If Argument is set to *'true'*, the interface will remain loaded until the HALCON process is terminated. If it is set to *'false'*, the interface will be unloaded as soon as all its device instances are closed. This is the default behavior.

Attention

On Windows Systems, error dialog boxes from the operating system can occur when dependency modules of the interface are not found, e.g., the according SDK was not installed. The occurrence of the error boxes can be controlled by setting Windows' Error Mode. Please refer to the description of SetErrorMode within the Windows MSDN documentation.

Parameters

- ▷ **IOInterfaceName** (input_control) . . . . . string ⇝ *string*
  HALCON I/O interface name.
  Default: []
  Suggested values: IOInterfaceName ∈ {'ADLINK-DAQPilot', 'ADLINK-EOS', 'Advantech', 'Contec', 'Hilscher-cifX', 'Interface', 'Linux-GPIO', 'NIDAQmx', 'OPC_Classic', 'OPC_UA'}
- ▷ **Action** (input_control) . . . . . string ⇝ *string*
  Name of the action to perform.
- ▷ **Argument** (input_control) . . . . . string(-array) ⇝ *string* / integer / real
  List of arguments for the action.
  Default: []
- ▷ **Result** (output_control) . . . . . string-array ⇝ *string* / integer / real
  List of results returned by the action.

Result

If the parameters are valid, the operator control_io_interface returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case an extended error information may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_io_channel_param (: : IOChannelHandle, GenParamName : GenParamValue)

Query specific parameters of I/O channels.

get_io_channel_param queries settings of specific I/O transmission channels. The query parameters are passed in GenParamName, the corresponding configuration values are returned in GenParamValue. IOChannelHandle specifies the channels returned in open_io_channel for a specific device instance.

Please check the directory doc/html/reference/io for documentation about your specific I/O device interface, where all supported channel-specific parameters are listed.

Parameters

- ▷ **IOChannelHandle** (input_control) . . . . . io_channel(-array) ⇝ *handle*
  Handles of the opened I/O channels.
- ▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
  Parameter names.
  Default: 'param_name'
  Suggested values: GenParamName ∈ {'io_channel_name', 'param_name'}
- ▷ **GenParamValue** (output_control) . . . . . string-array ⇝ *string* / integer / real / handle
  Parameter values.

Result

If the parameters are valid, the operator `get_io_channel_param` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator `get_extended_error_info`.

Execution Information

get_io_device_param (: : IODeviceHandle, GenParamName : GenParamValue)

Query settings of an I/O device instance.

`get_io_device_param` queries configuration settings of a specific device instance. The query parameters are passed in `GenParamName`, the corresponding configuration values are returned in `GenParamValue`. `IODeviceHandle` specifies the device returned in `open_io_device`.

Please check the directory `doc/html/reference/io` for documentation about your specific I/O device interface, where all supported device specific parameters are listed.

Parameters

▷ **IODeviceHandle** (input_control) . . . . . io_device ⇝ *handle*
Handle of the opened I/O device.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Parameter names.
Default: 'param_name'
Suggested values: `GenParamName` ∈ {'io_device_name', 'param_name'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real / handle
Parameter values.

Result

If the parameters are valid, the operator `get_io_device_param` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator `get_extended_error_info`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`open_io_device`, `set_io_device_param`

Possible Successors

`open_io_channel`

See also

open_io_device, query_io_interface, set_io_device_param

Module

Foundation

open_io_channel (: : IODeviceHandle, IOChannelName, GenParamName, GenParamValue : IOChannelHandle)

Open and configure I/O channels.

The operator open_io_channel opens and configures transmission channels of an opened I/O device instance. The device instance must have been opened by open_io_device before and is passed to IODeviceHandle. The transmission channels themselves are addressed by their names passed to IOChannelName. Available names can be queried using query_io_device with query parameter *'io_channel_name'*. The channels can be configured by the parameters GenParamName and GenParamValue. A reference to each transmission channel is returned in IOChannelHandle. If the instance of the channel is not needed any more, it should be released and closed via the operator close_io_channel. Besides, it will be closed automatically when closing the associated device instance by close_io_device.

Having opened a transmission channel, values can be read and written by the operators read_io_channel and write_io_channel on the channel.

An opened channel can be reconfigured by using the operators set_io_channel_param and get_io_channel_param.

Please check the directory doc/html/reference/io for documentation about your specific I/O device interface, where all supported device specific parameters are listed.

Parameters

- ▷ **IODeviceHandle** (input_control) ..... io_device ⇝ *handle*
  Handle of the opened I/O device.
- ▷ **IOChannelName** (input_control) ..... string(-array) ⇝ *string*
  HALCON I/O channel names of the specified device.
- ▷ **GenParamName** (input_control) ..... string-array ⇝ *string*
  Parameter names.
  Default: []
- ▷ **GenParamValue** (input_control) ..... string-array ⇝ *string* / integer / real
  Parameter values.
  Default: []
- ▷ **IOChannelHandle** (output_control) ..... io_channel(-array) ⇝ *handle*
  Handles of the opened I/O channel.

Example

```
query_io_device (IODeviceHandle, [], 'io_channel_names.digital_output', \
                 ChannelOutputNames)
open_io_channel (IODeviceHandle, ChannelOutputNames[0], [], [], \
                 IOChannelHandle)
write_io_channel (IOChannelHandle, 1, Status)
```

Result

If the parameters are valid, the operator open_io_channel returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

open_io_device, query_io_device

Possible Successors

set_io_channel_param, read_io_channel, write_io_channel

Module

Foundation

open_io_device (: : IOInterfaceName, IODeviceName, GenParamName, GenParamValue : IODeviceHandle)

Open and configure an I/O device.

The operator open_io_device opens and configures the chosen I/O device interface for the specific device. The device interface is specified by the base name of the underlying library and passed to IOInterfaceName. The interface library will be loaded dynamically when configuring the first specific device for this device interface. The specific device itself is addressed by a name passed to IODeviceName. Available names can be queried by query_io_interface. The device can be configured by the parameters GenParamName and GenParamValue. A reference to the device instance is returned in IODeviceHandle. If the instance of the device is not needed any more, it should be released and closed via the operator close_io_device.

Having opened a specific device, a transmission channel can be opened by calling open_io_channel. Values on the I/O channel can be read and written by the operators read_io_channel and write_io_channel on an opened transmission channel, afterwards.

An opened device instance can be reconfigured by using the operators set_io_device_param and get_io_device_param.

Please check the directory doc/html/reference/io for documentation about your specific I/O device interface, where all supported device specific parameters are listed.

Attention

On Windows Systems, error dialog boxes from the operating system can occur when dependency modules of the interface are not found, e.g., the according SDK was not installed. The occurrence of the error boxes can be controlled by setting Windows' Error Mode. Please refer to the description of SetErrorMode within the Windows MSDN documentation.

Parameters

▷ **IOInterfaceName** (input_control) ..... string ⇝ *string*
HALCON I/O interface name.
Default: []
Suggested values: IOInterfaceName ∈ {'ADLINK-DAQPilot', 'ADLINK-EOS', 'Advantech', 'Contec', 'Hilscher-cifX', 'Interface', 'Linux-GPIO', 'NIDAQmx', 'OPC_Classic', 'OPC_UA'}

▷ **IODeviceName** (input_control) ..... tuple ⇝ *string*
I/O device name.
Default: []

▷ **GenParamName** (input_control) ..... string-array ⇝ *string*
Dynamic parameter names.
Default: []

▷ **GenParamValue** (input_control) ..... string-array ⇝ *string* / integer / real
Dynamic parameter values.
Default: []

▷ **IODeviceHandle** (output_control) ..... io_device ⇝ *handle*
Handle of the opened I/O device.

Example

```
* Select a suitable i/o device interface of name IOInterfaceName
query_io_interface (IOInterfaceName, 'io_device_names', DeviceNames)
open_io_device (IOInterfaceName, DeviceNames[0], [], [], IODeviceHandle)
query_io_device (IODeviceHandle, [], 'io_channel_names.digital_input', \
                 ChannelInputNames)
open_io_channel (IODeviceHandle, ChannelInputNames[0], [], [], \
                 IOChannelHandle)
read_io_channel (IOChannelHandle, Value, Status)
```

Result

If the parameters are valid, the operator `open_io_device` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator `get_extended_error_info`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`query_io_interface`

Possible Successors

`set_io_device_param`, `get_io_device_param`, `open_io_channel`

Module

Foundation

query_io_device (: : IODeviceHandle, IOChannelName, Query : Result)

Query information about channels of the specified I/O device.

The operator `query_io_device` returns information about transmission channels of a specified I/O device. The handle to the I/O device is passed to in `IODeviceHandle`, whereas the channels are addressed by `IOChannelName`. The desired information about the I/O channels is specified via `Query`. A list of all supported channel names is usually returned when passing *'io_channel_name'* to `Query` while the input parameter `IOChannelName` is ignored.

Please check the directory `doc/html/reference/io` for documentation about your specific I/O device interface, where all supported channel-specific parameters are listed.

Parameters

▷ **IODeviceHandle** (input_control) ..... io_device ⇝ *handle*
Handle of the opened I/O device.

▷ **IOChannelName** (input_control) ..... string(-array) ⇝ *string*
Channel names to query.

▷ **Query** (input_control) ..... string-array ⇝ *string*
Name of the query.
Default: 'param_name'
List of values: `Query` ∈ {'io_channel_names', 'param_name'}

▷ **Result** (output_control) ..... string-array ⇝ *string* / integer / real
List of values (according to `Query`).

Example

```
* Select a suitable i/o device interface of name IOInterfaceName
query_io_interface (IOInterfaceName, 'io_device_names', DeviceNames)
open_io_device (IOInterfaceName, DeviceNames[0], [], [], IODeviceHandle)
query_io_device (IODeviceHandle, [], 'io_channel_names.digital_input', \
                 ChannelInputNames)
open_io_channel (IODeviceHandle, ChannelInputNames[0], [], [], \
                 IOChannelHandle)
read_io_channel (IOChannelHandle, Value, Status)
```

Result

If the parameters are valid, the operator `query_io_device` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator `get_extended_error_info`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`open_io_device`

Module

Foundation

query_io_interface (: : IOInterfaceName, Query : Result)

Query information about the specified I/O device interface.

The operator `query_io_interface` returns information about the I/O device interface `IOInterfaceName`. The desired information is specified via `Query`. If applicable, `Result` contains a list of supported values.

Generally, when passing the value *'interface_name'* for `Query`, all available I/O interfaces are returned. The value of the parameter `IOInterfaceName` is ignored in this case.

Please check the directory `doc/html/reference/io` for documentation about your specific I/O device interface, where all supported interface specific parameters are listed.

Attention

On Windows Systems, error dialog boxes from the operating system can occur when dependency modules of the interface are not found, e.g., the according SDK was not installed. The occurrence of the error boxes can be controlled by setting Windows' Error Mode. Please refer to the description of SetErrorMode within the Windows MSDN documentation.

Parameters

▷ **IOInterfaceName** (input_control) . . . . . string ⇝ *string*
HALCON I/O interface name.
Default: []
Suggested values: `IOInterfaceName` ∈ {'ADLINK-DAQPilot', 'ADLINK-EOS', 'Advantech', 'Contec', 'Hilscher-cifX', 'Interface', 'Linux-GPIO', 'NIDAQmx', 'OPC_Classic', 'OPC_UA'}

▷ **Query** (input_control) . . . . . string(-array) ⇝ *string*
Parameter name of the query.
Default: 'io_device_names'
Suggested values: `Query` ∈ {'interface_name', 'io_device_names', 'param_name', 'revision'}

▷ **Result** (output_control) . . . . . string-array ⇝ *string* / integer / real
List of result values (according to `Query`).

Example

```
* Select a suitable i/o device interface of name IOInterfaceName
query_io_interface (IOInterfaceName, 'io_device_names', DeviceNames)
open_io_device (IOInterfaceName, DeviceNames[0], [], [], IODeviceHandle)
query_io_device (IODeviceHandle, [], 'io_channel_names.digital_input', \
                 ChannelInputNames)
open_io_channel (IODeviceHandle, ChannelInputNames[0], [], [], \
                 IOChannelHandle)
read_io_channel (IOChannelHandle, Value, Status)
```

Result

If the parameters are valid, the operator `query_io_interface` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator `get_extended_error_info`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`open_io_device`

Module

Foundation

read_io_channel (: : IOChannelHandle : Value, Status)

Read a value from the specified I/O channels.

`read_io_channel` reads input values from the specified transmission channels. The channels are passed in `IOChannelHandle` and can be opened and configured by `open_io_channel`, the values are returned in `Value`. The parameter `Status` returns for each read value in `Value` a quality message. The value *0* indicates that the corresponding value of `Value` could be read. Any other status value depends on the interface. Please refer to the interface-specific documentation in the directory `doc/html/reference/io` for further explanation.

Parameters

▷ **IOChannelHandle** (input_control) ..... io_channel(-array) ⇝ *handle*
Handles of the opened I/O channels.

▷ **Value** (output_control) ..... tuple-array ⇝ *integer* / real / string / handle
Read value.

▷ **Status** (output_control) ..... integer-array ⇝ *integer*
Status of read value.

Result

If the parameters are valid, the operator `read_io_channel` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator `get_extended_error_info`.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_io_channel_param (: : IOChannelHandle, GenParamName, GenParamValue :)

Set specific parameters of I/O channels.

set_io_channel_param (re)configures the given transmission channels. The configuration parameters are passed in GenParamName, the corresponding values are passed in GenParamValue. IOChannelHandle specifies the transmission channels returned in open_io_channel.

Please check the directory doc/html/reference/io for documentation about your specific I/O device interface, where all supported channel-specific parameters are listed.

Parameters

▷ **IOChannelHandle** (input_control) ..... io_channel(-array) ⇝ *handle*
Handles of the opened I/O channels.

▷ **GenParamName** (input_control) ..... string-array ⇝ *string*
Parameter names.
Default: []

▷ **GenParamValue** (input_control) ..... string-array ⇝ *string* / integer / real / handle
Parameter values to set.
Default: []

Result

If the parameters are valid, the operator set_io_channel_param returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

set_io_device_param (: : IODeviceHandle, GenParamName, GenParamValue :)

Configure a specific I/O device instance.

set_io_device_param (re)configures a specific device instance. The configuration parameters are passed in GenParamName, the corresponding values are passed in GenParamValue. IODeviceHandle specifies the device specified in open_io_device.

Please check the directory doc/html/reference/io for documentation about your specific I/O device interface, where all supported device specific parameters are listed.

Parameters

▷ **IODeviceHandle** (input_control) . . . . . io_device ⇝ *handle*
Handle of the opened I/O device.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Parameter names.
Default: []

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real / handle
Parameter values to set.
Default: []

Result

If the parameters are valid, the operator set_io_device_param returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

write_io_channel (: : IOChannelHandle, Value : Status)

Write a value to the specified I/O channels.

write_io_channel writes values to the specified transmission channels. The channels are passed in IOChannelHandle and can be opened and configured by open_io_channel, the values are passed to Value. The parameter Status returns for each written value in Value a quality message. The value *0* indicates that the corresponding value of Value could be written. Any other status value depends on the interface. Please refer to the interface-specific documentation in the directory doc/html/reference/io for further explanation.

Parameters

▷ **IOChannelHandle** (input_control) . . . . . io_channel(-array) ⇝ *handle*
Handles of the opened I/O channels.

▷ **Value** (input_control) . . . . . tuple-array ⇝ *integer* / real / string / handle
Write values.

▷ **Status** (output_control) . . . . . integer-array ⇝ *integer*
Status of written values.

Result

If the parameters are valid, the operator write_io_channel returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. In this case, an extended error information may be set and can be queried with the operator get_extended_error_info.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

25.6 Information

get_chapter_info (: : Chapter : Info)

Get information concerning the chapters on operators.

The operator get_chapter_info gives information concerning the chapters on operators. If instead of Chapter the empty string is transmitted, the routine will provide in Info the names of all chapters. If on the other hand a certain chapter or a chapter and its subchapter(s) are indicated (by a tuple of names), the corresponding subchapters or - in case there are no further subchapters - the names of the corresponding operators will be given. The organization of the chapters on operators is the same as the organization of chapters and subchapters in the HALCON-manual. Please note: The chapters on operators respectively the subchapters concerning an individual operator can be called by using the operator get_operator_info(::<Name>,'chapter',Info:). The Online-texts will be taken from the files operators_[LANG].ref, operators_[LANG].sta, operators_[LANG].key, operators_[LANG].num and operators_[LANG].idx , which will be searched by HALCON in the currently used directory or the directory 'help_dir' (see also get_system and set_system).

Attention

The encoding of the result is UTF-8.

Parameters

▷ **Chapter** (input_control) ..... string(-array) ⇝ *string*
Operator class or subclass of interest.
Default: ''

▷ **Info** (output_control) ..... string-array ⇝ *string*
Operator classes (Chapter = '') or operator subclasses respectively operators.

Result

If the parameter values are correct and the helpfile is available, the operator get_chapter_info returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_system, set_system

See also

get_operator_info, get_system, set_system

Module

Foundation

get_keywords (: : OperatorName : Keywords)

Get keywords which are assigned to operators.

The operator get_keywords returns all the keywords in the online-texts corresponding to those operators which have the indicated substring OperatorName in their name. If instead of OperatorName the empty string is transmitted, the operator get_keywords returns all keywords. The keywords of an individual operator can also be called by using the operator get_operator_info. The online-texts will be taken from the files operators_[LANG].ref, operators_[LANG].sta, operators_[LANG].key, operators_[LANG].num and operators_[LANG].idx, which are searched by HALCON in the currently used directory and in the directory 'help_dir' (see also get_system and set_system).

Attention

The encoding of the result is UTF-8.

Parameters

▷ **OperatorName** (input_control) ..... proc_name ⇝ *string*
Substring in the names of those operators for which keywords are needed.
Default: 'get_keywords'

▷ **Keywords** (output_control) ..... string-array ⇝ *string*
Keywords for the operators.

Result

The operator get_keywords returns the value 2 (H_MSG_TRUE) if the parameters are correct and the helpfiles are available. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_chapter_info

Alternatives

get_operator_info

See also

get_operator_name, search_operator, get_param_info

Module

Foundation

get_operator_info (: : OperatorName, Slot : Information)

Get information concerning a HALCON-operator.

With the help of the operator get_operator_info the online-texts concerning a certain operator can be called (see also get_operator_name). The form of information available for all operators (Slot) can be called using the operator query_operator_info. For the time being the following slots are available:

'short': Short description of the operator.

'abstract': Description of the operator.

'chapter': Name(s) of the chapter(s) in the operator hierarchy (chapter, subchapter in the HALCON manual).

'functionality': Functionality is equivalent to the object class to which the operator can be assigned.

'keywords': Keywords of the operator (optional).

'example': Example for the use of the operator (optional). The operator 'example.LANGUAGE' (LANGUAGE ∈ {trias,c,c++,c#,vb.net}) calls up examples for a certain language if available. If the language is not indicated or if no example is available in this language, the TRIAS-example will be returned.

'complexity': Complexity of the operator (optional).

'effect': Not in use so far.

'parallelization': Characteristic timeout and parallel behavior of an operator.

'execution information': Characteristic timeout and parallel behavior of an operator.

'parallel_method': Method of automatic operator parallelization.

'interrupt_mode': Modes of interruption the operator can deal with. See `set_operator_timeout` and `interrupt_operator` on how to use and set these interrupt modes.

'alternatives': Alternative operators (optional).

'see_also': Operators containing further information (optional).

'predecessor': Possible and sensible predecessor

'successor': Possible and sensible successor

'result_state': Return value of the operator (`2` (`H_MSG_TRUE`), `3` (`H_MSG_FALSE`), `5` (`H_MSG_FAIL`), `4` (`H_MSG_VOID`) or EXCEPTION).

'attention': Restrictions and advice concerning the correct use of the operator (optional).

'parameter': Names of the parameter of the operator (see also `get_param_info`).

'references': Literary references (optional).

'module': The module to which the operator is assigned.

'dynamic_modules': List of modules the operator can be assigned to by dynamic licensing (depending on its usage).

'html_path': The directory where the HTML documentation of the operator resides.

'warning': Possible warnings for using the operator.

'compute_device': List of compute devices supported by the operator.

The texts will be taken from the `operators_[LANG].ref`, `operators_[LANG].sta`, `operators_[LANG].key`, `operators_[LANG].num` and `operators_[LANG].idx`, which will be searched by HALCON in the currently used directory or in the directory 'help_dir' (respectively 'user_help_dir') (see also `get_system` and `set_system`).

Attention

The encoding of the result is UTF-8.

Parameters

▷ **`OperatorName`** (input_control) ..... proc_name ⇝ *string*
Name of the operator on which more information is needed.
Default: 'get_operator_info'

▷ **`Slot`** (input_control) ..... string ⇝ *string*
Desired information.
Default: 'abstract'
List of values: `Slot` ∈ {'short', 'abstract', 'chapter', 'chapter_id', 'functionality', 'parallelization', 'execution information', 'parallel_method', 'interrupt_mode', 'compute_device', 'complexity', 'predecessor', 'successor', 'alternatives', 'parameter', 'see_also', 'keywords', 'example', 'attention', 'result_state', 'references', 'module', 'html_path', 'warning', 'dynamic_modules'}

▷ **`Information`** (output_control) ..... string(-array) ⇝ *string*
Information (empty if no information is available)

Result

The operator `get_operator_info` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct and the helpfiles are availabe. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

get_operator_name (: : Pattern : OperatorNames)

Get operators with the given string as a substring of their name.

The operator get_operator_name takes a string (Pattern) as input and searches all HALCON-operators having this string as a substring in their name. If an empty string is entered, the names of all operators available will be returned.

Parameters

▷ **Pattern** (input_control) ..... string ⇝ *string*
Substring of the seeked names (empty <=> all names).
Default: 'info'

▷ **OperatorNames** (output_control) ..... string-array ⇝ *string*
Detected operator names.

Result

The operator get_operator_name returns the value 2 (H_MSG_TRUE) if the helpfiles are available. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_operator_info, get_param_names, get_param_num, get_param_types

Alternatives

search_operator

See also

get_operator_info, get_param_names, get_param_num, get_param_types

Module

Foundation

get_param_info (: : OperatorName, ParamName, Slot : Information)

Get information concerning the operator parameters.

The operator get_param_info is used for calling up the online-texts assigned to a parameter of an indicated operator. The form of information available for each parameter (Slot), can be called up by using the operator query_param_info. Possible slots are given in the list below. For a more extensive description of the entries and their possible values we refer to the "Extension Package Programmer's Manual".

'description': Description of the parameter.

'parameter_class': Parameter classes.

'input_object'
'output_object'
'input_control'
'output_control'

'type_list': Permitted type(s) of data for parameter values.

'default_type': Default-type for parameter values (for control parameters only). This type of parameter is the one HALCON/C uses in the "simple mode". If *'none'* is indicated, the "tuple mode" must be used.

'sem_type': Semantic type of the parameter. This is important to allow the assignment of the parameters to object classes in object-oriented languages (C++, .NET, COM). If more than one parameter belongs semantically to one type, this fact is indicated as well.

'default_value': Default value for the parameter (for input control parameters only). It is the question of mere information only (the parameter value must be transmitted explicitly, even if the default value is used). This entry serves only as a notice, a point of departure for own experiments. The values have been selected so that they normally do not cause any errors but generate something that makes sense.

'modified':
'true', if the operator modifies this input parameter.

'multivalue':
'true', if an array of values must be passed,
'false', if exactly one value must be passed, and
'optional' allows both.

'multichannel':
'true', in case the input image object may be multichannel.

'multiinstance':
'true', if an array of semantic tuples (e.g., poses, camera parameters, etc.) must be passed,
'false', if exactly one semantic tuple must be passed, and
'optional' allows both.

'mixed_type': For control parameters exclusively and only if value tuples (*'multivalue'*-*'true'*/*'optional'*) and various types of data are permitted for the parameter values ('type_list' having more than one value). In this case `Slot` indicates, whether values of various types may be mixed in one tuple (*'true'* or *'false'*).

'values': Selection of values (optional).

'value_list': In case a parameter can take only a limited number of values, this fact will be indicated explicitly (optional).

'valuemin': Minimum value of a value interval.

'valuemax': Maximum value of a value interval.

'valuefunction': Function describing the course of the values for a series of tests (lin, log, quadr, ...).

'steprec': Recommended step width for the parameter values in a series of tests.

'stepmin': Minimum step width of the parameter values in a series of tests.

'valuenumber': Expression describing the number of parameters as such or in relation to other parameters.

'assertion': Expression describing the parameter values as such or in relation to other parameters.

'cd_type_list.[compute_device]': List of input image types the compute device implementation of the operator supports for a specific device (use 'cd_type_list.opencl' for OpenCL devices).

'cd_value_list.[compute_device]': List of input control parameters the compute device implementation of the operator supports for a specific device (use 'cd_value_list.opencl' for OpenCL devices).

The online-texts will be taken from the files `operators_[LANG].ref`, `operators_[LANG].sta`, `operators_[LANG].key`, `operators_[LANG].num` and `operators_[LANG].idx`, which will be searched by HALCON in the currently used directory or the directory 'help_dir' (see also `get_system` and `set_system`).

Attention

The encoding of the result is UTF-8.

Parameters

▷ **OperatorName** (input_control) ..... proc_name ⇝ *string*
Name of the operator on whose parameter more information is needed.
Default: 'get_param_info'

▷ **ParamName** (input_control) ..... string ⇝ *string*
Name of the parameter on which more information is needed.
Default: 'Slot'

▷ **Slot** (input_control) ..... string ⇝ *string*
Desired information.
Default: 'description'
List of values: `Slot` ∈ {'assertion', 'default_type', 'default_value', 'description', 'mixed_type', 'modified', 'multichannel', 'multivalue', 'sem_type', 'step_min', 'step_rec', 'type_list', 'value_function', 'value_list', 'value_max', 'value_min', 'value_number', 'values', 'cd_type_list.opencl', 'cd_value_list.opencl'}

▷ **Information** (output_control) ..... string(-array) ⇝ *string*
Information (empty in case there is no information available).

Result

The operator `get_param_info` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct and the help-files are available. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

get_param_names (: : OperatorName : InpObjPar, OutpObjPar, InpCtrlPar, OutpCtrlPar)

Get the names of the parameters of a HALCON-operator.

For the HALCON-operator indicated in `OperatorName` the operator `get_param_names` returns the names of the input objects, the output objects, of the input control parameters and the output control parameters.

Parameters

▷ **OperatorName** (input_control) ..... proc_name ⇝ *string*
Name of the operator.
Default: 'get_param_names'

▷ **InpObjPar** (output_control) ..... string-array ⇝ *string*
Names of the input objects.

▷ **OutpObjPar** (output_control) ..... string-array ⇝ *string*
Names of the output objects.

▷ **InpCtrlPar** (output_control) ..... string-array ⇝ *string*
Names of the input control parameters.

▷ **OutpCtrlPar** (output_control) ..... string-array ⇝ *string*
Names of the output control parameters.

Result

The operator get_param_names returns the value 2 (H_MSG_TRUE) if the name of the operator exists and the helpfiles are available. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_keywords, search_operator, get_operator_name, get_operator_info

Possible Successors

get_param_num, get_param_types

Alternatives

get_operator_info, get_param_info

See also

get_param_num, get_param_types, get_operator_name

Module

Foundation

get_param_num (: : OperatorName : CName, InpObjPar, OutpObjPar, InpCtrlPar, OutpCtrlPar, Type)

Get number of the different parameter classes of a HALCON-operator.

The operator get_param_num returns the number of the input and output object parameters, as well as the input and output control parameters for the indicated HALCON-operator. Further, you will receive the name of the C-function (CName) called by the operator. The output parameter Type indicates, whether the operator is a system operator or an user procedure.

Parameters

▷ **OperatorName** (input_control) ..... proc_name ⇝ *string*
Name of the operator.
Default: 'get_param_num'

▷ **CName** (output_control) ..... string ⇝ *string*
Name of the called C-function.

▷ **InpObjPar** (output_control) ..... integer ⇝ *integer*
Number of the input object parameters.

▷ **OutpObjPar** (output_control) ..... integer ⇝ *integer*
Number of the output object parameters.

▷ **InpCtrlPar** (output_control) ..... integer ⇝ *integer*
Number of the input control parameters.

▷ **OutpCtrlPar** (output_control) ..... integer ⇝ *integer*
Number of the output control parameters.

▷ **Type** (output_control) ..... string ⇝ *string*
System operator or user procedure.
Suggested values: Type ∈ {'system', 'user'}

Result

The operator get_param_num returns the value 2 (H_MSG_TRUE) if the name of the operator exists. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

get_param_names, get_param_types, get_operator_name

Module

Foundation

get_param_types (: : OperatorName : InpCtrlParType, OutpCtrlParType)

Get default data type for the control parameters of a HALCON-operator.

The operator get_param_types returns the default data type for each input and output control parameter. The default type of a parameter is the type used in "simple mode" in HALCON/C. This concerns parameters which allow more than one type as for example write_string. Hereby the types of input parameters are combined in the variable InpCtrlParType, whereas the types of output parameters are combined in the variable OutpCtrlParType. The following types are possible:

'integer': an integer.

'integer tuple': an integer or a tuple of integers.

'real': a floating point number.

'real tuple': a floating point number or a tuple of floating point numbers.

'string': a string.

'string tuple': a string or a tuple of strings.

'no_default': individual value of which the type cannot be determined.

'no_default tuple': individual value or tuple of values of which the type cannot be determined.

'default': individual value of unknown type, whereby the systems assumes it to be an integer.

Parameters

▷ **OperatorName** (input_control) ..... proc_name ⇝ *string*
Name of the operator.
Default: 'get_param_types'

▷ **InpCtrlParType** (output_control) ..... string-array ⇝ *string*
Default type of the input control parameters.

▷ **OutpCtrlParType** (output_control) ..... string-array ⇝ *string*
Default type of the output control parameters.

Result

The operator get_param_types returns the value 2 (H_MSG_TRUE) if the parameters are correct and the helpfiles are availabe. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Alternatives

get_param_info

See also

get_param_names, get_param_num, get_operator_info, get_operator_name

Module

Foundation

query_operator_info (: : : Slots)

Query slots concerning information with relation to the operator get_operator_info.

The operator query_operator_info returns the names of those online texts (Slots) which are available online for each operator. The information itself can be called up using

get_operator_info(::<OperatorName>,<Slot>:<Information>).

Parameters

▷ **Slots** (output_control) ..... string-array ⇝ *string*
Slot names of the operator get_operator_info.

Result

The operator query_operator_info always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_operator_info

See also

get_operator_info

Module

Foundation

query_param_info (: : : Slots)

Query slots of the online-information concerning the operator get_param_info.

The operator query_param_info returns the names of those pieces of information (Slots) which are available online for each parameter (online texts). The online texts themselves can be called up using

get_param_info(::<Procedurname>,<Parametername>,<Slot>:<Information>).

Parameters

▷ **Slots** (output_control) ..... string-array ⇝ *string*
Slot names for the operator get_param_info.

Result

query_param_info always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_param_info

See also

get_param_info

Module

Foundation

search_operator (: : Keyword : OperatorNames)

Search names of all operators assigned to one keyword.

The operator search_operator returns the names of all operators whose online-texts include the keyword Keyword (see also get_operator_info). All available keywords are called by using the operator get_keywords(::": <keywords>). The online-texts are taken from the files operators_[LANG].ref, operators_[LANG].sta, operators_[LANG].key, operators_[LANG].num and operators_[LANG].idx, which are searched by HALCON in the currently used directory or the directory 'help_dir' (see also get_system and get_system).

Parameters

▷ **Keyword** (input_control) ..... string ⇝ *string*
Keyword for which corresponding operators are searched.
Default: 'Information'

▷ **OperatorNames** (output_control) ..... string-array ⇝ *string*
Operators whose slot 'keyword' contains the keyword.

Result

The operator search_operator returns the value 2 (H_MSG_TRUE) if the parameters are correct and the helpfiles are available. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

25.7 Memory Block

compare_memory_block (: : MemoryBlocks1,
MemoryBlocks2 : IsEqual)

Compare contents of memory blocks regarding equality.

The operator compare_memory_block compares the contents of two memory block tuples and returns the comparison result in IsEqual. Therefore, each memory block in the tuple MemoryBlocks1 is compared to the respective block in the tuple MemoryBlocks2 with the same index. IsEqual is set to TRUE if the number

of elements of the two tuples matches and if the length and byte content of each pair of memory blocks coincides, otherwise to FALSE.

Attention

Note that `compare_memory_block` compares the memory blocks regarding their actual byte content, not their location in memory.

Parameters

- ▷ **`MemoryBlocks1`** (input_control) ..... memory_block(-array) ⇝ *handle*
  Tuple of reference memory blocks.
- ▷ **`MemoryBlocks2`** (input_control) ..... memory_block(-array) ⇝ *handle*
  Tuple of test memory blocks.
- ▷ **`IsEqual`** (output_control) ..... integer ⇝ *integer*
  Boolean result value.

Result

The operator `compare_memory_block` returns the value `2` (`H_MSG_TRUE`) if the passed handles are valid. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_memory_block_extern`, `create_memory_block_extern_copy`, `image_to_memory_block`, `read_memory_block`

Module

Foundation

`create_memory_block_extern` `( : : Pointer, Size, FreeFunction : MemoryBlockHandle )`

Create a memory block from an external pointer.

It is not recommended to use the operator `create_memory_block_extern` in HDevelop.

`create_memory_block_extern` creates a memory block and returns its handle `MemoryBlockHandle`. `Pointer` is a data pointer to the beginning of the memory block. `Size` controls the size in bytes of the memory block. `FreeFunction` is an optional callback function that frees the memory pointed to by `Pointer`. This function must have the following signature

```
void FreeFunction(void* ptr);
```

and will be called using `__cdecl` calling convention when deleting `MemoryBlockHandle`. Hence, HALCON gains ownership over the memory in this case and releases the memory via the callback function. If the memory shall not be released when deleting `MemoryBlockHandle`, i.e., HALCON shall not own the memory, the NULL-Pointer can be passed.

Attention

This operator does not copy any data. If a copy is required `create_memory_block_extern_copy` can be used.

Parameters

- ▷ **`Pointer`** (input_control) ..... pointer ⇝ *integer*
  Data pointer of the memory block.
- ▷ **`Size`** (input_control) ..... integer ⇝ *integer*
  Size of the memory block.

▷ **FreeFunction** (input_control) . . . . . pointer ⇝ *integer*
Function to free the memory block.
Default: 0

▷ **MemoryBlockHandle** (output_control) . . . . . memory_block ⇝ *handle*
Handle of the memory block.

Result

If the parameters are valid, the operator `create_memory_block_extern` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`get_memory_block_ptr`, `compare_memory_block`, `memory_block_to_image`, `write_memory_block`

Alternatives

`create_memory_block_extern_copy`

Module

Foundation

create_memory_block_extern_copy (: : Pointer, Size : MemoryBlockHandle)

Create a memory block from an external pointer by copying.

`create_memory_block_extern_copy` creates a memory block by copying bytes and returns its handle `MemoryBlockHandle`. `Pointer` is a data pointer to the beginning of the memory to be copied. `Size` determines the number of bytes to be copied and with that the size of the memory block in bytes. Note that the memory copied by this operator is released when deleting `MemoryBlockHandle`, whereas the original memory in `Pointer` that is copied from is not released.

Parameters

▷ **Pointer** (input_control) . . . . . pointer ⇝ *integer*
Data pointer of the memory block.

▷ **Size** (input_control) . . . . . integer ⇝ *integer*
Size of the memory block.

▷ **MemoryBlockHandle** (output_control) . . . . . memory_block ⇝ *handle*
Handle of the memory block.

Result

If the parameters are valid, the operator `create_memory_block_extern_copy` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

get_memory_block_ptr, compare_memory_block, memory_block_to_image, write_memory_block

Alternatives

create_memory_block_extern

Module

Foundation

get_memory_block_ptr (: : MemoryBlockHandle : Pointer, Size)

Return the data pointer and size of a memory block.

It is not recommended to use the operator get_memory_block_ptr in HDevelop.

get_memory_block_ptr returns the data pointer to the beginning of a memory block in Pointer and its size in bytes in Size. MemoryBlockHandle is the handle of the memory block.

Parameters

- ▷ **MemoryBlockHandle** (input_control) ..... memory_block ⇝ *handle*
  Handle of the memory block.
- ▷ **Pointer** (output_control) ..... pointer ⇝ *integer*
  Data pointer to the beginning of the memory block.
- ▷ **Size** (output_control) ..... integer ⇝ *integer*
  Size of the memory block.

Result

If the parameters are valid, the operator get_memory_block_ptr returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_memory_block_extern, create_memory_block_extern_copy, image_to_memory_block, read_memory_block

Module

Foundation

read_memory_block (: : FileName : MemoryBlockHandle)

Read a memory block from a file.

The operator read_memory_block reads the file FileName and creates a new memory block in MemoryBlockHandle that is an identical copy of the bytes in the file.

The default HALCON file extension for memory block files is '.bin'.

Parameters

- ▷ **FileName** (input_control) ..... filename.read ⇝ *string*
  Name of the file.
  Default: 'memory_block.bin'
  File extension: .bin
- ▷ **MemoryBlockHandle** (output_control) ..... memory_block ⇝ *handle*
  Memory block handle.

Result

The operator read_memory_block returns the value 2 (H_MSG_TRUE) if the named file was found and correctly read. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

get_memory_block_ptr, compare_memory_block, memory_block_to_image

See also

write_memory_block

Module

Foundation

write_memory_block (: : MemoryBlockHandle, FileName :)

Write a memory block to a file.

The operator write_memory_block writes the byte content of the memory block MemoryBlockHandle to the file FileName. The memory block can be read again with read_memory_block.

The default HALCON file extension for memory block files is '.bin', but any file extension can be chosen, including none.

Attention

Choosing a file extension that does not fit the byte content of the memory block MemoryBlockHandle only changes the name of the file, not the bytes written to disk.

Parameters

▷ **MemoryBlockHandle** (input_control) ..... memory_block ⇝ *handle*
Memory block handle.

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Name of the file.
Default: 'memory_block.bin'
File extension: .bin

Result

The operator write_memory_block returns the value 2 (H_MSG_TRUE) if the passed handle is valid and if the memory block was successfully written into the named file. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_memory_block_extern, create_memory_block_extern_copy, image_to_memory_block

See also

read_memory_block

Module

Foundation

25.8 Multithreading

broadcast_condition (: : ConditionHandle :)

Signal a condition synchronization object.

broadcast_condition restarts all the threads that are waiting on the condition variable ConditionHandle. Nothing happens if no threads are waiting on ConditionHandle.

Parameters

▷ **ConditionHandle** (input_control) ..... condition ⇝ *handle*
Condition synchronization object.

Result

If the condition handle is valid, the operator broadcast_condition returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_condition, wait_condition

See also

wait_condition, timed_wait_condition

Module

Foundation

clear_barrier (: : BarrierHandle :)

Destroy a barrier synchronization object.

clear_barrier destroys the barrier object given in BarrierHandle. No threads should be waiting on the barrier at the time clear_barrier is called. After calling clear_barrier, the barrier can no longer be used. The handle BarrierHandle becomes invalid.

Parameters

▷ **BarrierHandle** (input_control) ..... barrier ⇝ *handle*
Barrier synchronization object.

Result

If the barrier handle is valid, the operator clear_barrier returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- BarrierHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_barrier

See also

create_barrier

Module

Foundation

clear_condition (: : ConditionHandle :)

Destroy a condition synchronization object.

clear_condition destroys the condition object given in ConditionHandle. No threads should be waiting on the condition at the time clear_condition is called. After calling clear_condition, the condition can no longer be used. The handle ConditionHandle becomes invalid.

Parameters

▷ **ConditionHandle** (input_control) ..... condition ⇝ *handle*
Condition synchronization object.

Result

If the condition handle is valid, the operator clear_condition returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ConditionHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_condition

See also

create_condition

Module

Foundation

clear_event (: : EventHandle :)

Clear the event synchronization object.

clear_event destroys the mutex object given by EventHandle. No threads should be waiting on the event at the time clear_event is called. After calling clear_event, the event can no longer be used. The handle EventHandle becomes invalid.

Parameters

▷ **EventHandle** (input_control) . . . . . event ⇝ *handle*
Event synchronization object.

Result

If the event handle is valid, the operator `clear_event` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- EventHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`create_event`

See also

`create_event`

Module

Foundation

clear_message (: : MessageHandle :)

Close a message handle and release all associated resources.

`clear_message` closes a message handle `MessageHandle` that was previously opened with `create_message` or `dequeue_message`. Any resources owned by the message, in particular the tuple or object data stored in the message, will be released.

Multiple message handles can be closed in a single `clear_message` call, passing them as a tuple to the `MessageHandle` parameter.

Attention

The handle(s) must not be used again after being invalidated using `clear_message`. Using an invalid handle results in undefined behavior.

Parameters

▷ **MessageHandle** (input_control) . . . . . message(-array) ⇝ *handle*
Message handle(s) to be closed.
Number of elements: MessageHandle >= 1
Restriction: MessageHandle != 0

Example

```
MessageHandles := []
for idx := 0 to 4 by 1
  create_message (MessageHandle)
  MessageHandles[idx]:= MessageHandle
endfor
* ...
```

Result

If the message handle(s) passed to the operator are valid, `clear_message` returns `2` (`H_MSG_TRUE`). Otherwise

an exception is raised. If a tuple of handles is passed and some of them are invalid, clear_message attempts to clear as many handles from the tuple as possible before reporting the error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MessageHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_message, dequeue_message

See also

create_message, set_message_tuple, get_message_tuple, set_message_obj, get_message_obj, set_message_param, get_message_param, enqueue_message, dequeue_message

Module

Foundation

clear_message_queue (: : QueueHandle :)

Close a message queue handle and release all associated resources.

clear_message_queue closes a message queue handle QueueHandle that was previously opened with create_message_queue. Any resources owned by the message queue, in particular message data queued in the message queue will be released.

Multiple message queue handles can be closed in a single clear_message_queue call, passing them as a tuple to the QueueHandle parameter.

Attention

The handle(s) must not be used again after being invalidated using clear_message_queue. Using an invalid handle results in undefined behavior. Operator clear_message_queue must not be called while the handle is used concurrently from other threads, because this would result in undefined behavior.

Parameters

▷ **QueueHandle** (input_control) . . . . . message_queue(-array) ⇝ *handle*
Message queue handle(s) to be closed.
Number of elements: QueueHandle >= 1
Restriction: QueueHandle != 0

Example

```
create_message_queue (ProducerQueue)
create_message_queue (ResultQueue)
* ...
```

Result

If the message queue handle(s) passed to the operator are valid, clear_message_queue returns 2 (H_MSG_TRUE). Otherwise an exception is raised. If a tuple of handles is passed and some of them are invalid, clear_message_queue attempts to clear as many handles from the tuple as possible before reporting the error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- QueueHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

Module

Foundation

clear_mutex (: : MutexHandle :)

Clear the mutex synchronization object.

clear_mutex destroys the mutex object given by MutexHandle. The mutex must be unlocked. After calling clear_mutex, the mutex can no longer be used. The handle MutexHandle becomes invalid.

Parameters

▷ **MutexHandle** (input_control) ..... mutex ⇝ *handle*
Mutex synchronization object.

Result

If the mutex handle is valid, the operator clear_mutex returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MutexHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_mutex

See also

create_mutex

Module

Foundation

create_barrier (: : AttribName, AttribValue, TeamSize : BarrierHandle)

Create a barrier synchronization object.

A barrier is a synchronization object blocking a thread until a previous defined number of threads have reached this barrier. `create_barrier` allocates and initializes the barrier object returned in `BarrierHandle` according to the attributes specified in `AttribName` and `AttribValue`. `AttribName` specifies the attribute class and `AttribValue` the kind of the barrier. The description beneath lists all barrier kinds supported by following parameter classes:

'' empty string sets the default attributes.

'type' specifies what happens if a thread waits at a barrier:

'sleep' simply suspends the calling thread (default).

'spin' a fast barrier implementation for short waits that waits busy.

The `TeamSize` argument specifies the number of threads that must call `wait_barrier` before any of them successfully return from waiting. The value hold in `TeamSize` must be greater than zero.

Parameters

▷ **`AttribName`** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Barrier attribute.
Default: []
List of values: `AttribName` ∈ {'type'}

▷ **`AttribValue`** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Barrier attribute value.
Number of elements: AttribValue == AttribName
Default: []
List of values: `AttribValue` ∈ {'spin', 'sleep'}

▷ **`TeamSize`** (input_control) . . . . . number ⇝ *integer*
Barrier team size.
Default: 1

▷ **`BarrierHandle`** (output_control) . . . . . barrier ⇝ *handle*
Barrier synchronization object.

Result

`create_barrier` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`wait_barrier`, `clear_barrier`

Module

Foundation

`create_condition ( : : AttribName, AttribValue : ConditionHandle )`

Create a condition variable synchronization object.

A condition variable (short: "condition") is a synchronization device that allows threads to suspend execution and relinquish the processors until some predicate on shared data is satisfied. The basic operations on conditions are: signal the condition (when the predicate becomes true), and wait for the condition, suspending the thread execution until another thread signals the condition.

A condition variable must always be associated with a mutex, to avoid the race condition where a thread prepares to wait on a condition variable and another thread signals the condition just before the first thread actually waits on it.

create_condition creates and initializes the condition variable ConditionHandle, using the condition attributes specified in AttribName and AttribValue, or default attributes if AttribName is ''. The current implementation supports no attributes for conditions, hence the AttribName parameter must be set to ''.

Parameters

▷ **AttribName** (input_control) . . . . . number(-array) ⇝ *string* / integer / real
Mutex attribute.
Default: []

▷ **AttribValue** (input_control) . . . . . number(-array) ⇝ *string* / integer / real
Mutex attribute value.
Number of elements: AttribValue == AttribName
Default: []

▷ **ConditionHandle** (output_control) . . . . . condition ⇝ *handle*
Condition synchronization object.

Result

create_condition returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

wait_condition, timed_wait_condition, signal_condition

See also

clear_condition

Module

Foundation

create_event (: : AttribName, AttribValue : EventHandle)

Create an event synchronization object.

An event is a prelocked mutual exclusion that does not belong to a thread, i.e., it can be signaled by a thread different from the locking thread. This understanding is, e.g., close to the definition of an event in WIN32-API or a semaphore with count 0 in POSIX threads.

create_event allocates and initializes the event object according to the attributes specified in AttribName and AttribValue. AttribName specifies the attribute class and AttribValue the kind of the event. The description beneath lists all mutex kinds supported by following classes:

'' empty string sets the default attributes.

'type' specifies what happens if a thread waits on a signal to an event:

'sleep' simply suspends the calling thread (default).

'spin' a fast event implementation that waits busy on a signal. This type is non recursive.

Parameters

▷ **AttribName** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Mutex attribute.
Default: []
List of values: AttribName ∈ {'type'}

▷ **AttribValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Mutex attribute value.
Number of elements: AttribValue == AttribName
Default: []
List of values: AttribValue ∈ {'spin', 'sleep'}

▷ **EventHandle** (output_control) . . . . . event ⇝ *handle*
Event synchronization object.

Result

`create_event` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`wait_event`, `signal_event`, `clear_event`

See also

`clear_event`

Module

Foundation

create_message (: : : MessageHandle)

Create a new empty message.

`create_message` creates a new empty message. The output parameter `MessageHandle` is a handle to the newly created message and is used to identify the message in any subsequent operator call using the message.

The message serves as a dictionary-like container that can be passed between the threads of an application using asynchronous message queues. Alternatively, HALCON also provides dictionaries (`create_dict`) to group parameters in programs and procedures.

Messages can store an arbitrary number of entries, each having its unique key (string or integer) and associated value. Each key can refer either to a control parameter tuple or to an iconic object. These data are stored to the message using `set_message_tuple` or `set_message_obj`, respectively, from where they can be retrieved again using `get_message_tuple` or `get_message_obj`.

The control parameter tuples stored in the message are always deep copies of the original data. The original data can thus be reused immediately after the `set_message_tuple` call without affecting the message. Notable exceptions are handles: Storing any handle in the message will copy the handle value, but not the resource behind the handle.

As mentioned above, the messages can be passed between the threads of an application using asynchronous message queues. The data can be appended to the queue by multiple producer threads using `enqueue_message` and retrieved from the queue by multiple receiver threads using `dequeue_message`. All these operations are internally properly synchronized. Therefore, the queue can be safely accessed by all producers and consumers without any explicit locking. All the enqueued messages are copied by the `enqueue_message` operation. The original message(s) can thus be immediately reused after the `enqueue_message` call without affecting the enqueued copy.

Parameters

▷ **MessageHandle** (output_control) . . . . . message ⇝ *handle*
Handle of the newly created message.
Number of elements: MessageHandle == 1
Assertion: MessageHandle != 0

Example

```
MessageHandles := []
for idx := 0 to 4 by 1
  create_message (MessageHandle)
  MessageHandles[idx]:= MessageHandle
endfor
* ...
```

Result

Returns 2 (H_MSG_TRUE) unless a resource allocation error occurs.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

set_message_tuple, set_message_obj

Alternatives

create_dict

Module

Foundation

create_message_queue (: : : QueueHandle)

Create a new empty message queue.

create_message_queue creates a new empty message queue. The output parameter QueueHandle is a handle to the newly created message queue and is used to identify the queue in any subsequent operator calls using the queue.

The message queues are designed as FIFO pipes delivering arbitrary sets of data safely among different threads. The queue access is internally fully synchronized, no explicit locking is required from the application. The data is traveling through the queue in so called messages (see create_message).

Multiple producer threads can append data simultaneously (enqueue_message) while multiple consumer threads are simultaneously retrieving the data again (dequeue_message). Multiple messages can be enqueued together using a single enqueue_message operation. In such case, those messages will travel together through the queue and will be delivered through a single dequeue_message call.

All the enqueued messages are copied by the enqueue_message operation. The original message(s) can thus be immediately reused after the enqueue_message call without affecting the enqueued copy.

Parameters

▷ **QueueHandle** (output_control) . . . . . message_queue ⇝ *handle*
Handle of the newly created message queue.
Number of elements: QueueHandle == 1
Assertion: QueueHandle != 0

Example

```
create_message_queue (ProducerQueue)
create_message_queue (ResultQueue)
* ...
```

Result

Returns 2 (H_MSG_TRUE) unless a resource allocation error occurs. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Successors

enqueue_message, dequeue_message

Module

Foundation

create_mutex (: : AttribName, AttribValue : MutexHandle)

Create a mutual exclusion synchronization object.

A mutex is a synchronization object that negotiates mutual exclusion among threads of a single process to avoid simultaneous modifications on common resources such as global variables. A mutex has two possible states: unlocked, i.e., not owned by any thread, and locked, i.e., owned by one certain thread. Threads attempting to lock a mutex that is already owned by another thread, i.e., locked, wait until the owning thread unlocks the mutex first. Unlike events, a thread has to own a mutex to unlock it.

create_mutex allocates and initializes the mutex object according to the attributes specified in AttribName and AttribValue. AttribName specifies the attribute class and AttribValue the kind of the mutex. The description beneath lists all mutex kinds supported by following classes:

'' empty string sets the default attributes.

'type' specifies what happens if a thread attempts to lock a mutex that is already owned:

'sleep' simply suspends the calling thread (default). The behavior is undefined, if the thread is already owner of the mutex.

'spin' a fast mutex implementation that is busy waiting for the signaled mutex. The behavior is undefined, if the thread is already owner of the mutex.

'recursive' suspends the calling thread if the thread is not owner of the mutex. But a recursive mutex can be acquired again by the owning thread. A recursive mutex does not become unlocked until the number of unlock requests equals the number of successful lock requests.

The mutex is unlocked when created.

Parameters

▷ **AttribName** (input_control) . . . . . number(-array) ⇝ *string* / integer / real
Mutex attribute class.
Default: []
List of values: AttribName ∈ {'type'}

▷ **AttribValue** (input_control) . . . . . number(-array) ⇝ *string* / integer / real
Mutex attribute kind.
Number of elements: AttribValue == AttribName
Default: []
List of values: AttribValue ∈ {'spin', 'sleep', 'recursive'}

▷ **MutexHandle** (output_control) . . . . . mutex ⇝ *handle*
Mutex synchronization object.

Result

create_mutex returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

lock_mutex, clear_mutex

See also

clear_mutex

Module

Foundation

dequeue_message (: : QueueHandle, GenParamName, GenParamValue : MessageHandle)

Receive one or more messages from the message queue.

dequeue_message dequeues a message from the message queue denoted by the QueueHandle parameter. The message must have been enqueued by any thread using enqueue_message.

The messages are delivered in FIFO (first-in first-out) order, every message is delivered only once. If the queue is not empty, dequeue_message immediately delivers the oldest message from the queue. This message is removed from the queue and a handle to the message is returned in the MessageHandle output parameter. The message data ownership is transferred (no copy) from the message queue to the newly created message handle.

If the queue is empty, dequeue_message blocks until a message becomes available for delivery (being queued from another thread using enqueue_message).

The data stored in the message can be queried using get_message_tuple, get_message_obj, or get_message_param.

The message handles obtained through dequeue_message can be further reused (modified and/or enqueued to another message queue).

If multiple messages were enqueued using a single enqueue_message call, all those messages will be also retrieved together through a single dequeue_message call, delivering multiple message handles via the MessageHandle tuple.

The queue access is internally fully synchronized, no external locking is required.

During application reconfiguration or cleanup, it might be necessary to wake threads waiting for messages in dequeue_message. This can be achieved using the operator set_message_queue_param with the parameter *'abort_dequeuing'*. In such case the currently blocked dequeue_message calls return immediately with H_ERR_MQCNCL.

Finally, it is possible to adjust dequeue_message behavior through generic parameters within GenParamName and GenParamValue. Currently, just a single generic parameter is supported:

'timeout': Timeout controlling how long the operator will block while waiting for a message if the queue is empty. When expired, the operator returns with H_ERR_TIMEOUT. The timeout can be specified as an integer or double value in seconds or as the string *'infinite'*. When no timeout is specified, infinite timeout is used as default, meaning that the operator would block until a new message is enqueued or until the operation is aborted.

Parameters

▷ **QueueHandle** (input_control) . . . . . message_queue ⇝ *handle*
Message queue handle.
Number of elements: QueueHandle == 1
Restriction: QueueHandle != 0

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Names of optional generic parameters
Number of elements: GenParamName == GenParamValue
Default: 'timeout'
List of values: GenParamName ∈ {'timeout'}

▷ **GenParamValue** (input_control) . . . . . tuple(-array) ⇝ *string* / integer / real
Values of optional generic parameters
Number of elements: GenParamName == GenParamValue
Default: 'infinite'
List of values: GenParamValue ∈ {'infinite'}

▷ **MessageHandle** (output_control) . . . . . message(-array) ⇝ *handle*
Handle(s) of the dequeued message(s).
Number of elements: MessageHandle > 0
Assertion: MessageHandle != 0

Example

```
create_message_queue (Queue)
* ...
dequeue_message (Queue, [], [], Message)
get_message_obj (Image, Message, 'my_image')
```

Result

If the operation succeeds, `dequeue_message` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters, message dequeue wait timeout (H_ERR_TIMEOUT) or message dequeue wait abortion (H_ERR_MQCNCL). Note that in some rare cases, when an error occurs when finishing the operator call (after the message has already been removed from the queue), the operator will attempt to put the message back at the head of the queue to not lose it. This might lead to a different message delivery order if another thread removed another message from the queue in the meanwhile.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

enqueue_message (: : QueueHandle, MessageHandle, GenParamName, GenParamValue :)

Enqueue one or more messages to the message queue.

`enqueue_message` enqueues one or more messages to the message queue denoted by the `QueueHandle` parameter. The enqueued messages can be retrieved from the queue by any thread using `dequeue_message`.

The messages (see `create_message`) to be enqueued are specified in the `MessageHandle` parameter which accepts a single handle as well as tuple of handles. When enqueuing multiple handles together in a single `enqueue_message` call, they are delivered again together through a single `dequeue_message` call.

Multiple producer (enqueuing) threads and multiple consumer (dequeuing) threads can share the same queue at a time. The messages are delivered in FIFO (first-in first-out) order. Every message is delivered only once, even if multiple consumer threads are using the queue.

The queue access is internally fully synchronized, no external locking is required. If the queue is empty and there is at least one consumer thread waiting for the message data in `dequeue_message`, one of those threads is woken up by a successful `enqueue_message` call and the enqueued message data are immediately delivered. Otherwise the message data is appended to the queue asynchronously, to be delivered as soon as a consumer thread is ready to dequeue the message data again.

All the enqueued messages (MessageHandle) are copied by the enqueue_message operation. The original message(s) can thus be immediately reused after the enqueue_message call without affecting the enqueued copy.

Operator parameters GenParamName and GenParamValue are reserved in the operator's interface for future use, currently no generic parameters are supported.

If, after the operation, the queue would hold a larger number of messages than the maximum number specified with parameter value *'max_message_num'* of operator set_message_queue_param, the call would fail with H_ERR_MQOVL.

Parameters

▷ **QueueHandle** (input_control) . . . . . message_queue ⇝ *handle*
Message queue handle.
Number of elements: QueueHandle == 1
Restriction: QueueHandle != 0

▷ **MessageHandle** (input_control) . . . . . message(-array) ⇝ *handle*
Handle(s) of message(s) to be enqueued.
Number of elements: MessageHandle > 0
Restriction: MessageHandle != 0

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Names of optional generic parameters.
Number of elements: GenParamName == GenParamValue

▷ **GenParamValue** (input_control) . . . . . tuple-array ⇝ *string* / integer / real
Values of optional generic parameters.
Number of elements: GenParamName == GenParamValue

Example

```
create_message_queue (Queue)
* ...
create_message (Message)
set_message_tuple (Message, 'mixed_tuple', ['The answer', 42])
enqueue_message (Queue, Message, [], [])
```

Result

If the operation succeeds, enqueue_message returns 2 (H_MSG_TRUE). Otherwise an exception is raised. Possible error conditions include invalid parameters or resource allocation error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

get_current_hthread_id (: : : HThreadID)

Return the HALCON thread ID of the current thread.

get_current_hthread_id returns a thread ID that represents the currently running thread in HThreadID. This ID is identical to the windows thread ID or the POSIX thread ID on UNIX platforms and is also returned by the par_start operation of the HDevEngine. It can later be used to interrupt operators that are executed in this thread using interrupt_operator.

Parameters

▷ **HThreadID** (output_control) . . . . . integer ⇝ *integer*
ID representing the current thread.

Example

```
global tuple HThreadID
get_current_hthread_id (HThreadID)
* call some slow operator...

* In a different thread
wait_seconds(2)
* Interrupt the long-running operator in the other thread
interrupt_operator (HThreadID, 'break')
```

Result

If the current thread can be determined, get_current_hthread_id returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

interrupt_operator

See also

interrupt_operator, set_operator_timeout

Module

Foundation

get_message_obj (: ObjectData : MessageHandle, Key :)

Retrieve an object associated with the key from the message.

get_message_obj retrieves an object associated with the Key from the message denoted by the MessageHandle. The object has to be previously stored to the message using set_message_obj.

The operator returns the data in the parameter ObjectData. The iconic object is copied by the operation. Therefore, clearing or reusing the message object afterwards will not have any side-effect on the returned iconic object, afterwards.

If the given Key is not present in the message or if the data associated with the key is not an object, get_message_obj fails. Presence of keys and information about the data associated with the key can be verified using get_message_param.

Parameters

▷ **ObjectData** (output_object) . . . . . object(-array) ⇝ *object*
Tuple value retrieved from the message.

▷ **MessageHandle** (input_control) . . . . . message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Restriction: MessageHandle != 0

▷ **Key** (input_control) . . . . . string ⇝ *string* / integer
Key string or integer.
Number of elements: Key == 1

Example

```
* ...
get_message_param (Message,'key_exists',['simple_string','foo','my_image'],\
                   KeysPresence)
get_message_param (Message,'key_data_type',['simple_string','my_image'],\
                   KeysType)
get_message_obj (Image, Message, 'my_image')
```

Result

If the operation succeeds, `get_message_obj` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key), the required key not found in the message or other than object data associated with given key.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`get_message_param` (: : `MessageHandle`, `GenParamName`, `Key` : `GenParamValue`)

Query message parameters or information about the message.

`get_message_param` queries current values of message parameters or other information about the message status.

With each call of `get_message_param`, only a single parameter value can be queried. However, there are two types of parameters/queries:

- Parameters/queries applicable to the entire message. In this case no keys must be specified, the parameter `Key` must be an empty tuple.
- Parameters/queries applicable to the individual keys. In this case a non-empty list of keys must be specified in the parameter `Key`. The keys are processed in the same order as specified in the `Key` parameter.

Key-independent (global) parameter names:

'message_keys': Queries all the keys stored in the message, no matter whether they are associated with tuple or object data. The list of keys is reported as a string tuple via `GenParamValue`. For this query the parameter `Key` must be an empty tuple.

Currently supported key-specific parameter names are:

'key_exists': Reports *1* if the given key is stored in the message, *0* otherwise. The results are reported via GenParamValue, one value for each key.

'key_data_type': Reports *'tuple'* for keys associated with tuple data within the message (the data can be retrieved using get_message_tuple). Reports *'object'* for keys associated with object data (the data can be retrieved using get_message_obj). The results are reported via GenParamValue, one value for each key. This parameter is useful to decide dynamically whether to use get_message_tuple or get_message_obj to get the data of a specific key.

Parameters

▷ **MessageHandle** (input_control) . . . . . message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Restriction: MessageHandle != 0

▷ **GenParamName** (input_control) . . . . . string ⇝ *string*
Names of the message parameters or info queries.
Number of elements: GenParamName == GenParamValue
Default: 'message_keys'
List of values: GenParamName ∈ {'message_keys', 'key_exists', 'key_data_type'}

▷ **Key** (input_control) . . . . . string(-array) ⇝ *string* / integer
Message keys the parameter/query should be applied to.

▷ **GenParamValue** (output_control) . . . . . tuple(-array) ⇝ *string* / integer / real
Values of the message parameters or info queries.

Example

```
get_message_param (Message, 'message_keys', [], AllKeys)
get_message_param (Message, 'key_data_type', AllKeys, KeysType)
```

Result

If all the operator parameters, and the specified keys are valid, get_message_param returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

dequeue_message

Module

Foundation

get_message_queue_param (: : QueueHandle, GenParamName : GenParamValue)

Query message queue parameters or information about the queue.

get_message_queue_param queries current values of message queue parameters or other information about the queue status.

Multiple queries can be carried out with a single get_message_queue_param call, passing multiple parameter names to parameter GenParamName. The parameter values are returned in GenParamValue in the same order as the parameter names requested by the caller.

Currently, following parameter names are supported:

'is_empty': Returns *1* if the queue is empty, *0* otherwise.

'message_num': Returns the number of messages currently stored in the queue.

'max_message_num': Returns the current value of the *'max_message_num'* parameter of the message queue, as it was set using `set_message_queue_param`. The default value *-1* stands for no limit.

Parameters

▷ **`QueueHandle`** (input_control) . . . . . message_queue ⇝ *handle*
Message queue handle.
Number of elements: QueueHandle == 1
Restriction: QueueHandle != 0

▷ **`GenParamName`** (input_control) . . . . . string(-array) ⇝ *string*
Names of the queue parameters or info queries.
Number of elements: GenParamName == GenParamValue
Default: 'max_message_num'
List of values: `GenParamName` ∈ {'is_empty', 'message_num', 'max_message_num'}

▷ **`GenParamValue`** (output_control) . . . . . tuple(-array) ⇝ *string* / integer / real
Values of the queue parameters or info queries.
Number of elements: GenParamName == GenParamValue

Example

```
create_message_queue (QueueHandle)
set_message_queue_param ( QueueHandle, 'max_message_num', 10)
* ...
get_message_queue_param( QueueHandle, 'message_num', Num)
```

Result

If all the operator parameters are valid, `get_message_queue_param` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

`get_message_tuple` (: : MessageHandle, Key : TupleData)

Retrieve a tuple associated with the key from the message.

`get_message_tuple` retrieves a tuple associated with the `Key` from the message denoted by the `MessageHandle`. The tuple has to be previously stored to the message using `set_message_tuple`.

The operator returns the data in the parameter `TupleData`. The data including strings is copied by the operation, the message can thus be immediately reused.

If the given `Key` is not present in the message or if the data associated with the key is not a tuple, `get_message_tuple` fails. Presence of keys and information about the data associated with the key can be verified using `get_message_param`.

Parameters

▷ **MessageHandle** (input_control) . . . . . message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Restriction: MessageHandle != 0

▷ **Key** (input_control) . . . . . string ⇝ *string* / integer
Key string or integer.
Number of elements: Key == 1

▷ **TupleData** (output_control) . . . . . tuple(-array) ⇝ *string* / integer / real / handle
Tuple value retrieved from the message.

Example

```
* ...
get_message_param (Message,'key_exists',['simple_string','foo','my_image'],\
                   KeysPresence)
get_message_param (Message,'key_data_type',['simple_string','my_image'],\
                   KeysType)
get_message_tuple (Message,'simple_string',TupleString)
```

Result

If the operation succeeds, `get_message_tuple` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key), the required key not found in the message, or other than tuple data associated with given key.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_threading_attrib (: : ThreadingHandle : ThreadingClass, AttribName, AttribValue)

Query the attributes of a threading / synchronization object.

`get_threading_attrib` determines the type of threading object passed to `ThreadingHandle` and the attributes the threading object was created with.

Parameters

▷ **ThreadingHandle** (input_control) . . . . . number ⇝ *integer*
Threading object.

▷ **ThreadingClass** (output_control) . . . . . string-array ⇝ *string*
Class name of threading object.

▷ **AttribName** (output_control) . . . . . string-array ⇝ *string*
Name of an attribute.

▷ **AttribValue** (output_control) . . . . . number-array ⇝ *string* / integer / real
Value of the attribute.

Result

If the threading handle is valid, the operator `get_threading_attrib` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`create_mutex`, `create_event`, `create_condition`, `create_barrier`

See also

`create_mutex`, `create_event`, `create_condition`, `create_barrier`

Module

interrupt_operator (: : HThreadID, Mode :)

Attempt to interrupt an operator running in a different thread.

`interrupt_operator` attempts to gracefully interrupt the operator currently running in the HALCON thread represented by `HThreadID`. If that currently running operator supports interruption, it will abort its execution depending on `Mode` (see below). If the thread is currently not executing any operator, or if the currently running operator does not support interruptions, `interrupt_operator` is a no-op. The execution of any future operator in the other thread is not affected.

The ID representing a thread can be obtained with `get_current_hthread_id`.

`interrupt_operator` supports currently only one type of interruption, which can be set in `Mode`. Note that the corresponding type must also be supported by the operator currently running in the other thread. To determine if an operator is interruptible and which kind of interrupts it supports, please see the "Execution Information" section of the operator documentation or query the information using the parameter *'interrupt_mode'* of the operator `get_operator_info`.

Some operators, for which no interruptibility is mentioned in the reference documentation, can still be interrupted at some points of their execution. However, such interruptabilities are not guaranteed and can change without further notice between different versions of HALCON.

'cancel': Abort the execution of the operator. All results computed by the operator are discarded and the operator returns the error code H_ERR_CANCEL (22).

Attention

Note that not all operators support interruption. If a given operator supports interruptions and which modes are supported is described in the execution information section of the reference documentation of the corresponding operator.

Also note that there is no hard guarantee about the granularity of the interruption. The granularity can depend on the operator, its input data and the speed of the device. It is typically finer than 10 ms.

Parameters

▷ **HThreadID** (input_control) . . . . . integer ⇝ *integer*
Thread that runs the operator to interrupt.

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Interruption mode.
Default: 'cancel'
List of values: `Mode` ∈ {'cancel'}

Example

```
global tuple HThreadID
get_current_hthread_id (HThreadID)
* call some slow operator...

* In a different thread
wait_seconds(2)
* Interrupt the long-running operator in the other thread
interrupt_operator (HThreadID, 'cancel')
```

Result

If all the operator parameters are valid, `interrupt_operator` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`get_current_hthread_id`

Alternatives

`set_operator_timeout`

See also

`get_current_hthread_id`, `set_operator_timeout`

Module

Foundation

lock_mutex (: : MutexHandle :)

Lock a mutex synchronization object.

`lock_mutex` locks the mutex given by `MutexHandle`. If the mutex is currently unlocked, it becomes locked and owned by the calling thread, and `lock_mutex` returns immediately. If the mutex is already locked by another thread, the calling thread waits until the mutex is unlocked. The kind of wait is defined by the mutex' attributes set during creation in `create_mutex`.

Parameters

▷ **MutexHandle** (input_control) . . . . . mutex ⇝ *handle*
Mutex synchronization object.

Result

If the mutex handle is valid, the operator `lock_mutex` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_mutex`

Possible Successors

`unlock_mutex`

try_lock_mutex

Module

Foundation

read_message (: : FileName, GenParamName, GenParamValue : MessageHandle)

Read a message from a file.

read_message reads a message that has been stored with write_message. The default HALCON file extension for a message is 'hmsg'.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
File name.
File extension: .hmsg

▷ **GenParamName** (input_control) ..... attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'name'}

▷ **GenParamValue** (input_control) ..... attribute.name(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []

▷ **MessageHandle** (output_control) ..... message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Assertion: MessageHandle != 0

Result

If the parameters are valid, the operator read_message returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

write_message

write_message, serialize_handle, deserialize_handle

Module

Foundation

set_message_obj (ObjectData : : MessageHandle, Key :)

Add a key/object pair to the message.

set_message_obj stores an object associated with a key in the message, which behaves as a dictionary-like data container. The message is denoted by the MessageHandle parameter.

ObjectData is copied by the operation (copying the object data in HALCON's object database, see copy_obj), and can thus be immediately reused. Both an empty object or an object tuple are considered as a valid value that

can be associated with the key. If any data (tuple or object) was already associated with given key (Key), the old data is destroyed by set_message_obj and replaced by ObjectData.

The Key has to be a string or an integer. String keys are treated case sensitive.

The object data for the given key can be retrieved again from the message using get_message_obj.

Parameters

▷ **ObjectData** (input_object) ..... object(-array) ⇝ *object*
Object to be associated with the key.

▷ **MessageHandle** (input_control) ..... message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Restriction: MessageHandle != 0

▷ **Key** (input_control) ..... string ⇝ *string* / integer
Key string or integer.
Number of elements: Key == 1

Example

```
create_message (Message)
read_image( Image, 'filename')
set_message_obj (Image, Message, 'my_image')
```

Result

If the operation succeeds, set_message_tuple returns 2 (H_MSG_TRUE). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key) or resource allocation error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MessageHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

create_message, clear_message, set_message_tuple, get_message_tuple, get_message_obj, set_message_param, get_message_param, enqueue_message, dequeue_message

Module

Foundation

set_message_param (: : MessageHandle, GenParamName, Key, GenParamValue :)

Set message parameter or invoke commands on the message.

set_message_param sets message parameters or invokes action commands on the message.

For each call of set_message_param, only a single parameter can be set. However, there are two types of parameters/commands:

- Parameters/commands applicable to the entire message. In this case no keys must be specified, i.e., the parameter Key must be an empty tuple.
- Parameters/commands applicable to the individual keys. In this case a non-empty list of keys must be specified in parameter Key. The keys are processed in the same order as specified in the Key parameter.

Key-independent parameter names:

'remove_all_keys': Removes all the keys currently stored in the message and releases all the (control or iconic) data associated with those keys. The operation results in an empty message. Note that contents of GenParamValue is ignored for this parameter, while Key must be an empty tuple.

Key-specific parameter names:

'remove_key': Removes the keys specified in the Key parameter and releases all the (tuple or object) data associated with those keys. If an error occurs while processing one or more keys (in particular if the key is invalid), the operator attempts to continue removing as many keys as possible before reporting the failure. Note that the contents of GenParamValue is ignored for this parameter.

Parameters

▷ **MessageHandle** (input_control) . . . . . message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Restriction: MessageHandle != 0

▷ **GenParamName** (input_control) . . . . . string ⇝ *string*
Names of the message parameters or action commands.
Number of elements: GenParamName == 1
Default: 'remove_key'
List of values: GenParamName ∈ {'remove_key', 'remove_all_keys'}

▷ **Key** (input_control) . . . . . string(-array) ⇝ *string* / integer
Message keys the parameter/command should be applied to.

▷ **GenParamValue** (input_control) . . . . . tuple(-array) ⇝ *string* / integer / real
Values of the message parameters or action commands.

Example

```
* Remove some keys
set_message_param (Message, 'remove_key', ['my_image', 'simple_string'], [])
```

Result

If all the operator parameters, and their values, as well as specified keys are valid, set_message_param returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MessageHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

dequeue_message, create_message

Possible Successors

enqueue_message, clear_message

create_message, clear_message, set_message_tuple, get_message_tuple, set_message_obj, get_message_obj, get_message_param, enqueue_message, dequeue_message

Module

Foundation

set_message_queue_param (: : QueueHandle, GenParamName, GenParamValue :)

Set message queue parameters or invoke commands on the queue.

set_message_queue_param sets message queue parameters or invokes action commands on the queue.

Multiple parameters and action commands can be passed through a single set_message_queue_param call, passing multiple parameter names in a tuple GenParamName and corresponding values in GenParamValue. There must be always the same number of names and values and the values must be in the same order as the names. The parameters and action commands are applied in the same order passed in GenParamName. It is important to understand that in particular in case of the action commands, it might not be possible to revert the effect of previous action commands if a later command fails, the caller therefore might need to be careful when setting multiple commands in a single call.

Currently supported parameter names are:

'abort_dequeuing': Aborts any dequeue_message operator waiting in any thread for data to be delivered. Any currently waiting call will unblock and return H_ERR_MQCNCL. Any dequeue_message call invoked in the future will return H_ERR_MQCNCL immediately regardless of the queue status.

This command is typically needed for cleanup when any threads using the message queue and possibly blocked in dequeue_message must be released, because it is not allowed to destroy the queue (clear_message_queue) while any operators might still use it. It might be necessary to wait for the completion of those threads after invoking the *'abort_dequeuing'* command to be sure any operators using the queue are completed.

The message data currently stored in the message queue is not affected by the command. The effect of canceling any further *'abort_dequeuing'* calls can be reset again using the *'restore_queue'* command.

The parameter value must be integer *1*.

'restore_queue': Clears the effect of a previous *'abort_dequeuing'* command. This means the next call to dequeue_message will again attempt to deliver message data.

The parameter value must be integer *1*.

'flush_queue': Flushes the queue. All currently enqueued messages are removed from the queue and all associated resources, in particular the tuple or object data stored in the messages, are released.

The parameter value must be integer *1*.

'max_message_num': Sets the maximum number of messages that can be stored in the queue. The enqueue_message operator call would fail (H_ERR_MQOVL) if the queue would contain more messages after the operation than the defined maximum.

Setting the *'max_message_num'* parameter has no effect on the messages already present in the queue. No messages that are already in the queue can be removed by this operation.

The parameter value can be a positive integer or *-1* if the queue size should be unlimited. The string value *'infinite'* is accepted as well. The queue size is unlimited by default.

Parameters

▷ **QueueHandle** (input_control) . . . . . message_queue ⇝ *handle*
Message queue handle.
Number of elements: QueueHandle == 1
Restriction: QueueHandle != 0

▷ **GenParamName** (input_control) ..... string(-array) ⇝ *string*
Names of the queue parameters or action commands.
Number of elements: GenParamName == GenParamValue
Default: 'max_message_num'
List of values: GenParamName ∈ {'abort_dequeuing', 'restore_queue', 'flush_queue', 'max_message_num'}

▷ **GenParamValue** (input_control) ..... tuple(-array) ⇝ *string* / integer / real
Values of the queue parameters or action commands.
Number of elements: GenParamName == GenParamValue
Default: 1
Suggested values: GenParamValue ∈ {1, -1}

Example

```
* abort waiting dequeue_message operators
set_message_queue_param (Queue, 'abort_dequeuing', 1)
```

Result

If all the operator parameters and their values are valid, set_message_queue_param returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_message_tuple (: : MessageHandle, Key, TupleData :)

Add a key/tuple pair to the message.

set_message_tuple stores a tuple associated with a key in the message, which behaves as a dictionary-like data container. The message is denoted by the MessageHandle parameter.

TupleData including strings is copied by the operation, and can thus be immediately reused. An empty tuple is considered as a valid value that can be associated with the key. If any data (tuple or object) was already associated with given key (Key), the old data is destroyed by set_message_tuple and replaced by TupleData.

The Key has to be a string or an integer. String keys are treated case sensitive.

The tuple data for the given key can be retrieved again from the message using get_message_tuple.

Attention

Note that if the tuple contains any handles (which are treated as simple integers) only the handle values are copied by the operation, not the resources behind those handles.

Parameters

▷ **MessageHandle** (input_control) . . . . . message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Restriction: MessageHandle != 0

▷ **Key** (input_control) . . . . . string ⇝ *string* / integer
Key string or integer.
Number of elements: Key == 1

▷ **TupleData** (input_control) . . . . . tuple-array ⇝ *string* / integer / real / handle
Tuple value to be associated with the key.

Example

```
create_message (Message)
set_message_tuple (Message, 'simple_integer', 27)
set_message_tuple (Message, 'simple_string', 'Hello world')
set_message_tuple (Message, 'mixed_tuple', ['The answer', 42])
```

Result

If the operation succeeds, `set_message_tuple` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key) or resource allocation error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- MessageHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

signal_condition (: : ConditionHandle :)

Signal a condition synchronization object.

`signal_condition` restarts one of the threads that are waiting on the condition variable `ConditionHandle`. If no threads are waiting on `ConditionHandle`, nothing happens. If several threads are waiting on `ConditionHandle`, exactly one is restarted, but it is not specified which one.

Parameters

▷ **ConditionHandle** (input_control) . . . . . condition ⇝ *handle*
Condition synchronization object.

Result

If the condition handle is valid, the operator `signal_condition` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_condition`, `wait_condition`

See also

`wait_condition`, `timed_wait_condition`

Module

Foundation

signal_event (: : EventHandle :)

Unlock an event synchronization object.

`signal_event` releases the event given in `EventHandle`. Signaling an event that is already signaled has no effect.

Parameters

▷ **EventHandle** (input_control) . . . . . event ⇝ *handle*
Event synchronization object.

Result

If the event handle is valid, the operator `signal_event` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`wait_event`

Possible Successors

`wait_event`, `clear_event`

Module

Foundation

timed_wait_condition (: : ConditionHandle, MutexHandle, Timeout :)

Bounded wait on the signal of a condition synchronization object.

`timed_wait_condition` atomically unlocks `MutexHandle` and waits on `ConditionHandle`, as `wait_condition` does, but it also bounds the duration of the wait. If `ConditionHandle` has not been

signaled within the amount of time specified by Timeout in micro seconds, the mutex MutexHandle is re-acquired and timed_wait_condition returns the error H_ERR_TIMEOUT.

Using negative values for Timeout means an infinite waiting time.

Parameters

▷ **ConditionHandle** (input_control) ..... condition ⇝ *handle*
Condition synchronization object.

▷ **MutexHandle** (input_control) ..... mutex ⇝ *handle*
Mutex synchronization object.

▷ **Timeout** (input_control) ..... number ⇝ *integer*
Timeout in micro seconds.

Result

timed_wait_condition returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised. If a timeout occurs, the error H_ERR_TIMEOUT is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

signal_condition, clear_condition

Module

Foundation

try_lock_mutex (: : MutexHandle : Busy)

Lock a mutex synchronization object.

try_lock_mutex behaves identically to lock_mutex, except that it does not block the calling thread if the mutex is already locked by another thread but returns immediately. The state of the mutex before trying to lock it is returned in Busy. *1* indicates that the mutex was already locked before calling try_lock_mutex, *0* that the mutex was unlocked (signaled).

Parameters

▷ **MutexHandle** (input_control) ..... mutex ⇝ *handle*
Mutex synchronization object.

▷ **Busy** (output_control) ..... number ⇝ *integer*
Mutex already locked?

Result

If the mutex handle is valid, the operator try_lock_mutex returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_mutex

Possible Successors

unlock_mutex

lock_mutex

Module

Foundation

try_wait_event (: : EventHandle : Busy)

Lock an event synchronization object only if it is unlocked.

try_wait_event behaves identically to wait_event, except that it does not block the calling thread when waiting until the object is signaled but returns immediately. The state of the event before entering try_wait_event is returned in Busy. *1* indicates that the event was non-signaled before calling try_wait_event, *0* that the event was signaled.

Parameters

▷ **EventHandle** (input_control) ..... event ⇝ *handle*
Event synchronization object.

▷ **Busy** (output_control) ..... number ⇝ *integer*
Object already locked?

Result

If the event handle is valid, the operator try_wait_event returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_event

Possible Successors

signal_event

See also

wait_event

Module

Foundation

unlock_mutex (: : MutexHandle :)

Unlock a mutex synchronization object.

unlock_mutex unlocks the mutex object given by MutexHandle. The mutex must have been locked by the calling thread. Attempting to unlock a mutex that is not locked by the calling thread is undefined behavior.

Parameters

▷ **MutexHandle** (input_control) ..... mutex ⇝ *handle*
Mutex synchronization object.

Result

If the mutex handle is valid, the operator unlock_mutex returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Predecessors

lock_mutex, try_lock_mutex

Possible Successors

lock_mutex, try_lock_mutex, clear_mutex

Module

Foundation

wait_barrier (: : BarrierHandle :)

Wait on the release of a barrier synchronization object.

wait_barrier blocks the thread at a barrier object given by BarrierHandle until a specified number of threads have called the same barrier object. This number is specified by parameter TeamSize during the creation of the barrier object by create_barrier.

Parameters

▷ **BarrierHandle** (input_control) ..... barrier ⇝ *handle*
Barrier synchronization object.

Result

If the barrier handle is valid, the operator wait_barrier returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

clear_barrier

Module

Foundation

wait_condition (: : ConditionHandle, MutexHandle :)

wait on the signal of a condition synchronization object.

wait_condition atomically unlocks the MutexHandle (as per unlock_mutex) and waits for the condition variable ConditionHandle to be signaled. The thread execution is suspended and does not consume any CPU time until the condition variable is signaled. The mutex must be locked by the calling thread on entrance to wait_condition. Before returning to the calling thread, wait_condition re-acquires MutexHandle (as per lock_mutex).

Unlocking the mutex and suspending on the condition variable is done atomically. Thus, if all threads always acquire the mutex before signaling the condition, this guarantees that the condition cannot be signaled (and thus ignored) between the time a thread locks the mutex and the time it waits on the condition variable.

Parameters

▷ **ConditionHandle** (input_control) ..... condition ⇝ *handle*
Condition synchronization object.

▷ **MutexHandle** (input_control) ..... mutex ⇝ *handle*
Mutex synchronization object.

Result

`wait_condition` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`signal_condition`, `clear_condition`

Module

Foundation

wait_event (: : EventHandle :)

Lock an event synchronization object.

`wait_event` waits on the event object passed in `EventHandle` until it is signaled. When the event is signaled, `wait_event` succeeds and sets the state automatically to non-signaled again. The kind of wait depends on the event's attributes set during the creation in `create_event`.

Parameters

▷ **EventHandle** (input_control) ..... event ⇝ *handle*
Event synchronization object.

Result

If the event handle is valid, the operator `wait_event` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_event`

Possible Successors

`signal_event`

Module

Foundation

write_message (: : MessageHandle, FileName, GenParamName, GenParamValue :)

Write a message to a file.

`write_message` writes the message denoted by the `MessageHandle` to the file given by `FileName`. The default HALCON file extension for a message is 'hmsg'.

If `MessageHandle` contains a handle that can not be serialized or that has been freed already, an exception is raised per default. This behavior is controlled by `GenParamName` *'raise_error_if_content_not_serializable'*, and the corresponding `GenParamValue` can take the following values:

'true': The default: Errors are raised and the writing process aborted.

'low_level': Only low level errors are raised. Instead of the handle concerned an empty handle is written in `FileName` and the writing process will be continued. The behavior regarding HALCON low level errors is determined by *'do_low_error'* in `set_system`.

'false': The errors are suppressed. Instead of the handle concerned an empty handle is written in `FileName` and the writing process will be continued.

Parameters

▷ **`MessageHandle`** (input_control) . . . . . message ⇝ *handle*
Message handle.
Number of elements: MessageHandle == 1
Restriction: MessageHandle != 0

▷ **`FileName`** (input_control) . . . . . filename.write ⇝ *string*
File name.
File extension: `.hmsg`

▷ **`GenParamName`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: `GenParamName` ∈ {'raise_error_if_content_not_serializable'}

▷ **`GenParamValue`** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
Suggested values: `GenParamValue` ∈ {'true', 'false', 'low_level'}

Result

If the parameters are valid, the operator `write_message` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

25.9 Operating System

`count_seconds` (: : : Seconds)

Passed Time.

The operator `count_seconds` helps to measure time. Each operator call returns a time value. The difference of the values of two successive calls provides the time interval in seconds. The mode of measuring time can be set with `set_system('clock_mode',...)`.

Attention

The time measurement is not exact and depends on the load of the computer.

Parameters

▷ **Seconds** (output_control) ..... real ⇝ *real*
Process time since the program start.

Example

```
count_seconds(Start)
* program segment to be measured
count_seconds(End)
Seconds := End - Start
```

Result

The operator count_seconds always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_system_time (: : : MSecond, Second, Minute, Hour, Day, YDay, Month, Year)

Read out the system time.

The operator get_system_time reads out the current system time. The system time is read according to the local time zone or as UTC, see *'system_time_base'* in get_system.

Parameters

▷ **MSecond** (output_control) ..... integer ⇝ *integer*
Milliseconds (0..999).

▷ **Second** (output_control) ..... integer ⇝ *integer*
Seconds (0..59).

▷ **Minute** (output_control) ..... integer ⇝ *integer*
Minutes (0..59).

▷ **Hour** (output_control) ..... integer ⇝ *integer*
Hours (0..23).

▷ **Day** (output_control) ..... integer ⇝ *integer*
Day of the month (1..31).

▷ **YDay** (output_control) ..... integer ⇝ *integer*
Day of the year (1..366).

▷ **Month** (output_control) ..... integer ⇝ *integer*
Month (1..12).

▷ **Year** (output_control) ..... integer ⇝ *integer*
Year (xxxx).

Result

get_system_time always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

system_call (: : Command :)

Execute a system command.

The operator system_call executes the system command given in Command.

On Windows operating systems, the system command can be prefixed by *'start /b'* to avoid waiting for the started application. On Unix-like operating systems, an interactive shell ('csh -i') will be started, if Command contains an empty string.

Parameters

▷ **Command** (input_control) . . . . . string ⇝ *string*
Command to be called by the system.
Default: 'ls'

Result

On Windows operating systems,the operator system_call will always return the value 2 (H_MSG_TRUE) unless there was a problem creating a new process. On other operating systems, system_call will always return the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

count_seconds

See also

wait_seconds, count_seconds

Module

Foundation

wait_seconds (: : Seconds :)

Delaying the execution of the program.

The operator wait_seconds delays the execution by the number of seconds indicated in Seconds.

wait_seconds uses the *'performance_counter'* for the measurement of time intervals. The *'performance_counter'* is explained in the description of the parameter *'clock_mode'* of the operator set_system.

Parameters

▷ **Seconds** (input_control) . . . . . real ⇝ *real*
Number of seconds by which the execution of the program will be delayed.
Default: 10
Restriction: Seconds >= 0

Result

The operator wait_seconds always returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

25.10 Parallelization

get_aop_info (: : OperatorName, IndexName, IndexValue, InfoName : InfoValue)

Return AOP information for operators.

HALCON supports a mechanism to optimize the behavior of automatic operator parallelization (AOP) for a given hardware of a machine. The information for this optimization can be determined by the operator optimize_aop and can also be partly modified by the operator set_aop_info.

To address specific AOP information, the operator's optimization data is indexed within a 3-ary hierarchy that can be obtained by query_aop_info. The three hierarchy stages are indexed by the operator name, passed in OperatorName, the iconic type, and a parameter string value denoting a special mode or method supported by the indexed operator. The latter two indices are passed by IndexName and IndexValue. IndexName holds the dimension identifier whereas IndexValue holds the index value as returned in query_aop_info.

get_aop_info returns the specific information parts of an operator's AOP knowledge in InfoValue if exactly one index per stage was set. The scope of information is specified by InfoName and supports following values:

'max_threads' returns the maximum allowed thread number. If no optimization data is stored, InfoValue contains *-1*. In case the specified operator does not support automatic parallelization, *1* is returned.

'split_level' returns all allowed data split levels of the automatic parallelization for this operator, the specified iconic type and parameter value. Possible levels are *'split_tuple'*, *'split_channel'*, *'split_domain'*, and *'split_partial'*. If no split level is supported or every level was switched off for the indexed operator an empty string *''* is returned. Use get_operator_info to query all split levels generally supported by an operator.

'model' returns the stored model type. Possible values are *'threshold'*, *'linear'*, and *'mlp'* (see also the description of operator optimize_aop). If no optimization data is stored, an empty string is returned.

Parameters

▷ **OperatorName** (input_control) ..... string ⇝ *string* / integer
Operator to get information for
Suggested values: OperatorName ∈ {'mean_image', 'opening_circle', 'find_shape_model'}

▷ **IndexName** (input_control) ..... string-array ⇝ *string*
Further index stages
Default: ['iconic_type','parameter:0']

▷ **IndexValue** (input_control) ..... string-array ⇝ *string*
Further index values
Number of elements: IndexName == IndexValue
Default: ['byte','']

▷ **InfoName** (input_control) ..... string ⇝ *string*
Scope of information
Default: 'max_threads'
Suggested values: InfoName ∈ {'max_threads', 'split_level', 'model'}

▷ **InfoValue** (output_control) ..... string(-array) ⇝ *string*
Value of information

Result

`get_aop_info` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Module

Foundation

optimize_aop (: : OperatorName, IconicType, FileName, GenParamName, GenParamValue :)

Check hardware regarding its potential for automatic operator parallelization.

HALCON supports automatic operator parallelization (AOP) for various operators. `optimize_aop` is necessary for an efficient automatic parallelization, what HALCON uses to speed up the execution of operators. As the parallelization of operators is done automatically, there is no need for the user to explicitly prepare or change programs for their parallelization. Thus, all HALCON-based programs can be used without adaptations on multiprocessor hardware and users benefit from the potential of parallel hardware. By default, HALCON uses the maximum available number of threads for AOP, up to the number of processors. But, depending on the data size and the parameter set passed to an operator, parallelizing on the maximum thread number might be too excessive and inefficient. `optimize_aop` optimizes the AOP in terms of thread number and checks a given hardware with respect to a parallel processing of HALCON operators. In doing so, it examines every operator, which can be possibly be sped up by an automatic parallelization on tuple, channel, or domain level (the partial level is not considered). Each examined operator is executed several times - both sequentially and parallel - with a changing set of input parameter values/images. The latter helps to evaluate dependencies between an operator's input parameter characteristics (e.g., the size of an input image) and the efficiency of its parallel processing. This may take up to a couple of hours depending on the settings of the operator's parameters. It is essential for a correct optimization not to run any other computation-intensive application simultaneously on the machine, as this would strongly influence the time measurements of the hardware check and thus would lead to wrong results.

Overall, `optimize_aop` performs several test loops and collects a lot of hardware-specific information which enables HALCON to optimize the automatic parallelization for a given hardware. The hardware information can be stored in a binary file given by `FileName` so that it can be used again in future HALCON sessions or even transferred to other machines, identical in hardware. When passing an empty string `''` as file name, `optimize_aop` stores the optimization data to the specific HALCON system file '.aop_info' in the HALCON installation directory (in Linux, see environment variable $HALCONROOT) or within the common application data folder (Windows). This specific file is automatically read when initializing HALCON during the first operator call. Note that the user must have appropriate privileges for read and write access. `optimize_aop` will check the file access before starting the AOP optimization and return an appropriate error when failing. The written file can be read by using the operator `read_aop_knowledge` again.

Thus, it is sufficient, to start `optimize_aop` once on each multiprocessor machine that is used for parallel processing. Of course, it should be started again, if the hardware of the machine changes, for example, by installing a new CPU, new memory, or if the operating system of the machine changes. It is necessary to start `optimize_aop` once for each new processing environment as the time response of operators may differ. A new processing environment is given, if different operating systems, such as Windows and Linux, or different HALCON architectures, different HALCON variants are used, i.e., HALCON versus HALCON XL, or when updating to a new HALCON version or revision. Together with the machine's host name, these dependencies form the knowledge attributes and are stored to the file together with the AOP optimization data. The attributes identify the machine-specific AOP knowledge set and enable the storage of different knowledge sets to the same file.

`optimize_aop` offers a set of parameters to restrict the extensiveness and specify the behavior of the optimization process. A subset of HALCON operators can be passed to `OperatorName`. This will restrict the optimization process to the operators passed by their name. When passing an empty string `''`, all operators will be tested. A subset of iconic types that should be checked can be set by parameter `IconicType`. Again, passing an empty

string '' will test all supported iconic types. Further settings to modify the optimization process can be parameterized by a pair of values passed to GenParamName and GenParamValue. Every entry in GenParamName must have a corresponding entry in GenParamValue, meaning the tuples passed to the parameters must have the same length. GenParamName supports the values in following list, specifying for each possible value for GenParamName all possible applicable values for GenParamValue:

'none' does nothing specific but ignores the parameter GenParamValue.

'system_mode', *'file_mode'* set the way how the information of the system or file, respectively, gets updated.

- *'truncate'* for GenParamValue deletes all the existing information before the new knowledge loaded from file is added.
- *'renew'* overwrites existing knowledge and adds new one (default).
- *'append'* keeps all existing operator information and just adds the knowledge not already contained.
- *'nil'* performs the optimization process but refuses any update of the system or file, respectively.

'parameters' also tests for appropriate operator parameters if the corresponding value of GenParamValue is set to *'true'*. These operator parameters are supposed to show significant influence on the operator's processing time like string parameters picking up a certain operator mode or method or, e.g., parameters setting a filter size. *'false'* dismisses the parameter check in favor of a faster knowledge identification (default).

'model' sets the underlying simulation of the behavior of parallelizing operators on the current hardware. Different models can be selected by GenParamValue differing in hardware adaptability and computation time:

- *'threshold'* determines if it is profitable to run on the maximum thread number or not. This is default on dual processor systems.
- *'linear'* specifies a linear scale model to determine the best thread number for a given data size and parameter set. This is default on multiprocessor systems.
- *'mlp'* is the most complex but also most adaptable model. Note that the optimization process can take a couple of hours depending on the used hardware topology.

'timeout' sets a maximum execution time for a tested operator. If the execution of an operator exceeds the timeout, the test on this operator is aborted. No information about this operator will be stored in this case. The timeout value is set by GenParamValue in seconds. Specifying *'infinite'* prevents any abortion of an operator's optimization process (default).

'split_level' restricts the optimization process on a certain parallelization method. The corresponding value of GenParamValue can contain one of the following values, therefore:

- *'split_domain'* performs the check on all image processing operators supporting data parallelization on domain level.
- *'split_channel'* performs the check on all image processing operators supporting data parallelization on channel level.
- *'split_tuple'* performs the check on all operators supporting data parallelization on tuple level.

Attention

During its test loops optimize_aop has to start every examined operator several times. Thus, the processing time of optimize_aop can be rather long depending on the operator's parameter settings. It is essential for a correct optimization not run any other computation-intensive application simultaneously on the machine, as this would strongly influence the time measurements of the hardware check and thus would lead to wrong results. Note that according to the file location optimize_aop must be called by users with the appropriate privileges for storing the parallelization information. See the operator's description above for more details about these subjects.

Parameters

▷ **OperatorName** (input_control) ..... string(-array) ⇝ *string*
Operators to check
Default: ''

▷ **IconicType** (input_control) ..... string(-array) ⇝ *string*
Iconic object types to check
Default: ''
Suggested values: IconicType ∈ {'', 'byte', 'int1', 'int2', 'uint2', 'int4', 'int8', 'direction', 'cyclic', 'vector_field', 'complex', 'region', 'xld', 'xld_cont', 'xld_poly'}

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string* / integer
Knowledge file name
Default: ”

▷ **GenParamName** (input_control) . . . . . string-array ⇝ *string*
Parameter name
Default: ’none’
Suggested values: GenParamName ∈ {’parameters’, ’model’, ’timeout’, ’file_mode’, ’system_mode’, ’split_level’}

▷ **GenParamValue** (input_control) . . . . . string-array ⇝ *string* / real / integer
Parameter value
Number of elements: GenParamName == GenParamValue
Default: ’none’
Suggested values: GenParamValue ∈ {’true’, ’renew’, ’truncate’, ’threshold’, ’linear’, ’mlp’, -1.0}

Result

optimize_aop returns 2 (H_MSG_TRUE) if all parameters are correct and the file could be read. If necessary, an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

query_aop_info (: : OperatorName, IndexName, IndexValue : Name, Value)

Query indexing structure of AOP information for operators.

HALCON supports a mechanism to adapt the behavior of automatic parallelization of image processing operators (AOP) to the machine’s hardware capability. The information for this adaption can be obtained by the operator optimize_aop and can be partly read and modified by the operators get_aop_info and set_aop_info, respectively. To address specific AOP information the operator’s optimization data is indexed within a 3-ary hierarchy that can be obtained by query_aop_info. The three hierarchy stages are indexed by the operator name, the iconic type, and a parameter string value denoting a special mode or method supported by the operator.

If an empty string ” is passed to OperatorName, the parameters IndexName and IndexValue are ignored and all operator names in Value are returned, for which optimization data is stored. Name contains the index identifier *’operator’* as many times as operator names are returned. Specifying a single operator name in OperatorName and passing an empty string ” to the parameters IndexName and IndexValue queries all iconic types the operator holds optimization data for. Value contains the type strings, Name the index identifier *’iconic_type’*, respectively. Finally, when specifying a certain operator in OperatorName and a specific iconic type by passing the dimension identifier *’iconic_type’* to IndexName and the specific iconic type to IndexValue, Name contains the parameter index identifier Value holds the parameter string values supported by the operator. The format of the parameter identifier string is compound containing the string *parameter*, followed by a colon separator *:* and a digit, denoting the parameter index (starting with 1). If the operator does not support any mode parameter or the operator’s parameter values were not varied during optimization process of optimize_aop the string *’parameter:0’* is returned for Name and Value contains an empty string. In case no AOP information is stored for the specified index, Name returns an empty string.

Parameters

▷ **OperatorName** (input_control) . . . . . string ⇝ *string* / integer
Operator to get information for
Default: ”

▷ **IndexName** (input_control) ..... string(-array) ⇝ *string* / integer
Further specific index
Default: ''
Suggested values: IndexName ∈ {'', 'iconic_type'}

▷ **IndexValue** (input_control) ..... string(-array) ⇝ *string* / integer
Further specific address
Number of elements: IndexName == IndexValue
Default: ''
Suggested values: IndexValue ∈ {'', 'byte', 'int1', 'int2', 'uint2', 'int4', 'int8', 'direction', 'cyclic', 'vector_field', 'complex', 'region', 'xld', 'xld_cont', 'xld_poly'}

▷ **Name** (output_control) ..... string-array ⇝ *string*
Name of next index stage

▷ **Value** (output_control) ..... string-array ⇝ *string*
Values of next index stage

Result

query_aop_info returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Module

Foundation

read_aop_knowledge (: : FileName, GenParamName, GenParamValue : Attributes, OperatorNames)

Load knowledge about hardware dependent behavior of automatic operator parallelization.

read_aop_knowledge loads the automatic operator parallelization (AOP) knowledge of HALCON operators from file. The knowledge is used to better utilize multiprocessor hardware in order to speed up the processing of operators. To optimize the automatic operator parallelization, HALCON needs some knowledge about the speed of operators on the used hardware. This hardware-specific knowledge can be obtained and stored by calling the operator optimize_aop and write_aop_knowledge, respectively.

With read_aop_knowledge, it is possible to load this knowledge explicitly from a binary file. In doing so, FileName denotes the name of this file (incl. path and file extension). If an empty string '' is passed to FileName, HALCON reads the knowledge from the specific file .aop_info in the HALCON installation directory (Linux) or within the common application data folder (Windows). This file is read by HALCON automatically during the initialization phase but can easily be re-read by read_aop_knowledge. The read knowledge updates the system's parallelization information and can be controlled by pairs of additional parameter values passed to GenParamName and GenParamValue. Every entry in GenParamName must have one corresponding, specifying entry in GenParamValue, meaning that the tuples passed to the parameters must have the same length. GenParamName supports the values in following list, describing the possible applicable values for GenParamValue:

'ignore_attrib' suppresses to check knowledge attributes. E.g., while reading the file read_aop_knowledge checks whether its content was written for the currently used computer and whether the contained parallelization information regards the currently used HALCON version, revision, and architecture. The attributes to suppress are specified by passing any of the following values to GenParamValue:

'host' the host name of the current machine

'cpu_info' the machine topology information

'variant' the HALCON variant

'version' the HALCON version

'revision' the HALCON revision

'architecture' the HALCON architecture

Multiple suppressions of attribute checks are possible.

'mode' sets the way how the system's information gets updated.

'truncate' for GenParamValue deletes all the existing information before the new knowledge loaded from file is added.

'renew' overwrites existing knowledge and adds new one (default).

'append' keeps all existing operator information and just adds the knowledge not already contained.

'nil' refuses any updates but returns the knowledge attributes in Attributes and all the operators contained in file in OperatorNames.

'operator' denotes that the corresponding index value of GenParamValue contains an operator name. Multiple definitions of operators are possible. By default, information of any contained operator is loaded.

'iconic_type' focuses on AOP information for a specific iconic type, specified by following values of GenParamValue: *'byte'*,*'uint2'*,*'real'*,*'int1'*, *'int2'*,*'int4'*,*'int8'*,*'direction'*, *'vector_field'*,*'cyclic'*,*'vector_field'*, *'complex'*,*'region'*,*'xld'*. Multiple definitions of iconic types are possible.

The names of updated operators are returned in OperatorNames, the attributes of the read knowledge in Attributes. The latter tuple codes the following meaning by index beginning with index 0 in corresponding order: host name, HALCON variant, HALCON version, HALCON revision, HALCON architecture.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
Name of knowledge file
Default: ''

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Parameter name
Default: 'none'
Suggested values: GenParamName ∈ {'none', 'ignore_attrib', 'operator', 'iconic_type', 'mode'}

▷ **GenParamValue** (input_control) . . . . . string(-array) ⇝ *string* / integer / real
Parameter value
Number of elements: GenParamName == GenParamValue
Default: 'none'
Suggested values: GenParamValue ∈ {'none', 'host_name', 'variant', 'architecture', 'version', 'revision', 'byte', 'int1', 'int2', 'uint2', 'int4', 'int8', 'direction', 'cyclic', 'vector_field', 'complex', 'region', 'xld', 'xld_cont', 'xld_poly', 'nil', 'truncate', 'replace', 'renew', 'append'}

▷ **Attributes** (output_control) . . . . . string-array ⇝ *string*
Knowledge attributes

▷ **OperatorNames** (output_control) . . . . . string(-array) ⇝ *string*
Updated Operators

Result

read_aop_knowledge returns 2 (H_MSG_TRUE) if all parameters are correct and the file could be read. If necessary, an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_aop_info (: : OperatorName, IndexName, IndexValue, InfoName, InfoValue :)

Set AOP information for operators.

HALCON supports a mechanism to adapt the behavior of automatic parallelization of image processing operators (AOP) to the machine's hardware capability. The information for this adaption can be obtained by the operator optimize_aop and can also be partly read by the operator set_aop_info.

To address specific AOP information the operator's optimization data is indexed within a 3-ary hierarchy that can be obtained by query_aop_info. The three hierarchy stages are indexed by the operator name, passed in OperatorName, the iconic type, and a parameter string value denoting a special mode or method supported by the indexed operator. The latter two indices are passed by IndexName and IndexValue. IndexName holds the dimension identifier whereas IndexValue addresses the index as returned in query_aop_info. It is also possible to address multiple indices on the same stage to set a specific information value to multiple knowledge sets. Omitting an index name or passing an empty string as index value addresses this stage in all. E.g., passing '' to OperatorName, the tuple *['iconic_type','iconic_type']* to IndexName, and the tuple *['byte','uint2']* to IndexValue addresses all operators processing byte or uint2 images.

set_aop_info sets the specific information parts of an operator's AOP knowledge passed in InfoValue. The scope of information is specified by InfoName and supports the following:

'max_threads' sets the maximum allowed thread number this operator is allowed to run with the specified iconic type and parameter value.

'split_level' sets the allowed data split levels of the automatic parallelization for this operator, the specified iconic type and parameter value. Possible levels are *'split_tuple'*, *'split_channel'*, *'split_domain'*, and *'split_partial'*.

Attention

set_aop_info modifies the AOP system knowledge. These modifications will also be stored by write_aop_knowledge. It is advisable to have a backup knowledge file before modifying the system knowledge.

Parameters

▷ **OperatorName** (input_control) ..... string(-array) ⇝ *string* / integer
Operator to set information to
Default: ''

▷ **IndexName** (input_control) ..... string(-array) ⇝ *string* / integer
Further specific index
Default: ''
Suggested values: IndexName ∈ {'iconic_type', ['iconic_type','parameter:0']}

▷ **IndexValue** (input_control) ..... string(-array) ⇝ *string* / integer
Further specific address
Number of elements: IndexName == IndexValue
Default: ''
Suggested values: IndexValue ∈ {'byte', ['uint2','']}

▷ **InfoName** (input_control) ..... string ⇝ *string*
Scope of information
Default: 'max_threads'
Suggested values: InfoName ∈ {'max_threads', 'model'}

▷ **InfoValue** (input_control) ..... integer(-array) ⇝ *integer*
AOP information value

Result

set_aop_info returns 2 (H_MSG_TRUE) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Module

Foundation

write_aop_knowledge (: : FileName, GenParamName, GenParamValue :)

Write knowledge about hardware dependent behavior of automatic operator parallelization to file.

write_aop_knowledge stores the automatic parallelization knowledge of HALCON operators to file. The knowledge hold by the HALCON system is used to better utilize multiprocessor hardware in order to speed up the processing of operators. To optimize the automatic parallelization of operators, HALCON needs some specific knowledge about the speed of operators on the used hardware. This hardware-specific knowledge can be obtained by calling the operator optimize_aop or read from file by using read_aop_knowledge, respectively.

With write_aop_knowledge it is possible to store this knowledge explicitly in a binary file. At this, FileName denotes the name of this file (incl. path and file extension). If an empty string '' is passed to FileName, HALCON writes the knowledge to the specific file .aop_info in the HALCON installation directory (Linux) or within the common application data folder (Windows). This file is read by HALCON during the initialization phase automatically. write_aop_knowledge adds attributes to the knowledge like the host name and information about HALCON architecture, variant, version, and revision. This enables HALCON to write aop knowledge sets of different machines or HALCON systems into the same file. Therefore, write_aop_knowledge can control the updating of the files contents by a pair of values passed to GenParamName and GenParamValue. Every entry in GenParamName must have one corresponding, specifying entry in GenParamValue, meaning that the tuples passed to the parameters must have the same length. GenParamName supports the values in following list, describing the possible applicable values for GenParamValue:

'mode' sets the way how existing knowledge with same attributes would be updated in the file.

- *'truncate'* for GenParamValue deletes the existing knowledge with matching attributes before the new information is added to file.
- *'renew'* overwrites existing knowledge and adds new one (default).
- *'append'* keeps all existing operator information and just adds the knowledge not already contained.
- *'nil'* however refuses any update of the file but checks the user privileges, i.e., if read write access is available.

'operator' denotes that the corresponding index value of GenParamValue contains an operator name. It delimits the storage on a dedicated operator set. Multiple definitions of operators are possible. By default, information of any operator possessing AOP optimization data is written.

'iconic_type' focuses on AOP information for a specific iconic type, specified by following values of GenParamValue: *'byte'*, *'uint2'*, *'real'*, *'int1'*, *'int2'*, *'int4'*, *'int8'*, *'direction'*, *'vector_field'*, *'cyclic'*, *'complex'*, *'region'*, *'xld'*. Multiple definitions of iconic types are possible.

Parameters

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of knowledge file
Default: ''

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Parameter name
Default: 'none'
Suggested values: GenParamName ∈ {'mode', 'operator', 'iconic_type'}

▷ **GenParamValue** (input_control) . . . . . string(-array) ⇝ *string* / integer / real
Parameter value
Number of elements: GenParamName == GenParamValue
Default: 'none'
Suggested values: GenParamValue ∈ {'truncate', 'renew', 'append'}

Result

write_aop_knowledge returns 2 (H_MSG_TRUE) if all parameters are correct and the file could be read. If necessary, an exception is raised.

Execution Information

- Multithreading type: exclusive (runs in parallel only with independent operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Foundation

25.11 Parameters

get_system (: : Query : Information)

Get current value of HALCON system parameters.

The operator get_system returns information concerning the currently activated HALCON system parameters.

Readable and Writable Parameters

get_system returns information about all parameters that are set with set_system. For more information on read- and writable parameters, please refer to the reference documentation of set_system.

Read-Only Parameters

The following system parameters can be queried:

- **Versions:**

  'halcon_xl': The currently used variant of HALCON: HALCON XL, which allows images larger than 32768 × 32768 (*'true'*) or HALCON, which restricts the maximal image size to 32768 × 32768 (*'false'*).

  'version': HALCON version number.

  'last_update': Creation date of the HALCON library.

  'revision': Revision number of the HALCON library.

  'file_version': File version number of the HALCON library. The number is made up of the HALCON version number, the revision number, and the build number.

- **Upper Limits:**

  'max_inp_obj_par': Maximum number of input parameters.

  'max_outp_obj_par': Maximum number of output parameters.

  'max_inp_ctrl_par': Maximum number of input control parameters.

  'max_outp_ctrl_par': Maximum number of output control parameters.

  'max_window': Maximum number of windows.

- **Graphic:**

  'window_name': Returns the value that may have been set with set_window_attr ('window_title',...). If nothing has been set yet, the string *'default'* is returned.

- **Parallelization:**

  'processor_num': Returns the number of processors that HALCON has found on the hardware it is running on.

  'tsp_used_thread_num': Returns the number of threads the last operator was using for automatic operator parallelization. Only operators that were run by the calling thread and support automatic parallelization are considered. Note that using this parameter in HDevelop works only in run mode, not in single step mode.

  'tsp_used_split_levels' Returns all split levels the last operator was using for automatic parallelization. Only operators that were run by the calling thread and support automatic parallelization are considered. If the last operator was not parallelized, the string *'false'* is returned. Note that using this parameter in HDevelop works only in run mode, not in single step mode.

- **Licensing:**

  'available_license_files' The list of license files HALCON can find.

  'current_license_info' A tuple containing information about the current license. If the license is invalid, the tuple contains a single element with the value *'invalid'*. Otherwise, the tuple contains the following elements in order:

  – The name of the license file used to obtain the current license.

  - The type of license, either *'runtime'*, *'development'*, or *'sasl'*.
  - The highest version of HALCON licensed by the current license.
  - The expiration date of the current license in ISO 8601 format, or *'permanent'* for licenses without an expiration date.
  - The list of HALCON modules licensed by the current license as a single string, separated by ' | '.
  - The number of concurrent licenses, or 0 for unlimited concurrent use.
  - The number of concurrent sessions, or 0 for unlimited concurrent sessions.
  - The host ID used to obtain the current license.
  - The flags of the current license.
  - The contents of the license info field.

  If a particular piece of information is not available, an empty string is returned instead.

'expiration_date' The date the HALCON license will expire, in ISO 8601 format, or *'permanent'* if the license does not expire.

'failed_license_rechecks' The number of failed license rechecks since process start.

'is_license_valid' This parameter triggers an immediate license check and returns *'true'* if a valid license could be found, or *'false'* otherwise.

'licensed_hostid' The host ID used to obtain the current license.

'licensed_modules' A list of all modules licensed by the currently used license.

'licensed_version' The highest HALCON version the current license is valid for.

'licensed_product_edition' The HALCON product edition. Will be one of *'Progress'*, *'Steady'*, *'Steady Deep Learning'*, or *'Student Edition'* depending on the license being used. If there is no valid license, an empty string is returned instead.

'supported_editions' Return an array containing the editions this HALCON binary supports. Possible values are *'steady'* and *'progress'*.

'unlicensed_operators' A list of operators that require a module that is not licensed and thus cannot be used.

- **Other:**

'available_parameters' The list of parameters `get_system` understands.

'hostids': The host IDs of the computer that can be used for licensing HALCON.

'num_proc': Total number of the available HALCON procedures (*'num_sys_proc'* + *'num_user_proc'*).

'num_sys_proc': Number of the system procedures (supported procedures).

'num_user_proc': Number of the user defined procedures (see also "`Extension Package Programmer's Manual`").

'byte_order': Byte order of the processor (*'msb_first'* or *'lsb_first'*).

'operating_system': Name of the operating system of the computer on which the HALCON process is being executed. Note that for all Windows versions, 'Windows NT' is returned. Use the parameter *'operating_system_version'* to query the precise version.

'operating_system_version': Version number of the operating system of the computer on which the HALCON process is being executed. To decode the Windows version numbers, please refer to the website information on operating systems and version numbers provided by Microsoft.

'hostname': Name of the computer on which the HALCON process is being executed. On Windows systems, if the computer is part of a cluster the name of the cluster is returned, not the name of the local computer. If the name cannot be determined, an empty string is returned.

'locale_raw': Locale setting that is used by the runtime environment for encoding system strings (according to the locale category LC_CTYPE). The result corresponds to the result of the system C function setlocale or the result of the shell command 'locale' called in a Linux terminal. In general, it contains data about the language, the country, and the code page or code set - under Windows, for instance, *'German_Germany.1252'* or under Linux *'en_US.utf8'*. Note, that on Linux the names are not clearly defined because they depend on the system and the current configuration. Thus, the code set can be set to 'utf8' or 'UTF-8', or may completely be missing. On systems that do not support locale an empty string is returned.

'locale_codeset': Code set that is used by the runtime environment for encoding system strings (according to the locale category LC_CTYPE). In contrast to *'locale_raw'*, this result contains only the code set or code page and no information about language and country. The code set is returned in a normalized way so that it can easier be used in tests. The result contains only lowercase letters and numbers, with

different results for Windows code pages and Linux code sets, as the code sets used are usually not identical. Under Windows typically the code page number prefixed by 'cp' is returned, e.g., *'cp1252'* (for code page 1252 which is commonly used in the western world and correlates widely with Latin-1) or *'cp932'* (which correlates with ShiftJIS, which is common in Japan). Common results under Linux are *'utf8'* (which is the default locale on most of the recent Linux distributions), *'iso885915'* (Latin-9), *'shiftjis'*, and *'ascii'* (referred to as ANSI_X3.4-1968, US-ASCII, POSIX, C).

'halcon_64': Flag, if the HALCON version is a 64 bit version (*'true'*) or not, i.e., if it is a 32 bit version (*'false'*).

'halcon_arch': Name of the HALCON architecture of the running HALCON process.

'library_fullname': Path to the currently loaded HALCON library including the file name.

'temp_mem': Amount of temporary memory used by the last operator in byte. The return value is only defined if `set_check('memory')` was called before.

'mmx_supported': Flag, if the processor supports MMX operations (*'true'*) or not (*'false'*).

'sse_supported': Flag, if the processor supports SSE operations (*'true'*) or not (*'false'*).

'sse2_supported': Flag, if the processor supports SSE2 operations (*'true'*) or not (*'false'*).

'sse3_supported': Flag, if the processor supports SSE3 operations (*'true'*) or not (*'false'*).

'ssse3_supported': Flag, if the processor supports SSSE3 operations (*'true'*) or not (*'false'*).

'sse41_supported': Flag, if the processor supports SSE41 operations (*'true'*) or not (*'false'*).

'sse42_supported': Flag, if the processor supports SSE42 operations (*'true'*) or not (*'false'*).

'avx_supported': Flag, if the processor supports AVX operations (*'true'*) or not (*'false'*).

'avx2_supported': Flag, if the processor supports AVX2 operations (*'true'*) or not (*'false'*).

'avx2_gather_recommended': Flag, if the usage of AVX2 gather instructions is recommended on the processor (*'true'*) or not (*'false'*).

'avx512f_supported': Flag, if the processor supports AVX-512F operations (*'true'*) or not (*'false'*).

'avx512dq_supported': Flag, if the processor supports AVX-512DQ operations (*'true'*) or not (*'false'*).

'avx512bw_supported': Flag, if the processor supports AVX-512BW operations (*'true'*) or not (*'false'*).

'avx512cd_supported': Flag, if the processor supports AVX-512CD operations (*'true'*) or not (*'false'*).

'avx512vl_supported': Flag, if the processor supports AVX-512VL operations (*'true'*) or not (*'false'*).

'avx512vbmi_supported': Flag, if the processor supports AVX-512VBMI operations (*'true'*) or not (*'false'*).

'avx512ifma_supported': Flag, if the processor supports AVX-512IFMA operations (*'true'*) or not (*'false'*).

'avx512vbmi2_supported': Flag, if the processor supports AVX-512VBMI2 operations (*'true'*) or not (*'false'*).

'avx512vpopcntdq_supported': Flag, if the processor supports AVX-512VPOPCNTDQ operations (*'true'*) or not (*'false'*).

'avx512bitalg_supported': Flag, if the processor supports AVX-512BITALG operations (*'true'*) or not (*'false'*).

'avx512vnni_supported': Flag, if the processor supports AVX-512VNNI operations (*'true'*) or not (*'false'*).

'neon_supported': Flag, if the processor supports NEON operations (*'true'*) or not (*'false'*).

'opengl_hidden_surface_removal_available': Flag, if the graphic card supports the acceleration of the hidden surface removal used in `create_shape_model_3d`, `find_shape_model_3d`, `project_shape_model_3d`, and `project_object_model_3d`. The minimum requirements are OpenGL 2.0 and the extensions GL_EXT_framebuffer_object and GL_ARB_texture_float. Please note that these features are not available via Windows Remote Desktop or X11 forwarding.

'alloctmp_max_used' The maximum amount of temporary memory required so far for a thread, in bytes. The first element of the tuple contains the value for the current thread, while any following elements contain the values of currently idle threads from the thread pool.
The maximum is reset when the temporary memory cache mode is set to *'idle'*.

'tsp_temporary_mem_cache_block_sizes' Returns a tuple containing the block sizes of all temporary memory blocks currently cached in the thread's temporary memory cache, in bytes.

'temporary_mem_reservoir_block_sizes' Returns a tuple containing the block sizes of all temporary memory blocks currently cached in the global temporary memory reservoir, in bytes.

'legacy_handle_mode', *'tsp_legacy_handle_mode'*: Returns a flag if the legacy handle mode is activated.

'memory_allocators_supported': Returns a tuple containing the list of available memory allocators that can be set using parameter *'memory_allocator'* of `set_system`.

- **CUDA support for deep learning:**

  'cuda_loaded': Returns *'true'* if the CUDA library could be loaded.

  'cuda_version': Returns the version of the CUDA library. If the CUDA library could not be loaded, *-1* is returned.

  'cuda_devices': Returns the names of available devices that are compatible with CUDA.

  'cudnn_loaded': Returns *'true'* if the cuDNN library could be loaded.

  'cudnn_version': Returns the version of the cuDNN library. If the cuDNN library could not be loaded, *-1* is returned.

  'cublas_loaded': Returns *'true'* if the cuBLAS library could be loaded.

  'cublas_version': Returns the version of the cuBLAS library. If the cuBLAS library could not be loaded, *-1* is returned.

- **Arm Compute Library support:**

  'arm_compute_loaded': Returns *'true'* if the Arm Compute Library could be loaded, *'false'* otherwise.

  'arm_compute_version': Returns the version of the Arm Compute Library. If the Arm Compute Library could not be loaded, an empty string is returned.

Parameters

▷ **`Query`** (input_control) . . . . . attribute.name(-array) ⇝ *string*

Desired system parameter.
Default: 'init_new_image'
List of values: `Query` ∈ {'3d_model_dir', 'alloctmp_max_blocksize', 'alloctmp_min_blocksize', 'alloctmp_max_used', 'available_license_files', 'available_parameters', 'avx_enable', 'avx_supported', 'avx2_enable', 'avx2_supported', 'avx2_gather_enable', 'avx2_gather_recommended', 'avx512f_enable', 'avx512f_supported', 'avx512dq_enable', 'avx512dq_supported', 'avx512bw_enable', 'avx512bw_supported', 'avx512cd_enable', 'avx512cd_supported', 'avx512vl_enable', 'avx512vl_supported', 'avx512vbmi_enable', 'avx512vbmi_supported', 'avx512ifma_enable', 'avx512ifma_supported', 'avx512vbmi2_enable', 'avx512vbmi2_supported', 'avx512vpopcntdq_enable', 'avx512vpopcntdq_supported', 'avx512bitalg_enable', 'avx512bitalg_supported', 'avx512vnni_enable', 'avx512vnni_supported', 'neon_enable', 'neon_supported', 'backing_store', 'border_shape_models', 'bundle_version', 'byte_order', 'calib_dir', 'cancel_draw_result', 'clip_region', 'clock_mode', 'cuda_loaded', 'cuda_version', 'cuda_devices', 'cudnn_loaded', 'cudnn_version', 'cublas_loaded', 'cublas_version', 'current_license_info', 'current_runlength_number', 'database', 'default_font', 'disabled_operators', 'dl_dir', 'do_low_error', 'empty_region_result', 'example_dir', 'expiration_date', 'extern_alloc_funct', 'extern_free_funct', 'failed_license_rechecks', 'filename_encoding', 'file_version', 'filter_dir', 'flush_file', 'flush_graphic', 'global_mem_cache', 'halcon_arch', 'halcon_dir', 'halcon_xl', 'halcon_64', 'height', 'help_dir', 'hthread_id', 'hostids', 'hostname', 'icon_name', 'image_cache_capacity', 'image_dir', 'image_dpi', 'init_new_image', 'int2_bits', 'int_zooming', 'is_license_valid', 'language', 'last_update', 'legacy_handle_mode', 'library_fullname', 'licensed_hostid', 'licensed_modules', 'licensed_product_edition', 'licensed_version', 'locale_codeset', 'locale_raw', 'lut_dir', 'max_connection', 'max_inp_ctrl_par', 'max_inp_obj_par', 'max_outp_ctrl_par', 'max_outp_obj_par', 'max_window', 'memory_allocator', 'memory_allocators_supported', 'mmx_enable', 'mmx_supported', 'neighborhood', 'no_object_result', 'num_proc', 'num_sys_proc', 'num_user_proc', 'ocr_dir', 'ocr_trainf_version', 'opengl_hidden_surface_removal_available', 'opengl_hidden_surface_removal_enable', 'opengl_compatibility_mode_enable', 'opengl_context_cache_enable', 'operating_system', 'operating_system_version', 'parallelize_operators', 'pregenerate_shape_models', 'processor_num', 'read_halcon_files_encoding_fallback', 'reentrant', 'revision', 'seed_rand', 'sse_enable', 'sse_supported', 'sse2_enable', 'sse2_supported', 'sse3_enable', 'sse3_supported', 'ssse3_enable', 'ssse3_supported', 'sse41_enable', 'sse41_supported', 'sse42_enable', 'sse42_supported', 'store_empty_region', 'supported_editions', 'system_time_base', 'temp_mem', 'temporary_mem_cache', 'temporary_mem_reservoir', 'temporary_mem_reservoir_size', 'thread_num', 'thread_pool', 'timer_mode', 'tuple_string_operator_mode', 'tsp_cancel_draw_result', 'tsp_clip_region', 'tsp_current_runlength_number', 'tsp_empty_region_result', 'tsp_height', 'tsp_init_new_image', 'tsp_legacy_handle_mode', 'tsp_neighborhood', 'tsp_no_object_result', 'tsp_store_empty_region', 'tsp_temporary_mem_cache', 'tsp_temporary_mem_cache_block_sizes', 'tsp_temporary_mem_reservoir', 'tsp_thread_num', 'tsp_tuple_string_operator_mode', 'tsp_used_split_levels', 'tsp_used_thread_num', 'tsp_width', 'unlicensed_operators', 'update_lut', 'use_window_thread', 'version', 'width', 'window_name', 'write_halcon_files_encoding', 'x_package'}

▷ **Information** (output_control) . . . . . attribute.value(-array) ⇝ *integer* / real / string
Current value of the system parameter.

Result

The operator get_system returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_system_info (: : Query : Information)

Get current value of system information without requiring a license.

The operator get_system_info returns information concerning the currently activated HALCON system parameters. Unlike the very similar get_system, get_system_info can be called without a valid license.

get_system_info supports the same parameters supported by get_system. For more information about the parameters, please refer to the reference documentation of get_system and set_system.

Parameters

▷ **Query** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Desired system parameter.
Default: 'available_parameters'
List of values: Query ∈ {'3d_model_dir', 'alloctmp_max_blocksize', 'alloctmp_min_blocksize', 'alloctmp_max_used', 'available_license_files', 'available_parameters', 'avx_enable', 'avx_supported', 'avx2_enable', 'avx2_supported', 'avx2_gather_enable', 'avx2_gather_recommended', 'avx512f_enable', 'avx512f_supported', 'avx512dq_enable', 'avx512dq_supported', 'avx512bw_enable', 'avx512bw_supported', 'avx512cd_enable', 'avx512cd_supported', 'avx512vl_enable', 'avx512vl_supported', 'avx512vbmi_enable', 'avx512vbmi_supported', 'avx512ifma_enable', 'avx512ifma_supported', 'avx512vbmi2_enable', 'avx512vbmi2_supported', 'avx512vpopcntdq_enable', 'avx512vpopcntdq_supported', 'avx512bitalg_enable', 'avx512bitalg_supported', 'avx512vnni_enable', 'avx512vnni_supported', 'neon_enable', 'neon_supported', 'backing_store', 'border_shape_models', 'bundle_version', 'byte_order', 'calib_dir', 'cancel_draw_result', 'clip_region', 'clock_mode', 'cuda_loaded', 'cuda_version', 'cuda_devices', 'cudnn_loaded', 'cudnn_version', 'cublas_loaded', 'cublas_version', 'current_license_info', 'current_runlength_number', 'database', 'default_font', 'disabled_operators', 'dl_dir', 'do_low_error', 'edition', 'empty_region_result', 'example_dir', 'expiration_date', 'extern_alloc_funct', 'extern_free_funct', 'failed_license_rechecks', 'filename_encoding', 'file_version', 'filter_dir', 'flush_file', 'flush_graphic', 'global_mem_cache', 'halcon_arch', 'halcon_dir', 'halcon_xl', 'halcon_64', 'height', 'help_dir', 'hthread_id', 'hostids', 'hostname', 'icon_name', 'image_cache_capacity', 'image_dir', 'image_dpi', 'init_new_image', 'int2_bits', 'int_zooming', 'is_license_valid', 'language', 'last_update', 'legacy_handle_mode', 'library_fullname', 'licensed_hostid', 'licensed_modules', 'licensed_product_edition', 'licensed_version', 'locale_codeset', 'locale_raw', 'lut_dir', 'max_connection', 'max_inp_ctrl_par', 'max_inp_obj_par', 'max_outp_ctrl_par', 'max_outp_obj_par', 'max_window', 'memory_allocator', 'memory_allocators_supported', 'mmx_enable', 'mmx_supported', 'neighborhood', 'no_object_result', 'num_proc', 'num_sys_proc', 'num_user_proc', 'ocr_dir', 'ocr_trainf_version',

'opengl_hidden_surface_removal_available', 'opengl_hidden_surface_removal_enable', 'opengl_compatibility_mode_enable', 'opengl_context_cache_enable', 'operating_system', 'operating_system_version', 'parallelize_operators', 'pregenerate_shape_models', 'processor_num', 'read_halcon_files_encoding_fallback', 'reentrant', 'revision', 'seed_rand', 'sse_enable', 'sse_supported', 'sse2_enable', 'sse2_supported', 'sse3_enable', 'sse3_supported', 'ssse3_enable', 'ssse3_supported', 'sse41_enable', 'sse41_supported', 'sse42_enable', 'sse42_supported', 'store_empty_region', 'system_time_base', 'temp_mem', 'temporary_mem_cache', 'temporary_mem_reservoir', 'temporary_mem_reservoir_size', 'thread_num', 'thread_pool', 'timer_mode', 'tuple_string_operator_mode', 'tsp_cancel_draw_result', 'tsp_clip_region', 'tsp_current_runlength_number', 'tsp_empty_region_result', 'tsp_height', 'tsp_init_new_image', 'tsp_legacy_handle_mode', 'tsp_neighborhood', 'tsp_no_object_result', 'tsp_store_empty_region', 'tsp_temporary_mem_cache', 'tsp_temporary_mem_cache_block_sizes', 'tsp_temporary_mem_reservoir', 'tsp_thread_num', 'tsp_tuple_string_operator_mode', 'tsp_used_split_levels', 'tsp_used_thread_num', 'tsp_width', 'unlicensed_operators', 'update_lut', 'use_window_thread', 'version', 'width', 'window_name', 'write_halcon_files_encoding', 'x_package'}

▷ **Information** (output_control) . . . . . attribute.value(-array) ⇝ *integer* / real / string
Current value of the system parameter.

Result

The operator `get_system_info` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`get_system`

Module

none

set_operator_timeout (: : OperatorName, Timeout, Mode :)

Set a timeout for an operator.

`set_operator_timeout` sets a timeout for the operator `OperatorName`. `Timeout` is given in seconds. Setting `Timeout` to *0* or *'off'* clears the timeout. The timeout is set for the current thread only and is not inherited by child threads.

Multiple operator names can be passed to `OperatorName`. In this case, one can either pass a single timeout in `Timeout`, which is then set for all operators, or one timeout per operator.

Two timeout modes are supported and selected with `Mode`:

'cancel' Cancels the execution of the operator after the timeout expires, raises the exception H_ERR_TIMEOUT (9400). All results computed by the operator are discarded.

'break' Break the execution of the operator after the timeout expires. The operator returns normally. If possible, results computed by the operator up to the point of the timeout are returned.

Attention

Note that not all operators support timeouts. If a given operator supports timeouts and which modes are supported is described in the execution information section of the reference documentation of the corresponding operator.

Also note that there is no hard guarantee about the granularity of the timeout. The granularity can depend on the operator, its input data and the speed of the device. It is typically finer than 10 ms.

Parameters

▷ **OperatorName** (input_control) . . . . . string(-array) ⇝ *string*
Operator for which the timeout shall be set.

▷ **Timeout** (input_control) . . . . . number(-array) ⇝ *real* / integer / string
Timeout in seconds.
Default: 1
Suggested values: Timeout ∈ {1, 0.1, 0.5, 'off', 0}

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Timeout mode to be set.
Default: 'cancel'
Suggested values: Mode ∈ {'cancel', 'break'}

Result

The operator set_operator_timeout returns the value 2 (H_MSG_TRUE) if the parameters are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: local (may only be called from the same thread in which the window, model, or tool instance was created).
- Processed without parallelization.

Module

Foundation

set_system (: : SystemParameter, Value :)

Set HALCON system parameters.

The operator set_system allows to change different system parameters.

Parallelization information: Note that some of these parameters are set exclusively only, meaning they block other threads until no other operators are accessing the HALCON library.

- Parameters marked by a *) are globally valid and are set exclusively.
- Parameters without the mark *) and without the prefix *'tsp_'* are also globally valid but are not set exclusively, i.e., the operator call does not block other operator calls.
- Parameters with *'tsp_'* variant are thread specific.
  1. Without *'tsp_'*, they are set for all threads that are started after this call as well as for the current thread. Threads that are already running will not be affected.
  2. Parameters called with *'tsp_'* are only set for the current thread. Other threads that are already running will not be affected.

Available system parameters:

- **Graphic:**
  'backing_store': Determines whether the window content will be refreshed in case of overlapping of the windows. Some implementations of X Windows are faulty; in order to avoid these errors, the storing of contents can be deactivated. In some cases it may be advisable to deactivate the security mechanism, if e.g., performance / memory is critical.
  Value: *'true'*, *'false'*
  Default: *'true'*

'flush_graphic': After each HALCON operation which creates a graphic output, a flush operation will be executed in order to display the data immediately on screen. This is not necessary for all programs, e.g., if everything is done with the help of the mouse. In this case *'flush_graphic'* can be set to *'false'* to improve the runtime. Note that this parameter has no effect on Unix-like systems because there, the window managers flush the display buffer automatically.
Note: Using *'flush_graphic'* is not recommended, since it can lead to unexpected results. Instead, please set the parameter *'flush'* of `set_window_param` to *'false'* and call `flush_buffer` to transfer the buffer to the graphics window.
`Value`: *'true'*, *'false'*
Default: *'true'*

'int2_bits': Number of significant bits of int2 images. This number is used when scaling the gray values. If the value is set to -1 the gray values will be scaled automatically (default).
`Value`: *-1* or *9..16*
Default: *-1*

'icon_name': Name of iconified graphics windows under X Windows. By default the number of the graphics window is displayed.
`Value`: Name of iconified graphics window.
Default: *'default'*

'default_font' ***):** Default font for text output in text and graphic windows. Available fonts can be queried with `query_font`. The syntax of possible fontnames in `Value` is described at `set_font`.
`Value`: Name of Font.
Default: *'fixed'*

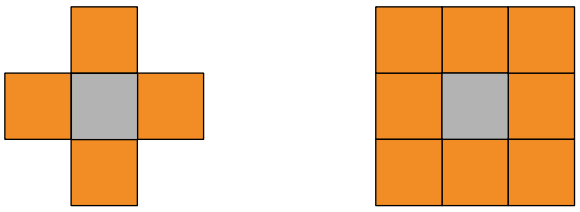
'update_lut': Determines whether the HALCON look-up color tables are adapted according to their environment or not. Such hardware-dependent color tables are no longer in use, so the parameter is obsolete. You can use the operator `query_lut` to query all possible look-up tables and set a specific one using `set_lut`.
`Value`: *'true'*, *'false'*
Default: *'false'*

'use_window_thread': On Microsoft Windows systems, calling any of the HALCON graphics operators from a thread other than the one that created the output window requires that there be an active message loop for that window. Setting this parameter to *'true'* will automatically open all top level HALCON graphics and text windows in a special window thread that will handle the message loop; all graphics operators directed at these windows will also be executed by that thread automatically. This parameter has no effect on non-Windows systems.
`Value`: *'true'*, *'false'*
Default: *'false'*

'x_package': The output of image data via the network may cause errors due to the heavy load on the computer or on the network. In order to avoid this, the data are transmitted in small packages. If the display is used locally (as opposed to using it via network), these units can be enlarged at will. This can lead to a recognizably improved output performance. On X Window systems the maximum request size is queried when the first window is opened.
`Value`: Package size (in bytes).
Default: *131072*

- **Image Processing:**

'neighborhood', *'tsp_neighborhood'*: This parameter checks either four pixels (in horizontal and vertical direction) or all eight neighboring pixels around one pixel. It is used with all operators that examine neighborhood relations: `connection`, `get_region_contour`, `get_region_polygon`, `get_region_thickness`, `boundary`, `paint_region`, `disp_region`, `fill_up`, `contlength`, `shape_histo_all`.
`Value`: *4* or *8*
Default: *8*



(1) (2)

(1) Four neighboring pixels, (2) eight neighboring pixels.

'init_new_image', *'tsp_init_new_image'*: Determines whether new images shall be set to 0 before using filters and thus to make sure that the values returned by a filtering are consistent if the program is executed repeatedly on systems with the same configuration. Note that this is not necessary if always the whole image is filtered or if the data of unfiltered image areas is unimportant.
Value: *'true'*, *'false'*
Default: *'true'*

'no_object_result', *'tsp_no_object_result'*: Determines how operations processing iconic objects shall react if the object tuple is empty (= no objects).
Available values for Value:

- *'true'*: The error will be ignored.
- *'exception'*: An exception is raised.

Default: *'true'*

'empty_region_result', *'tsp_empty_region_result'*: Controls the reaction of operators concerning input objects with empty regions which actually are not useful for such objects (e.g., certain region features, segmentation, etc.).
Available values for Value:

- *'true'*: The error will be ignored if possible.
- *'exception'*: An exception is raised.

Default: *'true'*

'store_empty_region', *'tsp_store_empty_region'*: Quite a number of operations will lead to the creation of objects with an empty region (= no image points) (e.g., intersection,threshold, etc.). This parameter determines whether the object with an empty region will be returned as a result ('true') or whether it will be ignored (*'false'*) that is no result will be returned.
Value: *'true'*, *'false'*
Default: *'true'*

'clip_region', *'tsp_clip_region'*: Determines whether the regions of iconic objects will be clipped to the currently used image size or not. This parameter can be used with operators that have a region as output, for example, gen_circle, gen_rectangle1 or dilation1.
See also: reset_obj_db
Value: *'true'*, *'false'*
Default: *'true'*

'int_zooming': Determines the precision of certain steps of the image processing. By setting *'int_zooming'* to *'true'* integer arithmetic or fast floating point arithmentic is used. High precision floating point arithmetic will be used by setting it to *'false'*. More information how a specific operator is affected by the parameter *'int_zooming'* can be found in the documentation of the directly concerned operator.
Value: *'true'*, *'false'*
Default: *'true'*

'pregenerate_shape_models': This parameter determines whether the shape models are completely pregenerated (*'true'*) or not (*'false'*) if this behavior is not explicitly specified in the shape model operator.
Affected operators:

- create_shape_model
- create_shape_model_xld
- create_scaled_shape_model
- create_scaled_shape_model_xld
- create_aniso_shape_model
- create_aniso_shape_model_xld

Value: *'true'*, *'false'*
Default: *'false'*

'border_shape_models': This parameter determines whether the shape models to be found may lie partially outside the image, i.e., whether they may cross the image border, (*'true'*) or not (*'false'*). Partially means that the model's origin still must be located within the image. A different origin set with set_shape_model_origin is not taken into account.
Affected operators:

- find_generic_shape_model

- find_shape_model
- find_shape_models
- find_scaled_shape_model
- find_scaled_shape_models
- find_aniso_shape_model
- find_aniso_shape_models
- find_planar_uncalib_deformable_model
- find_planar_calib_deformable_model
- find_local_deformable_model
- find_component_model (legacy)

Note, if a value has been set for shape models using set_generic_shape_model_param, the specific value set for the model dominates the system-wide setting. When searching multiple shape models *'border_shape_models'* is treated as *'true'* for all shape models even if *'border_shape_models'* only evaluates to *'true'* for one of the shape models in a search.
Value: *'true'*, *'false'*
Default: *'false'*

'opengl_context_cache_enable': This parameter determines if the graphic card context used in the operator render_object_model_3d is cached for future uses of this operator. The caching speeds up future uses of this operator but requires additional resources. To explicitly delete the context, set *'opengl_context_cache_enable'* to *'false'* and call render_object_model_3d once. *'opengl_context_cache_enable'* can only be set to *'true'* if the graphic card supports the rendering of 3D object models.
Value: *'true'*, *'false'*
Default: *'true'* if supported by the graphics card.

'opengl_hidden_surface_removal_enable': This parameter determines if the graphics card accelerated hidden surface removal is used in create_shape_model_3d, find_shape_model_3d, project_shape_model_3d, and project_object_model_3d. *'opengl_hidden_surface_removal_enable'* can only be set to *'true'* if the graphics card supports the acceleration of the hidden surface removal algorithm. The minimum requirements are OpenGL 2.0 and the extensions GL_EXT_framebuffer_object and GL_ARB_texture_float. Use get_system with the parameter Query set to *'opengl_hidden_surface_removal_available'* to determine if these requirements are fulfilled. Please note that these features are not available via Windows Remote Desktop or X11 forwarding.
Value: *'true'*, *'false'*
Default: *'true'* if supported by the graphics card.

'opengl_compatibility_mode_enable': This parameter determines if the visualization of 3D object models via disp_object_model_3d uses advanced OpenGL features or OpenGL 1.1 features only. If set to *'false'* HALCON determines the capabilities of the graphics card automatically. Set this parameter to *'true'*, if you face visualization problems.
Value: *'true'*, *'false'*
Default: *'false'*.

'image_dpi': This parameter determines the DPI resolution that is stored in image files written with write_image in a format that supports the storing of the DPI resolution.
Value: Resolution in DPI.
Default: *300*

'width', *'tsp_width'*: Determines the internal image width of the system. This size is used for clipping regions or implementing an assumption of memory sizes, if an operator has no further image information. This size is interpreted as maximum width of all HALCON image objects. It will be increased, if images of greater width will subsequently be instantiated. See also reset_obj_db. Note that the default value is *512* within HDevelop (also if you export your code), otherwise it is *128*.
Value: Internal image width.
Default: *128* or *512* (HDevelop)

'height', *'tsp_height'*: Determines the internal image height of the system. This size is used for clipping regions or implementing an assumption of memory sizes, if an operator has no further image information. This size is interpreted as maximum height of all HALCON image objects. It will be increased if images of greater height will subsequently be instantiated. See also reset_obj_db. Note that the default value is *512* within HDevelop (also if you export your code), otherwise it is *128*.

Value: Internal image height.
Default: *128* or *512* (HDevelop)

'current_runlength_number', *'tsp_current_runlength_number'*: Regions will be stored internally in a certain runlength code. This parameter can determine the maximum number of chords which may be used for representing a region. Please note that some operators raise the number automatically if necessary.
The value can be enlarged as well as reduced.
Value: Maximum number of chords.
Default: *50000*

- **Parallelization:**

'parallelize_operators' *): Determines whether HALCON uses an automatic parallelization to speed up the processing of operators on multiprocessor machines. This feature can be switched off by setting *'parallelize_operators'* to *'false'*. Even then, HALCON will remain reentrant (and thread-safe), unless the parameter *'reentrant'* is set to *'false'* via set_system. Changing the value for *'parallelize_operators'* can be helpful, for example, if HALCON operators are called by a multithreaded application that also automatically performs the scheduling and load balancing of operators and data. Then, it may be undesired that HALCON performs additional parallelization steps, which may disturb the application's scheduling and load balancing concepts. For a more detailed control of automatic parallelization, single methods of data parallelization can be switched on and off. *'split_tuple'* enables the tuple parallelization method, *'split_channel'* the parallelization on image channels, *'split_domain'* the parallelization on the image domain, and *'split_partial'* the partial, internal parallelization of an operator. A preceding '~' disables the corresponding method. The method strings can also be passed within a control tuple to switch on or off methods of automatic data parallelization at once. E.g., [*'split_tuple'*,*'split_channel'*, *'split_domain'*, *'split_partial'*] is equivalent to *'true'*.
The methods supported by a specific operator can be viewed in this reference manual or obtained via the operator get_operator_info with the parameter value *'parallel_method'*.
Value: *'true'*, *'false'*, *'split_tuple'*, *'split_channel'*, *'split_domain'*, *'split_partial'*, *' split_tuple'*, *' split_channel'*, *' split_domain'*, *' split_partial'*
Default: *'true'*

'reentrant' *): Determines whether HALCON must be reentrant for being used within a parallel programming environment (e.g., a multithreaded application). If it is set to *'true'*, HALCON internally uses synchronization mechanisms to protect shared data objects from concurrent accesses. Though this is inevitable with any effectively parallel working application, it may cause undesired overhead, if used within an application which works purely sequentially. The latter case can be signaled by setting *'reentrant'* to *'false'*. This switches off all internal synchronization mechanisms and thus reduces overhead. Of course, HALCON is then no longer thread-safe, which causes another side-effect: HALCON will as a consequence no longer use the internal parallelization of operators, because this requires reentrancy. Setting *'reentrant'* to *'true'* resets HALCON to its default state, i.e., it is reentrant (and thread-safe) and it uses the automatic parallelization to speed up the processing of operators on multiprocessor machines.
Value: *'true'*, *'false'*
Default: *'true'*

'thread_num' *), *'tsp_thread_num'*: Sets the number of threads used by the automatic operator parallelization (aop) of HALCON. The number includes the calling thread and is restricted to the number of processors for efficiency reasons. Decreasing the number of threads is helpful if processors are occupied by user worker threads besides the threads of the automatic parallelization. With this, the number of processing threads can be adapted to the number of processors for best efficiency. If a processor affinity was set for the HALCON process, the parameter value *'default'* resets the number of threads to the number of assigned processors. Else, *'default'* sets the number of threads to the number of processors. If the thread-specific variant is used, HALCON reserves the specified number of threads exclusively for the calling thread. If no thread number was set so far for a specific thread, get_system returns value -1 for parameter value *'tsp_thread_num'*. In case the sum of all thread-specific reserved aop threads exceeds the number of threads set by *'thread_num'*, the latter one is increased accordingly. Specifying thread number 1 switches off the automatic parallelization (thread-specific when indicated).
Value: *1* <= Value <= *'processor_num'*, *'default'*
Default: *'default'*

'thread_pool' *): Denotes whether HALCON always creates new threads for automatic parallelization (*'false'*) or uses an existing pool of threads (*'true'*). Using a pool is more efficient for automatic parallelization. When switching off automatic parallelization permanently, deactivating the pool can save resources of the operating system.

Value: *'true'*, *'false'*
Default: *'true'*

- **File:**

'flush_file': This parameter determines whether the output characters of the operator fwrite_string are displayed directly on the output medium. If set to *'false'* the characters will be flushed only after entering the operator fnew_line.
Value: *'true'*, *'false'*
Default: *'true'*

'ocr_trainf_version': This parameter determines the format that is used for writing an OCR training file. The operators write_ocr_trainf, write_ocr_trainf_image and concat_ocr_trainf write training data in ASCII format for version number *1* or in binary format for version number *2* and *3*. Version number *3* stores images of type byte and uint2. The binary version is faster in reading and writing data and stores training files more packed. The ASCII format is compatible to older HALCON releases. Depending on the file version, the OCR training files can be read by the following HALCON releases:

- *1* - All HALCON releases
- *2* - 7.0.2 and higher
- *3* - 7.1 and higher

Value: *1*, *2*, *3*
Default: *3*

'filename_encoding': This parameter only exists for legacy reasons and should not be used anymore. It determines how the HALCON library internally represents strings. The default is UTF-8, which supports all characters of the Unicode standard.
The string encoding of the data code readers, file handles, sockets, tuple operators, the HALCON/C++ interface and the HALCON/C interface is independent of this parameter. For each, the string encoding can individually be changed to local-8-bit encoding. See the respective documentation for details.
The setting of *'filename_encoding'* is a global setting and effects all threads. This means, changing this value in a thread while other threads are processing strings results in an undefined behavior which may lead to crashes. If a legacy application still requires the HALCON library to use local-8-bit encoding, see the Technical Updates for further explanations.
Value: *'utf8'* or *'locale'*
Default: *'utf8'*

'write_halcon_files_encoding': Starting with HALCON 18.05 all proprietary HALCON files which store user defined strings use UTF-8 as the default string encoding when the data is serialized or written into a file. The encoding concerns mainly HALCON tuples as well as OCR and OCV classifiers, training data, and sample identifiers, which all store user defined class or character names. This allows to share these files easily between different operating systems, countries, and locales. If such a file with special characters should be used by an application that was built with an older HALCON version (before HALCON 18.05) and relies on the locale encoding of the strings, this option can be used to force HALCON to write its files with the current locale system encoding instead of UTF-8. Note that the changed encoding concerns only files that store strings with special characters, i.e. characters that are not plain ASCII. In addition, this option does not affect user files which can be opened with open_file.
Value: *'locale'* or *'utf8'*
Default: *'utf8'*

'read_halcon_files_encoding_fallback': Older proprietary HALCON files (before HALCON 18.05) are read by default with the locale system encoding. If an old HALCON file was written with UTF-8 instead, this parameter can be used to change the encoding for reading. This concerns mainly the HALCON tuples as well as OCR and OCV classifiers, training data, and sample identifiers, which all store user defined class or character names. Note that this option has no effect on reading new HALCON files and on files which contain only plain ASCII characters. In addition, this option does not affect user files which can be opened with open_file.
Value: *'locale'* or *'utf8'*
Default: *'locale'*

'tuple_string_operator_mode', *'tsp_tuple_string_operator_mode'*: This parameters determines how UTF-8 strings are processed by tuple string operators, like tuple_ord, tuple_strlen, or tuple_substr, when *'filename_encoding'* is set to *'utf8'*, which is the default now. The standard behavior is that these strings are processed by characters or Unicode code points and not by bytes. I.e.,

the string length (operator tuple_strlen) of all characters that are build from a single Unicode code point is 1, and accessing the n-th element of a string will always return the corresponding Unicode code point, no matter how many bytes are used to represent that code point or the code points before in UTF-8. This behavior can be changed by setting *'tuple_string_operator_mode'* to *'byte'*. In that mode strings are processed byte by byte.
Value: *'codepoint'* or *'byte'*
Default: *'codepoint'*

- **Directories:**

'halcon_dir' ***):** This parameter returns the root directory of the HALCON installation.
Value: Name of the directory.

'example_dir' ***):** HDevelop example programs (e.g., loaded via the Browse HDevelop Program Examples dialog or via the HDevelop examples sections in the reference manual) will be looked for in the directory *'example_dir'*. Note that if you set *'example_dir'* to a directory that does not contain the installed HDevelop example programs, the above mentioned mechanisms to load HDevelop example programs will fail.
Value: Name of the directory.

'calib_dir' ***):** Camera parameter files (e.g., acquired via read_cam_par) will be looked for in the currently used directory and in *'calib_dir'* (if no absolute paths are indicated). More than one directory name can be indicated (search paths), separated by semicolons (Windows) or colons (Unix-like systems).
Value: Name of the directory.

'dl_dir' ***):** Deep learning models (e.g., acquired via read_dl_model) will be looked for in the currently used directory and in *'dl_dir'* (if no absolute paths are indicated). More than one directory name can be indicated (search paths), separated by semicolons (Windows) or colons (Unix-like systems).
Value: Name of the directory.

'filter_dir' ***):** Filter masks (e.g., used via convol_image) will be looked for in the currently used directory and in *'filter_dir'* (if no absolute paths are indicated). More than one directory name can be indicated (search paths), separated by semicolons (Windows) or colons (Unix-like systems).
Value: Name of the directory.

'image_dir' ***):** Image files (e.g., acquired via read_image and read_sequence) will be looked for in the currently used directory and in *'image_dir'* (if no absolute paths are indicated). More than one directory name can be indicated (search paths), separated by semicolons (Windows) or colons (Unix-like systems). The path can also be determined using the environment variable HALCONIMAGES.
Value: Name of the directory.

'3d_model_dir' ***):** 3D object model files (e.g., acquired via read_object_model_3d) will be looked for in the currently used directory and in *'3d_model_dir'* (if no absolute paths are indicated). More than one directory name can be indicated (search paths), separated by semicolons (Windows) or colons (Unix-like systems).
Value: Name of the directory.

'lut_dir' ***):** Color tables (set_lut) which are realized as an ASCII-file will be looked for in the currently used directory and in *'lut_dir'* (if no absolute paths are indicated). As default, HALCON will search the color tables in the sub-directory 'lut'.
Value: Name of the directory.

'help_dir' ***):** The online text files German or English.hlp, .sta, .key .num and .idx will be looked for in the currently used directory or in the path specified by *'help_dir'*. This system parameter is necessary for instance when using the operators get_operator_info and get_param_info. It can also be set by the environment variable HALCONROOT before initializing HALCON. In this case the variable must indicate the directory above the help directories (that is the HALCON home directory).
Value: Name of the directory.

'ocr_dir' ***):** OCR classifiers (e.g., acquired via read_ocr_class_knn) will be looked for in the currently used directory and in *'ocr_dir'* (if no absolute paths are indicated). More than one directory name can be indicated (search paths), separated by semicolons (Windows) or colons (Unix-like systems).
Value: Name of the directory.

- **Other:**

*'disabled_operators'***:** This parameter allows disabling of specific HALCON operators. This can be useful if a program allows running user-created HDevelop scripts, but certain operators should not be allowed for security reasons, e.g., the system_call operator. Any attempt to execute a disabled operator will

raise the exception H_ERR_OP_DISABLED (9055). Note that once an operator is disabled, it cannot be reenabled during the remaining lifetime of the process.
The value for this parameter is a tuple containing the names of all operators to be disabled.

'do_low_error' ***):** Determines the behavior regarding HALCON low level errors.

- If the parameter *'do_low_error'* is set to *'false'*, then no low level errors are thrown. However, the low level error messages still appear in the output console (a window containing a log of the most recent messages) that can be opened via the window menu.
- If the parameter *'do_low_error'* is set to *'disabled'*, the low level errors are suppressed and are not listed in the output console.
- If the parameter is set to *'stderr'*, the corresponding low level error message is printed to standard error.
- If it is set to *'message_box'*, then a message box containing the error text is opened (this functionality is implemented on Windows systems only).
- The parameter value *'callback'* can be used to determine a callback function, which should be called in case of a low level error. The address of this callback function is specified in the second index entry of the parameter `Value`.
  The signature of the callback function is the following:
  `Herror LowErrorCallbackProc(const char* err_text)`
  On Windows 32 bit systems, the __stdcall naming convention is used:
  `Herror (__stdcall LowErrorCallbackProc)(const char* err_text)`
  The parameter value *'callback'* can be used in HDevelop only if the callback procedure is set to 0, in which case the output of low level error messages is omitted.
  The string encoding of the message corresponds to the HALCON library encoding defined by *'filename_encoding'*.
- If low level error messages should be printed to file, then the parameter value *'file'* should be used together with a file handle referring to a corresponding file previously opened via `open_file`.
- The parameter values *'callback'* and *'file'* can be used only in combination with a corresponding procedure and file handle, respectively.
- With the exception of the parameter value *'false'*, the parameter *'do_low_error'* can be assigned multiple values. In case of a low level error, the corresponding actions are executed in the order of the values as passed in the input parameter tuple. If the tuple contains a certain parameter value multiple times, then only the first occurrence of the value in the tuple is taken into account, i.e., it is not possible to execute the same action multiple times in case of a low level error . If *'do_low_error'* is assigned multiple values or either the value *'file'* or *'callback'*, then it cannot be set in combination with other system parameters in the same call of `set_system`.
- Every setting of *'do_low_error'* via `set_system` overrides the previous setting of the parameter.
- The single parameter value *'true'* corresponds to the parameter value *'message_box'* on Windows systems and *'stderr'* on Unix-like systems.

`Value`: *'true'*, *'false'*, *'disabled'*, *'stderr'*, *'message_box'*, *'callback'*, *'file'*
Default: *'false'*

'cancel_draw_result', *'tsp_cancel_draw_result'***:** Many draw operators (like, e.g., `draw_region` or `draw_rectangle1`) can be canceled by ending the drawing with the right mouse button without new objects being drawn or existing objects being modified. The stop button of HDevelop can also be used to abort draw operators. The aborted draw operators return empty objects or empty tuples, respectively. *'cancel_draw_result'* controls the behavior of aborted draw operators.
The following values are available for `Value`:

- *'true'*: The draw operator returns no error.
- *'exception'*: An exception is raised.

Default: *'true'*

*'seed_rand'***:** Sets the seed of the thread specific random generator used in operators like, e.g., `tuple_rand`. If no seed has been set, the random generator is seeded with the current system time (amongst others) on the first call of one of the operators listed above. Afterwards the value used as seed can be queried with `get_system`.
This parameter accepts integer values or the string *'default'* to re-establish the default behavior.

*'cudnn_deterministic'***:** Determines whether the cuDNN library for deep learning uses deterministic algorithms to enforce bit-wise reproducibility "when executed on GPUs with the same architecture and the

same number of SMs." Please note that reproducibility is not guaranteed across different cuDNN versions. Further using deterministic algorithms can slow down the computation on some architectures.
Value: *'true'*, *'false'*
Default: *'false'*

'clock_mode': Determines the mode of the measurement of time intervals with count_seconds.
Value:

- *'performance_counter'* measures the elapsed system time with preferably high precision. HALCON uses the most accurate time measurement method provided by the operating system. If no high precision measurement method is available, a lower resolution method is used. On Windows systems the Performance Counter is used. For more information about the Performance Counter on Windows refer to the Microsoft Developer Network (MSDN) documentation. The Performance Counter provides the highest precision (below one millisecond). However, it may not work correctly on some systems due to issues with energy management and/or multithreading. If the Performance Counter is not supported by the operating system, the setting *'multimedia_timer'* applies. On Unix-like systems (e.g., Linux) the precision is also generally below one millisecond, and it may also be affected by problems due to energy management and/or multithreading. If you encounter such problems you should use the *'elapsed_time'* setting.
- *'elapsed_time'* measures the elapsed system time similar to the setting *'performance_counter'*. The difference is that other measurement methods are used which are less accurate but generally not much affected by problems due to energy management and/or multithreading. The precision is in general one millisecond. This setting should be used, if the measurements using *'performance_counter'* are unreliable and a precision of one millisecond is acceptable.
- *'multimedia_timer'* measures the elapsed system time using Multimedia Timers on Windows. Please refer to the Microsoft Developer Network (MSDN) documentation for more information on Multimedia Timers. This method has in general a resolution of one millisecond. If such a resolution cannot be achieved on your system you may use the Windows functions 'timerBeginPeriod' and 'timerEndPeriod' in order to increase the precision (see MSDN). On Unix-like systems there are no Multimedia Timers and therefor the setting *'performance_counter'* applies.
- *'processor_time'* measures the time the running HALCON process occupies the CPU. This kind of measuring time is independent of the CPU load caused by other processes, but it features a lower resolution on most systems and is therefore less accurate for smaller time intervals. Please note that the runtime of many applications is not only affected by CPU processing time. A lot of applications will be affected by input/output or memory management. For such applications the setting *'performance_counter'* or *'elapsed_time'* should be used instead.

Default: *'performance_counter'*
Please note that the settings *'performance_counter'* and *'elapsed_time'* measure the elapsed system time. As a consequence the measured time intervals are affected by the system load while measuring. If these settings are used to measure the runtime of a given application it should be ensured that other processes do not affect the measurement.

'timer_mode': Determines the mode of measurement used by the operators supporting timeouts.
Available values for Value:

- *'elapsed_time'*: see description in section *'clock_mode'*
- *'multimedia_timer'*: see description in section *'clock_mode'*
- *'performance_counter'*: see description in section *'clock_mode'*

Default: *'multimedia_timer'* on Windows systems, *'elapsed_time'* on Linux systems

'tsp_clear_extended_error': Clears the extended error information of the current thread.

'system_time_base': Determines how the system time is read. The system time can be read using get_system_time.
Value: *'UTC'* (Coordinated Universal Time), *'localtime'* (local time configured on the used system)
Default: *'localtime'*

'max_connection': Determines the maximum number of regions returned by connection. For Value=*0*, all regions are returned.
Value: >=*0*
Default: *0*

'extern_alloc_funct': Pointer to external function for memory allocation of result images. This function should have the following signature: 'void* ExternAllocFunc(size_t)'. If *0* is passed the HALCON allocation function will be used.

Value: Function pointer.
Default: *0*

'extern_free_funct' ***):** Pointer to external function for memory deallocation of result images. This function should have the following signature: 'void ExternFreeFunct(void*)'. If *0* is passed the HALCON deallocation function will be used.
Value: Function pointer.
Default: *0*

'image_cache_capacity' ***):** To speed up allocation of new images, HALCON does not free image memory of image objects but caches it to reuse it. With this parameter, you can set an upper limit in bytes for this HALCON image cache. Freed images are cached as long as the upper limit is not reached. This functionality can be switched off by setting *'image_cache_capacity'* to *0*.
Value: Limit for HALCON image cache.
Default: 16777216 (16MByte)

*'global_mem_cache'***:** Cache mode of global memory, i.e., memory that is visible beyond an operator. It specifies whether unused global memory should be cached for each thread separately (*'exclusive'*) or freed (*'idle'*). When using *'exclusive'* to cache memory, memory allocation and processing are sped up at the cost of memory consumption. With the action parameter *'cleanup'*, cached memory can be freed physically again. For more information on HALCON's caching mechanism, please refer to the technical note `HALCON Memory Management`.
Value: *'idle'*, *'exclusive'*, *'cleanup'*
Default: *'exclusive'*

'temporary_mem_cache' ***),** *'tsp_temporary_mem_cache'***:** This parameter controls the operating mode of the temporary memory cache. The temporary memory cache is used to speed up an application by caching memory used temporarily during the execution of an operator. For most applications the default setting (*'exclusive'*) will produce the best results. For more information on HALCON's caching mechanism, please refer to the technical note `HALCON Memory Management`.
The following modes are supported:

- *'idle'* The temporary memory cache is turned off. This mode will use the least memory, but will also reduce performance compared to the other modes.
- *'shared'* All temporary memory is cached globally in the temporary memory reservoir. This mode will use less memory than *'exclusive'* mode, but will also generally offer less performance.
- *'exclusive'* All temporary memory is cached locally for each thread. This mode will use the most memory, but will generally also offer the best performance.
- *'aggregate'* Temporary memory superblocks that are larger than the threshold set with the *'alloctmp_max_blocksize'* parameter are cached in the global memory reservoir, while all smaller superblocks are aggregated into a single superblock that is cached locally for each thread. If the global memory reservoir is disabled, the large superblocks are freed instead. The aggregated superblock will be sized according to the temporary memory usage the thread has seen so far, but it will not be larger than *'alloctmp_max_blocksize'* (if set) or smaller than *'alloctmp_min_blocksize'* (if set).

Note, the action of setting the temporary memory cache mode to *'idle'* (or *'false'*) itself runs exclusively, see the section "Parallelization information" above. In contrast, the action of setting the temporary memory cache mode to an other mode runs in reentrant mode, meaning without blocking other HALCON operators.
For backward compatibility, the values *'false'* and *'true'* are also accepted; they correspond to *'idle'* and *'exclusive'*, respectively.
Value: *'idle'*, *'shared'*, *'exclusive'*, or *'aggregate'*
Default: *'exclusive'*

*'temporary_mem_reservoir'***,** *'tsp_temporary_mem_reservoir'***:** If set to *'true'*, the global temporary memory reservoir is enabled. If it is set to *'false'*, it is disabled and any memory superblocks put into the reservoir are freed instead.
Any thread that needs new temporary memory will first check if the reservoir has a superblock available and only allocate more memory from the system if it does not. Superblocks are put into the reservoir by threads operating their caches in the *'shared'* or *'aggregate'* modes.
Note that the global setting of this parameter overrides the thread-specific setting, i.e., if *'temporary_mem_reservoir'* is set to *'false'*, *'tsp_temporary_mem_reservoir'* will have no effect.
Value: *'false'* or *'true'*
Default: *'true'*

'temporary_mem_reservoir_size': The maximum amount of memory the global temporary memory reservoir may cache, in bytes. If set to *-1*, the cache is limited only by the amount of available memory.
Value: *-1* or >= *0*
Default: *-1*

'alloctmp_min_blocksize', *'tsp_alloctmp_min_blocksize'*: Minimum size of memory superblocks used by the temporary memory cache, in bytes. (No effect if *'temporary_mem_cache'* == *'idle'*). With the default setting *-1*, HALCON will use a heuristic based on the current image size to determine a sensible superblock size. For most applications this will be the best choice. If the parameter is set to a value greater than or equal to zero, HALCON will use this size instead. Note that if an operator requires temporary memory objects larger than the *'alloctmp_min_blocksize'*, it will ignore this parameter.
Value: *-1* or >= *0*
Default: *-1*

'alloctmp_max_blocksize', *'tsp_alloctmp_max_blocksize'*: Setting this parameter to a value greater than or equal to zero will limit the size of temporary memory cache superblocks determined by a heuristic if *'alloctmp_min_blocksize'* is set to *-1* (no effect if *'temporary_mem_cache'* == *'idle'*). HALCON is still able to allocate superblocks larger than the limit, if necessary. With the default setting *-1*, the superblock size determined by the heuristic is not limited by HALCON. For most applications, this will be the best choice. In *'aggregate'* mode, this parameter additionally limits the size of the aggregated cache superblock, and determines the size threshold for superblocks to be placed into the temporary memory reservoir.
Value: *-1* or >= *0*
Default: *-1*

'database' *): Determines whether instantiated iconic objects should be listed in one of the five relations (gray-value data, region data, XLDs, iconic objects and object tuples) of the HALCON database. The relations can be used for, e.g., debugging purposes. See also count_relation, reset_obj_db. Note that collecting database information is not thread-safe when passing iconic objects between threads, meaning when deleting objects in a different thread than generating them.
Value: *'true'*, *'false'*
Default: *'false'*

'reset_used_modules' *): Set this to any value to reset the used modules reported by get_modules.

'mmx_enable': Flag, if MMX operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'mmx_supported'* == *'false'*, see also operator get_system)
Value: *'true'*, *'false'*
Default: *'true'* if CPU supports MMX, else *'false'*

'sse_enable': Flag, if SSE operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'sse_supported'* == *'false'*, see also operator get_system)
Value: *'true'*, *'false'*
Default: *'true'* if CPU supports SSE, else *'false'*

'sse2_enable': Flag, if SSE2 operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'sse2_supported'* == *'false'*, see also operator get_system)
Value: *'true'*, *'false'*
Default: *'true'* if CPU supports SSE2, else *'false'*

'sse3_enable': Flag, if SSE3 operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'sse3_supported'* == *'false'*, see also operator get_system)
Value: *'true'*, *'false'*
Default: *'true'* if CPU supports SSE3, else *'false'*

'ssse3_enable': Flag, if SSSE3 operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'ssse3_supported'* == *'false'*, see also operator get_system)
Value: *'true'*, *'false'*
Default: *'true'* if CPU supports SSSE3, else *'false'*

'sse41_enable': Flag, if SSE41 operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'sse41_supported'* == *'false'*, see also operator get_system)
Value: *'true'*, *'false'*
Default: *'true'* if CPU supports SSE41, else *'false'*

'sse42_enable': Flag, if SSE42 operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'sse42_supported'* == *'false'*, see also operator get_system)
Value: *'true'*, *'false'*
Default: *'true'* if CPU supports SSE42, else *'false'*

'avx_enable': Flag, if AVX operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX, else *'false'*

'avx2_enable': Flag, if AVX2 operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx2_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX2, else *'false'*

'avx2_gather_enable': Flag, if AVX2 gather operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx2_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: corresponds to *'avx2_gather_recommended'*

'avx512f_enable': Flag, if AVX-512F operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512f_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512F, else *'false'*

'avx512dq_enable': Flag, if AVX-512DQ operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512dq_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512DQ, else *'false'*

'avx512bw_enable': Flag, if AVX-512BW operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512bw_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512BW, else *'false'*

'avx512cd_enable': Flag, if AVX-512CD operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512cd_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512CD, else *'false'*

'avx512vl_enable': Flag, if AVX-512VL operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512vl_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512VL, else *'false'*

'avx512vbmi_enable': Flag, if AVX-512VBMI operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512vbmi_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512VBMI, else *'false'*

'avx512ifma_enable': Flag, if AVX-512IFMA operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512ifma_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512IFMA, else *'false'*

'avx512vbmi2_enable': Flag, if AVX-512VBMI2 operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512vbmi2_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512VBMI2, else *'false'*

'avx512vpopcntdq_enable': Flag, if AVX-512VPOPCNTDQ operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512vpopcntdq_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512VPOPCNTDQ, else *'false'*

'avx512bitalg_enable': Flag, if AVX-512BITALG operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512bitalg_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512BITALG, else *'false'*

'avx512vnni_enable': Flag, if AVX-512VNNI operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'avx512vnni_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports AVX-512VNNI, else *'false'*

'neon_enable': Flag, if NEON operations are used to accelerate selected image processing operators (*'true'*) or not (*'false'*). (No effect, if *'neon_supported'* == *'false'*, see also operator `get_system`)
`Value`: *'true'*, *'false'*
Default: *'true'* if CPU supports NEON, else *'false'*

'language' *): Language used for error messages.
`Value`: *'english'*, *'german'*.
Default: *'english'*

'add_progress_callback', *'remove_progress_callback'*: Adds or removes a callback function for operator progress and messages. The callback function is called by some operators in irregular intervals to signal their progress or a message to the application.
The signature of the callback is

```
void HProgressBarCallback(Hlong id, const char *operator_name,
double progress, const char *message)
```

On Windows 32 bit systems, the __stdcall naming convention is used:

```
void (__stdcall HProgressBarCallback)(Hlong id, const char
*operator_name, double progress, const char *message)
```

A corresponding delegate HalconAPI.HProgressBarCallback is defined for HALCON/.NET. Note that in order to pass a delegate to `set_system` you will need to call Marshal.GetFunctionPointerForDelegate and make sure the delegate is not garbage collected as long as the pointer remains in use.

```
public delegate void HProgressBarCallback(IntPtr id, string
operatorName, double progress, string message)
```

The parameters are:

- *'id'*: Thread-ID from which the operator was originally called. If the automatic operator parallelization is active, the callback might happen in a thread that is different from the one that was originally used to start the operator. Applications which display the progress in a GUI might have to consider this.
- *'operator_name'*: Name of the currently executed operator.
- *'progress'*: The interpretation of this parameter depends on its value. Between 0 and 1: The approximate current progress of the operator. -1: The operator shows only a message and does not set the progress. This parameter should be ignored. -2: The operator completed execution. This is the last callback for this operator and a chance for the application to perform cleanups. Note that this call happens only for operators that have called the callback at least once to set a progress or a message.
- *'message'*: Optional message in english that usually describes the progress of the operator such as the current error when training classifiers. If the operator has no message to show, this parameter can be NULL.

'legacy_handle_mode', *'tsp_legacy_handle_mode'*: Flag to activate or deactivate the legacy handle mode. If enabled, all handles returned by HALCON operators are converted into integers, and all HALCON operators accept integers as handles. Note that if the legacy handle mode is enabled, handles are no longer automatically cleared when they are overwritten. Instead, `clear_handle` or the corresponding clear operator of the handle type must be called.
Also note that the legacy handle mode is solely provided for running legacy code. It is not recommended to activate it in new code. New operators or language features might not work in legacy handle mode.
`Value`: *'true'*, *'false'*
Default: *'false'*

'gs1_syntax_dictionary' Provides a file containing the GS1 Application Identifier Syntax Dictionary to replace the list of GS1 Application Identifiers accepted by HALCON. The latest version can be obtained from the official GS1 website.
GS1 Application Identifiers are prefixes to define the meaning and format of data attributes.

The following values are supported:
- Filename of the file containing the syntax dictionary.
- *'default'*: Factory setting is recovered.

`Value`: Filename, *'default'*.

'memory_allocator' Set the memory allocator used to manage HALCON's heap. The available allocators can be queried with `get_system` using the parameter *'memory_allocators_supported'*. The following allocators are available:
- *'system'*: Use the system's default heap allocator. On Windows this is Win32's HeapAlloc, on other operating systems it is the C runtime's malloc function.
- *'mimalloc'*: Use the mimalloc heap allocator (see the official mimalloc documentation for more details).

Default: *'mimalloc'* on Windows systems, *'system'* otherwise
Please note that this setting does neither replace nor divert the system's standard heap allocator, it only changes which function HALCON calls to allocate memory internally. It also does not affect any of the third-party libraries HALCON uses. As a result, using any setting other than *'system'* will increase overall memory consumption, as the HALCON process will be using multiple separate heap managers. Depending on the operating system and application, this may improve performance.

Attention

Note that despite the information under 'Parallelization' concerning the multithreading type, not all parameters are reentrant. Operators that are followed by '*)' are set exclusively only.

Parameters

▷ **`SystemParameter`** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the system parameter to be changed.
Default: 'init_new_image'
List of values: `SystemParameter` ∈ {'3d_model_dir', 'add_progress_callback', 'alloctmp_min_blocksize', 'alloctmp_max_blocksize', 'avx_enable', 'avx2_enable', 'avx512f_enable', 'avx512dq_enable', 'avx512bw_enable', 'avx512cd_enable', 'avx512vl_enable', 'avx512vbmi_enable', 'avx512ifma_enable', 'avx512vbmi2_enable', 'avx512vpopcntdq_enable', 'avx512bitalg_enable', 'avx512vnni_enable', 'neon_enable', 'backing_store', 'border_shape_models', 'calib_dir', 'cancel_draw_result', 'clip_region', 'clock_mode', 'cudnn_deterministic', 'current_runlength_number', 'database', 'default_font', 'disabled_operators', 'dl_dir', 'do_low_error', 'empty_region_result', 'example_dir', 'extern_alloc_funct', 'extern_free_funct', 'filename_encoding', 'filter_dir', 'flush_file', 'flush_graphic', 'global_mem_cache', 'gs1_syntax_dictionary', 'height', 'help_dir', 'icon_name', 'image_cache_capacity', 'image_dir', 'image_dpi', 'init_new_image', 'int2_bits', 'int_zooming', 'language', 'legacy_handle_mode', 'lut_dir', 'max_connection', 'memory_allocator', 'mmx_enable', 'neighborhood', 'no_object_result', 'opengl_hidden_surface_removal_enable', 'opengl_compatibility_mode_enable', 'opengl_context_cache_enable', 'ocr_dir', 'ocr_trainf_version', 'parallelize_operators', 'pregenerate_shape_models', 'read_halcon_files_encoding_fallback', 'reentrant', 'remove_progress_callback', 'reset_used_modules', 'seed_rand', 'sse_enable', 'sse2_enable', 'sse3_enable', 'ssse3_enable', 'sse41_enable', 'sse42_enable', 'store_empty_region', 'system_time_base', 'temporary_mem_cache', 'temporary_mem_reservoir', 'temporary_mem_reservoir_size', 'thread_num', 'thread_pool', 'timer_mode', 'tuple_string_operator_mode', 'tsp_cancel_draw_result', 'tsp_clear_extended_error', 'tsp_alloctmp_max_blocksize', 'tsp_alloctmp_min_blocksize', 'tsp_clip_region', 'tsp_current_runlength_number', 'tsp_empty_region_result', 'tsp_height', 'tsp_init_new_image', 'tsp_legacy_handle_mode', 'tsp_neighborhood', 'tsp_no_object_result', 'tsp_store_empty_region', 'tsp_temporary_mem_cache', 'tsp_temporary_mem_reservoir', 'tsp_thread_num', 'tsp_tuple_string_operator_mode', 'tsp_width', 'update_lut', 'use_window_thread', 'width', 'write_halcon_files_encoding', 'x_package'}

▷ **`Value`** (input_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
New value of the system parameter.
Default: 'true'
Suggested values: `Value` ∈ {'true', 'false', 0, 4, 8}

Result

The operator `set_system` returns the value `2` (`H_MSG_TRUE`) if the parameters are correct. Otherwise an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

25.12 Serial

clear_serial (: : SerialHandle, Channel :)

Clear the buffer of a serial connection.

clear_serial discards data written to the serial device referred to by SerialHandle, but not transmitted (Channel = *'output'*), or data received, but not read (Channel = *'input'*), or performs both these operations at once (Channel = *'in_out'*).

Parameters

▷ **SerialHandle** (input_control) . . . . . serial ⇝ *handle*
Serial interface handle.

▷ **Channel** (input_control) . . . . . string ⇝ *string*
Buffer to be cleared.
Default: 'input'
List of values: Channel ∈ {'input', 'output', 'in_out'}

Result

If the parameters are correct and the buffers of the serial device could be cleared, the operator clear_serial returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SerialHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

open_serial

Possible Successors

read_serial, write_serial

See also

read_serial

Module

Foundation

close_serial (: : SerialHandle :)

Close a serial device.

close_serial closes a serial device that was opened with open_serial.

Parameters

▷ **SerialHandle** (input_control) . . . . . serial ⇝ *handle*
Serial interface handle.

Result

If the parameters are correct and the device could be closed, the operator close_serial returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SerialHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

get_serial_param (: : SerialHandle : BaudRate, DataBits, FlowControl, Parity, StopBits, TotalTimeOut, InterCharTimeOut)

Get the parameters of a serial device.

get_serial_param returns the current parameter settings of the serial device passed in SerialHandle. For a description of the parameters of a serial device, see set_serial_param.

Parameters

▷ **SerialHandle** (input_control) . . . . . serial ⇝ *handle*
Serial interface handle.

▷ **BaudRate** (output_control) . . . . . integer ⇝ *integer*
Speed of the serial interface.

▷ **DataBits** (output_control) . . . . . integer ⇝ *integer*
Number of data bits of the serial interface.

▷ **FlowControl** (output_control) . . . . . string ⇝ *string*
Type of flow control of the serial interface.

▷ **Parity** (output_control) . . . . . string ⇝ *string*
Parity of the serial interface.

▷ **StopBits** (output_control) . . . . . integer ⇝ *integer*
Number of stop bits of the serial interface.

▷ **TotalTimeOut** (output_control) . . . . . integer ⇝ *integer*
Total timeout of the serial interface in ms.

▷ **InterCharTimeOut** (output_control) . . . . . integer ⇝ *integer*
Inter-character timeout of the serial interface in ms.

Result

If the parameters are correct and the parameters of the device could be read, the operator `get_serial_param` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SerialHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

`open_serial`

Possible Successors

`read_serial`, `write_serial`

See also

`set_serial_param`

Module

Foundation

open_serial (: : PortName : SerialHandle)

Open a serial device.

`open_serial` opens a serial device. The name of the device is determined by the parameter `PortName` and is operating system specific. On Windows machines, *'COM1'-'COM4'* is typically used, while on Unix-like systems the serial devices usually are named *'/dev/tty*'*. The parameters of the serial device, e.g., its speed or number of data bits, are set to the system default values for the respective device after the device has been opened. They can be set or changed by calling `set_serial_param`.

Parameters

▷ **PortName** (input_control) . . . . . filename ⇝ *string*
Name of the serial port.
Default: 'COM1'
Suggested values: `PortName` ∈ {'COM1', 'COM2', 'COM3', 'COM4', '/dev/ttya', '/dev/ttyb', '/dev/tty00', '/dev/tty01', '/dev/ttyd1', '/dev/ttyd2', '/dev/cua0', '/dev/cua1'}

▷ **SerialHandle** (output_control) . . . . . serial ⇝ *handle*
Serial interface handle.

Result

If the parameters are correct and the device could be opened, the operator `open_serial` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_serial_param, read_serial, write_serial, close_serial

See also

set_serial_param, get_serial_param, open_file

Module

Foundation

read_serial (: : SerialHandle, NumCharacters : Data)

Read from a serial device.

read_serial tries to read NumCharacters from the serial device given in SerialHandle. The read characters are returned in Data as a tuple of integers. This allows to read NUL characters, which would otherwise be interpreted as the end of a string. If the timeout of the serial device has been set to a value greater than 0 with set_serial_param, read_serial waits at most as long for the arrival of the first character as indicated by the timeout. Otherwise, the operator returns immediately. In any case, the number of characters available at the time of return are passed back to the caller, i.e., fewer characters than requested can be returned. This can be checked by the length of the tuple Data.

Parameters

▷ **SerialHandle** (input_control) ..... serial ⇝ *handle*
Serial interface handle.

▷ **NumCharacters** (input_control) ..... integer ⇝ *integer*
Number of characters to read.
Default: 1
Suggested values: NumCharacters ∈ {1, 2, 3, 4, 5, 10, 20, 40, 100}

▷ **Data** (output_control) ..... integer(-array) ⇝ *integer*
Read characters (as tuple of integers).

Result

If the parameters are correct and the read from the device was successful, the operator read_serial returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_serial

write_serial

Module

Foundation

set_serial_param (: : SerialHandle, BaudRate, DataBits, FlowControl, Parity, StopBits, TotalTimeOut, InterCharTimeOut :)

Set the parameters of a serial device.

set_serial_param can be used to set the parameters of a serial device. The parameter BaudRate determines the input and output speed of the device. It should be noted that not all devices support all possible speeds. The number of sent and received data bits is set with DataBits. The parameter FlowControl determines if and what kind of data flow control should be used. Software control (*'xon_xoff'*) and hardware control (*'cts_rts'* and *'dtr_dsr'*) can be used. Multiple values can be set separated by a space within one string (e.g., *'cts_rts dtr_dsr'*).

If and what kind of parity check of the transmitted data should be performed can be determined by `Parity`. The number of stop bits sent is set with `StopBits`. Finally, two timeout for reading from the serial device can be set. The parameter `TotalTimeOut` determines the maximum time, which may pass in `read_serial` until the first character arrives, independent of the actual number of characters requested. The parameter `InterCharTimeOut` determines the time which may pass between the reading of individual characters, if multiple characters are requested with `read_serial`. If one of the timeouts is set to *-1*, the system waits an arbitrary amount of time for the arrival of characters. If both timeouts are set to *0* the system doesn't wait and returns the available or none characters. Thus, on Windows systems, a total timeout of `TotalTimeOut` + n`InterCharTimeOut` results if n characters are to be read. On Unix-like systems, only one of the two timeouts can be set. Thus, if both timeouts are passed larger than -1, only the total timeout is used. The unit of both timeouts is milliseconds. It should be noted, however, that the timeout is specified in increments of one tenths of a second on Unix-like systems, i.e., the minimum timeout that has any effect is *100*. For each parameter, the current values can be left in effect by passing *'unchanged'*.

Parameters

▷ **`SerialHandle`** (input_control) . . . . . serial ⇝ *handle*
Serial interface handle.

▷ **`BaudRate`** (input_control) . . . . . integer ⇝ *integer* / string
Speed of the serial interface.
Default: 'unchanged'
List of values: `BaudRate` ∈ {50, 75, 110, 134, 150, 200, 300, 600, 1200, 1800, 2400, 4800, 9600, 19200, 38400, 57600, 76800, 115200, 153600, 230400, 307200, 460800, 'unchanged'}

▷ **`DataBits`** (input_control) . . . . . integer ⇝ *integer* / string
Number of data bits of the serial interface.
Default: 'unchanged'
List of values: `DataBits` ∈ {5, 6, 7, 8, 'unchanged'}

▷ **`FlowControl`** (input_control) . . . . . string ⇝ *string*
Type of flow control of the serial interface.
Default: 'unchanged'
List of values: `FlowControl` ∈ {'none', 'cts_rts', 'dtr_dsr', 'xon_xoff', 'dtr_dsr xon_xoff', 'cts_rts xon_xoff', 'cts_rts dtr_dsr', 'cts_rts dtr_dsr xon_xoff', 'unchanged'}

▷ **`Parity`** (input_control) . . . . . string ⇝ *string*
Parity of the serial interface.
Default: 'unchanged'
List of values: `Parity` ∈ {'none', 'odd', 'even', 'unchanged'}

▷ **`StopBits`** (input_control) . . . . . integer ⇝ *integer* / string
Number of stop bits of the serial interface.
Default: 'unchanged'
List of values: `StopBits` ∈ {1, 2, 'unchanged'}

▷ **`TotalTimeOut`** (input_control) . . . . . integer ⇝ *integer* / string
Total timeout of the serial interface in ms.
Default: 'unchanged'
Suggested values: `TotalTimeOut` ∈ {-1, 0, 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000, 'unchanged'}

▷ **`InterCharTimeOut`** (input_control) . . . . . integer ⇝ *integer* / string
Inter-character timeout of the serial interface in ms.
Default: 'unchanged'
Suggested values: `InterCharTimeOut` ∈ {-1, 0, 100, 200, 300, 400, 500, 600, 700, 800, 900, 1000, 'unchanged'}

Result

If the parameters are correct and the parameters of the device could be set, the operator `set_serial_param` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SerialHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

open_serial, get_serial_param

Possible Successors

read_serial, write_serial

See also

get_serial_param

Module

Foundation

write_serial (: : SerialHandle, Data :)

Write to a serial connection.

write_serial writes the characters given in Data to the serial device given by SerialHandle. The data to be written is passed as a tuple of integers. This allows to write NUL characters, which would otherwise be interpreted as the end of a string. write_serial always waits until all data has been transmitted, i.e., a timeout for writing cannot be set.

Parameters

▷ **SerialHandle** (input_control) . . . . . serial ⇝ *handle*
Serial interface handle.

▷ **Data** (input_control) . . . . . integer(-array) ⇝ *integer*
Characters to write (as tuple of integers).

Result

If the parameters are correct and the write to the device was successful, the operator write_serial returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

25.13 Serialized Item

clear_serialized_item (: : SerializedItemHandle :)

Delete a serialized item.

clear_serialized_item deletes a serialized item, which is passed by the handle SerializedItemHandle (see fwrite_serialized_item for an introduction of the basics of serialization). If a serialized item is created only by a data pointer, it will not be deleted. Such a data pointer, that

points to the beginning of serialized item can be created by the operator get_serialized_item_ptr. After calling clear_serialized_item, the handle of the serialized item becomes invalid.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item(-array) ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator clear_serialized_item returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- SerializedItemHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

fwrite_serialized_item, receive_serialized_item

Module

Foundation

create_serialized_item_ptr (: : Pointer, Size,
Copy : SerializedItemHandle)

Create a serialized item.

It is not recommended to use the operator create_serialized_item_ptr in HDevelop.

create_serialized_item_ptr creates a serialized item and returns the handle SerializedItemHandle (see fwrite_serialized_item for an introduction of the basics of serialization). The data pointer, i.e., the beginning of the serialized item, is passed by the parameter Pointer. The size of the serialized item in bytes is passed by parameter Size. The behavior of the operator is controlled by the parameter Copy. If Copy is set to *'true'*, a new serialized item is created and the values of the existing serialized item are copied. If Copy is set to *'false'*, only the data pointer of the input serialized item is stored, i.e., the actual data are not copied, which leads to shorter execution times.

Attention

If the parameter Copy is set to *'false'*, the data pointer of the serialized item must not be deleted during using the new serialized item.

Parameters

▷ **Pointer** (input_control) . . . . . pointer ⇝ *integer*
Data pointer of the serialized item.

▷ **Size** (input_control) . . . . . integer ⇝ *integer*
Size of the serialized item.

▷ **Copy** (input_control) . . . . . string ⇝ *string*
Copy mode of the serialized item.
Default: 'true'
List of values: Copy ∈ {'true', 'false'}

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `create_serialized_item_ptr` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

`get_serialized_item_ptr`

Module

Foundation

decrypt_serialized_item (: : EncryptedItemHandle, DecryptionParam : SerializedItemHandle)

Decrypt an encrypted item.

The operator `decrypt_serialized_item` decrypts the encrypted item `EncryptedItemHandle` to the serialized item `SerializedItemHandle` using the secret in the dictionary `DecryptionParam`. The secret must be passed in the form of a password string in the dictionary key 'password'.

Parameters

▷ **EncryptedItemHandle** (input_control) ..... encrypted_item ⇝ *handle*
Encrypted item handle.

▷ **DecryptionParam** (input_control) ..... dict ⇝ *handle*
Parameters for the decryption.
Default: []

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Serialized item handle.

Result

The operator `decrypt_serialized_item` returns the value `2` (`H_MSG_TRUE`) if the passed handles and the parameters are valid. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

`encrypt_serialized_item`, `read_encrypted_item`

Possible Successors

`deserialize_handle`

Module

Foundation

encrypt_serialized_item (: : SerializedItemHandle, EncryptionParam : EncryptedItemHandle)

Encrypt a serialized item.

The operator encrypt_serialized_item encrypts the serialized item SerializedItemHandle to the encrypted item EncryptedItemHandle using the secret in the dictionary EncryptionParam. The secret must be passed in the form of a password string in the dictionary key 'password'.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Serialized item handle.

▷ **EncryptionParam** (input_control) ..... dict ⇝ *handle*
Parameters for the encryption.
Default: []

▷ **EncryptedItemHandle** (output_control) ..... encrypted_item ⇝ *handle*
Encrypted item handle.

Result

The operator encrypt_serialized_item returns the value 2 (H_MSG_TRUE) if the passed handles and the parameters are valid. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

serialize_handle

Possible Successors

write_encrypted_item, decrypt_serialized_item

Module

Foundation

fread_serialized_item (: : FileHandle : SerializedItemHandle)

Read a serialized item from a file.

fread_serialized_item reads a serialized item, that was written by fwrite_serialized_item from the current input file with the file handle FileHandle (see fwrite_serialized_item for an introduction of the basics of serialization). For this, a serialized item is created and the values read from file are stored in the serialized item. The operator returns the handle of the serialized item in the parameter SerializedItemHandle. The file can be opened by the operator open_file. Note that the file must be open in binary format. For reading more than on item from one file the operator fread_serialized_item must be called several times.

Parameters

▷ **FileHandle** (input_control) ..... file ⇝ *handle*
File handle.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator fread_serialized_item returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised. The error code 9581 indicates that the end of file is reached before a serialized item could be read.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

Possible Successors

close_file, get_serialized_item_ptr, deserialize_shape_model, deserialize_ncc_model

Module

Foundation

fwrite_serialized_item (: : FileHandle, SerializedItemHandle :)

Write a serialized item to a file.

fwrite_serialized_item writes a serialized item to the output file with the handle FileHandle. The serialized item is defined by the handle SerializedItemHandle. The file can be opened by the operator open_file. Note that the file must be open in binary format. For writing more than one item in one file, the operator fwrite_serialized_item must be called several times. A serialized item can be read with fread_serialized_item.

Basics of the serialization and deserialization

For writing or sending iconic objects, data, or models to a file or to another HALCON process over a socket connection, first, the iconic objects, data, or models must be converted to serialized items. For this purpose, a lot of operators are available. E.g., the operator serialize_shape_model performs the serialization for the shape model . After this, a serialized item can be written by fwrite_serialized_item in a file or can be transferred by send_serialized_item to another HALCON process over a socket connection.

To deserialize a serialized item, first a serialized item is read from a file (see fread_serialized_item) or is received over the socket connection from another HALCON process (see receive_serialized_item). There are also operators to convert the serialized item to the original format, i.e., to the iconic object, the data, or the model. These operators deserialize the iconic object, the data, or the model. E.g., the operator deserialize_shape_model deserializes the item for a serialized shape model .

Parameters

▷ **FileHandle** (input_control) ..... file ⇝ *handle*
File handle.

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator fwrite_serialized_item returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_file, serialize_shape_model, serialize_ncc_model

Possible Successors

close_file, fread_serialized_item

Module

Foundation

get_serialized_item_ptr (: : SerializedItemHandle : Pointer, Size)

Access the data pointer of a serialized item.

It is not recommended to use the operator get_serialized_item_ptr in HDevelop.

get_serialized_item_ptr returns the data pointer to the serialized item which is passed by the handle SerializedItemHandle (see fwrite_serialized_item for an introduction of the basics of serialization). The data pointer, i.e., the beginning of the serialized item is returned by the parameter Pointer. The size of the serialized item in bytes is passed by the parameter Size.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **Pointer** (output_control) . . . . . pointer ⇝ *integer*
Data pointer of the serialized item.

▷ **Size** (output_control) . . . . . integer ⇝ *integer*
Size of the serialized item.

Result

If the parameters are valid, the operator get_serialized_item_ptr returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_serialized_item_ptr

Module

Foundation

25.14 Sockets

close_socket (: : Socket :)

Close a socket.

close_socket closes a socket that was previously opened with open_socket_accept, open_socket_connect, or socket_accept_connect. For a detailed example, see open_socket_accept.

Parameters

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- Socket

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

open_socket_accept, open_socket_connect, socket_accept_connect

Module

Foundation

get_next_socket_data_type (: : Socket : DataType)

Determine the HALCON data type of the next socket data.

get_next_socket_data_type returns the data type of the next data that are present on the socket Socket and returns it in DataType. The possible values for DataType are:

'no_data': No data are present.

'no_halcon_data': Some data are present, but they are not HALCON data.

'tuple': The next data is a tuple.

'region': The next data is a region object.

'image': The next data is an image object.

'xld_cont': The next data is an XLD contour.

'xld_poly': The next data is an XLD polygon.

'xld_para': The next data is an XLD parallel.

'xld_mod_para': The next data is a modified XLD parallel.

'xld_ext_para': The next data is an extended XLD parallel.

'serialized_item': The next data is a serialized item.

Parameters

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

▷ **DataType** (output_control) ..... string ⇝ *string*
Data type of next HALCON data.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

send_image, receive_image, send_region, receive_region, send_tuple, receive_tuple, send_serialized_item, receive_serialized_item

Module

Foundation

get_socket_descriptor (: : Socket : SocketDescriptor)

Get the socket descriptor of a socket used by the operating system.

get_socket_descriptor returns the socket descriptor used by the operating system for the socket connection that is passed in Socket. The socket descriptor can be used in operating system calls such as select, read, write, recv, or send.

Parameters

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

▷ **SocketDescriptor** (output_control) . . . . . integer ⇝ *integer*
Socket descriptor used by the operating system.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_socket_accept, open_socket_connect, socket_accept_connect

set_socket_param

Module

Foundation

get_socket_param (: : Socket, GenParamName : GenParamValue)

Get the value of a socket parameter.

get_socket_param reads the GenParamValue of the GenParamName for the specified socket connection. Available parameters are *'timeout'*, *'address_info'*, *'SO_SNDBUF'*, *'SO_RCVBUF'*, *'SO_BROADCAST'*, and *'TCP_NODELAY'*.

The parameter *'address_info'* returns the IP address and port of the local and the remote side of the specified socket connection.

See set_socket_param for a description of the other values.

Parameters

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Name of the socket parameter.
List of values: GenParamName ∈ {'timeout', 'address_info', 'SO_SNDBUF', 'SO_RCVBUF', 'SO_BROADCAST', 'TCP_NODELAY'}

▷ **GenParamValue** (output_control) . . . . . string ⇝ *string* / real / integer
Value of the socket parameter.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_socket_connect, socket_accept_connect

Possible Successors

set_socket_param

See also

set_socket_param

Module

Foundation

open_socket_accept (: : Port, GenParamName, GenParamValue : AcceptingSocket)

Open a socket that accepts connection requests.

open_socket_accept opens a socket that will accept incoming connection requests. This operator is the necessary first step in the establishment of a communication channel between two HALCON processes. The socket listens for incoming connection requests on the port number given by Port.

It is possible to specify a Port of 0, triggering implementation-defined behavior. On most operating systems, using a port number of 0 instructs the operating system to choose a free port randomly.

The following parameters can be set for GenParamName.

'protocol': Specifies the protocol to be used. The *'HALCON'* protocol without a specific address family, will use IPv4 or IPv6 automatically depending on the network configuration of the computer. To use a specific address family a '4' or '6' (for IPv4 or IPv6, respectively) must be appended to the name of the protocol. For example, *'HALCON4'* designates a HALCON connection over IPv4. Possible values for a generic socket communication are *'UDP'* and *'TCP'* which also support appended '4' and '6'. Both communication partners must use the same protocol. To exchange data using generic sockets use send_data and receive_data only.

Default: *'HALCON'*

'address': Instructs the socket to accept only connection requests addressed to a specific address. This address is specified as either an IPv4 or IPv6 address in numerical form, or a hostname. For example, *'localhost'* would instruct the socket to accept only connections addressed to the address *'localhost'*, which normally maps to the local loopback network interface *'127.0.0.1'*.

'timeout': Sets a timeout for this socket. The timeout is given in seconds or as the string *'infinite'*. It is used especially as timeout and waiting mode in a following socket_accept_connect call with the parameter Wait set to *'auto'*.

'string_encoding': Sets the string encoding that is expected when sending and receiving strings with this socket. It is used for send_tuple and receive_tuple as well as send_data and receive_data. When the protocol *'HALCON'* is used, the setting only has effect on connections to HALCON versions prior to 18.11. If the connection partner is detected to have HALCON version 18.11 or newer, UTF-8 is used to encode tuples.

'reuseaddr': Controls the setting of the socket option SO_REUSEADDR. When *'reuseaddr'* is set to *'false'*, SO_REUSEADDR will not be set. On Windows Systems, conflicting access on a single port will only be detected, when *'reuseaddr'* is set to *'false'*.

Default: *'true'*

'tls_enable': Controls the use of Transport Layer Security (TLS) for the new Socket. When *'tls_enable'* is set to *'true'*, the created socket will accept TLS secured connections only. Furthermore, both generic parameters *'tls_private_key'* and *'tls_certificate'* must be set, each with a path to the private certificate key and the path to the public server certificate. Private key and server certificate must be provided in PEM-format.

Default: *'false'*

The accepting socket is returned in AcceptingSocket. open_socket_accept returns immediately without waiting for a request from another process, which must be initiated by calling open_socket_connect. This allows multiple other processes to connect to the particular HALCON process that calls open_socket_accept. To accept an incoming *'HALCON'* or *'TCP'* connection request, socket_accept_connect must be called to obtain a socket for the final communication.

Parameters

▷ **Port** (input_control) ..... number ⇝ *integer*
Port number.
Default: 3000
Suggested values: Port ∈ {3000, 4570}
Value range: 1024 ≤ Port ≤ 65535
Minimum increment: 1
Recommended increment: 1

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that can be adjusted for the socket.
Default: []
List of values: GenParamName ∈ {'address', 'protocol', 'timeout', 'string_encoding', 'tls_enable', 'tls_private_key', 'tls_certificate'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
Values of the generic parameters that can be adjusted for the socket.
Default: []
Suggested values: GenParamValue ∈ {0, 3.0, 'infinite', 'HALCON', 'UDP', 'TCP', 'HALCON4', 'UDP4', 'TCP4', 'HALCON6', 'UDP6', 'TCP6', 'utf8', 'locale', 'ignore', 'true', 'false'}

▷ **AcceptingSocket** (output_control) . . . . . socket ⇝ *handle*
Socket number.

Example

```
* Process 1
dev_set_colored (12)
open_socket_accept (3000, [], [], AcceptingSocket)
* Busy wait for an incoming connection
dev_error_var (Error, 1)
dev_set_check ('~give_error')
OpenStatus := 5
while (OpenStatus != 2)
    socket_accept_connect (AcceptingSocket, 'false', Socket)
    OpenStatus := Error
    wait_seconds (0.2)
endwhile
dev_set_check ('give_error')
* Connection established
receive_image (Image, Socket)
threshold (Image, Region, 0, 63)
send_region (Region, Socket)
receive_region (ConnectedRegions, Socket)
area_center (ConnectedRegions, Area, Row, Column)
send_tuple (Socket, Area)
send_tuple (Socket, Row)
send_tuple (Socket, Column)
close_socket (Socket)
close_socket (AcceptingSocket)

* Process 2
dev_set_colored (12)
open_socket_connect ('localhost', 3000, [], [], Socket)
read_image (Image, 'fabrik')
send_image (Image, Socket)
receive_region (Region, Socket)
connection (Region, ConnectedRegions)
send_region (ConnectedRegions, Socket)
receive_tuple (Socket, Area)
receive_tuple (Socket, Row)
receive_tuple (Socket, Column)
close_socket (Socket)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

socket_accept_connect

open_socket_connect, close_socket, get_socket_param, set_socket_param, send_image, receive_image, send_region, receive_region, send_tuple, receive_tuple, send_data, receive_data

Module

Foundation

open_socket_connect (: : HostName, Port, GenParamName, GenParamValue : Socket)

Open a socket and connect it to an accepting socket.

open_socket_connect opens a connecting socket to an accepting socket on the computer HostName, which listens on port Port.

The following parameters can be set for GenParamName.

'protocol': Specifies the protocol to be used. The *'HALCON'* protocol without a specific address family, will use IPv4 or IPv6 automatically depending on the network configuration of the computer. To use a specific address family a '4' or '6' (for IPv4 or IPv6, respectively) must be appended to the name of the protocol. For example, *'HALCON4'* designates a HALCON connection over IPv4. Possible values for a generic socket communication are *'UDP'* and *'TCP'* which also support appended '4' and '6'. Alternatively, the usage of addresses for IPv4 (e.g., *'127.0.0.1'*) or IPv6 (e.g., *'::1'*) for HostName determines the address family to be used. Both communication partners must use the same protocol. To exchange data using generic sockets use send_data and receive_data only.

Default: *'HALCON'*

'timeout': Sets a timeout for this operation. The timeout is given in seconds or as the string *'infinite'*.

'tls_enable': Controls the use of Transport Layer Security (TLS) for the new socket connection. When *'tls_enable'* is set to *'true'*, a connection attempt using TLS is undertaken. This requires TLS support on the server side. The certificate to optionally check against is specified with the generic parameter *'tls_certificate'*. Without a certificate, the connection will still be encrypted, but the authenticity of the server can not be verified.

Default: *'false'*

'tls_certificate': Specify the path to a certificate to check the authenticity of the server of connection using Transport Layer Security (TLS). The certificate must be provided in PEM-format. This parameter is ignored if *'tls_enable'* is not set to *'true'*.

'tsl_sni': Set the "server name indication" to use for the TLS connection. This tells the server for which domain the certificate should be valid, which is important if multiple domains are hosted on the same server. This parameter is ignored if *'tls_enable'* is not set to *'true'*.

'string_encoding': Sets the string encoding that is expected when sending and receiving strings with this socket. It is used for send_tuple and receive_tuple as well as send_data and receive_data. When the protocol *'HALCON'* is used, the setting only has effect on connections to HALCON versions prior to 18.11. If the connection partner is detected to have HALCON version 18.11 or newer, UTF-8 is used to encode tuples.

For the *'HALCON'* protocol the listening socket must have been created earlier with the operator open_socket_accept in another HALCON process. To establish the connection, the HALCON process, in which the accepting socket resides, must call socket_accept_connect. For a detailed example, see open_socket_accept.

For generic sockets the socket to connect to can be any socket from the same protocol type.

Parameters

▷ **HostName** (input_control) . . . . . string ⇝ *string*
Hostname of the computer to connect to.
Default: 'localhost'

▷ **Port** (input_control) . . . . . number ⇝ *integer*
Port number.
Suggested values: Port ∈ {3000, 4570}
Value range: 1024 ≤ Port ≤ 65535
Minimum increment: 1
Recommended increment: 1

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters that can be adjusted for the socket.
Default: []
List of values: GenParamName ∈ {'timeout', 'protocol', 'string_encoding', 'tls_enable', 'tls_certificate', 'tls_sni'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real / integer
Values of the generic parameters that can be adjusted for the socket.
Default: []
Suggested values: GenParamValue ∈ {0, 3.0, 'infinite', 'HALCON', 'UDP', 'TCP', 'HALCON4', 'UDP4', 'TCP4', 'HALCON6', 'UDP6', 'TCP6', 'utf8', 'locale', 'ignore', 'true', 'false'}

▷ **Socket** (output_control) . . . . . socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

receive_data (: : Socket, Format : Data, From)

Receive arbitrary data from external devices or applications using a generic socket connection.

receive_data receives arbitrary data over a generic socket connection. The received data is converted from a binary network packet to a value (or a tuple of values) using the parameter Format as specification and is well-suited to communicate with external devices or applications. This operator does not support the standard *'HALCON'* protocol, but is intended for arbitrary data transfer.

The received data is converted to a value or tuple of values using the parameter Format. It is possible to specify multiple formats. In this case the From parameter will contain a 3rd value which tells you which format has been used to convert the data. To decide which format to use the size of the necessary data for each format is calculated initially. When data is received, the first format string with the matching size is used to convert the data to values.

The parameter From contains the IP address or hostname and port of the communication partner. For UDP connections it can be used in the send_data operator to send a response.

Please see send_data for a detailed description of the format.

Parameters

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

▷ **Format** (input_control) . . . . . string(-array) ⇝ *string*
Specification how to convert the data to tuples.
Default: 'z'

▷ **Data** (output_control) . . . . . string ⇝ *string* / real / integer / handle
Value (or tuple of values) holding the received and converted data.

▷ **From** (output_control) . . . . . string ⇝ *string* / integer
IP address or hostname and network port of the communication partner.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

receive_image (: Image : Socket :)

Receive an image over a socket connection.

receive_image reads an image object that was sent over the socket connection determined by Socket by another HALCON process using the operator send_image. If no image has been sent, the HALCON process calling receive_image blocks until enough data arrives. For a detailed example, see open_socket_accept.

Attention

'int8' images can be received by 64 bit systems only!

Parameters

▷ **Image** (output_object) . . . . . image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Received image.

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_socket_connect, socket_accept_connect, get_socket_param, set_socket_param

See also

send_image, send_region, receive_region, send_tuple, receive_tuple, get_next_socket_data_type

Module

Foundation

receive_region (: Region : Socket :)

Receive regions over a socket connection.

receive_region reads a region object that was sent over the socket connection determined by Socket by another HALCON process using the operator send_region. If no regions have been sent, the HALCON process calling receive_region blocks until enough data arrives. For a detailed example, see open_socket_accept.

Parameters

▷ **Region** (output_object) ..... region(-array) ⇝ *object*
Received regions.

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_socket_connect, socket_accept_connect, get_socket_param, set_socket_param

See also

send_region, send_image, receive_image, send_tuple, receive_tuple, get_next_socket_data_type

Module

Foundation

receive_serialized_item (: : Socket : SerializedItemHandle)

Receive a serialized item over a socket connection.

receive_serialized_item receives a serialized item that was sent over the socket connection determined by Socket of another HALCON process using the operator send_serialized_item (see fwrite_serialized_item for an introduction of the basics of serialization). If no serialized item has been sent, the HALCON process calling receive_serialized_item blocks until enough data arrives. The data is stored in a new created serialized item. The operator returns the handle of the serialized item in parameter SerializedItemHandle. For a detailed example showing the use of a socket connection, see open_socket_accept.

Parameters

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator receive_serialized_item returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

send_serialized_item

Possible Successors

get_serialized_item_ptr, deserialize_matrix, deserialize_metrology_model

Module

Foundation

receive_tuple (: : Socket : Tuple)

Receive a tuple over a socket connection.

receive_tuple reads a Tuple that was sent over the socket connection determined by Socket by another HALCON process using the operator send_tuple. If no tuple has been sent, the HALCON process calling receive_tuple blocks until enough data arrives. For a detailed example, see open_socket_accept.

Attention

receive_tuple does not allow receiving tuples containing HALCON handles.

Parameters

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

▷ **Tuple** (output_control) . . . . . string ⇝ *string* / real / integer
Received tuple.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_socket_connect, socket_accept_connect, get_socket_param, set_socket_param

receive_xld (: XLD : Socket :)

Receive an XLD object over a socket connection.

receive_xld reads an XLD object that was sent over the socket connection determined by Socket by another HALCON process using the operator send_xld. If no XLD object has been sent, the HALCON process calling receive_xld blocks until enough data arrives. For a detailed example, see send_xld.

Parameters

▷ **XLD** (output_object) . . . . . xld(-array) ⇝ *object*
Received XLD object.

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

send_data (: : Socket, Format, Data, To :)

Send arbitrary data to external devices or applications using a generic socket communication.

send_data sends arbitrary data over a socket connection. The sent data is converted to a binary network packet from a value (or a tuple of values) using the parameter Format as specification and is well-suited to communicate with external devices or applications. This operator does not support the standard *'HALCON'* protocol, but is intended for arbitrary data transfer.

The parameter Format specifies how to convert the given tuples to a binary packet. It uses one or multiple qualifier characters each followed by an optional modifier and repeat count. Most qualifiers require a single value in the Data parameter which will be converted.

The following characters are allowed in this format string:

Integer values:

'c': One byte = 8 bit, signed.

'C': Same as 'c' but unsigned.

's': Two bytes = 16 bit, signed.

'S': Same as 's' but unsigned.

'i': Four bytes = 32 bit, signed.

'I': Same as 'i' but unsigned.

'q': Sight bytes = 64 bit, signed (only available on 64bit architectures).

'Q': Same as 'q' but unsigned.

Float values:

'f': Float, 4 bytes = 32 bit.

'd': Double, 8 bytes = 64 bit.

String values:

'A': String (default length 1024 bytes), padded with spaces.

'a': String with arbitrary binary data. When sending data, the whole memory block will be transmitted and the size will be determined automatically. When receiving, the length argument must always be provided explicitly.

'Z': String (default length 1024 bytes), padded with NULL-Bytes and will be NULL terminated when sending.

'z': String with variable length, the length modifier specifies the maximum length (default length 1024 bytes).

Special characters which do not require a value as Data parameter:

'-': A single byte is written as binary NULL or when reading, a NULL-Byte is skipped.

'_': A single byte is written as space (binary 0x20) or when reading, a space byte is skipped.

' ': Ignored, can be used to enhance readability of the format string.

Modifiers which can be used after one of the qualifiers above:

'n': Convert the integer or float value when writing to or when reading from network byte order (big endian) to host byte order.

'N': Convert the integer or float value when writing to or when reading from Intel byte order (little endian) to host byte order.

'0-n': Specify a repeat count for the preceding qualifier, e.g., 'c5' means the same as 'ccccc' (and requires therefore a tuple of 5 values) but 'A10' means a string with a size of 10 bytes (and requires only one value).

The modifiers 'n' and 'N' can also be used as first character in the format string and set the default byte order. 'n', which means network byte order, is the default byte order when nothing else is specified.

For UDP connections the binary data must be transferred in one network packet so that the size of the binary data must not be bigger than one network packet. Usually this means it should be smaller than the MTU (maximum transfer unit) of the interface, which is usually about 1500 bytes, but only 576 bytes are guaranteed (1280 bytes for IPv6).

The parameter `To` should be left empty for socket connections that are already bound (all TCP connections and bound UDP connections), but in case of an unbound UDP connection it must be used to specify the IP address or host name and port number of the communication partner.

Parameters

▷ **`Socket`** (input_control) . . . . . socket ⇝ *handle*
Socket number.

▷ **`Format`** (input_control) . . . . . string ⇝ *string*
Specification how to convert the data.
Default: 'z'

▷ **`Data`** (input_control) . . . . . string(-array) ⇝ *string* / real / integer / handle
Value (or tuple of values) holding the data to send.

▷ **`To`** (input_control) . . . . . string(-array) ⇝ *string* / integer
IP address or hostname and network port of the communication partner.
Default: []
List of values: `To` ∈ {[], ['localhost',3000]}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`send_image` (Image : : Socket :)

Send an image over a socket connection.

`send_image` sends an image object over the socket connection determined by `Socket`. The receiving HALCON process must call `receive_image` to read the image from the socket. For a detailed example, see `open_socket_accept`.

Parameters

▷ **Image** (input_object) ..... (multichannel-)image(-array) ⇝ *object :* byte / direction / cyclic / int1 / int2 / uint2 / int4 / int8 / real / complex / vector_field
Image to be sent.

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_socket_connect, socket_accept_connect

send_region (Region : : Socket :)

Send regions over a socket connection.

send_region sends a region object over the socket connection determined by Socket. The receiving HALCON process must call receive_region to read the regions from the socket. For a detailed example, see open_socket_accept.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Regions to be sent.

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

send_serialized_item (: : Socket, SerializedItemHandle :)

Send a serialized item over a socket connection.

send_serialized_item sends a serialized item over a socket connection determined by Socket (see fwrite_serialized_item for an introduction of the basics of serialization). The receiving HALCON process must call receive_serialized_item to read the serialized item from the socket. The serialized item is returned by the handle SerializedItemHandle. For a detailed example showing the use of a socket connection, see open_socket_accept.

Parameters

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator send_serialized_item returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

send_tuple (: : Socket, Tuple :)

Send a tuple over a socket connection.

send_tuple sends a tuple Tuple over the socket connection determined by Socket. The receiving HALCON process must call receive_tuple to read the tuple from the socket. For a detailed example, see open_socket_accept.

Attention

send_tuple does not allow sending tuples containing HALCON handles.

Parameters

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

▷ **Tuple** (input_control) ..... string ⇝ *string* / real / integer
Tuple to be sent.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

send_xld (XLD : : Socket :)

Send an XLD object over a socket connection.

send_xld sends an XLD object over the socket connection determined by Socket. The receiving HALCON process must call receive_xld to read the XLD object from the socket.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
XLD object to be sent.

▷ **Socket** (input_control) ..... socket ⇝ *handle*
Socket number.

Example

```
* Process 1
dev_set_colored (12)
open_socket_accept (3000, [], [], AcceptingSocket)
socket_accept_connect (AcceptingSocket, 'true', Socket)
receive_image (Image, Socket)
edges_sub_pix (Image, Edges, 'canny', 1.5, 20, 40)
send_xld (Edges, Socket)
receive_xld (Polygons, Socket)
split_contours_xld (Polygons, Contours, 'polygon', 1, 5)
gen_parallels_xld (Polygons, Parallels, 10, 30, 0.15, 'true')
send_xld (Parallels, Socket)
receive_xld (ModParallels, Socket)
receive_xld (ExtParallels, Socket)
stop ()
close_socket (Socket)
close_socket (AcceptingSocket)

* Process 2
dev_set_colored (12)
open_socket_connect ('localhost', 3000, [], [], Socket)
read_image (Image, 'mreut')
send_image (Image, Socket)
receive_xld (Edges, Socket)
gen_polygons_xld (Edges, Polygons, 'ramer', 2)
send_xld (Polygons, Socket)
split_contours_xld (Polygons, Contours, 'polygon', 1, 5)
receive_xld (Parallels, Socket)
mod_parallels_xld (Parallels, Image, ModParallels, ExtParallels, \
                   0.4, 160, 220, 10)
send_xld (ModParallels, Socket)
send_xld (ExtParallels, Socket)
stop ()
close_socket (Socket)
```

Execution Information

set_socket_param (: : Socket, GenParamName, GenParamValue :)

Set a socket parameter.

set_socket_param sets the GenParamName according to GenParamValue for the specified socket connection. Available parameters are *'timeout'*, *'SO_SNDBUF'*, *'SO_RCVBUF'*, *'SO_BROADCAST'*, and *'TCP_NODELAY'*.

The parameter *'timeout'* can be used to set a timeout for this socket. The timeout is given in seconds as a floating point number or as the string *'infinite'*.

The parameters starting with 'SO_' or 'TCP_' set the corresponding socket options. *'SO_SNDBUF'* and *'SO_RCVBUF'* specify the size of the send respectively receive buffer of the operating system for this socket. Please be aware that this does not mean the size of one network packet but the size of the buffers where all packets are temporarily stored by your operating system. *'SO_BROADCAST'* can only be used together with UDP connections and enables broadcasting of network packets. *'TCP_NODELAY'* controls the Nagle algorithm, which optimizes the flow of small TCP packets and can only be used with TCP connections.

Parameters

▷ **Socket** (input_control) . . . . . socket ⇝ *handle*
Socket number.

▷ **GenParamName** (input_control) . . . . . string(-array) ⇝ *string*
Name of the socket parameter.
List of values: GenParamName ∈ {'timeout', 'SO_SNDBUF', 'SO_RCVBUF', 'SO_BROADCAST', 'TCP_NODELAY'}

▷ **GenParamValue** (input_control) . . . . . string(-array) ⇝ *string* / real / integer
Value of the socket parameter.
Default: 'on'
Suggested values: GenParamValue ∈ {'on', 'off', 0, 1, 3.0, 'infinite', 530, 1460}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

open_socket_connect, socket_accept_connect

Possible Successors

send_data, receive_data

See also

get_socket_param

Module

Foundation

socket_accept_connect (: : AcceptingSocket, Wait : Socket)

Accept a connection request on a listening socket of the protocol type 'HALCON' or 'TCP'/'TCP4'/'TCP6'.

socket_accept_connect accepts an incoming connection request, generated by open_socket_connect in another HALCON process or from an external application, on the

listening socket AcceptingSocket. The listening socket must have been created earlier with open_socket_accept. Its timeout determines the timeout of the socket_accept_connect call. If Wait='true', socket_accept_connect waits until a connection request from another HALCON process arrives. If Wait='false', socket_accept_connect returns with the error 5 (H_MSG_FAIL), if currently there are no connection requests from other HALCON processes. The value 'auto' for Wait automatically waits if the timeout of the accepting socket is not equal 0. The result of socket_accept_connect is another socket Socket, which is used for a two-way communication with another process. After this connection has been established, data can be exchanged between the two processes by calling the appropriate send or receive operators. For a detailed example, see open_socket_accept.

For the data transfer with generic sockets only the operators send_data and receive_data are available.

Parameters

▷ **AcceptingSocket** (input_control) ..... socket ⇝ *handle*
Socket number of the accepting socket.

▷ **Wait** (input_control) ..... string ⇝ *string*
Should the operator wait until a connection request arrives?
Default: 'auto'
List of values: Wait ∈ {'auto', 'true', 'false'}

▷ **Socket** (output_control) ..... socket ⇝ *handle*
Socket number.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Chapter 26

Tools

26.1 Background Estimator

close_bg_esti (: : BgEstiHandle :)

Delete the background estimation data set.

close_bg_esti deletes the background estimation data set and releases all used memory.

Parameters

▷ **BgEstiHandle** (input_control) ..... bg_estimation ⇝ *handle*
ID of the BgEsti data set.

Example

```
* Read image for initialization:
read_image (InitImage, 'xing/init')
* Initialize BgEsti dataset with
* fixed gains and threshold adaption:
create_bg_esti(InitImage,0.7,0.7,'fixed',0.002,0.02, \
               'on',7.0,10,3.25,15.0,BgEstiHandle)
* Read the next image in sequence:
read_image(Image0, 'xing/xing001')
* Estimate the background:
run_bg_esti(Image0,ForegroundRegion1,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion1)
* Read the next image in sequence:
read_image(Image1, 'xing/xing002')
* Estimate the background:
run_bg_esti(Image1,ForegroundRegion2,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion2)
* etc.
* - End of background estimation -
* Close the dataset:
close_bg_esti(BgEstiHandle)
```

Result

close_bg_esti returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- BgEstiHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

create_bg_esti

Module

Foundation

create_bg_esti (InitializeImage : : Syspar1, Syspar2, GainMode, Gain1, Gain2, AdaptMode, MinDiff, StatNum, ConfidenceC, TimeC : BgEstiHandle)

Generate and initialize a data set for the background estimation.

create_bg_esti creates a new data set for the background estimation and initializes it with the appropriate parameters. The estimated background image is part of this data set. The newly created set automatically becomes the current set.

InitializeImage is used as an initial prediction for the background image. For a good prediction an image of the observed scene without moving objects should be passed in InitializeImage. That way the foreground adaptation rate can be held low. If there is no empty scene image available, a homogeneous gray image can be used instead. In that case the adaptation rate for the foreground image must be raised, because initially most of the image will be detected as foreground. The initialization image must to be of type byte or real. Because of processing single-channel images, data sets must be created for every channel. Size and region of InitializeImage determines size and region for all background estimations (run_bg_esti) that are performed with this data set.

Syspar1 and Syspar2 are the parameters of the Kalman system matrix. The system matrix describes the system of the gray value changes according to Kalman filter theory. The background estimator implements a different system for each pixel.

GainMode defines whether a fixed Kalman gain should be used for the estimation or whether the gain should adapt itself depending on the difference between estimation and actual value. If GainMode is set to *'fixed'*, then Gain1 is used as Kalman gain for pixels predicted as foreground and Gain2 as gain for pixels predicted as background. Gain1 should be smaller than Gain2, because adaptation of the foreground should be slower than adaptation of the background. Both Gain1 and Gain2 should be smaller than *1.0*.

If GainMode is set to *'frame'*, then tables for foreground and background estimation are computed containing Kalman gains for all the 256 possible gray value changes. Gain1 and Gain2 then denote the number of frames necessary to adapt the difference between estimated value and actual value. So with a fixed time for adaptation (i.e. number of frames) the needed Kalman gain grows with the gray value difference. Gain1 should therefore be larger than Gain2. Different gains for different gray value differences are useful if the background estimator is used for generating an 'empty' scene assuming that there are always moving objects in the observed area. In that case the adaptation time for foreground adaptation (Gain1) must not be too big. Gain1 and Gain2 should be bigger than *1.0*.

AdaptMode denotes, whether the foreground/background decision threshold applied to the gray value difference between estimation and actual value is fixed or whether it adapts itself depending on the gray value deviation of the background pixels.

If AdaptMode is set to *'off'*, the parameter MinDiff denotes a fixed threshold. The parameters StatNum, ConfidenceC and TimeC are meaningless in this case.

If AdaptMode is set to *'on'*, then MinDiff is interpreted as a base threshold. For each pixel an offset is added to this threshold depending on the statistical evaluation of the pixel value over time. StatNum holds the number

of data sets (past frames) that are used for computing the gray value variance (FIR-Filter). ConfidenceC is used to determine the confidence interval.

The confidence interval determines the values of the background statistics if background pixels are hidden by a foreground object and thus are detected as foreground. According to the student t-distribution the confidence constant is *4.30* (*3.25*, *2.82*, *2.26*) for a confidence interval of *99,8%* (*99,0%*, *98,0%*, *95,0%*). TimeC holds a time constant for the exp-function that raises the threshold in case of a foreground estimation of the pixel. That means, the threshold is raised in regions where movement is detected in the foreground. That way larger changes in illumination are tolerated if the background becomes visible again. The main reason for increasing this tolerance is the impossibility for a prediction of illumination changes while the background is hidden. Therefore no adaptation of the estimated background image is possible.

Attention

If GainMode was set to *'frame'*, the run-time can be extremely long for large values of Gain1 or Gain2, because the values for the gains' table are determined by a simple binary search.

Parameters

▷ **InitializeImage** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / real
initialization image.

▷ **Syspar1** (input_control) . . . . . real ⇝ *real*
1. system matrix parameter.
Default: 0.7
Suggested values: Syspar1 ∈ {0.65, 0.7, 0.75}
Value range: 0.05 ≤ Syspar1 ≤ 1.0
Recommended increment: 0.05

▷ **Syspar2** (input_control) . . . . . real ⇝ *real*
2. system matrix parameter.
Default: 0.7
Suggested values: Syspar2 ∈ {0.65, 0.7, 0.75}
Value range: 0.05 ≤ Syspar2 ≤ 1.0
Recommended increment: 0.05

▷ **GainMode** (input_control) . . . . . string ⇝ *string*
Gain type.
Default: 'fixed'
List of values: GainMode ∈ {'fixed', 'frame'}

▷ **Gain1** (input_control) . . . . . real ⇝ *real*
Kalman gain / foreground adaptation time.
Default: 0.002
Suggested values: Gain1 ∈ {10.0, 20.0, 50.0, 0.1, 0.05, 0.01, 0.005, 0.001}
Restriction: 0.0 <= Gain1

▷ **Gain2** (input_control) . . . . . real ⇝ *real*
Kalman gain / background adaptation time.
Default: 0.02
Suggested values: Gain2 ∈ {2.0, 4.0, 8.0, 0.5, 0.1, 0.05, 0.01}
Restriction: 0.0 <= Gain2

▷ **AdaptMode** (input_control) . . . . . string ⇝ *string*
Threshold adaptation.
Default: 'on'
List of values: AdaptMode ∈ {'on', 'off'}

▷ **MinDiff** (input_control) . . . . . real ⇝ *real*
Foreground/background threshold.
Default: 7.0
Suggested values: MinDiff ∈ {3.0, 5.0, 7.0, 9.0, 11.0}
Recommended increment: 0.2

▷ **StatNum** (input_control) . . . . . integer ⇝ *integer*
Number of statistic data sets.
Default: 10
Suggested values: StatNum ∈ {5, 10, 20, 30}
Value range: 1 ≤ StatNum
Recommended increment: 5

▷ **ConfidenceC** (input_control) . . . . . real ⇝ *real*
Confidence constant.
Default: 3.25
Suggested values: ConfidenceC ∈ {4.30, 3.25, 2.82, 2.62}
Recommended increment: 0.01
Restriction: 0.0 < ConfidenceC

▷ **TimeC** (input_control) . . . . . real ⇝ *real*
Constant for decay time.
Default: 15.0
Suggested values: TimeC ∈ {10.0, 15.0, 20.0}
Recommended increment: 5.0
Restriction: 0.0 < TimeC

▷ **BgEstiHandle** (output_control) . . . . . bg_estimation ⇝ *handle*
ID of the BgEsti data set.

Example

```
* read Init-Image:
read_image (InitImage, 'xing/init')
* initialize 1. BgEsti-Dataset with
* fixed gains and threshold adaption:
create_bg_esti(InitImage,0.7,0.7,'fixed',0.002,0.02, \
               'on',7.0,10,3.25,15.0,BgEstiHandle1)
* initialize 2. BgEsti-Dataset with
* frame orientated gains and fixed threshold
create_bg_esti(InitImage,0.7,0.7,'frame',30.0,4.0, \
               'off',9.0,10,3.25,15.0,BgEstiHandle2)
```

Result

create_bg_esti returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

get_bg_esti_params (: : BgEstiHandle : Syspar1, Syspar2, GainMode, Gain1, Gain2, AdaptMode, MinDiff, StatNum, ConfidenceC, TimeC)

Return the parameters of the data set.

get_bg_esti_params returns the parameters of the data set. The returned parameters are the same as in create_bg_esti and set_bg_esti_params (see these for an explanation).

Parameters

- ▷ **BgEstiHandle** (input_control) ..... bg_estimation ⇝ *handle*
  ID of the BgEsti data set.
- ▷ **Syspar1** (output_control) ..... real ⇝ *real*
  1. system matrix parameter.
- ▷ **Syspar2** (output_control) ..... real ⇝ *real*
  2. system matrix parameter.
- ▷ **GainMode** (output_control) ..... string ⇝ *string*
  Gain type.
- ▷ **Gain1** (output_control) ..... real ⇝ *real*
  Kalman gain / foreground adaptation time.
- ▷ **Gain2** (output_control) ..... real ⇝ *real*
  Kalman gain / background adaptation time.
- ▷ **AdaptMode** (output_control) ..... string ⇝ *string*
  Threshold adaptation.
- ▷ **MinDiff** (output_control) ..... real ⇝ *real*
  Foreground / background threshold.
- ▷ **StatNum** (output_control) ..... integer ⇝ *integer*
  Number of statistic data sets.
- ▷ **ConfidenceC** (output_control) ..... real ⇝ *real*
  Confidence constant.
- ▷ **TimeC** (output_control) ..... real ⇝ *real*
  Constant for decay time.

Example

```
* Read image for initialization:
read_image(InitImage,'xing/init')
* Initialize BgEsti dataset with
* fixed gains and threshold adaption:
create_bg_esti(InitImage,0.7,0.7,'fixed',0.002,0.02, \
               'on',7.0,10,3.25,15.0,BgEstiHandle)
* Read the next image in sequence:
read_image(Image0,'xing/xing000')
* Estimate the background:
run_bg_esti(Image0,ForegroundRegion1,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion1)
* Read the next image in sequence:
read_image(Image1,'xing/xing001')
* Estimate the background:
run_bg_esti(Image1,ForegroundRegion2,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion2)
* etc.
* Change only the gain parameter in dataset:
get_bg_esti_params(BgEstiHandle, Syspar1, Syspar2, \
                   GainMode, Gain1, Gain2, AdaptMode,\
                   MinDiff, StatNum, ConfidenceC, TimeC)
set_bg_esti_params(BgEstiHandle, Syspar1, Syspar2, \
                   GainMode, 0.004, 0.08, AdaptMode,\
                   MinDiff, StatNum, ConfidenceC, TimeC)
* Read the next image in sequence:
read_image(Image3,'xing/xing003')
* Estimate the background:
run_bg_esti(Image3,ForegroundRegion3,BgEstiHandle)
* Display the foreground region:
```

```
dev_display(ForegroundRegion3)
* etc
```

Result

`get_bg_esti_params` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`set_bg_esti_params`

Module

Foundation

give_bg_esti (: BackgroundImage : BgEstiHandle :)

Return the estimated background image.

`give_bg_esti` returns the estimated background image of the current BgEsti data set. The background image has the same type and size as the initialization image passed in `create_bg_esti`.

Parameters

▷ **BackgroundImage** (output_object) ..... image ⇝ *object :* byte / real
Estimated background image of the current data set.

▷ **BgEstiHandle** (input_control) ..... bg_estimation ⇝ *handle*
ID of the BgEsti data set.

Example

```
* Read image for initialization:
read_image(InitImage,'xing/init')
* Initialize BgEsti dataset with
* fixed gains and threshold adaption:
create_bg_esti(InitImage,0.7,0.7,'fixed',0.002,0.02, \
               'on',7.0,10,3.25,15.0,BgEstiHandle)
* Read the next image in sequence:
read_image(Image0,'xing/xing000')
* Estimate the background:
run_bg_esti(Image0,ForegroundRegion1,BgEstiHandle)
* Give the background image from the aktive dataset:
give_bg_esti(BgImage,BgEstiHandle)
* Display the background image:
dev_display(BgImage)
```

Result

`give_bg_esti` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

run_bg_esti

Possible Successors

run_bg_esti, create_bg_esti, update_bg_esti

See also

run_bg_esti, update_bg_esti, create_bg_esti

Module

Foundation

run_bg_esti (PresentImage : ForegroundRegion : BgEstiHandle :)

Estimate the background and return the foreground region.

run_bg_esti adapts the background image stored in the BgEsti data set using a Kalman filter on each pixel and returns a region of the foreground (detected moving objects).

For every pixel an estimation of its gray value is computed using the values of the current data set and its stored background image and the current image (PresentImage). By comparison to the threshold (fixed or adaptive, see create_bg_esti) the pixels are classified as either foreground or background.

The background estimation processes only single-channel images. Therefore the background has to be adapted separately for every channel.

The background estimation should be used on half- or even quarter-sized images. For this, the input images (and the initialization image!) has to be reduced using zoom_image_factor. The advantage is a shorter run-time on one hand and a low-band filtering on the other. The filtering eliminates high frequency noise and results in a more reliable estimation. As a result the threshold (see create_bg_esti) can be lowered. The foreground region returned by run_bg_esti then has to be enlarged again for further processing.

Attention

The passed image (PresentImage) must have the same type and size as the background image of the current data set (initialized with create_bg_esti).

Parameters

- ▷ **PresentImage** (input_object) ..... singlechannelimage ⇝ *object :* byte / real
  Current image.
- ▷ **ForegroundRegion** (output_object) ..... region ⇝ *object*
  Region of the detected foreground.
- ▷ **BgEstiHandle** (input_control) ..... bg_estimation ⇝ *handle*
  ID of the BgEsti data set.

Example

```
* Read image for initialization:
read_image(InitImage,'xing/init')
* Initialize BgEsti dataset with
* fixed gains and threshold adaption:
create_bg_esti(InitImage,0.7,0.7,'fixed',0.002,0.02, \
               'on',7.0,10,3.25,15.0,BgEstiHandle)
* Read the next image in sequence:
read_image(Image0,'xing/xing000')
* Estimate the background:
run_bg_esti(Image0,ForegroundRegion1,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion1)
* Read the next image in sequence:
read_image(Image1,'xing/xing001')
```

```
* Estimate the background:
run_bg_esti(Image1,ForegroundRegion2,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion2)
* etc.
```

Result

`run_bg_esti` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_bg_esti`, `update_bg_esti`

Possible Successors

`give_bg_esti`, `update_bg_esti`

See also

`set_bg_esti_params`, `create_bg_esti`, `update_bg_esti`, `give_bg_esti`

Module

Foundation

set_bg_esti_params (: : BgEstiHandle, Syspar1, Syspar2, GainMode, Gain1, Gain2, AdaptMode, MinDiff, StatNum, ConfidenceC, TimeC :)

Change the parameters of the data set.

`set_bg_esti_params` is used to change the parameters of the data set. The parameters passed by `set_bg_esti_params` are the same as in `create_bg_esti` (see there for an explanation).

The image format cannot be changed! To do this, a new data set with an initialization image of the appropriate format has to be created.

To exchange the background image completely, use `update_bg_esti`. The current image then has to be passed for both the input image and the update region.

Attention

If `GainMode` was set to *'frame'*, the run-time can be extremely long for large values of `Gain1` or `Gain2`, because the values for the gains' table are determined by a simple binary search.

Parameters

▷ **BgEstiHandle** (input_control) . . . . . bg_estimation ⇝ *handle*
ID of the BgEsti data set.

▷ **Syspar1** (input_control) . . . . . real ⇝ *real*
1. system matrix parameter.
Default: 0.7
Suggested values: `Syspar1` ∈ {0.65, 0.7, 0.75}
Value range: 0.05 ≤ `Syspar1` ≤ 1.0
Recommended increment: 0.05

▷ **Syspar2** (input_control) . . . . . real ⇝ *real*
2. system matrix parameter.
Default: 0.7
Suggested values: `Syspar2` ∈ {0.65, 0.7, 0.75}
Value range: 0.05 ≤ `Syspar2` ≤ 1.0
Recommended increment: 0.05

▷ **GainMode** (input_control) . . . . . string ⇝ *string*
Gain type.
Default: 'fixed'
List of values: GainMode ∈ {'fixed', 'frame'}

▷ **Gain1** (input_control) . . . . . real ⇝ *real*
Kalman gain / foreground adaptation time.
Default: 0.002
Suggested values: Gain1 ∈ {10.0, 20.0, 50.0, 0.1, 0.05, 0.01, 0.005, 0.001}
Restriction: 0.0 <= Gain1

▷ **Gain2** (input_control) . . . . . real ⇝ *real*
Kalman gain / background adaptation time.
Default: 0.02
Suggested values: Gain2 ∈ {2.0, 4.0, 8.0, 0.5, 0.1, 0.05, 0.01}
Restriction: 0.0 <= Gain2

▷ **AdaptMode** (input_control) . . . . . string ⇝ *string*
Threshold adaptation.
Default: 'on'
List of values: AdaptMode ∈ {'on', 'off'}

▷ **MinDiff** (input_control) . . . . . real ⇝ *real*
Foreground/background threshold.
Default: 7.0
Suggested values: MinDiff ∈ {3.0, 5.0, 7.0, 9.0, 11.0}
Recommended increment: 0.2

▷ **StatNum** (input_control) . . . . . integer ⇝ *integer*
Number of statistic data sets.
Default: 10
Suggested values: StatNum ∈ {5, 10, 20, 30}
Value range: 1 ≤ StatNum
Recommended increment: 5

▷ **ConfidenceC** (input_control) . . . . . real ⇝ *real*
Confidence constant.
Default: 3.25
Suggested values: ConfidenceC ∈ {4.30, 3.25, 2.82, 2.62}
Recommended increment: 0.01
Restriction: 0.0 < ConfidenceC

▷ **TimeC** (input_control) . . . . . real ⇝ *real*
Constant for decay time.
Default: 15.0
Suggested values: TimeC ∈ {10.0, 15.0, 20.0}
Recommended increment: 5.0
Restriction: 0.0 < TimeC

Example

```
* Read image for initialization:
read_image(InitImage,'xing/init')
* Initialize BgEsti dataset with
* fixed gains and threshold adaption:
create_bg_esti(InitImage,0.7,0.7,'fixed',0.002,0.02, \
               'on',7.0,10,3.25,15.0,BgEstiHandle)
* Read the next image in sequence:
read_image(Image0,'xing/xing000')
* Estimate the background:
run_bg_esti(Image0,ForegroundRegion1,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion1)
* Read the next image in sequence:
read_image(Image1,'xing/xing001')
* Estimate the background:
```

```
run_bg_esti(Image1,ForegroundRegion2,BgEstiHandle)
* Display the foreground region:
dev_display (ForegroundRegion2)
* etc.
* Change parameter in dataset:
set_bg_esti_params(BgEstiHandle,0.7,0.7,'fixed', \
                   0.004,0.08,'on',9.0,10,3.25,20.0)
* Read the next image in sequence:
read_image(Image2,'xing/xing002')
* Estimate the background:
run_bg_esti(Image2,ForegroundRegion3,BgEstiHandle)
* Display the foreground region:
dev_display(ForegroundRegion3)
* etc.
```

Result

`set_bg_esti_params` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`update_bg_esti`

Module

Foundation

update_bg_esti (PresentImage, UpDateRegion : : BgEstiHandle :)

Change the estimated background image.

`update_bg_esti` overwrites the image stored in the current BgEsti data set with the gray values of `PresentImage` within the bounds of `UpDateRegion`. This can be used for a "hard" adaptation: Image regions with a sudden change in (known) background can be adapted very fast this way.

Attention

The passed image (`PresentImage`) must have the same type and size as the background image of the current data set (initialized with `create_bg_esti`).

Parameters

▷ **PresentImage** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / real
Current image.

▷ **UpDateRegion** (input_object) . . . . . region ⇝ *object*
Region describing areas to change.

▷ **BgEstiHandle** (input_control) . . . . . bg_estimation ⇝ *handle*
ID of the BgEsti data set.

Example

```
* read Init-Image:
read_image(InitImage,'xing/init')
```

```
* initialize BgEsti-Dataset with
* fixed gains and threshold adaption
create_bg_esti(InitImage,0.7,0.7,'fixed',0.002,0.02, \
               'on',7,10,3.25,15.0,BgEstiHandle)
* read the next image in sequence:
read_image(Image0,'xing/xing000')
* estimate the Background:
run_bg_esti(Image0,Region1,BgEstiHandle)
* use the Region and the information of a knowledge base
* to calculate the UpDateRegion
update_bg_esti(Image0,UpdateRegion,BgEstiHandle)
* then read the next image in sequence:
read_image(Image1,'xing/xing001')
* estimate the Background:
run_bg_esti(Image1,Region2,BgEstiHandle)
* etc.
```

Result

`update_bg_esti` returns `2` (`H_MSG_TRUE`) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

26.2 Function

`abs_funct_1d` (: : `Function` : `FunctionAbsolute`)

Absolute value of the y values.

`abs_funct_1d` calculates the absolute values of all y values of `Function`.

Parameters

▷ **`Function`** (input_control) . . . . . function_1d ⇝ *real* / integer
Input function.

▷ **`FunctionAbsolute`** (output_control) . . . . . function_1d ⇝ *real* / integer
Function with the absolute values of the y values.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_funct_1d_pairs, create_funct_1d_array

Module

Foundation

compose_funct_1d (: : Function1, Function2, Border : ComposedFunction)

Compose two functions.

compose_funct_1d composes two functions, i.e., calculates

$$\texttt{ComposedFunction}(x) = \texttt{Function2}(\texttt{Function1}(x)) \ .$$

ComposedFunction has the same domain (x-range) as Function1. If the range (y value range) of Function1 is larger than the domain of Function2, the parameter Border determines the border treatment of Function2. For Border='*zero*' values outside the domain of Function2 are set to 0, for Border='*constant*' they are set to the corresponding value at the border, for Border='*mirror*' they are mirrored at the border, and for Border='*cyclic*' they are continued cyclically. To obtain y values, Function2 is interpolated linearly.

Parameters

- ▷ **Function1** (input_control) ..... function_1d ⇝ *real* / integer
  Input function 1.
- ▷ **Function2** (input_control) ..... function_1d ⇝ *real* / integer
  Input function 2.
- ▷ **Border** (input_control) ..... string ⇝ *string*
  Border treatment for the input functions.
  Default: 'constant'
  List of values: Border ∈ {'zero', 'constant', 'mirror', 'cyclic'}
- ▷ **ComposedFunction** (output_control) ..... function_1d ⇝ *real* / integer
  Composed function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_funct_1d_pairs, create_funct_1d_array

Module

Foundation

create_funct_1d_array (: : YValues : Function)

Create a function from a sequence of y values.

create_funct_1d_array creates a one-dimensional function from a set of y values YValues. The resulting function can then be processed and analyzed with the operators for 1d functions. YValues is interpreted as follows: the first value of YValues is the function value at zero, the second value is the function value at one, etc. Thus, the values define a function at equidistant x values (with distance $\Delta x = 1$), starting at $x_1 = 0$.

The created function is composed like this:

Function $= [0, \Delta x, x_1, y_1, y_2, ..., y_n]$

where

Function[0] = 0, denotes the function type as an equidistant function,

Δx is the equidistance of the x values,

x_1 is the starting x value (is always 0), and

y_i are the y values passed in YValues with $i \in [1, n]$.

Alternatively, the operator create_funct_1d_pairs can be used to create a function. create_funct_1d_pairs also allows to define a function with non-equidistant x values by specifying them explicitly. Thus to get the same definition as with create_funct_1d_array, one would pass a tuple of x values to create_funct_1d_pairs that has the same length as YValues and contains values starting at 0 and increasing by 1 in each position. Note, however, that create_funct_1d_pairs leads to a different internal representation of the function which needs more storage (because all (x,y) pairs are stored) and sometimes cannot be processed as efficiently as functions created by create_funct_1d_array.

Parameters

▷ **YValues** (input_control) ..... number(-array) ⇝ *real* / integer
X value for function points.

▷ **Function** (output_control) ..... function_1d ⇝ *real* / integer
Created function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

write_funct_1d, y_range_funct_1d, get_pair_funct_1d, transform_funct_1d

Alternatives

create_funct_1d_pairs, read_funct_1d

See also

funct_1d_to_pairs

Module

Foundation

create_funct_1d_pairs (: : XValues, YValues : Function)

Create a function from a set of (x,y) pairs.

create_funct_1d_pairs creates a one-dimensional function from a set of pairs of (x,y) values. The XValues of the functions have to be passed in ascending order. The resulting function can then be processed and analyzed with the operators for 1d functions.

The created function is composed like this:

Function $= [1, x_1, y_1, x_2, y_2, ..., x_n, y_n]$

where

Function[1] = 1 denotes the function type as a one-dimensional function from a set of pairs and

$[x_i, y_i]$ are pairs of (x,y) values passed in XValues and YValues with $i \in [1, n]$.

Alternatively, functions can be created with the operator create_funct_1d_array. In contrast to this operator, x values with arbitrary positions can be specified with create_funct_1d_pairs. Hence, it is the more general operator. It should be noted, however, that because of this generality the processing of a function created with create_funct_1d_pairs cannot be carried out as efficiently as for equidistant functions. In particular, not all operators accept such functions. If necessary, a function can be transformed into an equidistant function with the operator sample_funct_1d.

Attention

create_funct_1d_pairs examines whether the x values of type 'double' are ascending. Some other operators apply the same check but use the type 'float' instead of 'double'. If such an operator is called as successor, it

might happen that two consecutive x values seem to be equal for the 'float' variant, although they were ascending in the 'double' variant. If this happens, an error is thrown.

Parameters

▷ **XValues** (input_control) . . . . . number(-array) ⇝ *real* / integer
X value for function points.

▷ **YValues** (input_control) . . . . . number(-array) ⇝ *real* / integer
Y value for function points.

▷ **Function** (output_control) . . . . . function_1d ⇝ *real* / integer
Created function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`funct_1d_to_pairs`

Module

Foundation

derive_funct_1d (: : Function, Mode : Derivative)

Calculate the derivatives of a function.

`derivate_funct_1d` calculates the derivatives of the function `Function` up to the second degree. It uses a finite difference approximation of order $O(h^2)$. The derivative is also a function with the same sampling points as `Function`. With the parameter `Mode`, *'first'* and *'second'* derivatives can be selected.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Input function

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Type of derivative
Default: 'first'
List of values: `Mode` ∈ {'first', 'second'}

▷ **Derivative** (output_control) . . . . . function_1d ⇝ *real* / integer
Derivative of the input function

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

funct_1d_to_pairs (: : Function : XValues, YValues)

Access to the x/y values of a function.

`funct_1d_to_pairs` splits the input function `Function` into tuples for the x and y values.

Parameters

▷ **Function** (input_control) ..... function_1d ⇝ *real* / integer
Input function.

▷ **XValues** (output_control) ..... number-array ⇝ *real* / integer
X values of the function.

▷ **YValues** (output_control) ..... number-array ⇝ *real* / integer
Y values of the function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

get_pair_funct_1d (: : Function, Index : X, Y)

Access a function value using the index of the control points.

`get_pair_funct_1d` accesses a function value of `Function`. This is done by specifying the index of one or more control points of the function.

Parameters

▷ **Function** (input_control) ..... function_1d ⇝ *real* / integer
Input function.

▷ **Index** (input_control) ..... integer(-array) ⇝ *integer*
Index of the control points.

▷ **X** (output_control) ..... number(-array) ⇝ *real*
X value at the given control points.

▷ **Y** (output_control) ..... number(-array) ⇝ *real*
Y value at the given control points.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`create_funct_1d_pairs`, `create_funct_1d_array`

Module

Foundation

get_y_value_funct_1d (: : Function, X, Border : Y)

Return the value of a function at an arbitrary position.

get_y_value_funct_1d returns the y value of the function Function at the x coordinates specified by X. To obtain the y values, the input function is interpolated linearly. The parameter Border determines the values of the function Function outside of its domain. For Border='zero' these values are set to 0, for Border='constant' they are set to the corresponding value at the border, for Border='mirror' they are mirrored at the border, for Border='cyclic' they are continued cyclically, and for Border='error' an exception is raised.

Parameters

- ▷ **Function** (input_control) . . . function_1d ⇝ *real* / integer
  Input function.
- ▷ **X** (input_control) . . . number(-array) ⇝ *real*
  X coordinate at which the function should be evaluated.
- ▷ **Border** (input_control) . . . string ⇝ *string*
  Border treatment for the input function.
  Default: 'constant'
  List of values: Border ∈ {'zero', 'constant', 'mirror', 'cyclic', 'error'}
- ▷ **Y** (output_control) . . . number(-array) ⇝ *real*
  Y value at the given x value.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_funct_1d_pairs, create_funct_1d_array

Module

Foundation

integrate_funct_1d (: : Function : Positive, Negative)

Compute the positive and negative areas of a function.

integrate_funct_1d integrates the function Function (see create_funct_1d_array and create_funct_1d_pairs) and returns the integral of the positive and negative parts of the function in Positive and Negative, respectively. Hence, the integral of the function is the difference Positive - Negative. The integration is done on the interval on which the function is defined. For the integration, the function is interpolated linearly.

Parameters

- ▷ **Function** (input_control) . . . function_1d ⇝ *real*
  Input function.
- ▷ **Positive** (output_control) . . . number ⇝ *real*
  Area under the positive part of the function.
- ▷ **Negative** (output_control) . . . number-array ⇝ *real*
  Area under the negative part of the function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

See also

create_funct_1d_array, create_funct_1d_pairs

Module

Foundation

invert_funct_1d (: : Function : InverseFunction)

Calculate the inverse of a function.

invert_funct_1d calculates the inverse function of the input function Function and returns it in InverseFunction. The function Function must be monotonic. If this is not the case an error message is returned.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Input function.

▷ **InverseFunction** (output_control) . . . . . function_1d ⇝ *real* / integer
Inverse of the input function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_funct_1d_pairs, create_funct_1d_array

Module

Foundation

local_min_max_funct_1d (: : Function, Mode, Interpolation : Min, Max)

Calculate the local minimum and maximum points of a function.

local_min_max_funct_1d searches for the local minima Min and maxima Max of the function Function.

Since the function values are only known at discrete sampling points, the function can interpolated by parabolas between these points. Setting the parameter Interpolation to *'true'*, enables this feature. If Interpolation is *'false'*, extrema are always sampling points.

If Mode is set to *'strict_min_max'*, extrema are only calculated close to points with a function value that is strictly smaller or strictly greater than the values of its direct neighbors.

If Mode is set to *'plateaus_center'*, areas with a function value that is constant throughout several sampling points are also considered. If such an area is identified as being a flat extremum, its center coordinate is returned.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Input function

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Handling of plateaus
Default: 'strict_min_max'
List of values: Mode ∈ {'strict_min_max', 'plateaus_center'}

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Interpolation of the input function
Default: 'true'
List of values: Interpolation ∈ {'true', 'false'}

▷ **Min** (output_control) . . . . . real-array ⇝ *real*
Minimum points of the input function

▷ **Max** (output_control) . . . . . real-array ⇝ *real*
Maximum points of the input function

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

create_funct_1d_pairs, create_funct_1d_array, smooth_funct_1d_gauss, smooth_funct_1d_mean

Module

Foundation

match_funct_1d_trans (: : Function1, Function2, Border, ParamsConst, UseParams : Params, ChiSquare, Covar)

Calculate transformation parameters between two functions.

match_funct_1d_trans calculates the transformation parameters between two functions given as the tuples Function1 and Function2 (see create_funct_1d_array and create_funct_1d_pairs). The following model is used for the transformation between the two functions:

$$y_1(x) = a_1 y_2(a_3 x + a_4) + a_2 \ .$$

The transformation parameters are determined by a least-squares minimization of the following function:

$$\sum_{i=0}^{n-1} \left(y_1(x_i) - a_1 y_2(a_3 x_i + a_4) + a_2\right)^2 \ .$$

The values of the function y_2 are obtained by linear interpolation. The parameter Border determines the values of the function Function2 outside of its domain. For Border='*zero*' these values are set to 0, for Border='*constant*' they are set to the corresponding value at the border, for Border='*mirror*' they are mirrored at the border, and for Border='*cyclic*' they are continued cyclically. The calculated transformation parameters are returned as a 4-tuple $[a_1, a_2, a_3, a_4]$ in Params. If some of the parameter values are known, the respective parameters can be excluded from the least-squares adjustment by setting the corresponding value in the tuple UseParams to the value '*false*'. In this case, the tuple ParamsConst must contain the known value of the respective parameter. If a parameter is used for the adjustment (UseParams = '*true*'), the corresponding parameter in ParamsConst is ignored. On output, match_funct_1d_trans additionally returns the sum of the squared errors ChiSquare of the resulting function, i.e., the function obtained by transforming the input function with the transformation parameters, as well as the covariance matrix Covar of the transformation parameters Params. These parameters can be used to decide whether a successful matching of the functions was possible.

Note that in case that there is no unique solution for the transformation parameters, match_funct_1d_trans either returns one selected single solution or returns the error 9205 (Matrix is singular).

Parameters

▷ **Function1** (input_control) . . . . . function_1d ⇝ *real* / integer
Function 1.

▷ **Function2** (input_control) . . . . . function_1d ⇝ *real* / integer
Function 2.

▷ **Border** (input_control) . . . . . string ⇝ *string*
Border treatment for function 2.
Default: 'constant'
List of values: Border ∈ {'zero', 'constant', 'mirror', 'cyclic'}

▷ **ParamsConst** (input_control) . . . . . number-array ⇝ *real*
Values of the parameters to remain constant.
Number of elements: 4
Default: [1.0,0.0,1.0,0.0]

▷ **UseParams** (input_control) . . . . . string-array ⇝ *string*
Should a parameter be adapted for it?
Number of elements: 4
Default: ['true','true','true','true']
List of values: `UseParams` ∈ {'true', 'false'}

▷ **Params** (output_control) . . . . . number-array ⇝ *real*
Transformation parameters between the functions.
Number of elements: 4

▷ **ChiSquare** (output_control) . . . . . number ⇝ *real*
Quadratic error of the output function.

▷ **Covar** (output_control) . . . . . number-array ⇝ *real*
Covariance Matrix of the transformation parameters.
Number of elements: 16

Execution Information

Module

Foundation

read_funct_1d (: : FileName : Function)

Read a function from a file.

The operator read_funct_1d reads the contents of FileName and converts it into the function Function. The file has be generated by write_funct_1d.

Parameters

▷ **FileName** (input_control) ..... filename.read ⇝ *string*
Name of the file to be read.

▷ **Function** (output_control) ..... function_1d ⇝ *real / integer*
Function from the file.

Result

If the parameters are correct the operator read_funct_1d returns the value 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

fread_string, read_tuple

write_funct_1d, write_image, write_region, open_file

Module

Foundation

sample_funct_1d (: : Function, XMin, XMax, XDist, Border : SampledFunction)

Sample a function equidistantly in an interval.

sample_funct_1d samples the input function Function in the interval [XMin,XMax] at equidistant points with the distance XDist. The last point lies in the interval if XMax-XMin is not an integer multiple of XDist. To obtain the samples, the input function is interpolated linearly. The parameter Border determines the values of the function Function outside of its domain. For Border='zero' these values are set to 0, for Border='constant' they are set to the corresponding value at the border, for Border='mirror' they are mirrored at the border, and for Border='cyclic' they are continued cyclically.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Input function.

▷ **XMin** (input_control) . . . . . number ⇝ *real* / integer
Minimum x value of the output function.

▷ **XMax** (input_control) . . . . . number ⇝ *real* / integer
Maximum x value of the output function.
Restriction: XMax > XMin

▷ **XDist** (input_control) . . . . . number ⇝ *real* / integer
Distance of the samples.
Restriction: XDist > 0

▷ **Border** (input_control) . . . . . string ⇝ *string*
Border treatment for the input function.
Default: 'constant'
List of values: Border ∈ {'zero', 'constant', 'mirror', 'cyclic'}

▷ **SampledFunction** (output_control) . . . . . function_1d ⇝ *real* / integer
Sampled function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

scale_y_funct_1d (: : Function, Mult, Add : FunctionScaled)

Multiplication and addition of the y values.

scale_y_funct_1d multiplies and adds the y values of Function with the parameters Mult and Add.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Input function.

▷ **Mult** (input_control) . . . . . number ⇝ *real*
Factor for scaling of the y values.
Default: 2.0
Suggested values: Mult ∈ {0.1, 0.3, 0.5, 1.0, 2.0, 5.0, 10.0}

▷ **Add** (input_control) . . . . . number ⇝ *real*
Constant which is added to the y values.
Default: 0.0
Suggested values: Add ∈ {-10.0, -5.0, 1.0, 0.0, 5.0, 10.0}

▷ **FunctionScaled** (output_control) . . . . . function_1d ⇝ *real* / integer
Transformed function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_funct_1d_pairs, create_funct_1d_array

Module

Foundation

smooth_funct_1d_gauss (: : Function, Sigma : SmoothedFunction)

Smooth an equidistant 1D function with a Gaussian function.

The operator smooth_funct_1d_gauss smooths a one-dimensional function with a Gaussian function. The function must be equidistant, i.e., created with create_funct_1d_array, sample_funct_1d or similar. At the function borders the function values are mirrored.

Note that the smoothing parameter Sigma must not be larger than (Length-2) / 7.8 * Function[1], with Length-2 being the number of control points of Function and Function[1] specifying the equidistance of the x values. The value of Length can, e.g., be determined with num_points_funct_1d.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Function to be smoothed.

▷ **Sigma** (input_control) . . . . . number ⇝ *real*
Sigma of the Gaussian function for the smoothing.
Default: 2.0
Suggested values: Sigma ∈ {0.5, 1.0, 2.0, 3.0, 4.0, 5.0}
Value range: 0.1 ≤ Sigma ≤ 50.0 (lin)
Minimum increment: 0.01
Recommended increment: 0.2

▷ **SmoothedFunction** (output_control) . . . . . function_1d ⇝ *real* / integer
Smoothed function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

match_funct_1d_trans, distance_funct_1d

Alternatives

smooth_funct_1d_mean

Module

Foundation

smooth_funct_1d_mean (: : Function, SmoothSize,
Iterations : SmoothedFunction)

Smooth an equidistant 1D function by averaging its values.

The operator smooth_funct_1d_mean smooths a one dimensional function by applying an average (mean) filter multiple times. The function must be equidistant, i.e., created with create_funct_1d_array, sample_funct_1d or similar. At the function borders the function values are mirrored.

Attention

If an even value instead of an odd value is given for SmoothSize, the routine uses the next larger odd value instead (this way the center of the filter mask is always explicitly determined).

Parameters

- ▷ **Function** (input_control) . . . . . function_1d ⇝ *integer* / real
  1D function.
- ▷ **SmoothSize** (input_control) . . . . . integer ⇝ *integer*
  Size of the averaging mask.
  Default: 9
  Suggested values: SmoothSize ∈ {1, 3, 5, 7, 9, 11, 13, 15, 21, 31, 51}
  Value range: 0 ≤ SmoothSize ≤ 1001 (lin)
  Minimum increment: 1
  Recommended increment: 2
- ▷ **Iterations** (input_control) . . . . . integer ⇝ *integer*
  Number of iterations for the smoothing.
  Default: 3
  Suggested values: Iterations ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9}
  Value range: 1 ≤ Iterations ≤ 100 (lin)
  Minimum increment: 1
  Recommended increment: 1
- ▷ **SmoothedFunction** (output_control) . . . . . function_1d ⇝ *real* / integer
  Smoothed function.

Execution Information

- Processed without parallelization.

Possible Predecessors

create_funct_1d_array, sample_funct_1d

Alternatives

smooth_funct_1d_gauss

Module

Foundation

transform_funct_1d (: : Function, Params : TransformedFunction)

Transform a function using given transformation parameters.

transform_funct_1d transforms the input function Function using the transformation parameters given in Params. The function Function is passed as a tuple (see create_funct_1d_array and create_funct_1d_pairs). The following model is used for the transformation between the two functions (see match_funct_1d_trans):

$$y_t(x) = a_1 y(a_3 x + a_4) + a_2 \ .$$

The output function TransformedFunction is obtained by transforming the x and y values of the input function separately with the above formula, i.e., the output function is not sampled again. Therefore, the parameter a_3 is restricted to $a_3 \neq 0.0$. To resample a function, the operator sample_funct_1d can be used.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Input function.
▷ **Params** (input_control) . . . . . number-array ⇝ *real*
Transformation parameters between the functions.
Number of elements: 4
▷ **TransformedFunction** (output_control) . . . . . function_1d ⇝ *real* / integer
Transformed function.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

write_funct_1d (: : Function, FileName :)

Write a function to a file.

The operator `write_funct_1d` writes the contents of `Function` to a file. The data is written in an ASCII format. Therefore, the file can be exchanged between different architectures (see also Tuple / String Operations). The data can be read by the operator `read_funct_1d`. There is no specific extension for this kind of file.

Parameters

▷ **Function** (input_control) . . . . . function_1d ⇝ *real* / integer
Function to be written.
▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
Name of the file to be written.

Result

If the parameters are correct the operator `write_funct_1d` returns the value `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

26.3 Geometry

angle_ll (: : RowA1, ColumnA1, RowA2, ColumnA2, RowB1, ColumnB1, RowB2, ColumnB2 : Angle)

Calculate the angle between two lines.

The operator angle_ll calculates the angle between two lines. As input the coordinates of two points on the first line (RowA1,ColumnA1, RowA2,ColumnA2) and on the second line (RowB1,ColumnB1, RowB2,ColumnB2) are expected. The calculation is performed as follows: We interpret the lines as vectors with starting points RowA1,ColumnA1 and RowB1,ColumnB1 and end points RowA2,ColumnA2 and RowB2,ColumnB2, respectively. Rotating the vector A counter clockwise onto the vector B (the center of rotation is the intersection point of the two lines) yields the angle. The result depends on the order of the points and on the order of the lines. The parameter Angle returns the angle in radians, ranging from $-\pi \leq \text{Angle} \leq \pi$.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed angles is always *N*.

Parameters

▷ **RowA1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the first point of the first line.

▷ **ColumnA1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the first line.

▷ **RowA2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the first line.

▷ **ColumnA2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the first line.

▷ **RowB1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the first point of the second line.

▷ **ColumnB1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the second line.

▷ **RowB2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the second line.

▷ **ColumnB2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the second line.

▷ **Angle** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Angle between the lines [rad].

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
RowA1 := 255
ColumnA1 := 10
RowA2 := 255
ColumnA2 := 501
gen_contour_polygon_xld (Contour, [RowA1,RowA2], [ColumnA1,ColumnA2])
RowB1 := 255
ColumnB1 := 255
for I := 5 to 360 by 5
  RowB2 := 255 - sin(rad(I)) * 200
  ColumnB2 := 255 + cos(rad(I)) * 200
  gen_contour_polygon_xld (Contour, [RowB1,RowB2], [ColumnB1,ColumnB2])
  angle_ll (RowA1, ColumnA1, RowA2, ColumnA2,\
            RowB1, ColumnB1, RowB2, ColumnB2, Angle)
  AngleDeg := deg(Angle)
endfor
```

Result

`angle_ll` returns 2 (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

`angle_lx`

Module

Foundation

angle_lx (: : Row1, Column1, Row2, Column2 : Angle)

Calculate the angle between one line and the horizontal axis.

The operator `angle_lx` calculates the angle between one line and the horizontal axis. As input the coordinates of two points on the line (`Row1`,`Column1`, `Row2`,`Column2`) are expected. The calculation is performed as follows: We interpret the line as a vector with starting point `Row1`,`Column1` and end point `Row2`,`Column2`. The starting point is on the horizontal axis and defines the center of rotation in the following consideration. If the end point is above the horizontal axis, the angle (with positive sign) results from the rotation of the horizontal axis in counter clockwise direction onto the vector. If the end point is below the horizontal axis, the angle (with negative sign) results from the rotation of the horizontal axis in clockwise direction onto the vector. The result depends on the order of the two points defining the line. The parameter `Angle` returns the angle in radians, ranging from $-\pi \leq$ `Angle` $< \pi$.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed angles is always *N*.

Parameters

▷ **Row1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate the first point of the line.

▷ **Column1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the line.

▷ **Row2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the line.

▷ **Column2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the line.

▷ **Angle** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Angle between the line and the horizontal axis [rad].

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
RowA1 := 255
ColumnA1 := 10
RowA2 := 255
ColumnA2 := 501
gen_contour_polygon_xld (Contour, [RowA1,RowA2], [ColumnA1,ColumnA2])
Row1 := 255
Column1 := 255
for I := 5 to 360 by 5
  Row2 := 255 - sin(rad(I)) * 200
  Column2 := 255 + cos(rad(I)) * 200
  gen_contour_polygon_xld (Contour, [Row1,Row2], [Column1,Column2])
  angle_lx (Row1, Column1, Row2, Column2, Angle)
  AngleDeg := deg(Angle)
endfor
```

Result

`angle_lx` returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

`angle_ll`

Module

Foundation

apply_distance_transform_xld (Contour : ContourOut : DistanceTransformID :)

Determine the pointwise distance of two contours using an XLD distance transform.

The operator `apply_distance_transform_xld` determines for each point in `Contour` the minimal distance to the reference contour using its XLD distance transform `DistanceTransformID`. The returned contour `ContourOut` consists of `Contour` with the attribute *'distance'* containing the calculated distances. They can be accessed by querying the attribute *'distance'* with `get_contour_attrib_xld`. See the operator reference of `get_contour_attrib_xld` for further information about contour attributes.

Note that the distances depend on the parameters of `create_distance_transform_xld`: The distances are clipped to the maximum distance specified by the parameter MaxDistance. The parameter Mode determines whether the distances are calculated *'point_to_point'* or *'point_to_segment'*. For further details please refer to the documentation of `create_distance_transform_xld`.

Parameters

▷ **Contour** (input_object) . . . . . xld_cont(-array) ⇝ *object*
Contour(s) for whose points the distances are calculated.

▷ **ContourOut** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Copy of Contour containing the distances as an attribute.

▷ **DistanceTransformID** (input_control) . . . . . xld_dist_trans ⇝ *handle*
Handle of the XLD distance transform of the reference contour.

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_distance_transform_xld, read_distance_transform_xld, deserialize_distance_transform_xld, set_distance_transform_xld_param

Possible Successors

get_contour_attrib_xld, segment_contour_attrib_xld

Alternatives

distance_contours_xld

Module

Foundation

area_intersection_rectangle2 (: : Rect1Row, Rect1Column, Rect1Phi, Rect1Length1, Rect1Length2, Rect2Row, Rect2Column, Rect2Phi, Rect2Length1, Rect2Length2 : AreaIntersection)

Calculate the intersection area of oriented rectangles.

area_intersection_rectangle2 calculates the intersection area of two oriented rectangles (i.e., of type rectangle2), which are defined by their parameters (center (Rect1Row, Rect1Column), orientation Rect1Phi, and the half edge lengths Rect1Length1 and Rect1Length2) and (center (Rect2Row, Rect2Column), orientation Rect2Phi, and the half edge lengths Rect2Length1 and Rect2Length2), respectively. The intersection area is returned in AreaIntersection.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of results is always *N*.

Parameters

▷ **Rect1Row** (input_control) . . . . . rectangle2.center.y(-array) ⇝ *real* / integer
Center row coordinate of the first rectangle.

▷ **Rect1Column** (input_control) . . . . . rectangle2.center.x(-array) ⇝ *real* / integer
Center column coordinate of the first rectangle.

▷ **Rect1Phi** (input_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real* / integer
Angle between the positive horizontal axis and the first edge of the first rectangle (in radians).

▷ **Rect1Length1** (input_control) . . . . . rectangle2.hwidth(-array) ⇝ *real* / integer
Half length of the first edge of the first rectangle.

▷ **Rect1Length2** (input_control) . . . . . rectangle2.hheight(-array) ⇝ *real* / integer
Half length of the second edge of the first rectangle.

▷ **Rect2Row** (input_control) . . . . . rectangle2.center.y(-array) ⇝ *real* / integer
Center row coordinate of the second rectangle.

▷ **Rect2Column** (input_control) . . . . . rectangle2.center.x(-array) ⇝ *real* / integer
Center column coordinate of the second rectangle.

▷ **Rect2Phi** (input_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real* / integer
Angle between the positive horizontal axis and the first edge of the second rectangle (in radians).

▷ **Rect2Length1** (input_control) . . . . . rectangle2.hwidth(-array) ⇝ *real* / integer
Half length of the first edge of the second rectangle.

▷ **Rect2Length2** (input_control) . . . . . rectangle2.hheight(-array) ⇝ *real* / integer
Half length of the second edge of the second rectangle.

▷ **AreaIntersection** (output_control) . . . . . real(-array) ⇝ *real*
Intersection area of the first rectangle with the second rectangle.

Result

If the parameters are valid, the operator `area_intersection_rectangle2` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

clear_distance_transform_xld (: : DistanceTransformID :)

Clear a XLD distance transform.

`clear_distance_transform_xld` clears the XLD distance transform `DistanceTransformID` that was previously created by `create_distance_transform_xld`.

Parameters

▷ **DistanceTransformID** (input_control) . . . . . xld_dist_trans ⇝ *handle*
Handle of the XLD distance transform.

Result

If all parameters are correct, the operator returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DistanceTransformID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_distance_transform_xld, write_distance_transform_xld, serialize_distance_transform_xld

apply_distance_transform_xld, get_distance_transform_xld_contour, get_distance_transform_xld_param, set_distance_transform_xld_param, read_distance_transform_xld, deserialize_distance_transform_xld

Module

Foundation

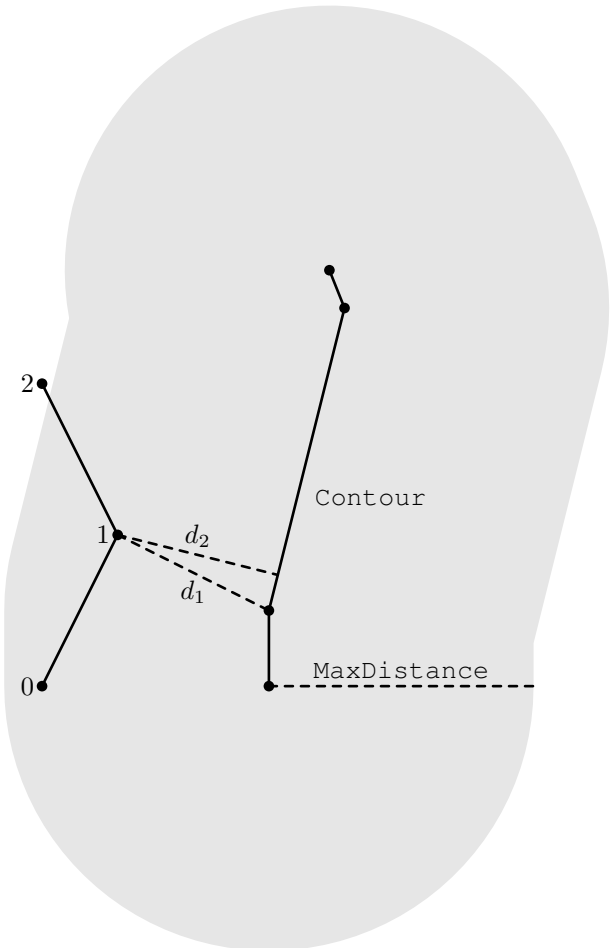
create_distance_transform_xld (Contour : : Mode, MaxDistance : DistanceTransformID)

Create the XLD distance transform.

create_distance_transform_xld creates the XLD distance transform of the reference contour Contour and returns the resulting handle in DistanceTransformID.

Once the XLD distance transform has been created, the operator apply_distance_transform_xld calculates pointwise distances from test contours to the reference contour Contour. More precisely, for each point of a test contour its minimal distance to the contours in Contour is calculated.

The parameter Mode determines which distances apply_distance_transform_xld calculates: *'point_to_point'* calculates the minimum distance to the base points of the Contour. In contrast, *'point_to_segment'* calculates the minimum distance to the contour segments in Contour (see the figure below).



The dashed lines illustrate the calculated distances starting from point 1 of the test contour on the left. The distance d_1 corresponds to the *'point_to_point'* mode, whereas the distance d_2 corresponds to the *'point_to_segment'* mode. The gray area illustrates the area within MaxDistance around the reference contour for which distances are calculated. The distance of point 2 of the test contour would be set to MaxDistance because it is outside of this area.

The parameter MaxDistance specifies a maximum distance from the reference contour Contour which is of interest to the caller. If the distance from a point of a test contour to the reference contour exceeds MaxDistance, the output distance of apply_distance_transform_xld is set to MaxDistance.

The operators create_distance_transform_xld and apply_distance_transform_xld are an alternative to distance_contours_xld, if the reference contour is repeatedly used. create_distance_transform_xld stores for each pixel in a relevant area around Contour its nearest points or segments (depending on Mode) of the reference contour Contour. This allows apply_distance_transform_xld to calculate the distances rather fast, nearly independent of the number of points or segments of the reference contour, the Mode and the position of the points of the test contour. However, the preparation of the XLD distance transform can take several seconds or minutes, depending on the number of points or segments of the reference contour and the relevant area around Contour which can be influenced by MaxDistance. Furthermore, create_distance_transform_xld is faster, if Mode is set to 'point_to_point'.

get_distance_transform_xld_contour and get_distance_transform_xld_param can be used to get back the reference contours and the parameters of the XLD distance transform DistanceTransformID.

Parameters

- ▷ **Contour** (input_object) ..... xld_cont(-array) ⇝ *object*
  Reference contour(s).
- ▷ **Mode** (input_control) ..... string ⇝ *string*
  Compute the distance to points ('point_to_point') or entire segments ('point_to_segment').
  Default: 'point_to_point'
  List of values: Mode ∈ {'point_to_point', 'point_to_segment'}
- ▷ **MaxDistance** (input_control) ..... real ⇝ *real* / integer
  Maximum distance of interest.
  Default: 20.0
- ▷ **DistanceTransformID** (output_control) ..... xld_dist_trans ⇝ *handle*
  Handle of the XLD distance transform.

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

Module

Foundation

deserialize_distance_transform_xld (: : SerializedItemHandle : DistanceTransformID)

Deserialize an XLD distance transform.

deserialize_distance_transform_xld deserializes an XLD distance transform. The serialized XLD distance transform is defined by the handle SerializedItemHandle. The deserialized XLD distance transform is returned in DistanceTransformID.

Note that the previous values of DistanceTransformID are overwritten, if the handle already exists.

get_distance_transform_xld_contour can be used to get the reference contour that was used to build the XLD distance transform DistanceTransformID.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized XLD distance transform.

▷ **DistanceTransformID** (output_control) . . . . . xld_dist_trans ⇝ *handle*
Handle of the deserialized XLD distance transform.

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

distance_cc (Contour1, Contour2 : : Mode : DistanceMin, DistanceMax)

Calculate the distance between two contours.

The operator distance_cc calculates the minimum and maximum distance between the base points of two contours (Contour1 and Contour2). The parameters DistanceMin and DistanceMax contain the resulting distance.

The parameter Mode sets the type of computing the distance: *'point_to_point'* only determines the minimum and maximum distance between the base points of the contours. This results in faster algorithm, but may lead to inaccurate minimum distances. In contrast, *'point_to_segment'* determines the actual minimum distance between the contour segments.

In both cases, the search algorithm has a quadratic complexity (n*n). If only the minimum distance is required, the operator distance_cc_min can be used alternatively since it offers algorithms with a complexity of n*log(n).

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

▷ **Contour1** (input_object) . . . . . xld_cont(-array) ⇝ *object*
First input contour.

▷ **Contour2** (input_object) . . . . . xld_cont(-array) ⇝ *object*
Second input contour.

▷ **Mode** (input_control) . . . . . string(-array) ⇝ *string*
Distance calculation mode.
Default: 'point_to_point'
List of values: Mode ∈ {'point_to_point', 'point_to_segment'}

▷ **DistanceMin** (output_control) . . . . . real(-array) ⇝ *real*
Minimum distance between both contours.

▷ **DistanceMax** (output_control) . . . . . real(-array) ⇝ *real*
Maximum distance between both contours.

Example

```
gen_contour_polygon_rounded_xld(Cont1, [0,100,100,0,0], [0,0,100,100,0],
                                [50,50,50,50,50], 0.5);
gen_contour_polygon_rounded_xld(Cont2, [41,91,91,41,41], [41,41,91,91,41],
                                [25,25,25,25,25], 0.5);
distance_cc(Cont1, Cont2, 'point_to_point', &distance_min, &distance_max);
```

Result

distance_cc returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

distance_sc, distance_pc, distance_cc_min, distance_contours_xld

See also

Module

Foundation

distance_cc_min (Contour1, Contour2 : : Mode : DistanceMin)

Calculate the minimum distance between two contours.

distance_cc_min calculates the minimum distance between two contours Contour1 and Contour2. The minimum distance is returned in DistanceMin.

The parameter Mode sets the type of computing the distance. *'point_to_point'* determines the distance between the closest contour points, *'fast_point_to_segment'* calculates the distance between the line segments adjacent to these points, and *'point_to_segment'* determines the actual minimum distance between the contour segments.

While *'point_to_point'* and *'fast_point_to_segment'* are efficient algorithms with a complexity of n*log(n), *'point_to_segment'* has quadratic complexity and thus takes a longer time to execute, especially for contours with many line segments.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

▷ **Contour1** (input_object) ..... xld_cont(-array) ⇝ *object*
First input contour.

▷ **Contour2** (input_object) ..... xld_cont(-array) ⇝ *object*
Second input contour.

▷ **Mode** (input_control) ..... string(-array) ⇝ *string*
Distance calculation mode.
Default: 'fast_point_to_segment'
List of values: Mode ∈ {'point_to_point', 'point_to_segment', 'fast_point_to_segment'}

▷ **DistanceMin** (output_control) ..... number(-array) ⇝ *real*
Minimum distance between the two contours.

Example

```
gen_contour_polygon_rounded_xld(Cont1, [0,100,100,0,0], [0,0,100,100,0],
                                [50,50,50,50,50], 0.5);
gen_contour_polygon_rounded_xld(Cont2, [41,91,91,41,41], [41,41,91,91,41],
                                [25,25,25,25,25], 0.5);
distance_cc_min(Cont1, Cont2, "fast_point_to_segment", &distance_min);
```

Result

distance_cc_min returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

distance_cc_min_points (Contour1, Contour2 : : Mode : DistanceMin, Row1, Column1, Row2, Column2)

Calculate the minimum distance between two contours and the points used for the calculation.

distance_cc_min_points calculates the minimum distance between Contour1 and Contour2. The minimum distance is returned in DistanceMin. In comparison to distance_cc_min, this operator also returns the points on the contours that provide the minimum distance. The point on Contour1 is returned in Row1 and Column1; the point on Contour2 is returned in Row2 and Column2.

The parameter Mode sets the type of computing the distance. *'fast_point_to_segment'* calculates the distance between the line segments adjacent to the closest contour points, and *'point_to_segment'* determines the actual minimum distance between the contour segments.

While *'fast_point_to_segment'* is an efficient algorithm with a complexity of n*log(n), *'point_to_segment'* has quadratic complexity and thus takes a longer time to execute, especially for contours with many line segments.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

▷ **Contour1** (input_object) ..... xld_cont(-array) ⇝ *object*
First input contour.

▷ **Contour2** (input_object) ..... xld_cont(-array) ⇝ *object*
Second input contour.

▷ **Mode** (input_control) ..... string(-array) ⇝ *string*
Distance calculation mode.
Default: 'fast_point_to_segment'
List of values: Mode ∈ {'point_to_segment', 'fast_point_to_segment'}

▷ **DistanceMin** (output_control) ..... number(-array) ⇝ *real*
Minimum distance between the two contours.

▷ **Row1** (output_control) ..... point.y(-array) ⇝ *real*
Row coordinate of the point on Contour1.

▷ **Column1** (output_control) ..... point.x(-array) ⇝ *real*
Column coordinate of the point on Contour1.

▷ **Row2** (output_control) ..... point.y(-array) ⇝ *real*
Row coordinate of the point on Contour2.

▷ **Column2** (output_control) ..... point.x(-array) ⇝ *real*
Column coordinate of the point on Contour2.

Example

```
gen_contour_polygon_rounded_xld(Cont1, [0,100,100,0,0], [0,0,100,100,0],
                                [50,50,50,50,50], 0.5);
gen_contour_polygon_rounded_xld(Cont2, [41,91,91,41,41], [41,41,91,91,41],
                                [25,25,25,25,25], 0.5);
distance_cc_min_points(Cont1, Cont2, "fast_point_to_segment", &distance_min,
                       &Row1, &Column1, &Row2, &Column2);
```

Result

distance_cc_min_points returns 2 (H_MSG_TRUE).

distance_sr, distance_pr

Module

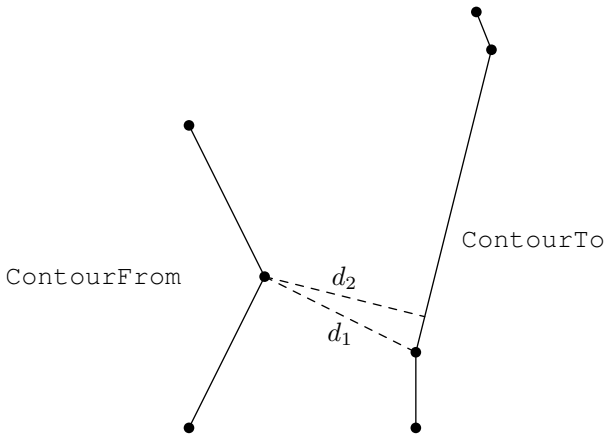
Foundation

distance_contours_xld (ContourFrom, ContourTo : ContourOut : Mode :)

Calculate the pointwise distance from one contour to another.

The operator distance_contours_xld calculates for each point in ContourFrom the minimal distance to the contours in ContourTo. The operator returns the contour ContourOut which consists of ContourFrom containing the computed distances in the attribute *'distance'*. The distances can be accessed by querying the attribute *'distance'* with the operator get_contour_attrib_xld. See the operator reference of get_contour_attrib_xld for further information about contour attributes.

The parameter Mode determines which distances are calculated for each point in ContourFrom: *'point_to_point'* calculates the minimal distance to the base points of ContourTo. In contrast, *'point_to_segment'* calculates the minimum distance to the contour segments in ContourTo (see the figure below).



The dashed lines illustrate the calculated distances starting from a point of ContourFrom on the left. The distance d_1 corresponds to the *'point_to_point'* mode, whereas the distance d_2 corresponds to the *'point_to_segment'* mode.

Note that in many applications the mode *'point_to_segment'* suggests itself for an accurate result, whereas *'point_to_point'* is considerably faster. If m is the number of points in ContourFrom, and n the number of points in ContourTo, then distance_contours_xld has complexity O(mlog(n)) for *'point_to_point'*, and O(mn) for *'point_to_segment'*. In case the template contour ContourTo is repeatedly used, the operators create_distance_transform_xld and apply_distance_transform_xld can be used as an alternative to distance_contours_xld. For further details, please refer to the documentation of create_distance_transform_xld.

Parameters

▷ **ContourFrom** (input_object) ..... xld_cont(-array) ⇝ *object*
Contours for whose points the distances are calculated.

▷ **ContourTo** (input_object) ..... xld_cont(-array) ⇝ *object*
Contours to which the distances are calculated to.

▷ **ContourOut** (output_object) ..... xld_cont(-array) ⇝ *object*
Copy of ContourFrom containing the distances as an attribute.

▷ **Mode** (input_control) ..... string ⇝ *string*
Compute the distance to points ('point_to_point') or to entire segments ('point_to_segment').
Default: 'point_to_point'
List of values: Mode ∈ {'point_to_point', 'point_to_segment'}

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

get_contour_attrib_xld, segment_contour_attrib_xld

Alternatives

Module

Foundation

distance_lc (Contour : : Row1, Column1, Row2, Column2 : DistanceMin, DistanceMax)

Calculate the distance between a line and one contour.

The operator distance_lc calculates the orthogonal distance between a line and the segments of a contour. As input the coordinates of two points on a line (Row1,Column1, Row2,Column2) and a contour (Contour) are expected. The parameters DistanceMin and DistanceMax return the result of the calculation.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of distances is always *N*.

Parameters

- ▷ **Contour** (input_object) ..... xld_cont(-array) ⇝ *object*
  Input contour.
- ▷ **Row1** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the first point of the line.
- ▷ **Column1** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the first point of the line.
- ▷ **Row2** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the second point of the line.
- ▷ **Column2** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the second point of the line.
- ▷ **DistanceMin** (output_control) ..... real(-array) ⇝ *real*
  Minimum distance between the line and the contour.
- ▷ **DistanceMax** (output_control) ..... real(-array) ⇝ *real*
  Maximum distance between the line and the contour.

Result

distance_lc returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

distance_lr, distance_pr, distance_sr

Module

Foundation

distance_lr (Region : : Row1, Column1, Row2, Column2 : DistanceMin, DistanceMax)

Calculate the distance between a line and a region.

The operator distance_lr calculates the orthogonal distance between a line and a region. As input the coordinates of two points on a line (Row1,Column1, Row2,Column2) and a region are expected. The parameters DistanceMin and DistanceMax return the result of the calculation.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of distances is always *N*.

Attention

Due to efficiency of distance_lr holes are ignored.

Parameters

▷ **Region** (input_object) ..... region(-array) ⇝ *object*
Input region.

▷ **Row1** (input_control) ..... point.y(-array) ⇝ *real* / integer
Row coordinate of the first point of the line.

▷ **Column1** (input_control) ..... point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the line.

▷ **Row2** (input_control) ..... point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the line.

▷ **Column2** (input_control) ..... point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the line.

▷ **DistanceMin** (output_control) ..... real(-array) ⇝ *real*
Minimum distance between the line and the region

▷ **DistanceMax** (output_control) ..... real(-array) ⇝ *real*
Maximum distance between the line and the region

Example

```
gen_circle (Circle, 200, 200, 100.5)
Column1 := 300
Column2 := 400
for Row := 50 to 350 by 50
  gen_contour_polygon_xld (Line, [Row,Row], [Column1,Column2])
  distance_lr (Circle, Row, Column1, Row, Column2, DistanceMin, DistanceMax)
endfor
```

Result

`distance_lr` returns `2` (`H_MSG_TRUE`).

Execution Information

Module

Foundation

distance_pc (Contour : : Row, Column : DistanceMin, DistanceMax)

Calculate the distance between a point and one contour.

The operator `distance_pc` calculates the distance between one or several points and a single contour. As input the coordinates of the points (`Row`,`Column`) and the contour (`Contour`) are expected. The parameters `DistanceMin` and `DistanceMax` return the result of the calculation. Note that the result corresponds to the distances between the points and the segments of the contour and not the distances between the points and the base points of the contour (see also `distance_contours_xld`).

Parameters

▷ **Contour** (input_object) . . . . . xld_cont ⇝ *object*
Input contour.
▷ **Row** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the point.
▷ **Column** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the point.
▷ **DistanceMin** (output_control) . . . . . real(-array) ⇝ *real*
Minimum distance between the point and the contour.
▷ **DistanceMax** (output_control) . . . . . real(-array) ⇝ *real*
Maximum distance between the point and the contour.

Result

`distance_pc` returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

distance_pl (: : Row, Column, Row1, Column1, Row2, Column2 : Distance)

Calculate the distance between one point and one line.

The operator `distance_pl` calculates the orthogonal distance between points (`Row`,`Column`) and lines, given by two arbitrary points on the line. The result is passed in `Distance`.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

▷ **Row** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the point.
▷ **Column** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column of the point.
▷ **Row1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the first point of the line.
▷ **Column1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the line.
▷ **Row2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the line.
▷ **Column2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the line.
▷ **Distance** (output_control) . . . . . real(-array) ⇝ *real*
Distance between the points.

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
draw_point (WindowHandle, Row, Column)
gen_cross_contour_xld (Cross, Row, Column, 15, 0)
draw_line (WindowHandle, Row1, Column1, Row2, Column2)
gen_contour_polygon_xld (Contour, [Row1,Row2], [Column1,Column2])
distance_pl (Row, Column, Row1, Column1, Row2, Column2, Distance)
```

Result

`distance_pl` returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

distance_point_line (: : PointX, PointY, PointZ, Point1X, Point1Y, Point1Z, Point2X, Point2Y, Point2Z : Distance)

Calculate the distance between a 3D point and a 3D line given by two points on the line.

`distance_point_line` calculates the orthogonal distance between 3D points and 3D lines. The lines are specified by two points on the line ($\mathbf{Q}$ and $\mathbf{R}$). The result is returned in `Distance`. The input tuples can define 1 or n points. The points are specified by (`PointX`, `PointY`, `PointZ`). The line is specified by two points on the line (`Point1X`, `Point1Y`, `Point1Z`) and (`Point2X`, `Point2Y`, `Point2Z`).

Let $\mathbf{P}$ denote the point (`PointX`, `PointY`, `PointZ`), $\mathbf{Q}$ the first point (`Point1X`, `Point1Y`, `Point1Z`) on the line, and $\mathbf{R}$ the second point (`Point2X`, `Point2Y`, `Point2Z`) on the line. First, the line direction $\mathbf{V} = \mathbf{R} - \mathbf{Q}$ and its length $\|\mathbf{V}\|$ are computed. If $\|\mathbf{V}\| = 0$, the points $\mathbf{Q}$ and $\mathbf{R}$ do not define a line and an error is returned. Furthermore, let D denote the distance `Distance`. Then, $D = \|(\mathbf{P} - \mathbf{Q}) \times \mathbf{V}\| / \|\mathbf{V}\|$, where $\times$ denotes the cross product of two vectors.

Parameters

▷ **PointX** (input_control) ..... point3d.x(-array) ⇝ *real*
X coordinate of the original points.

▷ **PointY** (input_control) ..... point3d.y(-array) ⇝ *real*
Y coordinate of the original points.

▷ **PointZ** (input_control) ..... point3d.z(-array) ⇝ *real*
Z coordinate of the original points.

▷ **Point1X** (input_control) ..... point3d.x(-array) ⇝ *real* / integer
X coordinate of the first point on the line.

▷ **Point1Y** (input_control) ..... point3d.y(-array) ⇝ *real* / integer
Y coordinate of the first point on the line.

▷ **Point1Z** (input_control) ..... point3d.z(-array) ⇝ *real* / integer
Z coordinate of the first point on the line.

▷ **Point2X** (input_control) ..... point3d.x(-array) ⇝ *real* / integer
X coordinate of the second point on the line.

▷ **Point2Y** (input_control) . . . . . point3d.y(-array) ⇝ *real* / integer
Y coordinate of the second point on the line.

▷ **Point2Z** (input_control) . . . . . point3d.z(-array) ⇝ *real* / integer
Z coordinate of the second point on the line.

▷ **Distance** (output_control) . . . . . real(-array) ⇝ *real*
Distance between the points and the lines.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

distance_point_pluecker_line (: : PointX, PointY, PointZ, LineDirectionX, LineDirectionY, LineDirectionZ, LineMomentX, LineMomentY, LineMomentZ : Distance)

Calculate the distance between a 3D point and a 3D line given by Plücker coordinates.

`distance_point_pluecker_line` calculates the orthogonal distance between 3D points and 3D lines. The result is returned in `Distance`. The input tuples can define 1 or n points $\mathbf{P}$ and lines, respectively. The points are specified by (`PointX`, `PointY`, `PointZ`). The lines are given in Plücker coordinates $\mathbf{L}$ (`LineDirectionX`, `LineDirectionY`, `LineDirectionZ`) and $\mathbf{M}$ (`LineMomentX`, `LineMomentY`, `LineMomentZ`). For the definition of Plücker coordinates, see "`Solution Guide III-C - 3D Vision`".

Let $\mathbf{P}$ denote the point (`PointX`, `PointY`, `PointZ`), $\mathbf{L}$ the direction (`LineDirectionX`, `LineDirectionY`, `LineDirectionZ`), and $\mathbf{M}$ the moment (`LineMomentX`, `LineMomentY`, `LineMomentZ`) of the Plücker line. Furthermore, let D denote the distance `Distance`. Then, $D = \|\mathbf{P} \times \mathbf{L} - \mathbf{M}\|$, where $\times$ denotes the cross product of two vectors.

Parameters

▷ **PointX** (input_control) . . . . . point3d.x(-array) ⇝ *real*
X coordinates of the original points.

▷ **PointY** (input_control) . . . . . point3d.y(-array) ⇝ *real*
Y coordinates of the original points.

▷ **PointZ** (input_control) . . . . . point3d.z(-array) ⇝ *real*
Z coordinates of the original points.

▷ **LineDirectionX** (input_control) . . . . . point3d.x(-array) ⇝ *real* / integer
X component of the direction vector of the corresponding line.

▷ **LineDirectionY** (input_control) . . . . . point3d.y(-array) ⇝ *real* / integer
Y component of the direction vector of the corresponding line.

▷ **LineDirectionZ** (input_control) . . . . . point3d.z(-array) ⇝ *real* / integer
Z component of the direction vector of the corresponding line.

▷ **LineMomentX** (input_control) . . . . . point3d.x(-array) ⇝ *real* / integer
X component of the moment vector of the corresponding line.

▷ **LineMomentY** (input_control) . . . . . point3d.y(-array) ⇝ *real* / integer
Y component of the moment vector of the corresponding line.

▷ **LineMomentZ** (input_control) . . . . . point3d.z(-array) ⇝ *real* / integer
Z component of the moment vector of the corresponding line.

▷ **Distance** (output_control) . . . . . real(-array) ⇝ *real*
Distance between the points and the lines.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

distance_point_line

See also

point_pluecker_line_to_hom_mat3d

Module

Foundation

distance_pp (: : Row1, Column1, Row2, Column2 : Distance)

Calculate the distance between two points.

The operator distance_pp calculates the distance between pairs of points according to the following formula:

$$\texttt{Distance} = \sqrt{((\texttt{Row1} - \texttt{Row2})^2 + (\texttt{Column1} - \texttt{Column2})^2)}$$

The result is returned in Distance.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

▷ **Row1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the first point.

▷ **Column1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point.

▷ **Row2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point.

▷ **Column2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point.

▷ **Distance** (output_control) . . . . . real(-array) ⇝ *real*
Distance between the points.

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
draw_point (WindowHandle, Row1, Column1)
gen_cross_contour_xld (Cross, Row1, Column1, 15, 0)
draw_point (WindowHandle, Row2, Column2)
gen_cross_contour_xld (Cross, Row2, Column2, 15, 0)
distance_pp (Row1, Column1, Row2, Column2, Distance)
```

Result

distance_pp returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

distance_ps

See also

distance_pl, distance_pr

Module

Foundation

distance_pr (Region : : Row, Column : DistanceMin, DistanceMax)

Calculate the distance between a point and a region.

The operator distance_pr calculates the distance between a point and one region. As input the coordinates of the points (Row,Column) and a region are expected. If a point is inside of the region, its minimum distance is zero. The parameters DistanceMin and DistanceMax return the result of the calculation.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of distances is always *N*.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Input region.
- ▷ **Row** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the point.
- ▷ **Column** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the point.
- ▷ **DistanceMin** (output_control) ..... real(-array) ⇝ *real*
  Minimum distance between the point and the region.
- ▷ **DistanceMax** (output_control) ..... real(-array) ⇝ *real*
  Maximum distance between the point and the region.

Example

```
gen_circle (Circle, 200, 200, 100.5)
draw_point (WindowHandle, Row, Column)
gen_cross_contour_xld (Cross, Row, Column, 15, 0)
distance_pr (Circle, Row, Column, DistanceMin, DistanceMax)
```

Result

distance_pr returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

distance_pc, distance_lr, distance_sr, diameter_region

See also

hamming_distance, select_region_point, test_region_point, smallest_rectangle2

Module

Foundation

distance_ps (: : Row, Column, Row1, Column1, Row2, Column2 : DistanceMin, DistanceMax)

Calculate the distances between a point and a line segment.

The operator distance_ps calculates the minimum and maximum distance between a point (Row,Column) and a line segment which is represented by the start point (Row1,Column1) and the end point (Row2,Column2). DistanceMax is the maximum distance between the point and the end points of the line segment. DistanceMin is identical to distance_pl in the case that the point is "between" the two endpoints. Otherwise, the minimum distance to one of the end points is used.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

- ▷ **Row** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the first point.
- ▷ **Column** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the first point.
- ▷ **Row1** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the first point of the line segment.
- ▷ **Column1** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the first point of the line segment.
- ▷ **Row2** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the second point of the line segment.
- ▷ **Column2** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the second point of the line segment.
- ▷ **DistanceMin** (output_control) ..... real(-array) ⇝ *real*
  Minimum distance between the point and the line segment.
- ▷ **DistanceMax** (output_control) ..... real(-array) ⇝ *real*
  Maximum distance between the point and the line segment.

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
draw_point (WindowHandle, Row, Column)
gen_cross_contour_xld (Cross, Row, Column, 15, 0)
draw_line (WindowHandle, Row1, Column1, Row2, Column2)
gen_contour_polygon_xld (Contour, [Row1,Row2], [Column1,Column2])
distance_ps (Row, Column, Row1, Column1, Row2, Column2, \
             DistanceMin, DistanceMax)
```

Result

distance_ps returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

distance_pl

See also

distance_pp, distance_pr

Module

Foundation

distance_rr_min (Regions1, Regions2 : : : MinDistance, Row1, Column1, Row2, Column2)

Minimum distance between the contour pixels of two regions each.

The operator distance_rr_min calculates the minimum distance of pairs of regions. If several regions are passed in Regions1 and Regions2 the distance between the contour pixels of each i-th element is calculated and then forms the i-th entry in the output parameter MinDistance. The Euclidean distance is used. The parameters (Row1, Column1) and (Row2, Column2) indicate the position on the contour of Regions1 and Regions2, respectively, that have the minimum distance.

The calculation is carried out by comparing all contour pixels (see get_region_contour). This means in particular that holes in the regions are ignored. Furthermore, it is not checked whether one region lies completely within the other region. In this case, a minimum distance > 0 is returned. It is also not checked whether both regions contain a nonempty intersection. In the latter case, a minimum distance of 0 or > 0 can be returned, depending on whether the contours of the regions contain a common point or not.

Attention

Both input parameters must contain the same number of regions. The regions must not be empty.

Parameters

- ▷ **Regions1** (input_object) . . . region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Regions2** (input_object) . . . region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **MinDistance** (output_control) . . . real(-array) ⇝ *real*
  Minimum distance between contours of the regions.
  Assertion: 0 <= MinDistance
- ▷ **Row1** (output_control) . . . point.y(-array) ⇝ *integer*
  Line index on contour in Regions1.
- ▷ **Column1** (output_control) . . . point.x(-array) ⇝ *integer*
  Column index on contour in Regions1.
- ▷ **Row2** (output_control) . . . point.y(-array) ⇝ *integer*
  Line index on contour in Regions2.
- ▷ **Column2** (output_control) . . . point.x(-array) ⇝ *integer*
  Column index on contour in Regions2.

Complexity

If $N1$,$N2$ are the lengths of the contours the runtime complexity is $O(N1 * N2)$.

Result

The operator distance_rr_min returns the value 2 (H_MSG_TRUE) if the input is not empty. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

Alternatives

distance_rr_min_dil, dilation1, intersection

Module

Foundation

distance_rr_min_dil (Regions1, Regions2 : : : MinDistance)

Minimum distance between two regions with the help of dilation.

The operator distance_rr_min_dil calculates the minimum distance between pairs of regions, by iteratively applying dilations on both regions until their intersection is non empty. If several regions are passed in Regions1 and Regions2 the distance between the i-th elements in each case is calculated. It then forms the i-th entry in the output parameter MinDistance. The calculation is carried out with the help of dilation with the Golay element *'h'* (see dilation_golay for further information). The result is:

$n_i * 2 - 1$ where n_i is the number of iterations. The mask *'h'* has the effect that precisely the maximum metrics are calculated.

Attention

Both parameters must contain the same number of regions. The regions must not be empty.

Parameters

- ▷ **Regions1** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **Regions2** (input_object) ..... region(-array) ⇝ *object*
  Regions to be examined.
- ▷ **MinDistance** (output_control) ..... integer(-array) ⇝ *integer*
  Minimum distances of the regions.
  Assertion: -1 <= MinDistance

Result

The operator distance_rr_min_dil returns the value 2 (H_MSG_TRUE) if the input is not empty. Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

threshold, regiongrowing, connection

Alternatives

distance_rr_min, dilation1, intersection

Module

Foundation

distance_sc (Contour : : Row1, Column1, Row2,
Column2 : DistanceMin, DistanceMax)

Calculate the distance between a line segment and one contour.

The operator distance_sc calculates the distance between a line segment and the line segments of a contour. Row1, Column1, Row2, Column2 are the start and end coordinates of a line segment, Contour represents the input contour. The parameters DistanceMin and DistanceMax contain the resulting distances.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of distances is always *N*.

Parameters

▷ **Contour** (input_object) . . . . . xld_cont(-array) ⇝ *object*
Input contour.

▷ **Row1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the first point of the line segment.

▷ **Column1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the line segment.

▷ **Row2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the line segment.

▷ **Column2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the line segment.

▷ **DistanceMin** (output_control) . . . . . real(-array) ⇝ *real*
Minimum distance between the line segment and the contour.

▷ **DistanceMax** (output_control) . . . . . real(-array) ⇝ *real*
Maximum distance between the line segment and the contour.

Result

distance_sr returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

Module

Foundation

distance_sl (: : RowA1, ColumnA1, RowA2, ColumnA2, RowB1, ColumnB1, RowB2, ColumnB2 : DistanceMin, DistanceMax)

Calculate the distances between a line segment and a line.

The operator distance_sl calculates the minimum and maximum orthogonal distance between a line segment and a line. As input the coordinates of two points on the line segment (RowA1,ColumnA1,RowA2,ColumnA2) and on the line (RowB1,ColumnB1,RowB2,ColumnB2) are expected. The parameters DistanceMin and DistanceMax return the result of the calculation. If the line segments are intersecting, DistanceMin returns zero.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

▷ **RowA1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the first point of the line segment.

▷ **ColumnA1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the line segment.

▷ **RowA2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the line segment.
▷ **ColumnA2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the line segment.
▷ **RowB1** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the first point of the line.
▷ **ColumnB1** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the first point of the line.
▷ **RowB2** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinate of the second point of the line.
▷ **ColumnB2** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinate of the second point of the line.
▷ **DistanceMin** (output_control) . . . . . real(-array) ⇝ *real*
Minimum distance between the line segment and the line.
▷ **DistanceMax** (output_control) . . . . . real(-array) ⇝ *real*
Maximum distance between the line segment and the line.

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
Row1 := 300
Column1 := 200
Row2 := 100
Column2 := 400
gen_contour_polygon_xld (Line1, [Row1,Row2], [Column1,Column2])
dev_display (Line1)
Column := 50
Row := 100
Offset := 0
for RowEnd := 100 to 500 by 100
  gen_contour_polygon_xld (Line2, [Row,RowEnd], \
                           [Column+Offset,Column+Offset])
  dev_display (Line1)
  distance_sl (Row, Column+Offset, RowEnd, Column+Offset, Row1, Column1, \
               Row2, Column2,DistanceMin, DistanceMax)
  Offset := Offset+40
endfor
```

Result

`distance_sl` returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

distance_sr (Region : : Row1, Column1, Row2, Column2 : DistanceMin, DistanceMax)

Calculate the distance between a line segment and one region.

The operator distance_sr calculates the distance between a line segment and a region. Row1, Column1, Row2, Column2 are the start and end coordinates of a line segment. The parameters DistanceMin and DistanceMax contain the resulting distances.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of distances is always *N*.

Attention

To enhance distance_sr, holes are ignored.

Parameters

- ▷ **Region** (input_object) ..... region(-array) ⇝ *object*
  Input region.
- ▷ **Row1** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the first point of the line segment.
- ▷ **Column1** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the first point of the line segment.
- ▷ **Row2** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the second point of the line segment.
- ▷ **Column2** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the second point of the line segment.
- ▷ **DistanceMin** (output_control) ..... real(-array) ⇝ *real*
  Minimum distance between the line segment and the region.
- ▷ **DistanceMax** (output_control) ..... real(-array) ⇝ *real*
  Maximum distance between the line segment and the region.

Example

```
gen_circle (Circle, 200, 200, 100.5)
Column1 := 300
Column2 := 400
for Row := 50 to 350 by 50
  gen_contour_polygon_xld (Line, [Row,Row], [Column1,Column2])
  distance_sr (Circle, Row, Column1, Row, Column2, DistanceMin, DistanceMax)
endfor
```

Result

distance_sr returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

distance_ss (: : RowA1, ColumnA1, RowA2, ColumnA2, RowB1, ColumnB1, RowB2, ColumnB2 : DistanceMin, DistanceMax)

Calculate the distances between two line segments.

The operator distance_ss calculates the minimum and maximum distance between two line segments. As input the coordinates of the start and end point of the first line segment (RowA1,ColumnA1, RowA2,ColumnA2) and of the second line segment (RowB1,ColumnB1,RowB2,ColumnB2) are used. The parameters DistanceMin and DistanceMax return the result of the calculation. If the line segments are intersecting, DistanceMin returns zero.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *N*.

Parameters

- ▷ **RowA1** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the first point of the line segment.
- ▷ **ColumnA1** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the first point of the line segment.
- ▷ **RowA2** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the second point of the line segment.
- ▷ **ColumnA2** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the second point of the line segment.
- ▷ **RowB1** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the first point of the line.
- ▷ **ColumnB1** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column of the first point of the line.
- ▷ **RowB2** (input_control) ..... point.y(-array) ⇝ *real* / integer
  Row coordinate of the second point of the line.
- ▷ **ColumnB2** (input_control) ..... point.x(-array) ⇝ *real* / integer
  Column coordinate of the second point of the line.
- ▷ **DistanceMin** (output_control) ..... real(-array) ⇝ *real*
  Minimum distance between the line segments.
- ▷ **DistanceMax** (output_control) ..... real(-array) ⇝ *real*
  Maximum distance between the line segments.

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
Row1 := 300
Column1 := 200
Row2 := 100
Column2 := 300
gen_contour_polygon_xld (Line1, [Row1,Row2], [Column1,Column2])
Column := 100
Offset := 30
for Row := 40 to 100 by 20
  gen_contour_polygon_xld (Line2, [Row, Row+Offset], \
                           [Column, Column+Offset])
  distance_ss (Row, Column, Row+Offset, Column+Offset, Row1, Column1, \
               Row2, Column2, DistanceMin, DistanceMax)
  Offset := Offset+50
endfor
```

Result

distance_ss returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on internal data level.

Alternatives

distance_pp

Module

Foundation

get_distance_transform_xld_contour (: Contour : DistanceTransformID :)

Get the reference contour used to build the XLD distance transform.

get_distance_transform_xld_contour returns the reference contour Contour that was used to build the XLD distance transform DistanceTransformID. This can be used for visualization purposes while comparing a given contour against the reference contour using apply_distance_transform_xld.

Parameters

▷ **Contour** (output_object) ..... xld_cont(-array) ⇝ *object*
Reference contour.

▷ **DistanceTransformID** (input_control) ..... xld_dist_trans ⇝ *handle*
Handle of the XLD distance transform.

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_distance_transform_xld_param (: : DistanceTransformID, GenParamName : GenParamValue)

Get the parameters used to build an XLD distance transform.

get_distance_transform_xld_param returns the parameters used to build the XLD distance transform DistanceTransformID. The names of the parameters are passed in GenParamName and their values are returned in GenParamValue. GenParamName can contain the names of parameters *'mode'* and *'max_distance'*.

Parameters

▷ **DistanceTransformID** (input_control) ..... xld_dist_trans ⇝ *handle*
Handle of the XLD distance transform.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters.
Default: 'mode'
List of values: GenParamName ∈ {'mode', 'max_distance'}

▷ **GenParamValue** (output_control) . . . . . attribute.value(-array) ⇝ *string* / real
Values of the generic parameters.
Number of elements: GenParamValue == 1 || GenParamValue == 2
List of values: GenParamValue ∈ {'point_to_point', 'point_to_segment', 5.0}

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

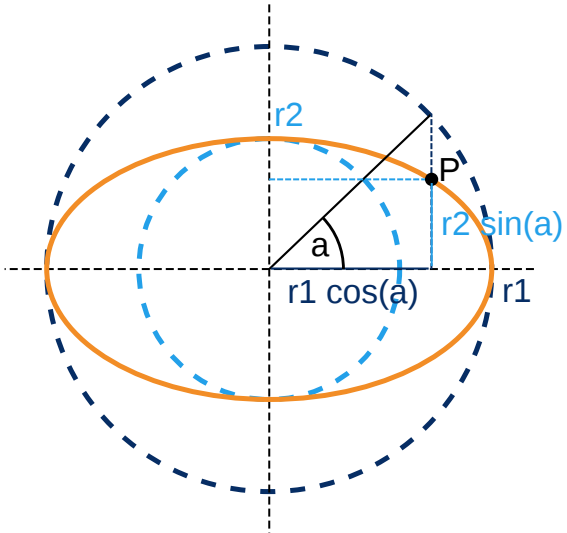
get_points_ellipse (: : Angle, Row, Column, Phi, Radius1, Radius2 : RowPoint, ColPoint)

Calculate points on the perimeter of an ellipse.

get_points_ellipse returns the point (RowPoint,ColPoint) on the specified ellipse corresponding to the angle in Angle. With the parameter Angle you are setting the eccentric anomaly, which denotes the angle used for the parametric equation (see the figure below) and refers to the main axis of the ellipse. The ellipse itself is characterized by the center (Row, Column), the orientation of the main axis Phi relative to the horizontal axis, the length of the larger (Radius1) and the smaller half axis (Radius2). The angles are measured counter clockwise in radiant.



The point P with its coordinates RowPoint and ColPoint belongs to the ellipse (orange). It is determined over the angle a and the lengths of the half axis r1 (Radius1) and r2 (Radius2). For simplicity of the visualization and angle Phi=*0* was used.

Parameters

▷ **Angle** (input_control) . . . . . angle.rad(-array) ⇝ *real*
Angle corresponding to the resulting point [rad].
Default: 0
Restriction: Angle >= 0 && Angle <= 6.283185307

▷ **Row** (input_control) . . . . . ellipse.center.y ⇝ *real*
Row coordinate of the center of the ellipse.

▷ **Column** (input_control) . . . . . ellipse.center.x ⇝ *real*
Column coordinate of the center of the ellipse.

▷ **Phi** (input_control) . . . . . ellipse.angle.rad ⇝ *real*
Orientation of the main axis [rad].
Restriction: Phi >= 0 && Phi <= 6.283185307

▷ **Radius1** (input_control) . . . . . ellipse.radius1 ⇝ *real*
Length of the larger half axis.
Restriction: Radius1 > 0

▷ **Radius2** (input_control) . . . . . ellipse.radius2 ⇝ *real*
Length of the smaller half axis.
Restriction: Radius2 >= 0

▷ **RowPoint** (output_control) . . . . . point.y(-array) ⇝ *real*
Row coordinate of the point on the ellipse.

▷ **ColPoint** (output_control) . . . . . point.x(-array) ⇝ *real*
Column coordinates of the point on the ellipse.

Example

```
draw_ellipse(WindowHandle,Row,Column,Phi,Radius1,Radius2)
get_points_ellipse([0,3.14],Row,Column,Phi,Radius1,Radius2,\
                   RowPoint,ColPoint)
```

Result

get_points_ellipse returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

intersection_circle_contour_xld (Contour : : CircleRow, CircleColumn, CircleRadius, CircleStartPhi, CircleEndPhi, CirclePointOrder : Row, Column)

Calculate the intersection points of a circle or circular arc and an XLD contour

intersection_circle_contour_xld calculates the intersection points of a circle or circular arc and the XLD Contour. The circle is defined by its center (CircleRow,CircleColumn) and its radius CircleRadius. In addition to that, a circular arc is characterized by the angle of the start point CircleStartPhi, the angle of the end point CircleEndPhi, and the point order CirclePointOrder along the boundary. If CirclePointOrder is set to *'positive'*, the circular arc is defined counterclockwise. If CirclePointOrder is set to *'negative'*, the circular arc is defined clockwise. The intersection points, if any, are returned in (Row,Column).

Parameters

- ▷ **Contour** (input_object) ..... xld_cont ⇝ *object*
  XLD contour.
- ▷ **CircleRow** (input_control) ..... circle.center.y ⇝ *real* / integer
  Row coordinate of the center of the circle or circular arc.
- ▷ **CircleColumn** (input_control) ..... circle.center.x ⇝ *real* / integer
  Column coordinate of the center of the circle or circular arc.
- ▷ **CircleRadius** (input_control) ..... circle.radius ⇝ *real* / integer
  Radius of the circle or circular arc.
- ▷ **CircleStartPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the start point of the circle or circular arc [rad].
  Default: 0.0
- ▷ **CircleEndPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the end point of the circle or circular arc [rad].
  Default: 6.28318
- ▷ **CirclePointOrder** (input_control) ..... string ⇝ *string*
  Point order along the circle or circular arc.
  Default: 'positive'
  List of values: CirclePointOrder ∈ {'positive', 'negative'}
- ▷ **Row** (output_control) ..... point.y(-array) ⇝ *real*
  Row coordinates of the intersection points.
- ▷ **Column** (output_control) ..... point.x(-array) ⇝ *real*
  Column coordinates of the intersection points.

Result

If the parameters are valid, the operator intersection_circle_contour_xld returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

intersection_circles (: : Circle1Row, Circle1Column, Circle1Radius, Circle1StartPhi, Circle1EndPhi, Circle1PointOrder, Circle2Row, Circle2Column, Circle2Radius, Circle2StartPhi, Circle2EndPhi, Circle2PointOrder : Row, Column, IsOverlapping)

Calculate the intersection points of two circles or circular arcs

intersection_circles calculates the intersection points of two circles or circular arcs. The points, if any, are returned in (Row,Column). The circles are defined by their center (Circle1Row,Circle1Column), and (Circle2Row,Circle2Column) respectively, and their radii Circle1Radius, and Circle2Radius respectively. In addition to that, a circular arc is characterized by the angle of the start point (Circle1StartPhi,Circle2StartPhi), the angle of the end point (Circle1EndPhi,Circle2EndPhi), and the point order (Circle1PointOrder,Circle2PointOrder) along the boundary. If Circle1PointOrder is set to *'positive'*, the circular arc is defined counterclockwise. If Circle1PointOrder is set to *'negative'*, the circular arc is defined clockwise. The same applies for Circle2PointOrder. If both circles or circular arcs have a part in common IsOverlapping returns the value 1, otherwise 0 is returned. In this case the endpoints of the mutual arc are returned in (Row,Column).

Parameters

- ▷ **Circle1Row** (input_control) ..... circle.center.y ⇝ *real* / integer
  Row coordinate of the center of the first circle or circular arc.
- ▷ **Circle1Column** (input_control) ..... circle.center.x ⇝ *real* / integer
  Column coordinate of the center of the first circle or circular arc.
- ▷ **Circle1Radius** (input_control) ..... circle.radius ⇝ *real* / integer
  Radius of the first circle or circular arc.
- ▷ **Circle1StartPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the start point of the first circle or circular arc [rad].
  Default: 0.0
- ▷ **Circle1EndPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the end point of the first circle or circular arc [rad].
  Default: 6.28318
- ▷ **Circle1PointOrder** (input_control) ..... string ⇝ *string*
  Point order along the first circle or circular arc.
  Default: 'positive'
  List of values: Circle1PointOrder ∈ {'positive', 'negative'}
- ▷ **Circle2Row** (input_control) ..... circle.center.y ⇝ *real* / integer
  Row coordinate of the center of the second circle or circular arc.
- ▷ **Circle2Column** (input_control) ..... circle.center.x ⇝ *real* / integer
  Column coordinate of the center of the second circle or circular arc.
- ▷ **Circle2Radius** (input_control) ..... circle.radius ⇝ *real* / integer
  Radius of the second circle or circular arc.
- ▷ **Circle2StartPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the start point of the second circle or circular arc [rad].
  Default: 0.0
- ▷ **Circle2EndPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the end point of the second circle or circular arc [rad].
  Default: 6.28318
- ▷ **Circle2PointOrder** (input_control) ..... string ⇝ *string*
  Point order along the second circle or circular arc.
  Default: 'positive'
  List of values: Circle2PointOrder ∈ {'positive', 'negative'}
- ▷ **Row** (output_control) ..... point.y(-array) ⇝ *real*
  Row coordinates of the intersection points.
- ▷ **Column** (output_control) ..... point.x(-array) ⇝ *real*
  Column coordinates of the intersection points.
- ▷ **IsOverlapping** (output_control) ..... integer ⇝ *integer*
  Do both circles or circular arcs have a part in common?

Result

If the parameters are valid, the operator intersection_circles returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

intersection_contours_xld (Contour1, Contour2 : : IntersectionType : Row, Column, IsOverlapping)

Calculate the intersection points of two XLD contours

intersection_contours_xld calculates the intersection points of the XLD Contour1 and XLD Contour2 which, if any, are returned in (Row,Column). The value in IntersectionType defines the way to calculate the intersections points. By setting IntersectionType = *'self'*, only the self intersections within both contours are returned, i.e., the intersections within Contour1 and XLD Contour2. For IntersectionType = *'mutual'*, only the intersections between both contours are taken into account. The default value is IntersectionType = *'all'*. In this case both, the self and the mutual intersections are returned in Row,Column). If parts of the contours overlap in more than one point IsOverlapping returns the value 1, otherwise 0 is returned. IsOverlapping is set with regard to both the self and mutual overlap, regardless of the setting in IntersectionType. In case of a mutual overlap, the endpoints of the mutual segment are returned in (Row,Column).

Parameters

▷ **Contour1** (input_object) ..... xld_cont ⇝ *object*
First XLD contour.

▷ **Contour2** (input_object) ..... xld_cont ⇝ *object*
Second XLD contour.

▷ **IntersectionType** (input_control) ..... string ⇝ *string*
Intersection points to be returned.
Default: 'all'
List of values: IntersectionType ∈ {'all', 'self', 'mutual'}

▷ **Row** (output_control) ..... point.y(-array) ⇝ *real*
Row coordinates of the intersection points.

▷ **Column** (output_control) ..... point.x(-array) ⇝ *real*
Column coordinates of the intersection points.

▷ **IsOverlapping** (output_control) ..... integer ⇝ *integer*
Does a part of a contour lie above another contour part?

Result

If the parameters are valid, the operator intersection_contours_xld returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

intersection_line_circle (: : LineRow1, LineColumn1, LineRow2, LineColumn2, CircleRow, CircleColumn, CircleRadius, CircleStartPhi, CircleEndPhi, CirclePointOrder : Row, Column)

Calculate the intersection points of a line and a circle or circular arc

intersection_line_circle calculates the intersection points of a line and a circle or circular arc. The line is defined by the points (LineRow1,LineColumn1) and (LineRow2,LineColumn2). The circle is defined by its center (CircleRow,CircleColumn) and its radius CircleRadius. In addition to that, a circular arc is characterized by the angle of the start point CircleStartPhi, the angle of the end point CircleEndPhi, and the point order CirclePointOrder along the boundary. If CirclePointOrder is set to *'positive'*, the circular arc is defined counterclockwise. If CirclePointOrder is set to *'negative'*, the circular arc is defined clockwise. The intersection points, if any, are returned in (Row,Column).

Parameters

- ▷ **LineRow1** (input_control) ..... point.y ⇝ *real* / integer
  Row coordinate of the first point of the line.
- ▷ **LineColumn1** (input_control) ..... point.x ⇝ *real* / integer
  Column coordinate of the first point of the line.
- ▷ **LineRow2** (input_control) ..... point.y ⇝ *real* / integer
  Row coordinate of the second point of the line.
- ▷ **LineColumn2** (input_control) ..... point.x ⇝ *real* / integer
  Column coordinate of the second point of the line.
- ▷ **CircleRow** (input_control) ..... circle.center.y ⇝ *real* / integer
  Row coordinate of the center of the circle or circular arc.
- ▷ **CircleColumn** (input_control) ..... circle.center.x ⇝ *real* / integer
  Column coordinate of the center of the circle or circular arc.
- ▷ **CircleRadius** (input_control) ..... circle.radius ⇝ *real* / integer
  Radius of the circle or circular arc.
- ▷ **CircleStartPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the start point of the circle or circular arc [rad].
  Default: 0.0
- ▷ **CircleEndPhi** (input_control) ..... angle.rad ⇝ *real*
  Angle of the end point of the circle or circular arc [rad].
  Default: 6.28318
- ▷ **CirclePointOrder** (input_control) ..... string ⇝ *string*
  Point order along the circle or circular arc.
  Default: 'positive'
  List of values: CirclePointOrder ∈ {'positive', 'negative'}
- ▷ **Row** (output_control) ..... point.y(-array) ⇝ *real*
  Row coordinates of the intersection points.
- ▷ **Column** (output_control) ..... point.x(-array) ⇝ *real*

intersection_lines (: : Line1Row1, Line1Column1, Line1Row2, Line1Column2, Line2Row1, Line2Column1, Line2Row2, Line2Column2 : Row, Column, IsOverlapping)

Calculate the intersection point of two lines

intersection_lines calculates the intersection point of two lines, which are defined by two of their points (Line1Row1,Line1Column1), (Line1Row2,Line1Column2), and (Line2Row1,Line2Column1), (Line2Row2,Line2Column2) respectively. The intersection point, if it exists, is returned in (Row,Column). If both lines are identical, IsOverlapping returns the value 1, otherwise 0 is returned. In this case no intersection point is returned in (Row,Column).

Parameters

▷ **Line1Row1** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the first point of the first line.

▷ **Line1Column1** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the first point of the first line.

▷ **Line1Row2** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the second point of the first line.

▷ **Line1Column2** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the second point of the first line.

▷ **Line2Row1** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the first point of the second line.

▷ **Line2Column1** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the first point of the second line.

▷ **Line2Row2** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the second point of the second line.

▷ **Line2Column2** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the second point of the second line.

▷ **Row** (output_control) . . . . . point.y ⇝ *real*
Row coordinate of the intersection point.

▷ **Column** (output_control) . . . . . point.x ⇝ *real*
Column coordinate of the intersection point.

▷ **IsOverlapping** (output_control) . . . . . integer ⇝ *integer*
Are both lines identical?

Result

If the parameters are valid, the operator `intersection_lines` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

intersection_segment_circle (: : SegmentRow1, SegmentColumn1, SegmentRow2, SegmentColumn2, CircleRow, CircleColumn, CircleRadius, CircleStartPhi, CircleEndPhi, CirclePointOrder : Row, Column)

Calculate the intersection points of a segment and a circle or circular arc

`intersection_segment_circle` calculates the intersection point of a segment and a circle or circular arc. The segment is defined by its endpoints (`SegmentRow1`,`SegmentColumn1`) and (`SegmentRow2`,`SegmentColumn2`). The circle is defined by its center (`CircleRow`,`CircleColumn`) and its radius `CircleRadius`. In addition to that, a circular arc is characterized by the angle of the start point `CircleStartPhi`, the angle of the end point `CircleEndPhi`, and the point order `CirclePointOrder` along the boundary. If `CirclePointOrder` is set to *'positive'*, the circular arc is defined counterclockwise. If `CirclePointOrder` is set to *'negative'*, the circular arc is defined clockwise. The intersection points, if any, are returned in (`Row`,`Column`).

Parameters

- ▷ **SegmentRow1** (input_control) . . . . . point.y ⇝ *real* / integer
  Row coordinate of the first point of the segment.
- ▷ **SegmentColumn1** (input_control) . . . . . point.x ⇝ *real* / integer
  Column coordinate of the first point of the segment.
- ▷ **SegmentRow2** (input_control) . . . . . point.y ⇝ *real* / integer
  Row coordinate of the second point of the segment.
- ▷ **SegmentColumn2** (input_control) . . . . . point.x ⇝ *real* / integer
  Column coordinate of the second point of the segment.
- ▷ **CircleRow** (input_control) . . . . . circle.center.y ⇝ *real* / integer
  Row coordinate of the center of the circle or circular arc.
- ▷ **CircleColumn** (input_control) . . . . . circle.center.x ⇝ *real* / integer
  Column coordinate of the center of the circle or circular arc.
- ▷ **CircleRadius** (input_control) . . . . . circle.radius ⇝ *real* / integer
  Radius of the circle or circular arc.
- ▷ **CircleStartPhi** (input_control) . . . . . angle.rad ⇝ *real*
  Angle of the start point of the circle or circular arc [rad].
  Default: 0.0
- ▷ **CircleEndPhi** (input_control) . . . . . angle.rad ⇝ *real*
  Angle of the end point of the circle or circular arc [rad].
  Default: 6.28318
- ▷ **CirclePointOrder** (input_control) . . . . . string ⇝ *string*
  Point order along the circle or circular arc.
  Default: 'positive'
  List of values: `CirclePointOrder` ∈ {'positive', 'negative'}
- ▷ **Row** (output_control) . . . . . point.y(-array) ⇝ *real*
  Row coordinates of the intersection points.
- ▷ **Column** (output_control) . . . . . point.x(-array) ⇝ *real*
  Column coordinates of the intersection points.

Result

If the parameters are valid, the operator `intersection_segment_circle` returns the value `2` (`H_MSG_TRUE`).

Execution Information

Module

Foundation

intersection_segment_contour_xld (Contour : : SegmentRow1, SegmentColumn1, SegmentRow2, SegmentColumn2 : Row, Column, IsOverlapping)

Calculate the intersection points of a segment and an XLD contour

`intersection_segment_contour_xld` calculates the intersection points of a segment and an XLD `Contour`. The segment is defined by its endpoints (`SegmentRow1`,`SegmentColumn1`) and (`SegmentRow2`,`SegmentColumn2`). The intersection points, if any, are returned in (`Row`,`Column`). If the

segment and the XLD contour have a part in common IsOverlapping returns the value 1, otherwise 0 is returned. In this case the endpoints of the mutual segment are returned in (Row,Column).

Parameters

- ▷ **Contour** (input_object) ..... xld_cont ⇝ *object*
  XLD contour.
- ▷ **SegmentRow1** (input_control) ..... point.y ⇝ *real* / integer
  Row coordinate of the first point of the segment.
- ▷ **SegmentColumn1** (input_control) ..... point.x ⇝ *real* / integer
  Column coordinate of the first point of the segment.
- ▷ **SegmentRow2** (input_control) ..... point.y ⇝ *real* / integer
  Row coordinate of the second point of the segment.
- ▷ **SegmentColumn2** (input_control) ..... point.x ⇝ *real* / integer
  Column coordinate of the second point of the segment.
- ▷ **Row** (output_control) ..... point.y(-array) ⇝ *real*
  Row coordinates of the intersection points.
- ▷ **Column** (output_control) ..... point.x(-array) ⇝ *real*
  Column coordinates of the intersection points.
- ▷ **IsOverlapping** (output_control) ..... integer ⇝ *integer*
  Do the segment and the XLD contour have a part in common?

Result

If the parameters are valid, the operator intersection_segment_contour_xld returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

intersection_segment_line (: : SegmentRow1, SegmentColumn1, SegmentRow2, SegmentColumn2, LineRow1, LineColumn1, LineRow2, LineColumn2 : Row, Column, IsOverlapping)

Calculate the intersection point of a segment and a line

intersection_segment_line calculates the intersection point of a segment and a line. The segment is defined by its endpoints (SegmentRow1,SegmentColumn1) and (SegmentRow2,SegmentColumn2). The line is defined by the two points (LineRow1,LineColumn1) and (LineRow2,LineColumn2). The intersection point, if it exists, is returned in (Row,Column). If the segment and the line have a part in common, IsOverlapping returns the value 1, otherwise 0 is returned. In this case the endpoints of the mutual segment are returned in (Row,Column).

Parameters

- ▷ **SegmentRow1** (input_control) ..... point.y ⇝ *real* / integer
  Row coordinate of the first point of the segment.
- ▷ **SegmentColumn1** (input_control) ..... point.x ⇝ *real* / integer
  Column coordinate of the first point of the segment.

▷ **SegmentRow2** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the second point of the segment.

▷ **SegmentColumn2** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the second point of the segment.

▷ **LineRow1** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the first point of the line.

▷ **LineColumn1** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the first point of the line.

▷ **LineRow2** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the second point of the line.

▷ **LineColumn2** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the second point of the line.

▷ **Row** (output_control) . . . . . point.y(-array) ⇝ *real*
Row coordinate of the intersection point.

▷ **Column** (output_control) . . . . . point.x(-array) ⇝ *real*
Column coordinate of the intersection point.

▷ **IsOverlapping** (output_control) . . . . . integer ⇝ *integer*
Do the segment and the line have a part in common?

Result

If the parameters are valid, the operator `intersection_segment_line` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

intersection_segments (: : Segment1Row1, Segment1Column1, Segment1Row2, Segment1Column2, Segment2Row1, Segment2Column1, Segment2Row2, Segment2Column2 : Row, Column, IsOverlapping)

Calculate the intersection point of two line segments

`intersection_segments` calculates the intersection point of two line segments, which are defined by their endpoints (`Segment1Row1`,`Segment1Column1`), (`Segment1Row2`,`Segment1Column2`), and (`Segment2Row1`,`Segment2Column1`), (`Segment2Row2`,`Segment2Column2`) respectively. The intersection point, if it exists, is returned in (`Row`,`Column`). If both segments have a part in common, `IsOverlapping` returns the value 1, otherwise 0 is returned. In this case the endpoints of the mutual segment are returned in (`Row`,`Column`).

Parameters

▷ **Segment1Row1** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the first point of the first segment.

▷ **Segment1Column1** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the first point of the first segment.

▷ **Segment1Row2** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the second point of the first segment.

▷ **Segment1Column2** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the second point of the first segment.

▷ **Segment2Row1** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the first point of the second segment.

▷ **Segment2Column1** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the first point of the second segment.

▷ **Segment2Row2** (input_control) . . . . . point.y ⇝ *real* / integer
Row coordinate of the second point of the second segment.

▷ **Segment2Column2** (input_control) . . . . . point.x ⇝ *real* / integer
Column coordinate of the second point of the second segment.

▷ **Row** (output_control) . . . . . point.y(-array) ⇝ *real*
Row coordinate of the intersection point.

▷ **Column** (output_control) . . . . . point.x(-array) ⇝ *real*
Column coordinate of the intersection point.

▷ **IsOverlapping** (output_control) . . . . . integer ⇝ *integer*
Do both segments have a part in common?

Result

If the parameters are valid, the operator `intersection_segments` returns the value `2` (`H_MSG_TRUE`).

Execution Information

Module

Foundation

pluecker_line_to_point_direction (: : LineDirectionX, LineDirectionY, LineDirectionZ, LineMomentX, LineMomentY, LineMomentZ : PointX, PointY, PointZ, DirectionX, DirectionY, DirectionZ)

Convert a 3D line given by Plücker coordinates to a 3D line given by a point and a direction.

`pluecker_line_to_point_direction` converts a 3D line given by Plücker coordinates to a line given by a point on the line and the direction of the line. The line is given in Plücker coordinates $\mathbf{L}$ (`LineDirectionX`, `LineDirectionY`, `LineDirectionZ`) and $\mathbf{M}$ (`LineMomentX`, `LineMomentY`, `LineMomentZ`). The direction is given by (`DirectionX`, `DirectionY`, `DirectionZ`) of the line. and the point on the line by (`PointX`, `PointY`, `PointZ`). For the definition of Plücker coordinates, see "`Solution Guide III-C - 3D Vision`". All input tuples must be of same length.

Let $\mathbf{L}$ denote the line direction (`LineDirectionX`, `LineDirectionY`, `LineDirectionZ`), $\mathbf{M}$ the line moment (`LineMomentX`, `LineMomentY`, `LineMomentZ`), $\mathbf{P}$ the point (`PointX`, `PointY`, `PointZ`) on the line, and $\mathbf{D}$ the direction (`DirectionX`, `DirectionY`, `DirectionZ`) of the line. Then, $\mathbf{P} = \mathbf{L} \times \mathbf{M}$ and $\mathbf{D} = \mathbf{L}$. Note that $\mathbf{P}$ is the point on the line closest to the origin.

Parameters

▷ **LineDirectionX** (input_control) . . . . . point3d.x(-array) ⇝ *real*
X component of the direction vector of the line.

▷ **LineDirectionY** (input_control) . . . . . point3d.y(-array) ⇝ *real*
Y component of the direction vector of the line.

▷ **LineDirectionZ** (input_control) . . . . . point3d.z(-array) ⇝ *real*
Z component of the direction vector of the line.

▷ **LineMomentX** (input_control) . . . . . point3d.x(-array) ⇝ *real*
X component of the moment vector of the line.

▷ **LineMomentY** (input_control) . . . . . point3d.y(-array) ⇝ *real*
Y component of the moment vector of the line.

▷ **LineMomentZ** (input_control) . . . . . point3d.z(-array) ⇝ *real*
Z component of the moment vector of the line.

▷ **PointX** (output_control) . . . . . point3d.x(-array) ⇝ *real*
X coordinate of the first point on the line.

▷ **PointY** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Y coordinate of the first point on the line.

▷ **PointZ** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Z coordinate of the first point on the line.

▷ **DirectionX** (output_control) . . . . . point3d.x(-array) ⇝ *real*
X coordinates of the direction of the line.

▷ **DirectionY** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Y coordinates of the direction of the line.

▷ **DirectionZ** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Z coordinates of the direction of the line.

Foundation

pluecker_line_to_points (: : LineDirectionX, LineDirectionY, LineDirectionZ, LineMomentX, LineMomentY, LineMomentZ : Point1X, Point1Y, Point1Z, Point2X, Point2Y, Point2Z)

Convert a 3D line given by Plücker coordinates to a 3D line given by two points.

pluecker_line_to_points converts a 3D line given by Plücker coordinates $\mathbf{L}$ (LineDirectionX, LineDirectionY, LineDirectionZ) and $\mathbf{M}$ (LineMomentX, LineMomentY, LineMomentZ). to a line given by two points on the line (Point1X, Point1Y, Point1Z) and (Point2X, Point2Y, Point2Z). For the definition of Plücker coordinates, see "Solution Guide III-C - 3D Vision". All input tuples must be of same length.

Let $\mathbf{L}$ denote the line direction (LineDirectionX, LineDirectionY, LineDirectionZ), $\mathbf{M}$ the line moment (LineMomentX, LineMomentY, LineMomentZ), $\mathbf{P}$ the first point (Point1X, Point1Y, Point1Z) on the line, and $\mathbf{Q}$ the second point (Point2X, Point2Y, Point2Z) on the line. Then, $\mathbf{P} = \mathbf{L} \times \mathbf{M}$ and $\mathbf{Q} = \mathbf{P} + \mathbf{L}$. Note that $\mathbf{P}$ is the point on the line closest to the origin.

Parameters

▷ **LineDirectionX** (input_control) . . . . . point3d.x(-array) ⇝ *real*
X component of the direction vector of the line.

▷ **LineDirectionY** (input_control) . . . . . point3d.y(-array) ⇝ *real*
Y component of the direction vector of the line.

▷ **LineDirectionZ** (input_control) . . . . . point3d.z(-array) ⇝ *real*
Z component of the direction vector of the line.

▷ **LineMomentX** (input_control) . . . . . point3d.x(-array) ⇝ *real*
X component of the moment vector of the line.

▷ **LineMomentY** (input_control) . . . . . point3d.y(-array) ⇝ *real*
Y component of the moment vector of the line.

▷ **LineMomentZ** (input_control) . . . . . point3d.z(-array) ⇝ *real*
Z component of the moment vector of the line.

▷ **Point1X** (output_control) . . . . . point3d.x(-array) ⇝ *real*
X coordinate of the first point on the line.

▷ **Point1Y** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Y coordinate of the first point on the line.

▷ **Point1Z** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Z coordinate of the first point on the line.

▷ **Point2X** (output_control) . . . . . point3d.x(-array) ⇝ *real*
X coordinate of the second point on the line.

▷ **Point2Y** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Y coordinate of the second point on the line.

▷ **Point2Z** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Z coordinate of the second point on the line.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Foundation

point_direction_to_pluecker_line (: : PointX, PointY, PointZ, DirectionX, DirectionY, DirectionZ : LineDirectionX, LineDirectionY, LineDirectionZ, LineMomentX, LineMomentY, LineMomentZ)

Convert a 3D line given by a point and a direction to Plücker coordinates.

point_direction_to_pluecker_line converts the 3D line given by the point (PointX, PointY, PointZ) and the direction (DirectionX, DirectionY, DirectionZ) to Plücker coordinates $\mathbf{L}$ (LineDirectionX, LineDirectionY, LineDirectionZ) and $\mathbf{M}$ (LineMomentX, LineMomentY, LineMomentZ). For the definition of Plücker coordinates, see "Solution Guide III-C - 3D Vision". All input tuples must be of same length.

Let $\mathbf{P}$ denote the point (PointX, PointY, PointZ) and $\mathbf{D}$ the direction (DirectionX, DirectionY, DirectionZ) of the line. To compute the line direction $\mathbf{L}$, the length $\|\mathbf{D}\|$ of the vector $\mathbf{D}$ is computed. If $\|\mathbf{D}\| = 0$, the direction $\mathbf{D}$ does not define a line and an error is returned. The further calculations to Plücker coordinates are given in points_to_pluecker_line.

Parameters

▷ **PointX** (input_control) . . . . . point3d.x(-array) ⇝ *real*
X coordinates of the point on the line.

▷ **PointY** (input_control) . . . . . point3d.y(-array) ⇝ *real*
Y coordinates of the point on the line.

▷ **PointZ** (input_control) . . . . . point3d.z(-array) ⇝ *real*
Z coordinates of the point on the line.

▷ **DirectionX** (input_control) . . . . . point3d.x(-array) ⇝ *real*
X coordinates of the direction of the line.

▷ **DirectionY** (input_control) . . . . . point3d.y(-array) ⇝ *real*
Y coordinates of the direction of the line.

▷ **DirectionZ** (input_control) . . . . . point3d.z(-array) ⇝ *real*
Z coordinates of the direction of the line.

▷ **LineDirectionX** (output_control) . . . . . point3d.x(-array) ⇝ *real*
X component of the direction vector of the line.

▷ **LineDirectionY** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Y component of the direction vector of the line.

▷ **LineDirectionZ** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Z component of the direction vector of the line.

▷ **LineMomentX** (output_control) . . . . . point3d.x(-array) ⇝ *real*
X component of the moment vector of the line.

▷ **LineMomentY** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Y component of the moment vector of the line.

▷ **LineMomentZ** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Z component of the moment vector of the line.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

points_to_pluecker_line (: : Point1X, Point1Y, Point1Z, Point2X, Point2Y, Point2Z : LineDirectionX, LineDirectionY, LineDirectionZ, LineMomentX, LineMomentY, LineMomentZ)

Convert a 3D line given by two points to Plücker coordinates.

points_to_pluecker_line converts the 3D line given by the two points (Point1X, Point1Y, Point1Z) and (Point2X, Point2Y, Point2Z) to Plücker coordinates $\mathbf{L}$ = (LineDirectionX, LineDirectionY, LineDirectionZ) and $\mathbf{M}$ = (LineMomentX, LineMomentY, LineMomentZ). For the definition of Plücker coordinates, see "Solution Guide III-C - 3D Vision". All input tuples must be of same length.

Let $\mathbf{P}$ denote the first point (Point1X, Point1Y, Point1Z) and $\mathbf{Q}$ the second point (Point2X, Point2Y, Point2Z) on the line. To compute the line direction $\mathbf{L}$, the vector $\mathbf{D} = \mathbf{Q} - \mathbf{P}$ and its length $\|\mathbf{D}\|$ are computed.

If $\|\mathbf{D}\| = 0$, the points do not define a line and an error is returned. The line direction is given by $\mathbf{L} = \mathbf{D}/\|\mathbf{D}\|$. The line moment is given by the cross product $\mathbf{M} = \mathbf{P} \times \mathbf{L}$.

Parameters

- ▷ **Point1X** (input_control) ..... point3d.x(-array) ⇝ *real*
  X coordinates of the first point on the line.
- ▷ **Point1Y** (input_control) ..... point3d.y(-array) ⇝ *real*
  Y coordinates of the first point on the line.
- ▷ **Point1Z** (input_control) ..... point3d.z(-array) ⇝ *real*
  Z coordinates of the first point on the line.
- ▷ **Point2X** (input_control) ..... point3d.x(-array) ⇝ *real*
  X coordinates of the second point on the line.
- ▷ **Point2Y** (input_control) ..... point3d.y(-array) ⇝ *real*
  Y coordinates of the second point on the line.
- ▷ **Point2Z** (input_control) ..... point3d.z(-array) ⇝ *real*
  Z coordinates of the second point on the line.
- ▷ **LineDirectionX** (output_control) ..... point3d.x(-array) ⇝ *real*
  X component of the direction vector of the line.
- ▷ **LineDirectionY** (output_control) ..... point3d.y(-array) ⇝ *real*
  Y component of the direction vector of the line.
- ▷ **LineDirectionZ** (output_control) ..... point3d.z(-array) ⇝ *real*
  Z component of the direction vector of the line.
- ▷ **LineMomentX** (output_control) ..... point3d.x(-array) ⇝ *real*
  X component of the moment vector of the line.
- ▷ **LineMomentY** (output_control) ..... point3d.y(-array) ⇝ *real*
  Y component of the moment vector of the line.
- ▷ **LineMomentZ** (output_control) ..... point3d.z(-array) ⇝ *real*
  Z component of the moment vector of the line.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`pluecker_line_to_points`

Module

Foundation

projection_pl (: : Row, Column, Row1, Column1, Row2, Column2 : RowProj, ColProj)

Calculate the projection of a point onto a line.

The operator `projection_pl` calculates the projection of a point (`Row`,`Column`) onto a line which is represented by the two points (`Row1`,`Column1`) and (`Row2`,`Column2`). The coordinates of the projected point are returned in `RowProj` and `ColProj`.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of projections is always *N*.

Parameters

▷ **Row** (input_control) ..... point.y(-array) ⇝ *real* / integer
Row coordinate of the point.

▷ **Column** (input_control) ..... point.x(-array) ⇝ *real* / integer
Column coordinate of the point.

▷ **Row1** (input_control) ..... point.y(-array) ⇝ *real* / integer
Row coordinate of the first point on the line.

▷ **Column1** (input_control) ..... point.x(-array) ⇝ *real* / integer
Column coordinate of the first point on the line.

▷ **Row2** (input_control) ..... point.y(-array) ⇝ *real* / integer
Row coordinate of the second point on the line.

▷ **Column2** (input_control) ..... point.x(-array) ⇝ *real* / integer
Column coordinate of the second point on the line.

▷ **RowProj** (output_control) ..... real(-array) ⇝ *real*
Row coordinate of the projected point.

▷ **ColProj** (output_control) ..... real(-array) ⇝ *real*
Column coordinate of the projected point

Example

```
dev_open_window (0, 0, 512, 512, 'black', WindowHandle)
Row1 := 300
Column1 := 200
Row2 := 140
Column2 := 400
Rows := 300
Columns := 170
dev_set_color ('cadet blue')
gen_contour_polygon_xld (Contour, [Row1,Row2], [Column1,Column2])
Offset := 0
for Rows := 40 to 280 by 40
  dev_set_color ('red')
  gen_cross_contour_xld (Point,Rows+Offset, Columns, 6, 0)
  projection_pl (Rows+Offset, Columns, Row1, Column1, Row2, Column2, \
                 RowProj, ColProj)
  dev_set_color ('blue')
  gen_cross_contour_xld (RowP, RowProj, ColProj, 6, 0)
  Offset := Offset+30
endfor
```

Result

`projection_pl` returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

read_distance_transform_xld (: : FileName : DistanceTransformID)

Read an XLD distance transform from a file.

read_distance_transform_xld reads an XLD distance transform which previously has been stored with write_distance_transform_xld from the file given by FileName and returns the handle DistanceTransformID. The default HALCON extension for the XLD distance transform is 'hdtc'.

get_distance_transform_xld_contour can be used to get the reference contour that was used to build the XLD distance transform DistanceTransformID.

Parameters

▷ **FileName** (input_control) ..... filename.write ⇝ *string*
Name of the file.
File extension: .hdtc

▷ **DistanceTransformID** (output_control) ..... xld_dist_trans ⇝ *handle*
Handle of the XLD distance transform.

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Module

Foundation

serialize_distance_transform_xld (
: : DistanceTransformID : SerializedItemHandle)

Serialize an XLD distance transform.

serialize_distance_transform_xld serializes the XLD distance transform DistanceTransformID. The serialized XLD distance transform is returned in the handle SerializedItemHandle and can be deserialized with deserialize_distance_transform_xld.

Parameters

▷ **DistanceTransformID** (input_control) ..... xld_dist_trans ⇝ *handle*
Handle of the XLD distance transform.

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized XLD distance transform.

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

set_distance_transform_xld_param (: : DistanceTransformID, GenParamName, GenParamValue :)

Set new parameters for an XLD distance transform.

set_distance_transform_xld_param sets new parameters for the XLD distance transform DistanceTransformID. The names and values of the parameters are passed in GenParamName and GenParamValue, respectively. GenParamName can contain the names of parameters *'mode'* and *'max_distance'*. The XLD distance transform of the original reference contour is then rebuilt with updated values of parameters.

Parameters

▷ **DistanceTransformID** (input_control) . . . . . xld_dist_trans ⇝ *handle*
Handle of the XLD distance transform.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Names of the generic parameters.
Default: 'mode'
List of values: GenParamName ∈ {'mode', 'max_distance'}

▷ **GenParamValue** (input_control) . . . . . attribute.value(-array) ⇝ *string* / real
Values of the generic parameters.
Default: 'point_to_point'
Suggested values: GenParamValue ∈ {'point_to_point', 'point_to_segment', 5.0}

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DistanceTransformID

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

write_distance_transform_xld (: : DistanceTransformID, FileName :)

Write an XLD distance transform into a file.

write_distance_transform_xld writes the XLD distance transform DistanceTransformID into the file given by FileName. The default HALCON extension for the XLD distance transform is 'hdtc'.

The stored XLD distance transform can be read in with read_distance_transform_xld.

Parameters

- ▷ **DistanceTransformID** (input_control) ..... xld_dist_trans ⇝ *handle*
  Handle of the XLD distance transform.
- ▷ **FileName** (input_control) ..... filename.write ⇝ *string*
  Name of the file.
  File extension: .hdtc

Result

If all parameters are correct, the operator returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

26.4 Grid Rectification

connect_grid_points (Image : ConnectingLines : Row, Column, Sigma, MaxDist :)

Establish connections between the grid points of the rectification grid.

connect_grid_points searches for connecting lines between the grid points (Row,Column) of the rectification grid. The connecting lines are extracted from the input image Image by a combination of an edge detector, a smoothing filter, and a line detector, each of size σ. The σ to be used is determined as follows: When a single value is passed in Sigma, this value is used. When a tuple of three values (*'sigma_min'*, *'sigma_max'*, *'sigma_step'*) is passed, connect_grid_points tests every σ within a range from *'sigma_min'* to *'sigma_max'* with a step width of *'sigma_step'* and chooses the σ that causes the greatest number of connecting lines. The same happens

when a tuple of only two values *'sigma_min'* and *'sigma_max'* is passed. However, in this case a fixed step width of *0.05* is used.

Then, the extracted connecting lines are split at the grid points and those line segments are selected that start as well as end at a grid point. Note that edge detectors typically don't work very accurately in the proximity of edge junctions, and thus in general the connecting lines will not hit the grid points. Therefore, actually those connecting lines are split and selected that start at, end at, or pass a grid point at a maximum distance of `MaxDist`. The connecting lines are modified in order to start and end exactly in the corresponding grid points, and are returned in `ConnectingLines` as XLD contours.

Additionally, `connect_grid_points` calculates for each output XLD contour its type of transition and stores it in its global attribute *'bright_dark'*. The attribute is set to *1.0*, if the connecting line forms a bright-dark transition (left to right, viewed from start point to end point), otherwise it is set to *0.0*. For further information about global contour attributes see `get_contour_global_attrib_xld`.

Attention

For a reliable determination of the type of bright-dark transition as well as for the following rectification, it is necessary that each connecting line has at least three contour points. Therefore, connecting lines with only two contour points are not returned. Note, that the parameter `MaxDist` has a substantial influence on the length of the returned connecting lines, because all contour points of a possible connecting line that are closer than `MaxDist` to a grid point are replaced by one single contour point. If `MaxDist` is too big, some of the connecting lines might get lost.

Parameters

- ▷ **`Image`** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
  Input image.
- ▷ **`ConnectingLines`** (output_object) ..... xld-array ⇝ *object*
  Output contours.
- ▷ **`Row`** (input_control) ..... point.y-array ⇝ *real*
  Row coordinates of the grid points.
- ▷ **`Column`** (input_control) ..... point.x-array ⇝ *real*
  Column coordinates of the grid points.
  Restriction: number(Column) == number(Row)
- ▷ **`Sigma`** (input_control) ..... number(-array) ⇝ *integer* / real
  Size of the applied Gaussians.
  Number of elements: 1 <= Sigma && Sigma <= 3
  Default: 0.9
  Suggested values: `Sigma` ∈ {0.7, 0.9, 1.1, 1.3, 1.5}
  Restriction: 0.7 <= Sigma
- ▷ **`MaxDist`** (input_control) ..... number ⇝ *real* / integer
  Maximum distance of the connecting lines from the grid points.
  Default: 5.5
  Suggested values: `MaxDist` ∈ {1.5, 3.5, 5.5, 7.5, 9.5}
  Restriction: 0.0 <= MaxDist

Result

`connect_grid_points` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`saddle_points_sub_pix`

Possible Successors

`gen_grid_rectification_map`

Module

Calibration

create_rectification_grid (: : Width, NumSquares, GridFile :)

Generate a PostScript file, which describes the rectification grid.

create_rectification_grid generates a checkered pattern with NumSquares × NumSquares alternating black and white squares. This pattern is Width meters wide (and high). Around the pattern there is an inner frame of *0.3* times the width of one square, which continues the checkered pattern. The pattern is completed by a solid white outer frame of *0.7* times the width of one square. In the center of the pattern there are two circular marks, one black on a white square and one white on a black square. The radius of both marks correspond to one third of the side length of the respective enclosing square. These marks are used by gen_grid_rectification_map to rotate the detected layout of the grid points into the correct orientation. It is assumed that the black mark is positioned to the left of the white mark, when oriented correctly. The file GridFile contains the PostScript description of the rectification grid.

Parameters

▷ **Width** (input_control) . . . . . real ⇝ *real*
Width of the checkered pattern in meters (without the two frames).
Default: 0.17
Suggested values: Width ∈ {1.2, 0.8, 0.6, 0.4, 0.2, 0.1}
Recommended increment: 0.1
Restriction: 0.0 < Width

▷ **NumSquares** (input_control) . . . . . integer ⇝ *integer*
Number of squares per row and column.
Default: 17
Suggested values: NumSquares ∈ {11, 13, 15, 17, 19, 21, 23, 25, 27}
Recommended increment: 2
Restriction: 2 <= NumSquares

▷ **GridFile** (input_control) . . . . . filename.write ⇝ *string*
File name of the PostScript file.
Default: 'rectification_grid.ps'
File extension: .ps

Result

find_rectification_grid returns 2 (H_MSG_TRUE) if all parameter values are correct and the file has been written successfully. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

find_rectification_grid (Image : GridRegion : MinContrast, Radius :)

Segment the rectification grid region in the image.

find_rectification_grid searches in the image Image for image parts that contain the rectification grid and returns them in the region GridRegion. To do so, essentially image areas with a contrast of at least MinContrast are extracted and the holes in these areas are filled up. Then, an opening with the radius Radius is applied to these areas to eliminate smaller areas of high contrast.

During grid-rectification, a careful reduction of the input region to those image parts that actually contain the rectification grid is useful for two purposes: First, the computing time can be reduced and secondly, saddle_points_sub_pix and connect_grid_points can be prevented from detecting false grid points and connecting lines.

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
Input image.

▷ **GridRegion** (output_object) ..... region ⇝ *object*
Output region containing the rectification grid.

▷ **MinContrast** (input_control) ..... number ⇝ *real* / integer
Minimum contrast.
Default: 8.0
Suggested values: MinContrast ∈ {2.0, 4.0, 8.0, 16.0, 32.0}
Restriction: MinContrast >= 0

▷ **Radius** (input_control) ..... real ⇝ *real* / integer
Radius of the circular structuring element.
Default: 7.5
Suggested values: Radius ∈ {1.5, 2.5, 3.5, 4.5, 5.5, 7.5, 9.5, 12.5, 15.5, 19.5, 25.5, 33.5, 45.5, 60.5, 110.5}
Restriction: Radius >= 0.5

Example

```
find_rectification_grid (Image, GridRegion, 8, 10)
dilation_circle (GridRegion, GridRegionDilated, 5.5)
reduce_domain (Image, GridRegionDilated, ImageReduced)
saddle_points_sub_pix (ImageReduced, 'facet', 1.5, 5, Row, Column)
connect_grid_points (ImageReduced, ConnectingLines, Row, Column, 1.1, 5.5)
gen_grid_rectification_map (ImageReduced, ConnectingLines, Map, Meshes, 20, \
                            'auto', Row, Column, 'bilinear')
map_image (Image, Map, ImageMapped)
```

Result

find_rectification_grid returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

dilation_circle, reduce_domain

Module

Calibration

gen_arbitrary_distortion_map (: Map : GridSpacing, Row, Column, GridWidth, ImageWidth, ImageHeight, MapType :)

Generate a projection map that describes the mapping between an arbitrarily distorted image and the rectified image.

gen_arbitrary_distortion_map computes the mapping Map between an arbitrarily distorted image and the rectified image. The coordinates Row and Column describe a distorted grid, which will be mapped onto a regular grid in the rectified image. The coordinates of the (distorted) grid points must be passed line by line in Row and Column. GridWidth is the width of the point grid in grid points. GridSpacing is the distance between

two adjacent grid points in the rectified image. Because the grid points are always mapped to the centers of their corresponding pixels a grid cell requires (GridSpacing + 1) × (GridSpacing + 1) pixels in the rectified image. Note however, that, of course, adjacent grid cells overlap by one pixel.

To compute the mapping Map, additionally the width ImageWidth and height ImageHeight of the images to be rectified must be passed.

MapType is used to specify the type of the output Map. If *'bilinear'* interpolation is chosen, Map consists of one image containing five channels. In the first channel for each pixel in the resulting image the linearized coordinates of the pixel in the input image is stored that is in the upper left position relative to the transformed coordinates. The four other channels contain the weights of the four neighboring pixels of the transformed coordinates which are used for the bilinear interpolation, in the following order:

2	3
4	5

The second channel, for example, contains the weights of the pixels that lie to the upper left relative to the transformed coordinates. If *'coord_map_sub_pix'* is chosen, Map consists of one vector field image, in which for each pixel of the resulting image the subpixel precise coordinates in the input image are stored.

As mentioned above, four adjacent pixels in the distorted image are required to interpolate the gray value of one pixel in the mapped image. If at least one of these pixels is located outside of the distorted image the gray value can not be calculated. The domain of the resulting Map domain is reduced accordingly.

In contrary to gen_grid_rectification_map, gen_arbitrary_distortion_map is used when the coordinates (Row,Column) of the grid points in the distorted image are already known or the relevant part of the image consist of regular grid structures, which the coordinates can be derived from.

If you want to re-use the created map in another program, you can save it as a multi-channel image with the operator write_image, using the format *'tiff'*.

Parameters

- ▷ **Map** (output_object) ..... multichannel-image ⇝ *object :* int4 / uint2 / vector_field
  Image containing the mapping data.
- ▷ **GridSpacing** (input_control) ..... integer ⇝ *integer*
  Distance of the grid points in the rectified image.
  Restriction: GridSpacing > 0
- ▷ **Row** (input_control) ..... point.y-array ⇝ *real*
  Row coordinates of the grid points in the distorted image.
- ▷ **Column** (input_control) ..... point.x-array ⇝ *real*
  Column coordinates of the grid points in the distorted image.
  Restriction: number(Row) == number(Column)
- ▷ **GridWidth** (input_control) ..... integer ⇝ *integer*
  Width of the point grid (number of grid points).
- ▷ **ImageWidth** (input_control) ..... extent.x ⇝ *integer*
  Width of the images to be rectified.
  Restriction: ImageWidth > 0
- ▷ **ImageHeight** (input_control) ..... extent.y ⇝ *integer*
  Height of the images to be rectified.
  Restriction: ImageHeight > 0
- ▷ **MapType** (input_control) ..... string ⇝ *string*
  Type of mapping.
  Default: 'bilinear'
  List of values: MapType ∈ {'bilinear', 'coord_map_sub_pix'}

Result

gen_arbitrary_distortion_map returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

gen_grid_rectification_map (Image, ConnectingLines : Map, Meshes : GridSpacing, Rotation, Row, Column, MapType :)

Compute the mapping between the distorted image and the rectified image based upon the points of a regular grid.

gen_grid_rectification_map calculates the mapping between the grid points (Row,Column), which have been actually detected in the distorted image Image (typically using saddle_points_sub_pix), and the corresponding grid points of the ideal regular point grid. First, all paths that lead from their initial point via exactly four different connecting lines back to the initial point are assembled from the grid points (Row,Column) and the connecting lines ConnectingLines (detected by connect_grid_points). In case that the input of grid points (Row,Column) and of connecting lines ConnectingLines was meaningful, one such 'mesh' corresponds to exactly one grid cell in the rectification grid. Afterwards, the meshes are combined to the point grid. According to the value of Rotation, the point grid is rotated by *0*, *90*, *180* or *270* degrees. Note that the point grid does not necessarily have the correct orientation. When passing *'auto'* in Rotation, the point grid is rotated such that the black circular mark in the rectification grid is positioned to the left of the white one (see also create_rectification_grid). Finally, the mapping Map between the distorted image and the rectified image is calculated by interpolation between the grid points. Each grid cell, for which the coordinates (Row,Column) of all four corner points are known, is projected onto a square of GridSpacing × GridSpacing pixels.

MapType is used to specify the type of the output Map. If *'bilinear'* interpolation is chosen, Map consists of one image containing five channels. In the first channel for each pixel in the resulting image the linearized coordinates of the pixel in the input image is stored that is in the upper left position relative to the transformed coordinates. The four other channels contain the weights of the four neighboring pixels of the transformed coordinates which are used for the bilinear interpolation, in the following order:

2	3
4	5

The second channel, for example, contains the weights of the pixels that lie to the upper left relative to the transformed coordinates. If *'coord_map_sub_pix'* is chosen, Map consists of one vector field image, in which for each pixel of the resulting image the subpixel precise coordinates in the input image are stored.

gen_grid_rectification_map additionally returns the calculated meshes as XLD contours in Meshes.

In contrary to gen_arbitrary_distortion_map, gen_grid_rectification_map and its predecessors are used when the coordinates (Row,Column) of the grid points in the distorted image are neither known nor can be derived from the image contents.

If you want to re-use the created map in another program, you can save it as a multi-channel image with the operator write_image, using the format *'tiff'*.

Attention

Each input XLD contour ConnectingLines must own the global attribute *'bright_dark'*, as it is described with connect_grid_points!

Parameters

▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2
Input image.

▷ **ConnectingLines** (input_object) ..... xld-array ⇝ *object*
Input contours.

▷ **Map** (output_object) ..... multichannel-image ⇝ *object :* int4 / uint2 / vector_field
Image containing the mapping data.

▷ **Meshes** (output_object) ..... xld-array ⇝ *object*
Output contours.

▷ **GridSpacing** (input_control) ..... integer ⇝ *integer*
Distance of the grid points in the rectified image.
Restriction: GridSpacing > 0

▷ **Rotation** (input_control) ..... string ⇝ *string* / integer
Rotation to be applied to the point grid.
Default: 'auto'
List of values: `Rotation` ∈ {'auto', 0, 90, 180, 270}

▷ **Row** (input_control) ..... point.y-array ⇝ *real*
Row coordinates of the grid points.

▷ **Column** (input_control) ..... point.x-array ⇝ *real*
Column coordinates of the grid points.
Restriction: number(Column) == number(Row)

▷ **MapType** (input_control) ..... string ⇝ *string*
Type of mapping.
Default: 'bilinear'
List of values: `MapType` ∈ {'bilinear', 'coord_map_sub_pix'}

Result

`gen_grid_rectification_map` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`gen_arbitrary_distortion_map`

Module

Calibration

26.5 Hough

hough_circle_trans (Region : HoughImage : Radius :)

Return the Hough-Transform for circles with a given radius.

The operator `hough_circle_trans` calculates the Hough transform for circles with a certain `Radius` in the regions passed by `Region`. Hereby the centers of all possible circles in the parameter space (the Hough or accumulator space respectively) will be accumulated for each point in the image space. Circle hypotheses supported by many points in the input region thereby generate a maximum in the area showing the circle's center in the output image (`HoughImage`). The circles' centers in the image space can be deduced from the coordinates of these maximums by subtracting the `Radius`. If more than one radius is transmitted, all Hough images will be shifted according to the maximal radius.

Parameters

▷ **Region** (input_object) . . . . . region ⇝ *object*
Binary edge image in which the circles are to be detected.

▷ **HoughImage** (output_object) . . . . . image(-array) ⇝ *object :* int2
Hough transform for circles with a given radius.
Number of elements: HoughImage == Radius

▷ **Radius** (input_control) . . . . . integer(-array) ⇝ *integer*
Radius of the circle to be searched in the image.
Number of elements: 1 <= Radius <= 500
Default: 12
Value range: 3 ≤ Radius (lin)
Minimum increment: 1
Recommended increment: 1

Result

The operator `hough_circle_trans` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator `set_system ('no_object_result',<Result>)`, the behavior in case of empty region is set via `set_system ('empty_region_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

hough_circles (RegionIn : RegionOut : Radius, Percent, Mode :)

Detect centers of circles for a specific radius using the Hough transform.

`hough_circles` detects the centers of circles in regions with the help of the Hough transform for circles with a specific radius.

Parameters

▷ **RegionIn** (input_object) . . . . . region ⇝ *object*
Binary edge image in which the circles are to be detected.

▷ **RegionOut** (output_object) . . . . . region(-array) ⇝ *object*
Centers of those circles which are included in the edge image by `Percent` percent.
Number of elements: RegionOut == Radius * Percent * Mode

▷ **Radius** (input_control) . . . . . integer(-array) ⇝ *integer*
Radius of the circle to be searched in the image.
Number of elements: 1 <= Radius <= 500
Default: 12
Value range: 2 ≤ `Radius` ≤ 500 (lin)
Minimum increment: 1
Recommended increment: 1

▷ **Percent** (input_control) . . . . . integer(-array) ⇝ *integer*
Indicates the percentage (approximately) of the (ideal) circle which must be present in the edge image `RegionIn`.
Number of elements: 1 <= Percent <= 100
Default: 60
Value range: 10 ≤ `Percent` ≤ 100 (lin)
Minimum increment: 1
Recommended increment: 5

▷ **Mode** (input_control) . . . . . integer(-array) ⇝ *integer*
The mode defines the position of the circle in question:
0 - the radius is equivalent to the outer border of the set pixels.
1 - the radius is equivalent to the centers of the circle lines' pixels.
2 - both 0 and 1 (a little more fuzzy, but more reliable in contrast to circles set slightly differently, necessitates 50 % more processing capacity compared to 0 or 1 alone).
Number of elements: 1 <= Mode <= 3
List of values: Mode ∈ {0, 1, 2}

Result

The operator hough_circles returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>), the behavior in case of empty region is set via set_system ('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

hough_line_trans (Region : HoughImage : AngleResolution :)

Produce the Hough transform for lines within regions.

The operator hough_line_trans calculates the Hough transform for lines in those regions transmitted by Region. Thereby the angles and the lengths of the lines' normal vectors are registered in the parameter space (the Hough- or accumulator space respectively). This means that the parametrization is executed according to the HNF.

The result is registered in a newly generated Int2-Image (HoughImage), whereby the x-axis is equivalent to the angle between the normal vector and the x-axis (in the original image), and the y-axis is equivalent to the distance of the line from the origin.

The angle ranges from -90 to 180 degrees and will be registered with a resolution of $1/$AngleResolution, which means that one pixel in x-direction is equivalent to $1/$AngleResolution and that the HoughImage has a width of $270 *$ AngleResolution $+ 1$ pixel. The height of the HoughImage corresponds to the distance between the lower right corner of the surrounding rectangle of the input region and the origin.

The maxima in the result image are equivalent to the parameter values of the lines in the original image.

Parameters

▷ **Region** (input_object) . . . . . region ⇝ *object*
Binary edge image in which lines are to be detected.

▷ **HoughImage** (output_object) . . . . . image ⇝ *object :* int2
Hough transform for lines.

▷ **AngleResolution** (input_control) . . . . . integer ⇝ *integer*
Adjusting the resolution in the angle area.
Default: 4
List of values: AngleResolution ∈ {1, 2, 4, 8}

Result

The operator hough_line_trans returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>), the behavior in case of empty region is set via set_system ('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

hough_circle_trans, gen_region_hline

Module

Foundation

hough_line_trans_dir (ImageDir : HoughImage : DirectionUncertainty, AngleResolution :)

Compute the Hough transform for lines using local gradient direction.

The operator hough_line_trans_dir calculates the Hough transform for lines in those regions passed in the domain of ImageDir. To do so, the angles and the lengths of the lines' normal vectors are registered in the parameter space (the so-called Hough or accumulator space).

In contrast to hough_line_trans, additionally the edge direction in ImageDir (e.g., returned by sobel_dir or edges_image) is taken into account. This results in a more efficient computation and in a reduction of the noise in the Hough space.

The parameter DirectionUncertainty describes how much the edge direction of the individual points within a line is allowed to vary. For example, with DirectionUncertainty = *10* a horizontal line (i.e., edge direction = 0 degrees) may contain points with an edge direction between -10 and +10 degrees. The higher DirectionUncertainty is chosen, the higher the computation time will be. For DirectionUncertainty = *180* hough_line_trans_dir shows the same behavior as hough_line_trans, i.e., the edge direction is ignored. DirectionUncertainty should be chosen at least as high as the step width of the edge direction stored in ImageDir. The minimum step width is 2 degrees (defined by the image type 'direction').

The result is stored in a newly generated UINT2-Image (HoughImage), where the x-axis (i.e., columns) represents the angle between the normal vector and the x-axis of the original image, and the y-axis (i.e., rows) represents the distance of the line from the origin.

The angle ranges from -90 to 180 degrees and will be stored with a resolution of $1/$AngleResolution, which means that one pixel in x-direction is equivalent to $1/$AngleResolution degrees and that the HoughImage has a width of $270 * $AngleResolution$ + 1$ pixels. The height of the HoughImage corresponds to the distance between the lower right corner of the surrounding rectangle of the input region and the origin.

The local maxima in the result image are equivalent to the parameter values of the lines in the original image.

Parameters

▷ **ImageDir** (input_object) ..... singlechannelimage ⇝ *object :* direction
Image containing the edge direction. The edges must be described by the image domain.

▷ **HoughImage** (output_object) ..... image ⇝ *object :* uint2
Hough transform.

▷ **DirectionUncertainty** (input_control) ..... angle.deg ⇝ *integer*
Uncertainty of the edge direction (in degrees).
Default: 2
Value range: $2 \leq$ DirectionUncertainty ≤ 180
Minimum increment: 2

▷ **AngleResolution** (input_control) ..... integer ⇝ *integer*
Resolution in the angle area (in 1/degrees).
Default: 4
List of values: AngleResolution $\in \{1, 2, 4, 8\}$

Result

The operator hough_line_trans_dir returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input is set via the operator set_system('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

hough_lines (RegionIn : : AngleResolution, Threshold, AngleGap, DistGap : Angle, Dist)

Detect lines in edge images with the help of the Hough transform and returns it in HNF.

The operator hough_lines allows the selection of linelike structures in a region, whereby it is not necessary that the individual points of a line are connected. This process is based on the Hough transform.

The parameter AngleResolution defines the degree of exactness concerning the determination of the angles. It amounts to 1/AngleResolution degree. The parameter Threshold determines by how many points of the original region a line's hypothesis must at least be supported in order to be selected into the output. The parameters AngleGap and DistGap define a neighborhood of the points in the Hough image in order to determine the local maxima: AngleGap describes the minimum distance of two maxima in the Hough image in angle direction and DistGap in distance direction, respectively. Thus, maxima exceeding Threshold but lying close to an even higher maximum are eliminated. If multiple maxima in this neighborhood are equally high, all of them are returned. This elimination can particularly be helpful when searching for short and long lines simultaneously. The lines are returned in Hessian Normal Form (HNF), that is by the direction Angle and length Dist of their normal vectors.

Parameters

▷ **RegionIn** (input_object) ..... region ⇝ *object*
Binary edge image in which the lines are to be detected.

▷ **AngleResolution** (input_control) ..... integer ⇝ *integer*
Adjusting the resolution in the angle area.
Default: 4
List of values: AngleResolution ∈ {1, 2, 4, 8}

▷ **Threshold** (input_control) ..... integer ⇝ *integer*
Threshold value in the Hough image.
Default: 100
Value range: 2 ≤ Threshold

▷ **AngleGap** (input_control) ..... integer ⇝ *integer*
Minimal distance of two maxima in the Hough image (direction: angle).
Default: 5
Value range: 0 ≤ AngleGap

▷ **DistGap** (input_control) . . . . . integer ⇝ *integer*
Minimal distance of two maxima in the Hough image (direction: distance).
Default: 5
Value range: 0 ≤ DistGap

▷ **Angle** (output_control) . . . . . hesseline.angle.rad-array ⇝ *real*
Angles (in radians) of the detected lines' normal vectors.
Value range: -1.5707963 ≤ Angle ≤ 3.1415927

▷ **Dist** (output_control) . . . . . hesseline.distance-array ⇝ *real*
Distance of the detected lines from the origin.
Number of elements: Dist == Angle
Value range: 0 ≤ Dist

Result

The operator hough_lines returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>), the behavior in case of empty region is set via set_system ('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

```
hough_lines_dir ( ImageDir : HoughImage,
    Lines : DirectionUncertainty, AngleResolution, Smoothing,
    FilterSize, Threshold, AngleGap, DistGap, GenLines : Angle,
    Dist )
```

Detect lines in edge images with the help of the Hough transform using local gradient direction and return them in normal form.

The operator hough_lines_dir selects line-like structures in a region based on the Hough transform. The individual points of a line can be unconnected. The region is given by the domain of ImageDir.

In contrast to hough_lines, additionally the edge direction in ImageDir (e.g., returned by sobel_dir or edges_image) is taken into account. This results in a more efficient computation and in a reduction of the noise in the Hough space.

The parameter DirectionUncertainty describes how much the edge direction of the individual points within a line is allowed to vary. For example, with DirectionUncertainty = *10* a horizontal line (i.e., edge direction = 0 degrees) may contain points with an edge direction between -10 and +10 degrees. The higher DirectionUncertainty is chosen, the higher the computation time will be. For DirectionUncertainty = *180* hough_lines_dir shows the same behavior as hough_lines, i.e., the edge direction is ignored. DirectionUncertainty should be chosen at least as high as the step width of the edge direction stored in ImageDir. The minimum step width is 2 degrees (defined by the image type 'direction').

The parameter AngleResolution defines how accurately the angles are determined. The accuracy amounts to 1/AngleResolution degrees. A subsequent smoothing of the Hough space results in an increased stability. The smoothing filter can be selected by Smoothing, the degree of smoothing by the parameter FilterSize (see mean_image or gauss_image for details). The parameter Threshold determines by how many points

of the original region a line's hypothesis must at least be supported in order to be selected into the output. The parameters AngleGap and DistGap define a neighborhood of the points in the Hough image in order to determine the local maxima: AngleGap describes the minimum distance of two maxima in the Hough image in angle direction and DistGap in distance direction, respectively. Thus, maxima exceeding Threshold but lying close to an even higher maximum are eliminated. If multiple maxima in this neighborhood are equally high, all of them are returned. This elimination can particularly be helpful when searching for short and long lines simultaneously. Besides the not smoothed Hough image HoughImage, the lines are returned in Hessian Normal Form (HNF), that is by the direction Angle and length Dist of their normal vectors. If the parameter GenLines is set to *'true'*, additionally those regions in ImageDir are returned that contributed to the local maxima in Hough space. They are stored in the parameter Lines.

Parameters

- ▷ **ImageDir** (input_object) . . . . . singlechannelimage ⇝ *object :* direction
  Image containing the edge direction. The edges are described by the image domain.
- ▷ **HoughImage** (output_object) . . . . . image ⇝ *object :* uint2
  Hough transform.
- ▷ **Lines** (output_object) . . . . . region-array ⇝ *object*
  Regions of the input image that contributed to the local maxima.
- ▷ **DirectionUncertainty** (input_control) . . . . . angle.deg ⇝ *integer*
  Uncertainty of edge direction (in degrees).
  Default: 2
  Value range: 2 ≤ DirectionUncertainty ≤ 180
  Minimum increment: 2
- ▷ **AngleResolution** (input_control) . . . . . integer ⇝ *integer*
  Resolution in the angle area (in 1/degrees).
  Default: 4
  List of values: AngleResolution ∈ {1, 2, 4, 8}
- ▷ **Smoothing** (input_control) . . . . . string ⇝ *string*
  Smoothing filter for hough image.
  Default: 'mean'
  List of values: Smoothing ∈ {'none', 'mean', 'gauss'}
- ▷ **FilterSize** (input_control) . . . . . integer ⇝ *integer*
  Required smoothing filter size.
  Default: 5
  List of values: FilterSize ∈ {3, 5, 7, 9, 11}
- ▷ **Threshold** (input_control) . . . . . integer ⇝ *integer*
  Threshold value in the Hough image.
  Default: 100
  Value range: 1 ≤ Threshold
- ▷ **AngleGap** (input_control) . . . . . integer ⇝ *integer*
  Minimum distance of two maxima in the Hough image (direction: angle).
  Default: 5
  Value range: 0 ≤ AngleGap
- ▷ **DistGap** (input_control) . . . . . integer ⇝ *integer*
  Minimum distance of two maxima in the Hough image (direction: distance).
  Default: 5
  Value range: 0 ≤ DistGap
- ▷ **GenLines** (input_control) . . . . . string ⇝ *string*
  Create line regions if *'true'*.
  Default: 'true'
  List of values: GenLines ∈ {'true', 'false'}
- ▷ **Angle** (output_control) . . . . . hesseline.angle.rad-array ⇝ *real*
  Angles (in radians) of the detected lines' normal vectors.
  Value range: -1.5707963 ≤ Angle ≤ 3.1415927
- ▷ **Dist** (output_control) . . . . . hesseline.distance-array ⇝ *real*
  Distance of the detected lines from the origin.
  Number of elements: Dist == Angle
  Value range: 0 ≤ Dist

Result

The operator hough_lines returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

select_matching_lines (RegionIn : RegionLines : AngleIn, DistIn, LineWidth, Thresh : AngleOut, DistOut)

Select those lines from a set of lines (in HNF) which fit best into a region.

Lines which fit best into a region can be selected from a set of lines which are available in HNF with the help of the operator select_matching_lines; the region itself is also transmitted as a parameter (RegionIn). The width of the lines can be indicated by the parameter LineWidth. The selected lines will be returned in HNF and as regions (RegionLines).

The lines are selected iteratively in a loop: At first, the line showing the greatest overlap with the input region is selected from the set of input lines. This line will then be taken over into the output set whereby all points belonging to that line will not be considered in the further steps determining overlaps. The loop will be left when the maximum overlap value of the region and the lines falls below a certain threshold value (Thresh). The selected lines will be returned as regions as well as in HNF.

Parameters

▷ **RegionIn** (input_object) . . . . . region ⇝ *object*
Region in which the lines are to be matched.

▷ **RegionLines** (output_object) . . . . . region(-array) ⇝ *object*
Region array containing the matched lines.

▷ **AngleIn** (input_control) . . . . . hesseline.angle.rad(-array) ⇝ *real*
Angles (in radians) of the normal vectors of the input lines.
Value range: -1.5707963 ≤ AngleIn ≤ 3.1415927

▷ **DistIn** (input_control) . . . . . hesseline.distance(-array) ⇝ *real*
Distances of the input lines form the origin.
Number of elements: DistIn == AngleIn

▷ **LineWidth** (input_control) . . . . . integer ⇝ *integer*
Widths of the lines.
Default: 7
Value range: 1 ≤ LineWidth

▷ **Thresh** (input_control) . . . . . integer ⇝ *integer*
Threshold value for the number of line points in the region.
Default: 100
Value range: 1 ≤ Thresh

▷ **AngleOut** (output_control) ..... hesseline.angle.rad(-array) ⇝ *real*
Angles (in radians) of the normal vectors of the selected lines.
Number of elements: AngleOut <= AngleIn
Value range: -1.5707963 ≤ AngleOut ≤ 3.1415927

▷ **DistOut** (output_control) ..... hesseline.distance(-array) ⇝ *real*
Distances of the selected lines from the origin.
Number of elements: DistOut == AngleOut
Value range: 0 ≤ DistOut

Result

The operator select_matching_lines returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input regions available) is set via the operator set_system ('no_object_result',<Result>), the behavior in case of empty region is set via set_system ('empty_region_result',<Result>). If necessary an exception is raised.

Execution Information

26.6 Interpolation

clear_scattered_data_interpolator (
: : ScatteredDataInterpolatorHandle :)

Clear a scattered data interpolator.

clear_scattered_data_interpolator clears the scattered data interpolator given by ScatteredDataInterpolatorHandle and frees all memory required for the interpolator. After calling clear_scattered_data_interpolator, the scattered data interpolator can no longer be used. The handle ScatteredDataInterpolatorHandle becomes invalid.

Parameters

▷ **ScatteredDataInterpolatorHandle** (input_control) ..... scattered_data_interpolator(-array) ⇝ *handle*
Handle of the scattered data interpolator

Result

If the parameters are valid, the operator clear_scattered_data_interpolator returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- ScatteredDataInterpolatorHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_scattered_data_interpolator, interpolate_scattered_data

Module

Foundation

create_scattered_data_interpolator (: : Method, Rows, Columns, Values, GenParamName, GenParamValue : ScatteredDataInterpolatorHandle)

Creates an interpolator for the interpolation of scattered data.

create_scattered_data_interpolator creates the interpolator ScatteredDataInterpolatorHandle for the interpolation of scattered data, given as data points in Rows and Columns with the corresponding measurement Values. With the parameter Method the algorithm is specified, which should be used for the interpolation with interpolate_scattered_data. So far, only the *'thin_plate_splines'* are supported. This method interpolates on a global scale, which means that all points are regarded for the interpolation, no matter how far away they are. The influence of far points is correlated to $r^2 \cdot \log(r)$ where r defines the distance of two points. In comparison to interpolate_scattered_data_image, create_scattered_data_interpolator also supports subpixel coordinates for Rows and Columns. After the creation, interpolate_scattered_data is called for the interpolation of the unknown values. By splitting up the creation (create_scattered_data_interpolator) and the evaluation (interpolate_scattered_data) of the interpolator, interpolating at different data points in subsequent steps becomes more efficient since the interpolator has to be created only once.

The following parameters can be adjusted with GenParamName and GenParamValue:

'alpha': The parameter *'alpha'* is a smoothing factor. For *'alpha'* $= 0$, all points passed in Rows, Columns, and Values are interpolated exactly. With *'alpha'* getting larger, the interpolation smoothes the points in way that all interpolated points lie on a common plane.
Default: 0
Restriction: 'alpha' ≥ 0

Parameters

▷ **Method** (input_control) . . . . . string ⇝ *string*
Method for the interpolation
Default: 'thin_plate_splines'
Suggested values: Method ∈ {'thin_plate_splines'}

▷ **Rows** (input_control) . . . . . point.y-array ⇝ *real* / integer
Row coordinates of the points used for the interpolation

▷ **Columns** (input_control) . . . . . point.x-array ⇝ *real* / integer
Column coordinates of the points used for the interpolation

▷ **Values** (input_control) . . . . . number-array ⇝ *real* / integer
Values of the points used for the interpolation

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters that can be adjusted
Default: []
Suggested values: GenParamName ∈ {'alpha'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / string / integer
Values of the generic parameters that can be adjusted
Default: []
Suggested values: GenParamValue ∈ {0, 1.0, 10.0, 100.0}

▷ **ScatteredDataInterpolatorHandle** (output_control) . . . . . scattered_data_interpolator ⇝ *handle*
Handle of the scattered data interpolator

Result

If the parameters are valid, the operator create_scattered_data_interpolator returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

interpolate_scattered_data

Module

Foundation

interpolate_scattered_data (: : ScatteredDataInterpolatorHandle, Row, Column : ValueInterpolated)

Interpolation of scattered data using a scattered data interpolator.

interpolate_scattered_data interpolates the values of the scattered data points (Row,Column) by using the scattered data interpolator ScatteredDataInterpolatorHandle and returns the result in ValueInterpolated. In comparison to interpolate_scattered_data_image, interpolate_scattered_data also supports subpixel coordinates for Row and Column. Before calling interpolate_scattered_data, the scattered data interpolator must be created with create_scattered_data_interpolator.

Parameters

▷ **ScatteredDataInterpolatorHandle** (input_control) . . . . . scattered_data_interpolator ⇝ *handle*
Handle of the scattered data interpolator

▷ **Row** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
Row coordinates of points to be interpolated

▷ **Column** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
Column coordinates of points to be interpolated

▷ **ValueInterpolated** (output_control) . . . . . number(-array) ⇝ *real* / integer
Values of interpolated points

Result

If the parameters are valid, the operator interpolate_scattered_data returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_scattered_data_interpolator

Possible Successors

clear_scattered_data_interpolator, gen_object_model_3d_from_points

Module

Foundation

interpolate_scattered_data_image (Image, RegionInterpolate : ImageInterpolated : Method, GenParamName, GenParamValue :)

Interpolation of an image.

interpolate_scattered_data_image interpolates the Image at the region RegionInterpolate and returns the result in ImageInterpolated. The difference of the domain of the Image and the region RegionInterpolate specifies the valid data points that can be used for the interpolation whereas RegionInterpolate specifies the points, where the gray values of the Image should be determined. With the parameter Method the interpolation algorithm is specified. So far, only the *'thin_plate_splines'* are supported. This method interpolates on a global scale, which means that all points are regarded for the interpolation, no matter how far away they are. The influence of far points is correlated to $r^2 \cdot \log(r)$ where r defines the distance of two points. If the same Image is interpolated at different points in subsequent steps, the operator create_scattered_data_interpolator may be more efficient.

The following parameters can be adjusted with GenParamName and GenParamValue:

'alpha': The parameter *'alpha'* is a smoothing factor. For *'alpha'* = 0, all points in the image Image are interpolated exactly. With *'alpha'* getting larger, the interpolation smoothes the image points in way that all interpolated points of the result image ImageInterpolated lie on a common plane.
Default: is *0*
Restriction: 'alpha' $\geq$ *0*

interpolate_scattered_data_image is best used with very few data points, e.g, less than 1000. In order to reconstruct destroyed image data in the region RegionInterpolate, the data points should be reduced to an appropriate number, e.g., by only using the border pixels of the hole regions. An example program is shown below.

Parameters

- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte / uint2 / real
  Image to interpolate
- ▷ **RegionInterpolate** (input_object) ..... region ⇝ *object*
  Region to interpolate
- ▷ **ImageInterpolated** (output_object) ..... singlechannelimage ⇝ *object :* real
  Interpolated image
- ▷ **Method** (input_control) ..... string ⇝ *string*
  Method for the interpolation
  Default: 'thin_plate_splines'
  Suggested values: Method ∈ {'thin_plate_splines'}
- ▷ **GenParamName** (input_control) ..... attribute.name-array ⇝ *string*
  Names of the generic parameters that can be adjusted
  Default: []
  Suggested values: GenParamName ∈ {'alpha'}
- ▷ **GenParamValue** (input_control) ..... attribute.value-array ⇝ *string* / integer / real
  Values of the generic parameters that can be adjusted
  Default: []
  Suggested values: GenParamValue ∈ {0, 1.0, 10.0, 100.0}

Example

```
* This example program shows how to use the scattered data interpolator
* to fill holes in an image
gen_image_surface_second_order (ImageData, 'real', 1, 1, 0, 0, 0, 1, \
                                24, 24, 48, 48)
gen_circle (Circle, 12, 12, 6)
difference (ImageData, Circle, Region)
reduce_domain (ImageData, Region, ImageReduced)
dev_clear_window ()
dev_display (ImageReduced)
stop()
*
* Select only border pixels for the interpolation
dilation_circle (Circle, CircleDilation, 1.5)
intersection (CircleDilation, Region, RegionBorderData)
dev_clear_window ()
```

```
dev_display (ImageReduced)
dev_display (RegionBorderData)
stop()
*
* Interpolate pixels
reduce_domain (ImageData, RegionBorderData, ImageReducedBorder)
interpolate_scattered_data_image (ImageReducedBorder, Circle, \
                                  ImageInterpolated, \
                                  'thin_plate_splines', [], [])
paint_gray (ImageInterpolated, ImageData, ImageFilled)
dev_clear_window ()
dev_display (ImageFilled)
```

Result

If the parameters are valid, the operator `interpolate_scattered_data_image` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`interpolate_scattered_data_points_to_image`

Module

Foundation

interpolate_scattered_data_points_to_image (
: ImageInterpolated : Method, Rows, Columns, Values, Width, Height, GenParamName, GenParamValue :)

Creating an image from the interpolation of scattered data.

`interpolate_scattered_data_points_to_image` interpolates the data points, given in `Rows` and `Columns` with the corresponding measurement `Values`, and returns the result in `ImageInterpolated`. The size of the output image is defined by its `Width` and its `Height` with the upper left corner at (0,0). In order to interpolate at negative coordinates of (`Rows`,`Columns`), simply translate all input points accordingly. With the parameter `Method` the interpolation algorithm is specified. So far, only the *'thin_plate_splines'* are supported. This method interpolates on a global scale, which means that all points are regarded for the interpolation, no matter how far away they are. The influence of far points is correlated to $r^2 \cdot \log(r)$ where r defines the distance of two points. In comparison to `interpolate_scattered_data_image`, `interpolate_scattered_data_points_to_image` also supports subpixel coordinates for `Rows` and `Columns`. If the same data points (`Rows`,`Columns`,`Values`) are used for the interpolation of different output images in subsequent steps, the operator `create_scattered_data_interpolator` may be more efficient.

The following parameters can be adjusted with `GenParamName` and `GenParamValue`:

'alpha': The parameter *'alpha'* is a smoothing factor. For *'alpha'* = 0, all points passed in (`Rows`,`Columns`,`Values`) are interpolated exactly. With *'alpha'* getting larger, the interpolation smoothes the points in way that all interpolated points of the result image `ImageInterpolated` lie on a common plane.

Default: 0.

Restriction: 'alpha' ≥ 0

Parameters

▷ **ImageInterpolated** (output_object) . . . . . singlechannelimage ⇝ *object :* real
Interpolated image

▷ **Method** (input_control) . . . . . string ⇝ *string*
Method for the interpolation
Default: 'thin_plate_splines'
Suggested values: Method ∈ {'thin_plate_splines'}

▷ **Rows** (input_control) . . . . . point.y-array ⇝ *real* / integer
Row coordinates of the points used for the interpolation

▷ **Columns** (input_control) . . . . . point.x-array ⇝ *real* / integer
Column coordinates of the points used for the interpolation

▷ **Values** (input_control) . . . . . number-array ⇝ *real* / integer
Values of the points used for the interpolation

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the interpolated image
Default: 640

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the interpolated image
Default: 480

▷ **GenParamName** (input_control) . . . . . attribute.name-array ⇝ *string*
Names of the generic parameters that can be adjusted
Default: []
Suggested values: GenParamName ∈ {'alpha'}

▷ **GenParamValue** (input_control) . . . . . attribute.value-array ⇝ *real* / string / integer
Values of the generic parameters that can be adjusted
Default: []
Suggested values: GenParamValue ∈ {0, 1.0, 10.0, 100.0}

Result

If the parameters are valid, the operator interpolate_scattered_data_points_to_image returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

interpolate_scattered_data_image

Module

Foundation

26.7 Lines

line_orientation (: : RowBegin, ColBegin, RowEnd, ColEnd : Phi)

Calculate the orientation of lines.

The operator line_orientation returns the orientation ($-pi/2 < \texttt{Phi} \leq pi/2$) of the given lines. If more than one line is to be treated the line and column indices can be passed as tuples. In this case Phi is, of course, also a tuple and contains the corresponding orientations.

Parameters

▷ **RowBegin** (input_control) . . . . . line.begin.y(-array) ⇝ *real* / integer
Row coordinates of the starting points of the input lines.

▷ **ColBegin** (input_control) . . . . . line.begin.x(-array) ⇝ *real* / integer
Column coordinates of the starting points of the input lines.

▷ **RowEnd** (input_control) . . . . . line.end.y(-array) ⇝ *real* / integer
Row coordinates of the ending points of the input lines.

▷ **ColEnd** (input_control) . . . . . line.end.x(-array) ⇝ *real* / integer
Column coordinates of the ending points of the input lines.

▷ **Phi** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Orientation of the input lines.

Result

`line_orientation` always returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`line_position`

See also

`line_position`, `detect_edge_segments`

Module

Foundation

line_position (: : RowBegin, ColBegin, RowEnd, ColEnd : RowCenter, ColCenter, Length, Phi)

Calculate the center of gravity, length, and orientation of a line.

The operator `line_position` returns the center (`RowCenter`, `ColCenter`), the (Euclidean) length (`Length`) and the orientation ($-pi/2 <$ `Phi` $\leq pi/2$) of the given lines. If more than one line is to be treated the line and column indices can be passed as tuples. In this case the output parameters, of course, are also tuples.

The routine is applied, for example, to model lines in order to determine search regions for the edge detection (`detect_edge_segments`).

Parameters

▷ **RowBegin** (input_control) . . . . . line.begin.y(-array) ⇝ *real* / integer
Row coordinates of the starting points of the input lines.

▷ **ColBegin** (input_control) . . . . . line.begin.x(-array) ⇝ *real* / integer
Column coordinates of the starting points of the input lines.

▷ **RowEnd** (input_control) . . . . . line.end.y(-array) ⇝ *real* / integer
Row coordinates of the ending points of the input lines.

▷ **ColEnd** (input_control) . . . . . line.end.x(-array) ⇝ *real* / integer
Column coordinates of the ending points of the input lines.

▷ **RowCenter** (output_control) . . . . . point.y(-array) ⇝ *real*
Row coordinates of the centers of gravity of the input lines.

▷ **ColCenter** (output_control) . . . . . point.x(-array) ⇝ *real*
Column coordinates of the centers of gravity of the input lines.

▷ **Length** (output_control) . . . . . real(-array) ⇝ *real*
Euclidean length of the input lines.

▷ **Phi** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Orientation of the input lines.

Result

`line_position` always returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

26.8 Mosaicking

```
adjust_mosaic_images ( Images : CorrectedImages : From, To,
    ReferenceImage, HomMatrices2D, EstimationMethod,
    EstimateParameters, OECFModel : )
```

Apply an automatic color correction to panorama images.

`adjust_mosaic_images` performs the radiometric adjustment of images in panoramas. The images to be corrected have to be passed in `Images`, the corrected images will be returned in `CorrectedImages`.

The parameters `From` and `To` must contain the source and destination indices of all image pairs in the panorama. The projective 3x3-matrix of each image pair has to be passed in `HomMatrices2D`. The image, which will be used as the reference for brightness and white balance, is selected with the parameter `ReferenceImage`.

This means, that one image specifies the "ideal" brightness and white balance settings. All other images will be corrected such that their brightness and white balance match that of the reference image. In other words, the reference image will not be changed, but all other images will be.

`EstimationMethod` is used for choosing whether a fast but less accurate, or a slower but more accurate determination method should be used. This is done by setting `EstimationMethod` either to *'standard'* or *'gold_standard'*.

The methods based on *'standard'* use only the average gray value difference of all images in the overlap area between each image pair. With *'gold_standard'* the gray value difference for each pixel in the overlap area is taken into account explicitly.

The error function that is minimized in all cases is computed as the summed square of the difference between the corresponding gray values.

The availability of the individual method is depending on the selected `EstimateParameters`, which determines the model to be used for estimating the radiometric adjustment terms. It is always possible to determine the

amount of vignetting in the images by selecting *'vignetting'*. However, if selected, EstimationMethod must be set to *'gold_standard'*. For the remainder of the radiometric adjustment three different options are available:

Estimation of vignetting in images is based on the commonly known

$$\cos^4 Alpha$$

approach. This approach assumes that vignetting does not exist in the center of the image and increases with the opening angle by the above equation.

1. Image adjustment with the additive model. This should only be used to adjust images with very small differences in exposure or white balance. To choose this method, EstimateParameters must be set to *'add_gray'*. This model can be selected either exclusively and only with EstimationMethod = *'standard'* or in combination with EstimateParameters = *'vignetting'* and only with EstimationMethod = *'gold_standard'*.

This model is based on the assumption, that the gray value differences between the images can be corrected by adding an individual value to each image accept the reference image. Basically, the modification to every image can be expressed as a call of scale_image:

```
scale_image(Image_n,CorrectedImage_n,1.0,Add_n)
```

where Add_n is the correction term for this image.

2. Image adjustment with the linear model. In this model, images are expected to be taken with a camera using a linear transfer function. The adjustment terms are consequently represented as multiplication factors. To select this model, EstimateParameters must be set to *'mult_gray'*. It can be called with EstimationMethod = *'standard'* or EstimationMethod = *'gold_standard'*. A combined call with EstimateParameters = *'vignetting'* is also possible, EstimationMethod must be set to *'gold_standard'* in that case.

This model is based on the assumption that the gray value differences between the images can be corrected by multiplying the gray values in each image by a factor. Basically, the modification to every image can again be expressed as a call of scale_image:

```
scale_image(Image_n,CorrectedImage_n,Mult_n,0)
```

where Mult_n is the correction term for this image.

3. Image adjustment with the calibrated model. In this model, images are assumed to be taken with a camera using a nonlinear transfer function. A function of the OECF class selected with OECFModel is used to approximate the actually used OECF in the process of image acquisition. As with the linear model, the correction terms are represented as multiplication factors. This model can be selected by choosing EstimateParameters = *['mult_gray','response']* and must be called with EstimationMethod = *'gold_standard'*. It is possible to determine the amount of vignetting as well in this case by choosing EstimateParameters = *'vignetting'*.

This model is similar to the linear model. However, in this case the camera may have a nonlinear response. This means that before the gray values of the images can be multiplied by their respective correction factor, the gray values must be backprojected to a linear response. To do so, the camera's response must be determined. Since the response usually does not change over an image sequence, this parameter is assumed to be constant throughout the whole image sequence.

Any kind of function could be considered to be used as an OECF. As in the operator radiometric_self_calibration, a polynomial fitting might be used, but for typical images in a mosaicking application this would not work very well. The reason for this is that polynomial fitting has too many parameters that need to be determined. Instead, only simpler types of response functions can be estimated. Currently, only so-called Laguerre-functions are available.

The response of a Laguerre-type OECF is determined by only one parameter called Phi. In a first step, the whole gray value spectrum (in case of 8bit images the values 0 to 255) is converted to floating point numbers in the interval [0:1]. Then, the OECF backprojection is calculated based on this and the resulting gray values are once again converted to the original interval.

The inverse transform of the gray values back to linear values based on a Laguerre-type OECF is described by the following equation:

$$I\_l = I\_nl + \frac{2}{\pi} \cdot \arctan\left(\frac{Phi \cdot \sin(\pi \cdot I\_nl)}{1 - Phi \cdot \cos(\pi \cdot I\_nl)}\right)$$

with I_l the linear gray value and I_nl the (nonlinear) gray value.

The parameter `OECFModel` is only used if the calibrated model has been chosen. Otherwise, any input for `OECFModel` will be ignored.

The parameter `EstimateParameters` can also be used to influence the performance and memory consumption of the operator. With *'no_cache'* the internal caching mechanism can be disabled. This switch only has and influence if `EstimationMethod` is set to *'gold_standard'*. Otherwise this switch will be ignored. When disabling the internal caching, the operator uses far less memory, but therefore calculates the corresponding gray value pairs in each iteration of the minimization algorithm again. Therefore, disabling caching is only advisable if all physical memory is used up at some point of the calculation and the operating system starts using swap space.

A second option to influence the performance is using subsampling. When setting `EstimateParameters` to *'subsampling_2'*, images are internally zoomed down by a factor of 2. Despite the suggested value list, not only factors of 2 and 4 are available, but any integer number might be specified by appending it to subsampling_ in `EstimateParameters`. With this, the amount of image data is tremendously reduced, which leads to a much faster computation of the internal minimization. In fact, using moderate subsampling might even lead to better results since it also decreases the influence of slightly misaligned pixels. Although subsampling also influences the minimization if `EstimationMethod` is set to *'standard'*, it is mostly useful for *'gold_standard'*.

Some more general remarks on using `adjust_mosaic_images` in applications:

- Estimation of vignetting will only work well if significant vignetting is visible in the images. Otherwise, the operator may lead to erratic results.
- Estimation of the response is rather slow because the problem is quite complex. Therefore, it is advisable not to determine the response in time critical applications. Apart from this, the response can only be determined correctly if there are relatively large brightness differences between the images.
- It is not possible to correct saturation. If there are saturated areas in an image, they will remain saturated.
- `adjust_mosaic_images` can only be used to correct different brightness in images, which is caused by different exposure (shutter time, aperture) or different light intensity. It cannot be used to correct brightness differences based on inhomogeneous illumination within each image.

Parameters

▷ **`Images`** (input_object) ..... (multichannel-)image-array ⇝ *object :* byte
Input images.

▷ **`CorrectedImages`** (output_object) ..... (multichannel-)image-array ⇝ *object :* byte
Output images.

▷ **`From`** (input_control) ..... integer-array ⇝ *integer*
List of source images.

▷ **`To`** (input_control) ..... integer-array ⇝ *integer*
List of destination images.

▷ **`ReferenceImage`** (input_control) ..... integer ⇝ *integer*
Reference image.

▷ **`HomMatrices2D`** (input_control) ..... real-array ⇝ *real*
Projective matrices.

▷ **`EstimationMethod`** (input_control) ..... string ⇝ *string*
Estimation algorithm for the correction.
Default: 'standard'
List of values: `EstimationMethod` ∈ {'standard', 'gold_standard'}

▷ **`EstimateParameters`** (input_control) ..... string(-array) ⇝ *string*
Parameters to be estimated.
Default: ['mult_gray']
Suggested values: `EstimateParameters` ∈ {'add_gray', 'mult_gray', 'response', 'vignetting', 'subsampling_2', 'subsampling_4', 'no_cache'}

▷ **`OECFModel`** (input_control) ..... string ⇝ *string*
Model of OECF to be used.
Default: ['laguerre']
List of values: `OECFModel` ∈ {'laguerre'}

Example

```
* For the input data to stationary_camera_self_calibration, please
* refer to the example for stationary_camera_self_calibration.
stationary_camera_self_calibration (4, 640, 480, 1, From, To, \
                                    HomMatrices2D, Rows1, Cols1, \
                                    Rows2, Cols2, NumMatches, \
                                    'gold_standard', \
                                    ['focus','principal_point'], \
                                    'true', CameraMatrix, Kappa, \
                                    RotationMatrices, X, Y, Z, Error)
adjust_mosaic_images(Images,CorrectedImages,From,To,1,HomMatrices2D, \
                     'gold_standard',['mult_gray','response'],'laguerre')
```

Result

If the parameters are valid, the operator `adjust_mosaic_images` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

bundle_adjust_mosaic (: : NumImages, ReferenceImage, MappingSource, MappingDest, HomMatrices2D, Rows1, Cols1, Rows2, Cols2, NumCorrespondences, Transformation : MosaicMatrices2D, Rows, Cols, Error)

Perform a bundle adjustment of an image mosaic.

`bundle_adjust_mosaic` performs a bundle adjustment of an image mosaic. This can be used to determine the geometry of a mosaic as robustly as possible, and hence to determine the transformations of the images in the mosaic more accurately than with single image pairs.

To achieve this, the projective transformation for each overlapping image pair in the mosaic should be determined with `proj_match_points_ransac`. For example, for a 2×2 block of images in the following layout

1	2
3	4

the following projective transformations should be determined, assuming that all images overlap each other: 1↦2, 1↦3, 1↦4, 2↦3, 2↦4 and 3↦4. The indices of the images that determine the respective transformation are given by `MappingSource` and `MappingDest`. The indices are start at 1. Consequently, in the above example `MappingSource` = *[1,1,1,2,2,3]* and `MappingDest` = *[2,3,4,3,4,4]* must be used. The number of images in the mosaic is given by `NumImages`. It is used to check whether each image can be reached by a chain of

transformations. The index of the reference image is given by ReferenceImage. On output, this image has the identity matrix as its transformation matrix.

The 3×3 projective transformation matrices that correspond to the image pairs are passed in HomMatrices2D. Additionally, the coordinates of the matched point pairs in the image pairs must be passed in Rows1, Cols1, Rows2, and Cols2. They can be determined from the output of proj_match_points_ransac with tuple_select or with the HDevelop function subset. To enable bundle_adjust_mosaic to determine which point pair belongs to which image pair, NumCorrespondences must contain the number of found point matches for each image pair.

The parameter Transformation determines the class of transformations that is used in the bundle adjustment to transform the image points. This can be used to restrict the allowable transformations. For Transformation = *'projective'*, projective transformations are used (see vector_to_proj_hom_mat2d). For Transformation = *'affine'*, affine transformations are used (see vector_to_hom_mat2d), for Transformation = *'similarity'*, similarity transformations (see vector_to_similarity), and for Transformation = *'rigid'* rigid transformations (see vector_to_rigid).

The resulting bundle-adjusted transformations are returned as an array of 3×3 projective transformation matrices in MosaicMatrices2D. In addition, the points reconstructed by the bundle adjustment are returned in (Rows, Cols). The average projection error of the reconstructed points is returned in Error. This can be used to check whether the optimization has converged to useful values.

Parameters

- ▷ **NumImages** (input_control) ..... integer ⇝ *integer*
  Number of different images that are used for the calibration.
  Restriction: NumImages >= 2
- ▷ **ReferenceImage** (input_control) ..... integer ⇝ *integer*
  Index of the reference image.
- ▷ **MappingSource** (input_control) ..... integer-array ⇝ *integer*
  Indices of the source images of the transformations.
- ▷ **MappingDest** (input_control) ..... integer-array ⇝ *integer*
  Indices of the target images of the transformations.
- ▷ **HomMatrices2D** (input_control) ..... hom_mat2d-array ⇝ *real*
  Array of 3×3 projective transformation matrices.
- ▷ **Rows1** (input_control) ..... point.x-array ⇝ *real* / integer
  Row coordinates of corresponding points in the respective source images.
- ▷ **Cols1** (input_control) ..... point.y-array ⇝ *real* / integer
  Column coordinates of corresponding points in the respective source images.
- ▷ **Rows2** (input_control) ..... point.x-array ⇝ *real* / integer
  Row coordinates of corresponding points in the respective destination images.
- ▷ **Cols2** (input_control) ..... point.y-array ⇝ *real* / integer
  Column coordinates of corresponding points in the respective destination images.
- ▷ **NumCorrespondences** (input_control) ..... integer-array ⇝ *integer*
  Number of point correspondences in the respective image pair.
- ▷ **Transformation** (input_control) ..... string ⇝ *string*
  Transformation class to be used.
  Default: 'projective'
  List of values: Transformation ∈ {'projective', 'affine', 'similarity', 'rigid'}
- ▷ **MosaicMatrices2D** (output_control) ..... hom_mat2d-array ⇝ *real*
  Array of 3×3 projective transformation matrices that determine the position of the images in the mosaic.
- ▷ **Rows** (output_control) ..... point.x-array ⇝ *real*
  Row coordinates of the points reconstructed by the bundle adjustment.
- ▷ **Cols** (output_control) ..... point.y-array ⇝ *real*
  Column coordinates of the points reconstructed by the bundle adjustment.
- ▷ **Error** (output_control) ..... real(-array) ⇝ *real*
  Average error per reconstructed point.

Example

```
* Assume that Images contains the four images of the mosaic in the
* layout given in the above description.  Then the following example
* computes the bundle-adjusted transformation matrices.
From := [1,1,1,2,2,3]
To := [2,3,4,3,4,4]
HomMatrices2D := []
Rows1 := []
Cols1 := []
Rows2 := []
Cols2 := []
NumMatches := []
for J := 0 to |From|-1 by 1
    select_obj (Images, ImageF, From[J])
    select_obj (Images, ImageT, To[J])
    points_foerstner (ImageF, 1, 2, 3, 100, 0.1, 'gauss', 'true', \
                      RowsF, ColsF, _, _, _, _, _, _, _, _)
    points_foerstner (ImageT, 1, 2, 3, 100, 0.1, 'gauss', 'true', \
                      RowsT, ColsT, _, _, _, _, _, _, _, _)
    proj_match_points_ransac (ImageF, ImageT, RowsF, ColsF, RowsT, ColsT, \
                              'ncc', 10, 0, 0, 480, 640, 0, 0.5, \
                              'gold_standard', 2, 42, HomMat2D, \
                              Points1, Points2)
    HomMatrices2D := [HomMatrices2D,HomMat2D]
    Rows1 := [Rows1,subset(RowsF,Points1)]
    Cols1 := [Cols1,subset(ColsF,Points1)]
    Rows2 := [Rows2,subset(RowsT,Points2)]
    Cols2 := [Cols2,subset(ColsT,Points2)]
    NumMatches := [NumMatches,|Points1|]
endfor
bundle_adjust_mosaic (4, 1, From, To, HomMatrices2D, Rows1, Cols1, \
                      Rows2, Cols2, NumMatches, 'rigid', MosaicMatrices, \
                      Rows, Columns, Error)
gen_bundle_adjusted_mosaic (Images, MosaicImage, HomMatrices2D, \
                            'default', 'false', TransMat2D)
```

Result

If the parameters are valid, the operator `bundle_adjust_mosaic` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

Module

Matching

gen_bundle_adjusted_mosaic (Images : MosaicImage : HomMatrices2D, StackingOrder, TransformDomain : TransMat2D)

Combine multiple images into a mosaic image.

gen_bundle_adjusted_mosaic combines the input images contained in the object Images into a mosaic image MosaicImage. The relative positions of the images are defined by 3×3 projective transformation matrices. The array HomMatrices2D contains a sequence of these linearized matrices. The transformation matrices can be computed with bundle_adjust_mosaic.

The origin of MosaicImage and its size are automatically chosen so that all of the input images are completely visible.

The order in which the images are added to the mosaic is given by the array StackingOrder. The first index in this array will end up at the bottom of the image stack while the last one will be on top. If *'default'* is given instead of an array of integers, the canonical order (images in the order used in Images) will be used.

The parameter TransformDomain can be used to determine whether the domains of Images are also transformed. Since the transformation of the domains costs runtime, this parameter should be used to specify whether this is desired or not. If TransformDomain is set to *'false'* the domain of the input images is ignored and the complete images are transformed.

On output, the parameter TransMat2D contains a 3×3 projective transformation matrix that describes the translation that was necessary to transform all images completely into the output image.

Parameters

- ▷ **Images** (input_object) ..... (multichannel-)image-array ⇝ *object :* byte / uint2 / real
  Input images.
- ▷ **MosaicImage** (output_object) ..... (multichannel-)image ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **HomMatrices2D** (input_control) ..... hom_mat2d-array ⇝ *real*
  Array of 3×3 projective transformation matrices.
- ▷ **StackingOrder** (input_control) ..... string(-array) ⇝ *string* / integer
  Stacking order of the images in the mosaic.
  Default: 'default'
  Suggested values: StackingOrder ∈ {'default'}
- ▷ **TransformDomain** (input_control) ..... string ⇝ *string*
  Should the domains of the input images also be transformed?
  Default: 'false'
  List of values: TransformDomain ∈ {'true', 'false'}
- ▷ **TransMat2D** (output_control) ..... hom_mat2d ⇝ *real*
  3×3 projective transformation matrix that describes the translation that was necessary to transform all images completely into the output image.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Matching

gen_cube_map_mosaic (Images : Front, Rear, Left, Right, Top, Bottom : CameraMatrices, RotationMatrices, CubeMapDimension, StackingOrder, Interpolation :)

Create 6 cube map images of a spherical mosaic.

gen_cube_map_mosaic creates 6 cube map images of a spherical mosaic Front, Left, Rear, Right, Top and Bottom from the input images passed in Images. The pose of the images in space, which is used to compute the position of the images with respect to the surface of the sphere, can be determined with stationary_camera_self_calibration. The camera and rotation matrices computed with stationary_camera_self_calibration can be used in CameraMatrices and RotationMatrices. A spherical mosaic can only be created from images that were taken with a stationary camera (see stationary_camera_self_calibration).

The width and height of the output cube map images can be selected by setting the parameter CubeMapDimension. The value represents the width and height in pixels.

The mode in which the images are added to the mosaic is given by StackingOrder. For StackingOrder $=$ *'voronoi'*, the points in the mosaic image are determined from the Voronoi cell of the respective input image. This means that the gray values are taken from the points of the input image to whose center the pixel in the mosaic image has the smallest distance on the sphere. This mode has the advantage that vignetting and uncorrected radial distortions are less noticeable in the mosaic image because they typically are symmetric with respect to the image center. Alternatively, with the choice of parameters described in the following, a mode can be selected that has the same effect as if the images were painted successively into the mosaic image. Here, the order in which the images are added to the mosaic image is important. Therefore, an array of integer values can be passed in StackingOrder. The first index in this array will end up at the bottom of the image stack while the last one will be on top. If *'default'* is given instead of an array of integers, the canonical order (images in the order used in Images) will be used. Hence, if neither *'voronoi'* nor *'default'* are used, StackingOrder must contain a permutation of the numbers 1,...,n, where n is the number of images passed in Images. It should be noted that the mode *'voronoi'* cannot always be used. For example, at least two images must be passed to use this mode. Furthermore, for very special configurations of the positions of the image centers on the sphere, the Voronoi cells cannot be determined uniquely. With StackingOrder $=$ *'blend'*, an additional mode is available, which blends the images of the mosaic smoothly. This way seams between the images become less apparent. The seam lines between the images are the same as in *'voronoi'*. This mode leads to visually more appealing images, but requires significantly more resources. If the mode *'voronoi'* or *'blend'* cannot be used for whatever reason the mode is switched internally to *'default'* automatically.

The parameter Interpolation selects the desired interpolation mode for creating the cube maps. *'bilinear'* and *'bicubic'* interpolation is available for all modes of StackingOrder. *'nearest_neighbor'* is only available if StackingOrder is set to *'default'* or *'voronoi'*.

Parameters

- ▷ **Images** (input_object) ..... (multichannel-)image-array ⇝ *object :* byte / uint2 / real
  Input images.
- ▷ **Front** (output_object) ..... (multichannel-)image ⇝ *object :* byte / uint2 / real
  Front cube map.
- ▷ **Rear** (output_object) ..... (multichannel-)image ⇝ *object :* byte / uint2 / real
  Rear cube map.
- ▷ **Left** (output_object) ..... (multichannel-)image ⇝ *object :* byte / uint2 / real
  Left cube map.
- ▷ **Right** (output_object) ..... (multichannel-)image ⇝ *object :* byte / uint2 / real
  Right cube map.
- ▷ **Top** (output_object) ..... (multichannel-)image ⇝ *object :* byte / uint2 / real
  Top cube map.

▷ **Bottom** (output_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2 / real
Bottom cube map.

▷ **CameraMatrices** (input_control) . . . . . hom_mat2d-array ⇝ *real*
(Array of) 3×3 projective camera matrices that determine the internal camera parameters.

▷ **RotationMatrices** (input_control) . . . . . hom_mat2d-array ⇝ *real*
Array of 3×3 transformation matrices that determine rotation of the camera in the respective image.

▷ **CubeMapDimension** (input_control) . . . . . number ⇝ *integer*
Width and height of the resulting cube maps.
Default: 1000
Restriction: CubeMapDimension >= 0

▷ **StackingOrder** (input_control) . . . . . string(-array) ⇝ *string* / integer
Mode of adding the images to the mosaic image.
Default: 'voronoi'
Suggested values: `StackingOrder` ∈ {'blend', 'voronoi', 'default'}

▷ **Interpolation** (input_control) . . . . . string ⇝ *string*
Mode of image interpolation.
Default: 'bilinear'
Suggested values: `Interpolation` ∈ {'nearest_neighbor', 'bilinear', 'bicubic'}

Example

```
* For the input data to stationary_camera_self_calibration, please
* refer to the example for stationary_camera_self_calibration.
stationary_camera_self_calibration (4, 640, 480, 1, From, To, \
                                    HomMatrices2D, Rows1, Cols1, \
                                    Rows2, Cols2, NumMatches, \

                     CameraMatrix, RotationMatrices, 1000, 'default', \
                     'bicubic')
```

Result

If the parameters are valid, the operator `gen_cube_map_mosaic` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

stationary_camera_self_calibration

Alternatives

gen_spherical_mosaic, gen_projective_mosaic

Matching

gen_projective_mosaic (Images : MosaicImage : StartImage, MappingSource, MappingDest, HomMatrices2D, StackingOrder, TransformDomain : MosaicMatrices2D)

Combine multiple images into a mosaic image.

gen_projective_mosaic combines the input images contained in the object Images into a mosaic image MosaicImage. The relative positions of the images are defined by 3×3 projective transformation matrices. The array HomMatrices2D contains a sequence of these linearized matrices. The values in MappingSource and MappingDest are the indices of the images that the corresponding matrix applies to. MappingSource=*4* and MappingDest=*7* means that the matrix describes the transformation of the image number *4* into the projective plane of image *7*. The transformation matrices between the respective image pairs given by MappingSource and MappingDest are typically determined with proj_match_points_ransac.

As usual for operators that access image objects (e.g., select_obj), the images are numbered starting from 1, i.e., MappingSource, MappingDest, StartImage, and StackingOrder) must contain values between 1 and the number of images passed in Images.

The parameter StartImage states which image defines the image plane of the final image, that is, which input image remains unchanged in the output image. This is usually an image that is located near the center of the image mosaic.

The origin of MosaicImage and its size are automatically chosen so that all of the input images are completely visible.

The order in which the images are added to the mosaic is given by the array StackingOrder. The first index in this array will end up at the bottom of the image stack while the last one will be on top. If *'default'* is given instead of an array of integers, the canonical order (images in the order used in Images) will be used.

The parameter TransformDomain can be used to determine whether the domains of Images are also transformed. Since the transformation of the domains costs runtime, this parameter should be used to specify whether this is desired or not. If TransformDomain is set to *'false'* the domain of the input images is ignored and the complete images are transformed.

On output, the parameter MosaicMatrices2D contains a set of 3×3 projective transformation matrices that describe for each image in Images the mapping of the image to its position in the mosaic.

Parameters

▷ **Images** (input_object) . . . . . (multichannel-)image-array ⇝ *object :* byte / uint2 / real
Input images.

▷ **MosaicImage** (output_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2 / real
Output image.

▷ **StartImage** (input_control) . . . . . integer ⇝ *integer*
Index of the central input image.

▷ **MappingSource** (input_control) . . . . . integer-array ⇝ *integer*
Indices of the source images of the transformations.

▷ **MappingDest** (input_control) . . . . . integer-array ⇝ *integer*
Indices of the target images of the transformations.

▷ **HomMatrices2D** (input_control) . . . . . hom_mat2d-array ⇝ *real*
Array of 3×3 projective transformation matrices.

▷ **StackingOrder** (input_control) . . . . . string(-array) ⇝ *string* / integer
Stacking order of the images in the mosaic.
Default: 'default'
Suggested values: StackingOrder ∈ {'default'}

▷ **TransformDomain** (input_control) . . . . . string ⇝ *string*
Should the domains of the input images also be transformed?
Default: 'false'
List of values: TransformDomain ∈ {'true', 'false'}

▷ **MosaicMatrices2D** (output_control) . . . . . hom_mat2d-array ⇝ *real*
Array of 3×3 projective transformation matrices that determine the position of the images in the mosaic.

Example

```
gen_empty_obj (Images)
for J := 1 to 6 by 1
    read_image (Image, 'mosaic/pcb_'+J$'02')
    concat_obj (Images, Image, Images)
endfor
From := [1,2,3,4,5]
To := [2,3,4,5,6]
Num := |From|
ProjMatrices := []
for J := 0 to Num-1 by 1
    F := From[J]
    T := To[J]
    select_obj (Images, ImageF, F)
    select_obj (Images, ImageT, T)
    points_foerstner (ImageF, 1, 2, 3, 200, 0.3, 'gauss', 'false', \
                      RowJunctionsF, ColJunctionsF, CoRRJunctionsF, \
                      CoRCJunctionsF, CoCCJunctionsF, RowAreaF, \
                      ColAreaF, CoRRAreaF, CoRCAreaF, CoCCAreaF)
    points_foerstner (ImageT, 1, 2, 3, 200, 0.3, 'gauss', 'false', \
                      RowJunctionsT, ColJunctionsT, CoRRJunctionsT, \
                      CoRCJunctionsT, CoCCJunctionsT, RowAreaT, \
                      ColAreaT, CoRRAreaT, CoRCAreaT, CoCCAreaT)
    proj_match_points_ransac (ImageF, ImageT, RowJunctionsF, \
                               ColJunctionsF, RowJunctionsT, \
                               ColJunctionsT, 'ncc', 21, 0, 0, 480, 640, \
                               0, 0.5, 'gold_standard', 1, 4364537, \
                               ProjMatrix, Points1, Points2)
    ProjMatrices := [ProjMatrices,ProjMatrix]
endfor
gen_projective_mosaic (Images, MosaicImage, 2, From, To, ProjMatrices, \
                       'default', 'false', MosaicMatrices2D)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

gen_spherical_mosaic (Images : MosaicImage : CameraMatrices, RotationMatrices, LatMin, LatMax, LongMin, LongMax, LatLongStep, StackingOrder, Interpolation :)

Create a spherical mosaic image.

gen_spherical_mosaic creates a spherical mosaic image MosaicImage from the input images passed in Images. The pose of the images in space, which is used to compute the position of the images with respect to the surface of the sphere, can be determined with stationary_camera_self_calibration. The camera and rotation matrices computed with stationary_camera_self_calibration can be used in CameraMatrices and RotationMatrices. A spherical mosaic can only be created from images that were taken with a stationary camera (see stationary_camera_self_calibration).

The mosaic is computed in spherical coordinates (longitude and latitude). The row axis of MosaicImage corresponds to the latitude, while the column axis corresponds to the longitude. The part of the sphere that is computed by gen_spherical_mosaic is determined by LatMin, LatMax, LongMin, and LongMax. These parameters are specified in degrees and determine a rectangular part of the latitude and longitude coordinates. The latitude *-90* corresponds to the north pole (i.e., the straight up viewing direction), while *90* corresponds to the south pole (i.e., the straight down viewing direction). The longitude *0* corresponds to the straight ahead viewing direction. Negative longitudes correspond to viewing directions to the left, while positive longitudes correspond to viewing directions to the right. Hence, to obtain a complete image of the sphere, LatMin = *-90*, LatMax = *90*, LongMin = *-180*, and LongMax = *180* must be used. In many cases, the mosaic will not cover the entire sphere. In these cases, it is useful to select the desired part of the sphere with the above parameters. This can be done by explicitly specifying the desired rectangle. However, often it is desirable to determine the smallest rectangle that encloses all images automatically. This can be done by using LatMin < *-90*, LatMax > *90*, LongMin < *-180*, and LongMax > *180*. Only the parameters that lie outside the normal range of values are determined automatically.

The angle step per pixel in MosaicImage can be selected with LatLongStep, which also is an angle specified in degrees. With this, the resolution of the mosaic image can be controlled. If LatLongStep is set to *0* the angle step is calculated automatically by trying to preserve the pixel size of the original images as well as possible.

The mode in which the images are added to the mosaic is given by StackingOrder. For StackingOrder = *'voronoi'*, the points in the mosaic image are determined from the Voronoi cell of the respective input image. This means that the gray values are taken from the points of the input image to whose center the pixel in the mosaic image has the smallest distance on the sphere. This mode has the advantage that vignetting and uncorrected radial distortions are less noticeable in the mosaic image because they typically are symmetric with respect to the image center. Alternatively, with the choice of parameters described described in the following, a mode can be selected that has the same effect as if the images were painted successively into the mosaic image. Here, the order in which the images are added to the mosaic image is important. Therefore, an array of integer values can be passed in StackingOrder. The first index in this array will end up at the bottom of the image stack while the last one will be on top. If *'default'* is given instead of an array of integers, the canonical order (images in the order used in Images) will be used. Hence, if neither *'voronoi'* nor *'default'* are used, StackingOrder must contain a permutation of the numbers 1,...,n, where n is the number of images passed in Images. It should be noted that the mode *'voronoi'* cannot always be used. For example, at least two images must be passed to use this mode. Furthermore, for very special configurations of the positions of the image centers on the sphere, the Voronoi cells cannot be determined uniquely. With StackingOrder = *'blend'*, an additional mode is available, which blends the images of the mosaic smoothly. This way seams between the images become less apparent. The seam lines

between the images are the same as in *'voronoi'*. This mode leads to visually more appealing images, but requires significantly more resources. If the mode *'voronoi'* or *'blend'* cannot be used for whatever reason the mode is switched internally to *'default'* automatically.

The parameter `Interpolation` selects the desired interpolation mode for creating the mosaic. *'bilinear'* and *'bicubic'* interpolation is available for all modes of `StackingOrder`. *'nearest_neighbor'* is only available if `StackingOrder` is set to *'default'* or *'voronoi'*.

Parameters

- ▷ **`Images`** (input_object) . . . . . (multichannel-)image-array ⇝ *object :* byte / uint2 / real
  Input images.
- ▷ **`MosaicImage`** (output_object) . . . . . (multichannel-)image ⇝ *object :* byte / uint2 / real
  Output image.
- ▷ **`CameraMatrices`** (input_control) . . . . . hom_mat2d-array ⇝ *real*
  (Array of) 3×3 projective camera matrices that determine the internal camera parameters.
- ▷ **`RotationMatrices`** (input_control) . . . . . hom_mat2d-array ⇝ *real*
  Array of 3×3 transformation matrices that determine rotation of the camera in the respective image.
- ▷ **`LatMin`** (input_control) . . . . . angle.deg ⇝ *real* / integer
  Minimum latitude of points in the spherical mosaic image.
  Default: -90
  Suggested values: `LatMin` ∈ {-100, -90, -80, -70, -60, -50, -40, -30, -20, -10}
  Restriction: LatMin <= 90
- ▷ **`LatMax`** (input_control) . . . . . angle.deg ⇝ *real* / integer
  Maximum latitude of points in the spherical mosaic image.
  Default: 90
  Suggested values: `LatMax` ∈ {10, 20, 30, 40, 50, 60, 70, 80, 90, 100}
  Restriction: LatMax >= -90 && LatMax > LatMin
- ▷ **`LongMin`** (input_control) . . . . . angle.deg ⇝ *real* / integer
  Minimum longitude of points in the spherical mosaic image.
  Default: -180
  Suggested values: `LongMin` ∈ {-200, -180, -160, -140, -120, -100, -90, -80, -70, -60, -50, -40, -30, -20, -10}
  Restriction: LongMin <= 180
- ▷ **`LongMax`** (input_control) . . . . . angle.deg ⇝ *real* / integer
  Maximum longitude of points in the spherical mosaic image.
  Default: 180
  Suggested values: `LongMax` ∈ {10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 120, 140, 160, 180, 200}
  Restriction: LongMax >= -90 && LongMax > LongMin
- ▷ **`LatLongStep`** (input_control) . . . . . angle.deg ⇝ *real* / integer
  Latitude and longitude angle step width.
  Default: 0.1
  Suggested values: `LatLongStep` ∈ {0, 0.02, 0.05, 0.1, 0.2, 0.5, 1}
  Restriction: LatLongStep >= 0
- ▷ **`StackingOrder`** (input_control) . . . . . string(-array) ⇝ *string* / integer
  Mode of adding the images to the mosaic image.
  Default: 'voronoi'
  Suggested values: `StackingOrder` ∈ {'blend', 'voronoi', 'default'}
- ▷ **`Interpolation`** (input_control) . . . . . string ⇝ *string* / integer
  Mode of interpolation when creating the mosaic image.
  Default: 'bilinear'
  Suggested values: `Interpolation` ∈ {'nearest_neighbor', 'bilinear', 'bicubic'}

Example

```
* For the input data to stationary_camera_self_calibration, please
* refer to the example for stationary_camera_self_calibration.
stationary_camera_self_calibration (4, 640, 480, 1, From, To, \

Module

Matching

proj_match_points_distortion_ransac (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, GrayMatchMethod, MaskSize, RowMove, ColMove, RowTolerance, ColTolerance, Rotation, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : HomMat2D, Kappa, Error, Points1, Points2)

Compute a projective transformation matrix between two images and the radial distortion coefficient by automatically finding correspondences between points.

Given a set of coordinates of characteristic points (Rows1, Cols1) and (Rows2, Cols2) in both input images Image1 and Image2, which must be of identical size, proj_match_points_distortion_ransac automatically determines corresponding points, the homogeneous projective transformation matrix HomMat2D, and the radial distortion coefficient Kappa (κ) that optimally fulfill the following equation:

$$\begin{pmatrix} r_2 \\ c_2 \\ 1 \end{pmatrix} = \texttt{HomMat2D} \cdot \begin{pmatrix} r_1 \\ c_1 \\ 1 \end{pmatrix}.$$

Here, (r_1, c_1) and (r_2, c_2) denote image points that are obtained by undistorting the input image points with the division model (see Calibration):

$$r = \frac{\tilde{r}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)} \qquad c = \frac{\tilde{c}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)}$$

Here, $(\tilde{r}_1, \tilde{c}_1) = (\texttt{Rows1} - 0.5(h-1), \texttt{Cols1} - 0.5(w-1))$
and $(\tilde{r}_2, \tilde{c}_2) = (\texttt{Rows2} - 0.5(h-1), \texttt{Cols2} - 0.5(w-1))$
denote the distorted image points, specified relative to the image center, and w and h denote the width and height of the input images. Thus, proj_match_points_distortion_ransac assumes that the principal point of the camera, i.e., the center of the radial distortions, lies at the center of the image.

The returned Kappa can be used to construct camera parameters that can be used to rectify images or points (see change_radial_distortion_cam_par, change_radial_distortion_image, and change_radial_distortion_points):

$$\begin{aligned} \texttt{CamPar} \quad = \quad & ['area\_scan\_telecentric\_division', 1.0, \texttt{Kappa}, 1.0, 1.0, \\ & 0.5(w-1), 0.5(h-1), w, h] \end{aligned}$$

The matching process is based on characteristic points, which can be extracted with point operators like points_foerstner or points_harris. The matching itself is carried out in two steps: first, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images. Then, the RANSAC algorithm is applied to find the projective transformation matrix and radial distortion coefficient that maximizes the number of correspondences under the above constraint.

The size of the mask windows used for the matching is MaskSize×MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A thus found matching is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the algorithm's performance, the search area for the match candidates can be limited to a rectangle by specifying its size and offset. Only points within a window of $2 \cdot$ RowTolerance $\times 2 \cdot$ ColTolerance points are considered. The offset of the center of the search window in the second image with respect to the position of the current point in the first image is given by RowMove and ColMove.

If the transformation contains a rotation, i.e., if the first image is rotated with respect to the second image, the parameter Rotation may contain an estimate for the rotation angle or an angle interval in radians. A good guess will increase the quality of the gray value matching. If the actual rotation differs too much from the specified estimate, the matching will typically fail. In this case, an angle interval should be specified and Rotation is a tuple with two elements. The larger the given interval is the slower the operator is since the RANSAC algorithm is run over all (automatically determined) angle increments within the interval.

After the initial matching has been completed, a randomized search algorithm (RANSAC) is used to determine the projective transformation matrix HomMat2D and the radial distortion coefficient Kappa. It tries to find the parameters that are consistent with a maximum number of correspondences. For a point to be accepted, the distance in pixels to its corresponding transformed point must not exceed the threshold DistanceThreshold.

The parameter EstimationMethod determines which algorithm is used to compute the projective transformation matrix. A linear algorithm is used if EstimationMethod is set to *'linear'*. This algorithm is very

fast and returns accurate results for small to moderate noise of the point coordinates and for most distortions (except for small distortions). For `EstimationMethod` = *'gold_standard'*, a mathematically optimal but slower optimization is used, which minimizes the geometric reprojection error. In general, it is preferable to use `EstimationMethod` = *'gold_standard'*.

The value `Error` indicates the overall quality of the estimation procedure and is the mean symmetric euclidean distance in pixels between the points and their corresponding transformed points.

Point pairs consistent with the above constraints are considered to be corresponding points. `Points1` contains the indices of the matched input points from the first image and `Points2` contains the indices of the corresponding points in the second image.

The parameter `RandSeed` can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If `RandSeed` is set to a positive number, the operator returns the same result on every call with the same parameters because the internally used random number generator is initialized with `RandSeed`. If `RandSeed` = *0*, the random number generator is initialized with the current time. In this case the results may not be reproducible. The value set for the HALCON system variable *'seed_rand'* (see `set_system`) does not affect the results of `proj_match_points_distortion_ransac`.

Parameters

▷ **`Image1`** (input_object) . . . singlechannelimage ⇝ *object :* byte / uint2
Input image 1.

▷ **`Image2`** (input_object) . . . singlechannelimage ⇝ *object :* byte / uint2
Input image 2.

▷ **`Rows1`** (input_control) . . . point.y-array ⇝ *real* / integer
Input points in image 1 (row coordinate).
Restriction: length(Rows1) >= 5

▷ **`Cols1`** (input_control) . . . point.x-array ⇝ *real* / integer
Input points in image 1 (column coordinate).
Restriction: length(Cols1) == length(Rows1)

▷ **`Rows2`** (input_control) . . . point.y-array ⇝ *real* / integer
Input points in image 2 (row coordinate).
Restriction: length(Rows2) >= 5

▷ **`Cols2`** (input_control) . . . point.x-array ⇝ *real* / integer
Input points in image 2 (column coordinate).
Restriction: length(Cols2) == length(Rows2)

▷ **`GrayMatchMethod`** (input_control) . . . string ⇝ *string*
Gray value match metric.
Default: 'ncc'
List of values: `GrayMatchMethod` ∈ {'ncc', 'ssd', 'sad'}

▷ **`MaskSize`** (input_control) . . . integer ⇝ *integer*
Size of gray value masks.
Default: 10
Suggested values: `MaskSize` ∈ {3, 7, 15}
Value range: 1 ≤ MaskSize

▷ **`RowMove`** (input_control) . . . integer ⇝ *integer*
Average row coordinate offset of corresponding points.
Default: 0

▷ **`ColMove`** (input_control) . . . integer ⇝ *integer*
Average column coordinate offset of corresponding points.
Default: 0

▷ **`RowTolerance`** (input_control) . . . integer ⇝ *integer*
Half height of matching search window.
Default: 200
Restriction: RowTolerance >= 1

▷ **`ColTolerance`** (input_control) . . . integer ⇝ *integer*
Half width of matching search window.
Default: 200
Restriction: ColTolerance >= 1

▷ **Rotation** (input_control) ..... angle.rad(-array) ⇝ *real* / integer
Estimate of the relative rotation of the second image with respect to the first image.
Default: 0.0
Suggested values: Rotation ∈ {0.0, 0.1, -0.1, 0.7854, 1.571, 3.142}

▷ **MatchThreshold** (input_control) ..... number ⇝ *integer* / real
Threshold for gray value matching.
Default: 0.7
Suggested values: MatchThreshold ∈ {0.9, 0.7, 0.5, 10, 20, 50, 100}

▷ **EstimationMethod** (input_control) ..... string ⇝ *string*
Algorithm for the computation of the projective transformation matrix.
Default: 'gold_standard'
List of values: EstimationMethod ∈ {'linear', 'gold_standard'}

▷ **DistanceThreshold** (input_control) ..... number ⇝ *real* / integer
Threshold for the transformation consistency check.
Default: 1
Restriction: DistanceThreshold > 0

▷ **RandSeed** (input_control) ..... integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **HomMat2D** (output_control) ..... hom_mat2d ⇝ *real*
Computed homogeneous projective transformation matrix.

▷ **Kappa** (output_control) ..... real ⇝ *real*
Computed radial distortion coefficient.

▷ **Error** (output_control) ..... real ⇝ *real*
Root-Mean-Square transformation error.

▷ **Points1** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 2.

Example

```
points_foerstner (Image1, 1, 2, 3, 50, 0.1, 'gauss', 'true', \

Matching

proj_match_points_distortion_ransac_guided (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, GrayMatchMethod, MaskSize, HomMat2DGuide, KappaGuide, DistanceTolerance, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : HomMat2D, Kappa, Error, Points1, Points2)

Compute a projective transformation matrix and the radial distortion coefficient between two images by finding correspondences between points based on known approximations of the projective transformation matrix and the radial distortion coefficient.

Given a set of coordinates of characteristic points (Rows1, Cols1) and (Rows2Cols2) in both input images Image1 and Image2, which must have identical size, and given known approximations HomMat2DGuide and KappaGuide for the transformation matrix and the radial distortion coefficient between Image1 and Image2, proj_match_points_distortion_ransac_guided automatically determines corresponding points, the homogeneous projective transformation matrix HomMat2D, and the radial distortion coefficient Kappa (κ) that optimally fulfill the following equation:

$$\begin{pmatrix} r_2 \\ c_2 \\ 1 \end{pmatrix} = \texttt{HomMat2D} \cdot \begin{pmatrix} r_1 \\ c_1 \\ 1 \end{pmatrix}.$$

Here, (r_1, c_1) and (r_2, c_2) denote image points that are obtained by undistorting the input image points with the division model (see Calibration):

$$r = \frac{\tilde{r}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)} \qquad c = \frac{\tilde{c}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)}$$

Here, $(\tilde{r}_1, \tilde{c}_1) = (\texttt{Rows1} - 0.5(h-1), \texttt{Cols1} - 0.5(w-1))$
and $(\tilde{r}_2, \tilde{c}_2) = (\texttt{Rows2} - 0.5(h-1), \texttt{Cols2} - 0.5(w-1))$

denote the distorted image points, specified relative to the image center, and w and h denote the width and height of the input images. Thus, proj_match_points_distortion_ransac_guided assumes that the principal point of the camera, i.e., the center of the radial distortions, lies at the center of the image.

The returned Kappa can be used to construct camera parameters that can be used to rectify images or points (see change_radial_distortion_cam_par, change_radial_distortion_image, and change_radial_distortion_points):

$$\begin{aligned} \texttt{CamPar} \quad = \quad & [\textit{'area\_scan\_telecentric\_division'}, 1.0, \texttt{Kappa}, 1.0, 1.0, \\ & 0.5(w-1), 0.5(h-1), w, h] \end{aligned}$$

The approximations HomMat2DGuide and KappaGuide can, for example, be calculated with proj_match_points_distortion_ransac on lower resolution versions of Image1 and Image2. See the example below.

The matching process is based on characteristic points, which can be extracted with point operators like points_foerstner or points_harris. The matching itself is carried out in two steps: first, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images. Then, the RANSAC algorithm is applied to find the projective transformation matrix and radial distortion coefficient that maximizes the number of correspondences under the above constraint.

The size of the mask windows used for the matching is MaskSize×MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A thus found matching is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the algorithm's performance, the search area for the match candidates is limited based on the approximate transformation specified by HomMat2DGuide and KappaGuide. Only points within a distance of DistanceTolerance around the point in Image2 that is obtained when transforming a point in Image1 via HomMat2DGuide and KappaGuide are considered for the matching.

After the initial matching has been completed, a randomized search algorithm (RANSAC) is used to determine the projective transformation matrix HomMat2D and the radial distortion coefficient Kappa. It tries to find the parameters that are consistent with a maximum number of correspondences. For a point to be accepted, the distance to its corresponding transformed point must not exceed the threshold DistanceThreshold. Consequently, DistanceThreshold should be smaller than DistanceTolerance.

The parameter EstimationMethod determines which algorithm is used to compute the projective transformation matrix. A linear algorithm is used if EstimationMethod is set to *'linear'*. This algorithm is very fast and returns accurate results for small to moderate noise of the point coordinates and for most distortions (except for small distortions). For EstimationMethod = *'gold_standard'*, a mathematically optimal but slower optimization is used, which minimizes the geometric reprojection error. In general, it is preferable to use EstimationMethod = *'gold_standard'*.

The value Error indicates the overall quality of the estimation procedure and is the mean symmetric euclidean distance in pixels between the points and their corresponding transformed points.

Point pairs consistent with the above constraints are considered to be corresponding points. Points1 contains the indices of the matched input points from the first image and Points2 contains the indices of the corresponding points in the second image.

The parameter RandSeed can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If RandSeed is set to a positive number, the operator returns the same result on every call with the same parameters because the internally used random number generator is initialized with RandSeed. If RandSeed = *0*, the random number generator is initialized with the current time. In this case the results may not be reproducible. The value set for the HALCON system variable *'seed_rand'* (see set_system) does not affect the results of proj_match_points_distortion_ransac_guided.

Parameters

▷ **Image1** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image 1.

▷ **Image2** (input_object) . . . . . singlechannelimage ⇝ *object :* byte / uint2
Input image 2.

▷ **Rows1** (input_control) . . . . . point.y-array ⇝ *real* / integer
Input points in image 1 (row coordinate).
Restriction: length(Rows1) >= 5

▷ **Cols1** (input_control) . . . . . point.x-array ⇝ *real* / integer
Input points in image 1 (column coordinate).
Restriction: length(Cols1) == length(Rows1)

▷ **Rows2** (input_control) . . . . . point.y-array ⇝ *real* / integer
Input points in image 2 (row coordinate).
Restriction: length(Rows2) >= 5

▷ **Cols2** (input_control) . . . . . point.x-array ⇝ *real* / integer
Input points in image 2 (column coordinate).
Restriction: length(Cols2) == length(Rows2)

▷ **GrayMatchMethod** (input_control) . . . . . string ⇝ *string*
Gray value match metric.
Default: 'ncc'
List of values: `GrayMatchMethod` ∈ {'ncc', 'ssd', 'sad'}

▷ **MaskSize** (input_control) . . . . . integer ⇝ *integer*
Size of gray value masks.
Default: 10
Suggested values: `MaskSize` ∈ {3, 7, 15}
Value range: 1 ≤ MaskSize

▷ **HomMat2DGuide** (input_control) . . . . . hom_mat2d ⇝ *real*
Approximation of the homogeneous projective transformation matrix between the two images.

▷ **KappaGuide** (input_control) . . . . . real ⇝ *real*
Approximation of the radial distortion coefficient in the two images.

▷ **DistanceTolerance** (input_control) . . . . . real ⇝ *real*
Tolerance for the matching search window.
Default: 20.0
Suggested values: `DistanceTolerance` ∈ {0.2, 0.5, 1.0, 2.0, 3.0, 5.0, 10.0, 20.0, 50.0}
Restriction: DistanceTolerance > 0

▷ **MatchThreshold** (input_control) . . . . . number ⇝ *integer* / real
Threshold for gray value matching.
Default: 0.7
Suggested values: `MatchThreshold` ∈ {0.9, 0.7, 0.5, 10, 20, 50, 100}

▷ **EstimationMethod** (input_control) . . . . . string ⇝ *string*
Algorithm for the computation of the projective transformation matrix.
Default: 'gold_standard'
List of values: `EstimationMethod` ∈ {'linear', 'gold_standard'}

▷ **DistanceThreshold** (input_control) . . . . . number ⇝ *real* / integer
Threshold for transformation consistency check.
Default: 1
Restriction: DistanceThreshold > 0

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **HomMat2D** (output_control) . . . . . hom_mat2d ⇝ *real*
Computed homogeneous projective transformation matrix.

▷ **Kappa** (output_control) . . . . . real ⇝ *real*
Computed radial distortion coefficient.

▷ **Error** (output_control) . . . . . real ⇝ *real*
Root-Mean-Square transformation error.

▷ **Points1** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 2.

Matching

proj_match_points_ransac (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, GrayMatchMethod, MaskSize, RowMove, ColMove, RowTolerance, ColTolerance, Rotation, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : HomMat2D, Points1, Points2)

Compute a projective transformation matrix between two images by finding correspondences between points.

Given a set of coordinates of characteristic points (Cols1, Rows1) and (Cols2, Rows2) in both input images Image1 and Image2, proj_match_points_ransac automatically determines corresponding points and the homogeneous projective transformation matrix HomMat2D that best transforms the corresponding points from the different images into each other. The characteristic points can, for example, be extracted with points_foerstner or points_harris.

The transformation is determined in two steps: First, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images.

The size of the mask windows is MaskSize $\times$ MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A thus found matching is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the algorithm's performance, the search area for the matching operations can be limited. Only points within a window of $2 \cdot$ RowTolerance $\times 2 \cdot$ ColTolerance points are considered. The offset of the center of the search window in the second image with respect to the position of the current point in the first image is given by RowMove and ColMove.

If the transformation contains a rotation, i.e., if the first image is rotated with respect to the second image, the parameter Rotation may contain an estimate for the rotation angle or an angle interval in radians. A good guess will increase the quality of the gray value matching. If the actual rotation differs too much from the specified estimate the matching will typically fail. The larger the given interval, the slower the operator is since the entire algorithm is run for all relevant angles within the interval.

Once the initial matching is complete, a randomized search algorithm (RANSAC) is used to determine the transformation matrix HomMat2D. It tries to find the matrix that is consistent with a maximum number of correspondences. For a point to be accepted, its distance from the coordinates predicted by the transformation must not exceed the threshold DistanceThreshold.

Once a choice has been made, the matrix is further optimized using all consistent points. For this optimization, the `EstimationMethod` can be chosen to either be the slow but mathematically optimal *'gold_standard'* method or the faster *'normalized_dlt'*. Here, the algorithms of `vector_to_proj_hom_mat2d` are used.

Point pairs that still violate the consistency condition for the final transformation are dropped, the matched points are returned as control values. `Points1` contains the indices of the matched input points from the first image, `Points2` contains the indices of the corresponding points in the second image.

The parameter `RandSeed` can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If `RandSeed` is set to a positive number, the operator yields the same result on every call with the same parameters because the internally used random number generator is initialized with the seed value. If `RandSeed` = *0*, the random number generator is initialized with the current time. Hence, the results may not be reproducible in this case. The value set for the HALCON system variable *'seed_rand'* (see `set_system`) does not affect the results of `proj_match_points_ransac`.

Parameters

- ▷ **`Image1`** (input_object) . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 1.
- ▷ **`Image2`** (input_object) . . . singlechannelimage ⇝ *object :* byte / uint2
  Input image 2.
- ▷ **`Rows1`** (input_control) . . . point.x-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 1.
- ▷ **`Cols1`** (input_control) . . . point.y-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 1.
- ▷ **`Rows2`** (input_control) . . . point.x-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 2.
- ▷ **`Cols2`** (input_control) . . . point.y-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 2.
- ▷ **`GrayMatchMethod`** (input_control) . . . string ⇝ *string*
  Gray value comparison metric.
  Default: 'ssd'
  List of values: `GrayMatchMethod` ∈ {'ssd', 'sad', 'ncc'}
- ▷ **`MaskSize`** (input_control) . . . integer ⇝ *integer*
  Size of gray value masks.
  Default: 10
  Value range: MaskSize ≤ 90
- ▷ **`RowMove`** (input_control) . . . integer ⇝ *integer*
  Average row coordinate shift.
  Default: 0
- ▷ **`ColMove`** (input_control) . . . integer ⇝ *integer*
  Average column coordinate shift.
  Default: 0
- ▷ **`RowTolerance`** (input_control) . . . integer ⇝ *integer*
  Half height of matching search window.
  Default: 256
- ▷ **`ColTolerance`** (input_control) . . . integer ⇝ *integer*
  Half width of matching search window.
  Default: 256
- ▷ **`Rotation`** (input_control) . . . real(-array) ⇝ *real*
  Range of rotation angles.
  Default: 0.0
  Suggested values: `Rotation` ∈ {0.0, 0.7854, 1.571, 3.142}
- ▷ **`MatchThreshold`** (input_control) . . . number ⇝ *integer* / real
  Threshold for gray value matching.
  Default: 10
  Suggested values: `MatchThreshold` ∈ {10, 20, 50, 100, 0.9, 0.7}
- ▷ **`EstimationMethod`** (input_control) . . . string ⇝ *string*
  Transformation matrix estimation algorithm.
  Default: 'normalized_dlt'
  List of values: `EstimationMethod` ∈ {'normalized_dlt', 'gold_standard'}

▷ **DistanceThreshold** (input_control) . . . . . real ⇝ *real*
Threshold for transformation consistency check.
Default: 0.2

▷ **RandSeed** (input_control) . . . . . integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **HomMat2D** (output_control) . . . . . hom_mat2d ⇝ *real*
Homogeneous projective transformation matrix.

▷ **Points1** (output_control) . . . . . integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) . . . . . integer-array ⇝ *integer*
Indices of matched input points in image 2.

Matching

proj_match_points_ransac_guided (Image1, Image2 : : Rows1, Cols1, Rows2, Cols2, GrayMatchMethod, MaskSize, HomMat2DGuide, DistanceTolerance, MatchThreshold, EstimationMethod, DistanceThreshold, RandSeed : HomMat2D, Points1, Points2)

Compute a projective transformation matrix between two images by finding correspondences between points based on a known approximation of the projective transformation matrix.

Given a set of coordinates of characteristic points (Cols1,Rows1) and (Cols2,Rows2) in both input images Image1 and Image2, and given a known approximation HomMat2DGuide for the transformation matrix between Image1 and Image2, proj_match_points_ransac_guided automatically determines corresponding points and the homogeneous projective transformation matrix HomMat2D that best transforms the corresponding points from the different images into each other. The characteristic points can, for example, be extracted with points_foerstner or points_harris. The approximation HomMat2DGuide can, for example, be calculated with proj_match_points_ransac on lower resolution versions of Image1 and Image2.

The transformation is determined in two steps: First, gray value correlations of mask windows around the input points in the first and the second image are determined and an initial matching between them is generated using the similarity of the windows in both images.

The size of the mask windows is MaskSize × MaskSize. Three metrics for the correlation can be selected. If GrayMatchMethod has the value *'ssd'*, the sum of the squared gray value differences is used, *'sad'* means the sum of absolute differences, and *'ncc'* is the normalized cross correlation. For details please refer to binocular_disparity. The metric is minimized (*'ssd'*, *'sad'*) or maximized (*'ncc'*) over all possible point pairs. A thus found matching is only accepted if the value of the metric is below the value of MatchThreshold (*'ssd'*, *'sad'*) or above that value (*'ncc'*).

To increase the algorithm's performance, the search area for the matching operations is limited based on the approximate transformation HomMat2DGuide. Only points within a distance of DistanceTolerance around the transformed a point in Image2 of a point in Image1 via HomMat2DGuide are considered for the matching.

Once the initial matching is complete, a randomized search algorithm (RANSAC) is used to determine the transformation matrix HomMat2D. It tries to find the matrix that is consistent with a maximum number of correspondences. For a point to be accepted, its distance from the coordinates predicted by the transformation must not exceed the threshold DistanceThreshold.

Once a choice has been made, the matrix is further optimized using all consistent points. For this optimization, the EstimationMethod can be chosen to either be the slow but mathematically optimal *'gold_standard'* method or the faster *'normalized_dlt'*. Here, the algorithms of vector_to_proj_hom_mat2d are used.

Point pairs that still violate the consistency condition for the final transformation are dropped, the matched points are returned as control values. Points1 contains the indices of the matched input points from the first image, Points2 contains the indices of the corresponding points in the second image.

The parameter RandSeed can be used to control the randomized nature of the RANSAC algorithm, and hence to obtain reproducible results. If RandSeed is set to a positive number, the operator yields the same result on every call with the same parameters because the internally used random number generator is initialized with the seed value. If RandSeed = *0*, the random number generator is initialized with the current time. Hence, the results may not be reproducible in this case. The value set for the HALCON system variable *'seed_rand'* (see set_system) does not affect the results of proj_match_points_ransac_guided.

Parameters

- ▷ **Image1** (input_object) . . . . . singlechannelimage ⇝ *object* : byte / uint2
  Input image 1.
- ▷ **Image2** (input_object) . . . . . singlechannelimage ⇝ *object* : byte / uint2
  Input image 2.
- ▷ **Rows1** (input_control) . . . . . point.x-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 1.
- ▷ **Cols1** (input_control) . . . . . point.y-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 1.
- ▷ **Rows2** (input_control) . . . . . point.x-array ⇝ *real* / integer
  Row coordinates of characteristic points in image 2.
- ▷ **Cols2** (input_control) . . . . . point.y-array ⇝ *real* / integer
  Column coordinates of characteristic points in image 2.
- ▷ **GrayMatchMethod** (input_control) . . . . . string ⇝ *string*
  Gray value comparison metric.
  Default: 'ssd'
  List of values: GrayMatchMethod ∈ {'ssd', 'sad', 'ncc'}
- ▷ **MaskSize** (input_control) . . . . . integer ⇝ *integer*
  Size of gray value masks.
  Default: 10
  Value range: MaskSize ≤ 90
- ▷ **HomMat2DGuide** (input_control) . . . . . hom_mat2d ⇝ *real*
  Approximation of the Homogeneous projective transformation matrix between the two images.
- ▷ **DistanceTolerance** (input_control) . . . . . real ⇝ *real*
  Tolerance for the matching search window.
  Default: 20.0
  Suggested values: DistanceTolerance ∈ {0.2, 0.5, 1.0, 2.0, 3.0, 5.0, 10.0, 20.0, 50.0}
- ▷ **MatchThreshold** (input_control) . . . . . number ⇝ *integer* / real
  Threshold for gray value matching.
  Default: 10
  Suggested values: MatchThreshold ∈ {10, 20, 50, 100, 0.9, 0.7}

▷ **EstimationMethod** (input_control) ..... string ⇝ *string*
Transformation matrix estimation algorithm.
Default: 'normalized_dlt'
List of values: EstimationMethod ∈ {'normalized_dlt', 'gold_standard'}

▷ **DistanceThreshold** (input_control) ..... real ⇝ *real*
Threshold for transformation consistency check.
Default: 0.2

▷ **RandSeed** (input_control) ..... integer ⇝ *integer*
Seed for the random number generator.
Default: 0

▷ **HomMat2D** (output_control) ..... hom_mat2d ⇝ *real*
Homogeneous projective transformation matrix.

▷ **Points1** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 1.

▷ **Points2** (output_control) ..... integer-array ⇝ *integer*
Indices of matched input points in image 2.

Example

```
zoom_image_factor (Image1, Image1Zoomed, 0.5, 0.5, 'constant')
zoom_image_factor (Image2, Image2Zoomed, 0.5, 0.5, 'constant')

Chapter 27

Transformations

27.1 2D Transformations

To specify a location in an image, we need a convention how to do so. Such a convention is set via a coordinate system. There are different coordinate systems used in HALCON. Here, we explain the ones used in 2D.

Pixels are discrete and to address them, we have a coordinate system using only integer values, the pixel coordinate system. For a higher accuracy that goes beyond the pixel grid, we need floating point coordinates, like e.g., $(3.6, 4.1)$. This leads to subpixel accurate coordinate systems. In HALCON, we have three different implementations of subpixel coordinate systems:

- Pixel Centered Coordinates, the HALCON Standard Subpixel Coordinate System
- Edge Centered Coordinates
- Polar Coordinates

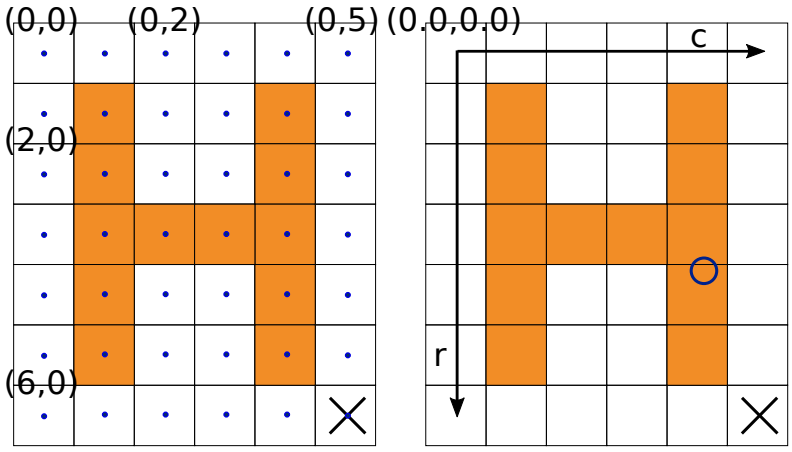
Thereof the first two vary only in the coordinate origin, as visible in the figures below. Calibration makes it possible to map the image coordinates distances to real-world distances. For more information about these Calibrated Coordinates we refer to the "`Solution Guide III-C - 3D Vision`".

HALCON Standard Coordinate System

Pixel Accurate Coordinate System The pixel coordinate system treats the image as a grid of discrete elements, the pixels. In HALCON, we put the origin $(0, 0)$ in the middle of the upper left pixel. Now, we assign the pixel coordinates specifying its row and column like in a matrix.

Note that this implies for an image of size height $\times$ width = $m \times n$ pixels that the row coordinate values run from 0 to $m - 1$ and the column coordinate values from 0 to $n - 1$, as visualized in the figure below.

Subpixel Accurate Coordinate System: Pixel Centered The origin of this coordinate system is in the center of the upper left image pixel, the axes are in row (r) and column (c) direction, respectively. Therewith this convention embeds the pixel coordinate system. The upper left image corner has the coordinates $(-0.5, -0.5)$ and for an image of size height $\times$ width = $m \times n$ pixels the bottom right corner has the coordinates $(m - 0.5, n - 0.5)$ (=$(m - 1 + 0.5, n - 1 + 0.5)$, remember the coordinate values start at 0). It also implies that a pixel (k,l) covers the area of the rectangle $(k - 0.5, l - 0.5)$, $(k + 0.5, l - 0.5)$, $(k - 0.5, l + 0.5)$, $(k+0.5, l+0.5)$. This convention is called the standard coordinate system, or also Image Coordinate System.



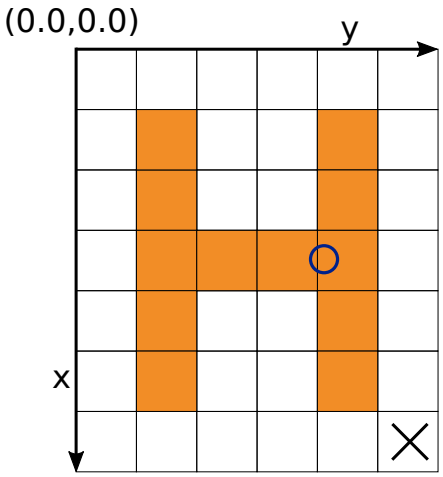
(1) (2)

Visualization of the HALCON standard pixel and subpixel Cartesian coordinate systems. The cross indicates the pixel in the bottom right image corner. Its center has the coordinates $(6, 5)$ (in pixel coordinates (1)), $(6.0, 5.0)$ (in standard subpixel coordinates (2)). The circle center has the coordinates $(3.6, 4.1)$.

HALCON Non-Standard Cartesian Coordinate System

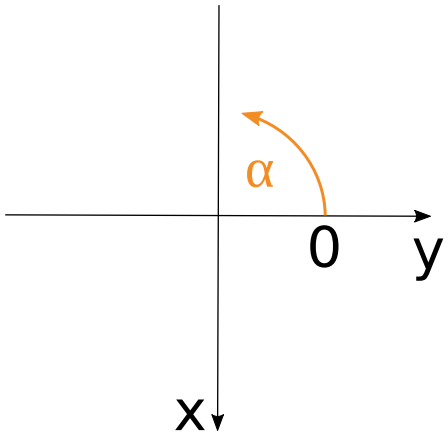
If we rotate an image around its origin by $\pi/2$ (=90 degrees), we want the two images with touching edges but not overlapping with each other. Also, scaling the image is not expected to result in negative image coordinates. For this, the origin $(0.0, 0.0)$ has to be set in an image corner. This motivates the following coordinate system.

Subpixel Accurate Coordinate System: Edge Centered For this coordinate system we set the origin $(0.0, 0.0)$ in the upper left image corner. Thus the center of the upper left pixel has the coordinates $(0.5, 0.5)$ and for an image of size height $\times$ width = $m \times n$ pixels the bottom right corner has the coordinates (m, n). A pixel (k, l) covers the area of the rectangle (k, l), $(k, l + 1)$, $(k + 1, l)$, $(k + 1, l + 1)$.



Visualization of the HALCON non-standard subpixel Cartesian coordinate system. The cross indicates the pixel in the bottom right image corner. Its center has the coordinates $(6.5, 5.5)$. The circle center has the coordinates $(3.6, 4.1)$.

For this coordinate system rotations are defined in the mathematically positive direction and thus counter-clockwise. A rotation of $\pi/2$ (=90 degrees) maps the first axis (= x-axis) onto the second axis (= y-axis). Accordingly, the axes have the assignment row: x coordinate, column: y coordinate.



Visualization of a rotation (α) using the edge centered coordinate system.

Operators Expecting Parameters in any Cartesian Coordinate System

The operator affine_trans_point_2d applies the transformation given by HomMat2D to the point coordinates. This means, affine_trans_point_2d works in both Cartesian Coordinate systems, as long you make sure that the point and the transformation are given in the same coordinate system.

The operators angle_ll and angle_lx may take the input points in pixel centered coordinates, but the returned angle is in the convention of rotations in a mathematically positive direction, thus counterclockwise, and with the horizontal axis as *0*, like in the edge centered coordinate system.

Operators Expecting Parameters in Different Coordinate Systems

In HALCON there is also the case that an operator expects its input in different coordinate systems. On the one hand, the object is expected in its usual coordinates, the standard coordinates. On the other hand, for the transformation matrix HomMat2D, the operator expects edge centered coordinates with their advantages regarding transformations described above. The operator converts the coordinates of the object from HALCON's standard coordinate system (with the origin in the center of the upper left pixel) to the edge centered coordinate system (with the origin in the upper left corner of the upper left pixel). After the transformation with HomMat2D, the result is converted back to the standard coordinate system.

These operators are

- affine_trans_contour_xld
- affine_trans_image
- affine_trans_image_size
- affine_trans_pixel
- affine_trans_polygon_xld
- affine_trans_region
- projective_trans_contour_xld
- projective_trans_image
- projective_trans_image_size
- projective_trans_pixel
- projective_trans_region

A matrix representing a transformation in pixel centered coordinates can be converted to represent the same transformation (e.g., a rotation around the same point) written in edge centered coordinates, e.g., through

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
```

Note, the operators beginning with `projective_` mentioned above use a projective transformation matrix. These transformation matrices can, e.g., be obtained from a 3D camera pose. Doing so, the matrix used is written in a projection of the xy-plane within the 3D coordinate system. Accordingly, the axes have the assignment row: y coordinate, column: x coordinate and therewith the coordinates need to be converted.

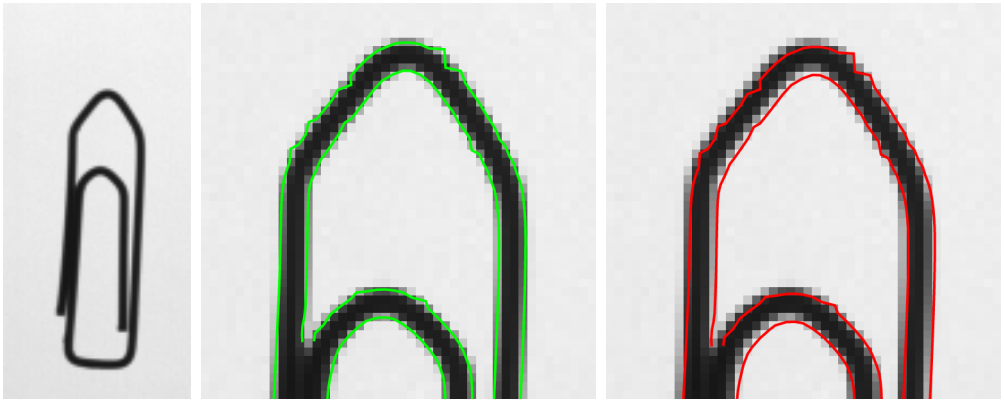
Shape-based Matching and Correlation-based Matching

Results from shape-based matching, like e.g., `find_generic_shape_model`, are given in edge centered coordinates. The returned matches are already transformed. The respective homographic transformation matrices can be retrieved using `get_generic_shape_model_result`.

Results from correlation-based matching, like e.g., `find_ncc_model` and `find_ncc_models`, are computed in edge centered coordinates as well, however the parameters for the transformation are returned separately. With these results one can create a transformation `HomMat2D` directly applicable for, e.g., `affine_trans_contour_xld` and the other operators listed in the paragraph above, entitled `Operators Expecting Parameters in Different Coordinate Systems`.

To display the results found by correlation-based matching, we highly recommend the usage of the procedure `dev_display_ncc_matching_results`.

In the following images we give an example how a displayed match may look when using the transformation matrix in the correct and the erroneous coordinate system, respectively. For the latter one, shown in image (3), the transition matrix is given in pixel centered coordinates as well and therefore the match shown by `affine_trans_contour_xld` is off by 0.5 pixels. Note, this effect is only visible when a rotation is involved.



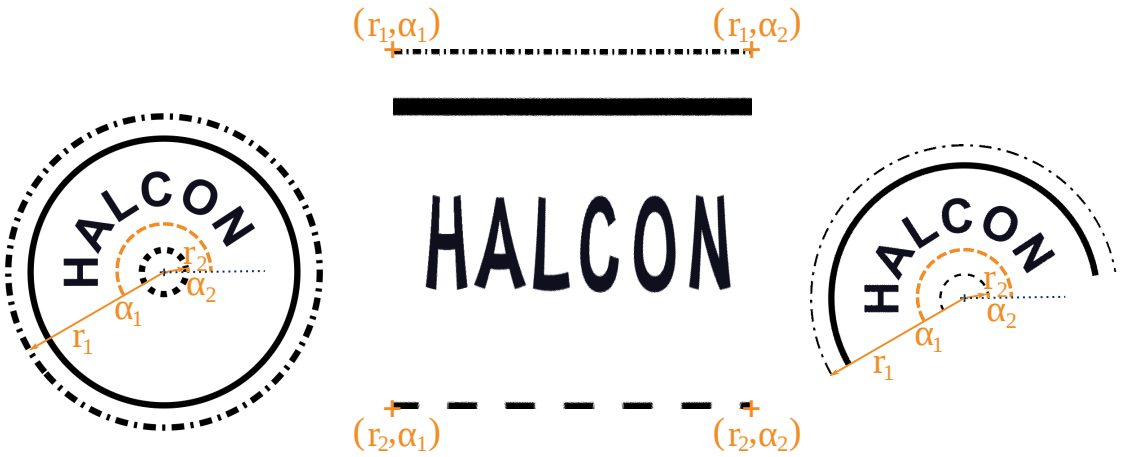
(1) (2) (3)

The original image of the paperclip (1), a part of the match where the inputs are given in the correct coordinates (2), and a match with inputs given in wrong coordinates.

Non-Cartesian Coordinate Systems

Subpixel Accurate Coordinate System: Polar Coordinates In polar coordinates, points are defined through a distance and an angle. The distance is called the radial coordinate and is given in relation to the fix point, the pole. The angular coordinate is given with respect to a defined axis, the polar axis. In HALCON, the pole is specified by (`Row`, `Column`) and the polar axis is the horizontal axis. The angular coordinate is given in radians.

After a transformation with `polar_trans_image_ext`, the upper left pixel in the output image always corresponds to the point in the input image that is specified by `RadiusStart` and `AngleStart`. Analogously, the lower right pixel in the output image corresponds to the point in the input image that is specified by `RadiusEnd` and `AngleEnd`. In the usual mode (`AngleStart` < `AngleEnd` and `RadiusStart` < `RadiusEnd`), the polar transformation is performed in the mathematically positive orientation (counterclockwise). Furthermore, points with smaller radius lie in the upper part of the output image. By suitably exchanging the values of these parameters (e.g., `AngleStart` > `AngleEnd` or `RadiusStart` > `RadiusEnd`), any desired orientation of the output image can be achieved.



As an example, we show an annular arc defined by its pole (Row,Column) (+), the polar axis (...), two angular coordinates AngleStart ($\alpha 1$), AngleEnd ($\alpha 2$) and two radial coordinates RadiusStart ($r1$), RadiusEnd ($r2$). (1) The original image and the parameters defining the annular arc. (2) The annular arc, shown in a figure where the polar coordinates form an equidistant grid obtained by polar_trans_image_ext. (3) The annular arc in the representation of the original image. The Cartesian coordinates have been obtained through polar_trans_image_inv on image (2). The origin is in the center of the pixel in the upper left corner.

Polar coordinates are used by the following operators:

- polar_trans_image_ext
- polar_trans_image_inv
- polar_trans_region
- polar_trans_region_inv
- polar_trans_contour_xld
- polar_trans_contour_xld_inv
- polar_trans_image (legacy)

Images with a reduced domain, regions, and models

In the part before we spoke about coordinates of images. When it comes to the location of the origin of the coordinate system used, images with reduced domains, regions, and models are treated differently than images.

Images with a reduced domain and regions Both images with a reduced domain and regions keep the coordinate system of the image from which they were created. This means, they inherit the origin and the points keep the coordinate values they had in the original image.

Models Models, on the other side, can have a local coordinate system. E.g., models obtained over create_generic_shape_model have their origin in the center of gravity of the ROI they are created from. For further information see the "Solution Guide II-B - Matching".

Calibrated Coordinates

While working with pixel units, we can not extract any information about real-world distances directly. When a camera is calibrated, it is possible to rectify the images. In this case one can assign world coordinates to the image. For further information we refer to the "Solution Guide III-C - 3D Vision".

```
affine_trans_pixel ( : : HomMat2D, Row, Col : RowTrans,
    ColTrans )
```

Apply an arbitrary affine 2D transformation to pixel coordinates.

affine_trans_pixel applies an arbitrary affine 2D transformation, i.e., scaling, rotation, translation, and slant (skewing), to the input pixels (Row,Col) and returns the resulting pixels in (RowTrans,ColTrans); the input and output pixels are subpixel precise coordinates. The affine transformation is described by the homogeneous transformation matrix given in HomMat2D.

In contrast to affine_trans_point_2d, affine_trans_pixel first converts the input coordinates from HALCON's standard coordinate system (with the origin in the center of the upper left pixel) to a coordinate system with the origin in the upper left corner of the upper left pixel. After the transformation with HomMat2D the result is converted back to the standard coordinate system. This way, affine_trans_pixel is compatible with affine_trans_image, affine_trans_image_size, affine_trans_region, affine_trans_contour_xld, and affine_trans_polygon_xld.

Applying affine_trans_pixel corresponds to the following chain of transformations (input and output pixels as homogeneous vectors):

$$\begin{pmatrix} \texttt{RowTrans} \\ \texttt{ColTrans} \\ 1 \end{pmatrix} = \begin{bmatrix} 1 & 0 & -0.5 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D} \cdot \begin{bmatrix} 1 & 0 & +0.5 \\ 0 & 1 & +0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} \texttt{Row} \\ \texttt{Col} \\ 1 \end{pmatrix}$$

Hence, affine_trans_pixel(HomMat2D, Row, Col, RowTrans, ColTrans) corresponds to the following operator sequence:

```
affine_trans_point_2d(HomMat2D, Row+0.5, Col+0.5, RowTmp, ColTmp)
RowTrans := RowTmp-0.5
ColTrans := ColTmp-0.5
```

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- ▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
  Input transformation matrix.
- ▷ **Row** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
  Input pixel(s) (row coordinate).
  Default: 64
  Suggested values: Row ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **Col** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
  Input pixel(s) (column coordinate).
  Default: 64
  Suggested values: Col ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **RowTrans** (output_control) . . . . . point.x(-array) ⇝ *real*
  Output pixel(s) (row coordinate).
- ▷ **ColTrans** (output_control) . . . . . point.y(-array) ⇝ *real*
  Output pixel(s) (column coordinate).

Result

If the matrix HomMat2D represents an affine transformation (i.e., not a projective transformation), affine_trans_pixel returns 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

hom_mat2d_translate, hom_mat2d_translate_local, hom_mat2d_scale, hom_mat2d_scale_local, hom_mat2d_rotate, hom_mat2d_rotate_local,

hom_mat2d_slant, hom_mat2d_slant_local, hom_mat2d_reflect, hom_mat2d_reflect_local

Alternatives

affine_trans_point_2d

Module

Foundation

affine_trans_point_2d (: : HomMat2D, Px, Py : Qx, Qy)

Apply an arbitrary affine 2D transformation to points.

affine_trans_point_2d applies an arbitrary affine 2D transformation, i.e., scaling, rotation, translation, and slant (skewing), to the input points (Px,Py) and returns the resulting points in (Qx,Qy). The affine transformation is described by the homogeneous transformation matrix given in HomMat2D. This corresponds to the following equation (input and output points as homogeneous vectors):

$$\begin{pmatrix} Qx \\ Qy \\ 1 \end{pmatrix} = HomMat2D \cdot \begin{pmatrix} Px \\ Py \\ 1 \end{pmatrix}$$

If the points to transform are specified in standard image coordinates, their *row* coordinates must be passed in Px and their *column* coordinates in Py. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

The transformation matrix can be created using the operators hom_mat2d_identity, hom_mat2d_rotate, hom_mat2d_translate, etc., or can be the result of operators like vector_angle_to_rigid.

For example, if HomMat2D corresponds to a rigid transformation, i.e., if it consists of a rotation and a translation, the points are transformed as follows:

$$\begin{pmatrix} Qx \\ Qy \\ 1 \end{pmatrix} = \begin{bmatrix} \mathbf{R} & \mathbf{T} \\ 0\,0 & 1 \end{bmatrix} \cdot \begin{pmatrix} Px \\ Py \\ 1 \end{pmatrix} = \begin{pmatrix} \mathbf{R} \cdot \begin{pmatrix} Px \\ Py \end{pmatrix} + \mathbf{T} \\ 1 \end{pmatrix}$$

Parameters

- ▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
  Input transformation matrix.
- ▷ **Px** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
  Input point(s) (x or row coordinate).
  Default: 64
  Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **Py** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
  Input point(s) (y or column coordinate).
  Default: 64
  Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **Qx** (output_control) . . . . . point.x(-array) ⇝ *real*
  Output point(s) (x or row coordinate).
- ▷ **Qy** (output_control) . . . . . point.y(-array) ⇝ *real*
  Output point(s) (y or column coordinate).

Result

If the matrix HomMat2D represents an affine transformation (i.e., not a projective transformation), affine_trans_point_2d returns 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

Module

Foundation

deserialize_hom_mat2d (: : SerializedItemHandle : HomMat2D)

Deserialize a serialized homogeneous 2D transformation matrix.

deserialize_hom_mat2d deserializes a homogeneous 2D transformation matrix, that was serialized by serialize_hom_mat2d (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized transformation matrix is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created transformation matrix with the handle HomMat2D.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **HomMat2D** (output_control) ..... hom_mat2d ⇝ *real*
Transformation matrix.

Result

If the parameters are valid, the operator deserialize_hom_mat2d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_hom_mat2d

Module

Foundation

hom_mat2d_compose (: : HomMat2DLeft, HomMat2DRight : HomMat2DCompose)

Multiply two homogeneous 2D transformation matrices.

hom_mat2d_compose composes a new 2D transformation matrix by multiplying the two input matrices:

$$\text{HomMat2DCompose} = \text{HomMat2DLeft} \cdot \text{HomMat2DRight}$$

For example, if the two input matrices correspond to rigid transformations, i.e., to transformations consisting of a rotation and a translation, the resulting matrix is calculated as follows:

$$\texttt{HomMat2DCompose} = \begin{bmatrix} \mathbf{R}_l & \mathbf{T}_l \\ 0\,0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R}_r & \mathbf{T}_r \\ 0\,0 & 1 \end{bmatrix} = \begin{bmatrix} \mathbf{R}_l \cdot \mathbf{R}_r & \mathbf{R}_l \cdot \mathbf{T}_r + \mathbf{T}_l \\ 0\quad 0 & 1 \end{bmatrix}$$

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2DLeft** (input_control) ..... hom_mat2d ⇝ *real*
Left input transformation matrix.

▷ **HomMat2DRight** (input_control) ..... hom_mat2d ⇝ *real*
Right input transformation matrix.

▷ **HomMat2DCompose** (output_control) ..... hom_mat2d ⇝ *real*
Output transformation matrix.

Result

If the parameters are valid, the operator `hom_mat2d_compose` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Possible Successors

`hom_mat2d_compose`, `hom_mat2d_translate`, `hom_mat2d_translate_local`, `hom_mat2d_scale`, `hom_mat2d_scale_local`, `hom_mat2d_rotate`, `hom_mat2d_rotate_local`, `hom_mat2d_slant`, `hom_mat2d_slant_local`, `hom_mat2d_reflect`, `hom_mat2d_reflect_local`

Module

Foundation

hom_mat2d_determinant (: : HomMat2D : Determinant)

Compute the determinant of a homogeneous 2D transformation matrix.

`hom_mat2d_determinant` computes the determinant of the homogeneous 2D transformation matrix given by `HomMat2D` and returns it in `Determinant`.

Parameters

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Determinant** (output_control) . . . . . real ⇝ *real*
Determinant of the input matrix.

Result

`hom_mat2d_determinant` always returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`hom_mat2d_translate`, `hom_mat2d_translate_local`, `hom_mat2d_scale`, `hom_mat2d_scale_local`, `hom_mat2d_rotate`, `hom_mat2d_rotate_local`, `hom_mat2d_slant`, `hom_mat2d_slant_local`, `hom_mat2d_reflect`, `hom_mat2d_reflect_local`

Module

Foundation

hom_mat2d_identity (: : : HomMat2DIdentity)

Generate the homogeneous transformation matrix of the identical 2D transformation.

`hom_mat2d_identity` generates the homogeneous transformation matrix `HomMat2DIdentity` describing the identical 2D transformation:

$$\texttt{HomMat2DIdentity} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is not stored because it is identical for all homogeneous matrices that describe an affine transformation. Thus, `HomMat2DIdentity` is stored as the tuple [1,0,0,0,1,0].

Parameters

▷ **HomMat2DIdentity** (output_control) . . . . . hom_mat2d ⇝ *real*
Transformation matrix.

Result

`hom_mat2d_identity` always returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`hom_mat2d_translate`, `hom_mat2d_translate_local`, `hom_mat2d_scale`, `hom_mat2d_scale_local`, `hom_mat2d_rotate`, `hom_mat2d_rotate_local`, `hom_mat2d_slant`, `hom_mat2d_slant_local`, `hom_mat2d_reflect`, `hom_mat2d_reflect_local`

Module

Foundation

hom_mat2d_invert (: : HomMat2D : HomMat2DInvert)

Invert a homogeneous 2D transformation matrix.

hom_mat2d_invert inverts the homogeneous 2D transformation matrix given by HomMat2D. The resulting matrix is returned in HomMat2DInvert.

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **HomMat2DInvert** (output_control) . . . . . hom_mat2d ⇝ *real*
Output transformation matrix.

Result

hom_mat2d_invert returns 2 (H_MSG_TRUE) if the parameters are valid and the input matrix is invertible. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

hom_mat2d_translate, hom_mat2d_translate_local, hom_mat2d_scale, hom_mat2d_scale_local, hom_mat2d_rotate, hom_mat2d_rotate_local, hom_mat2d_slant, hom_mat2d_slant_local, hom_mat2d_reflect, hom_mat2d_reflect_local

Possible Successors

hom_mat2d_translate, hom_mat2d_translate_local, hom_mat2d_scale, hom_mat2d_scale_local, hom_mat2d_rotate, hom_mat2d_rotate_local, hom_mat2d_slant, hom_mat2d_slant_local, hom_mat2d_reflect, hom_mat2d_reflect_local

Module

Foundation

hom_mat2d_reflect (: : HomMat2D, Px, Py, Qx, Qy : HomMat2DReflect)

Add a reflection to a homogeneous 2D transformation matrix.

hom_mat2d_reflect adds a reflection about the axis given by the two points (Px,Py) and (Qx,Qy) to the homogeneous 2D transformation matrix HomMat2D and returns the resulting matrix in HomMat2DReflect. The reflection is described by a 2×2 reflection matrix $\mathbf{M}$. It is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chain of transformation matrices:

$$\text{HomMat2DReflect} = \begin{bmatrix} \mathbf{M} & & 0 \\ & & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \text{HomMat2D} \qquad \mathbf{M} = \mathbf{I} - \frac{2}{v^T v} v v^T$$

where $v = (\texttt{Py} - \texttt{Qy}, \texttt{Qx} - \texttt{Px})^T$ is the normal vector to the axis.

The axis $(\texttt{Px}, \texttt{Py}) - (\texttt{Qx}, \texttt{Qy})$ is fixed in the transformation, i.e., the points on the axis remain unchanged when transformed using HomMat2DReflect. To obtain this behavior, first a translation is added to the input transformation matrix that moves the axis onto the origin of the global coordinate system. Then, the reflection is added, and finally a translation that moves the axis back to its original position. This corresponds to the following chain of transformations:

$$\texttt{HomMat2DReflect} = \begin{bmatrix} 1 & 0 & +\texttt{Px} \\ 0 & 1 & +\texttt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} & \mathbf{M} & 0 \\ & & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & -\texttt{Px} \\ 0 & 1 & -\texttt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat2D, use hom_mat2d_reflect_local.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

- ▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
  Input transformation matrix.
- ▷ **Px** (input_control) ..... point.x ⇝ *real* / integer
  First point of the axis (x coordinate).
  Default: 0
  Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **Py** (input_control) ..... point.y ⇝ *real* / integer
  First point of the axis (y coordinate).
  Default: 0
  Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **Qx** (input_control) ..... point.x ⇝ *real* / integer
  Second point of the axis (x coordinate).
  Default: 16
  Suggested values: Qx ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **Qy** (input_control) ..... point.y ⇝ *real* / integer
  Second point of the axis (y coordinate).
  Default: 32
  Suggested values: Qy ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **HomMat2DReflect** (output_control) ..... hom_mat2d ⇝ *real*
  Output transformation matrix.

Result

hom_mat2d_reflect returns 2 (H_MSG_TRUE) if both points on the axis are not identical. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

hom_mat2d_reflect_local

Module

Foundation

hom_mat2d_reflect_local (: : HomMat2D, Px, Py : HomMat2DReflect)

Add a reflection to a homogeneous 2D transformation matrix.

hom_mat2d_reflect_local adds a reflection about the axis given by the two points (0,0) and (Px,Py) to the homogeneous 2D transformation matrix HomMat2D and returns the resulting matrix in HomMat2DReflect. The reflection is described by a 2×2 reflection matrix $\mathbf{M}$. In contrast to hom_mat2d_reflect, it is performed relative to the local coordinate system, i.e., the coordinate system described by HomMat2D; this corresponds to the following chain of transformation matrices:

$$\texttt{HomMat2DReflect} = \begin{bmatrix} \mathbf{M} & \begin{matrix}0\\0\end{matrix} \\ \begin{matrix}0 & 0\end{matrix} & 1 \end{bmatrix} \cdot \texttt{HomMat2D} \qquad \mathbf{M} = \mathbf{I} - \frac{2}{v^T v} v v^T$$

where $v = (-\texttt{Py}, \texttt{Px})^T$ is the normal vector to the axis.

The axis $(0,0) - (\texttt{Px}, \texttt{Py})$ is fixed in the transformation, i.e., the points on the axis remain unchanged when transformed using HomMat2DReflect.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Px** (input_control) ..... point.x ⇝ *real* / integer
Point that defines the axis (x coordinate).
Default: 16
Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Py** (input_control) . . . . . point.y ⇝ *real* / integer
Point that defines the axis (y coordinate).
Default: 32
Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **HomMat2DReflect** (output_control) . . . . . hom_mat2d ⇝ *real*
Output transformation matrix.

Result

hom_mat2d_reflect_local returns 2 (H_MSG_TRUE) if the point (Px, Py) is not $(0, 0)$. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

hom_mat2d_rotate (: : HomMat2D, Phi, Px, Py : HomMat2DRotate)

Add a rotation to a homogeneous 2D transformation matrix.

hom_mat2d_rotate adds a rotation by the angle Phi to the homogeneous 2D transformation matrix HomMat2D and returns the resulting matrix in HomMat2DRotate. The rotation is described by a 2×2 rotation matrix $\mathbf{R}$. It is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chain of transformation matrices:

$$\texttt{HomMat2DRotate} = \begin{bmatrix} \mathbf{R} & & 0 \\ & & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D} \qquad \mathbf{R} = \begin{bmatrix} \cos(\texttt{Phi}) & -\sin(\texttt{Phi}) \\ \sin(\texttt{Phi}) & \cos(\texttt{Phi}) \end{bmatrix}$$

The point (Px,Py) is the fixed point of the transformation, i.e., this point remains unchanged when transformed using HomMat2DRotate. To obtain this behavior, first a translation is added to the input transformation matrix that moves the fixed point onto the origin of the global coordinate system. Then, the rotation is added, and finally a translation that moves the fixed point back to its original position. This corresponds to the following chain of transformations:

$$\texttt{HomMat2DRotate} = \begin{bmatrix} 1 & 0 & +\texttt{Px} \\ 0 & 1 & +\texttt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & & 0 \\ & & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & -\texttt{Px} \\ 0 & 1 & -\texttt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat2D, use hom_mat2d_rotate_local.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in

the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Phi** (input_control) . . . . . angle.rad ⇝ *real* / integer

hom_mat2d_rotate

Module

Foundation

hom_mat2d_scale (: : HomMat2D, Sx, Sy, Px, Py : HomMat2DScale)

Add a scaling to a homogeneous 2D transformation matrix.

hom_mat2d_scale adds a scaling by the scale factors Sx and Sy to the homogeneous 2D transformation matrix HomMat2D and returns the resulting matrix in HomMat2DScale. The scaling is described by a 2×2 scaling matrix $\mathbf{S}$. It is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chain of transformation matrices:

$$\mathtt{HomMat2DScale} = \begin{bmatrix} & \mathbf{S} & & 0 \\ & & & 0 \\ 0 & 0 & & 1 \end{bmatrix} \cdot \mathtt{HomMat2D} \qquad \mathbf{S} = \begin{bmatrix} \mathtt{Sx} & 0 \\ 0 & \mathtt{Sy} \end{bmatrix}$$

The point (Px,Py) is the fixed point of the transformation, i.e., this point remains unchanged when transformed using HomMat2DScale. To obtain this behavior, first a translation is added to the input transformation matrix that moves the fixed point onto the origin of the global coordinate system. Then, the scaling is added, and finally a translation that moves the fixed point back to its original position. This corresponds to the following chain of transformations:

$$\mathtt{HomMat2DScale} = \begin{bmatrix} 1 & 0 & +\mathtt{Px} \\ 0 & 1 & +\mathtt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} & \mathbf{S} & & 0 \\ & & & 0 \\ 0 & 0 & & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & -\mathtt{Px} \\ 0 & 1 & -\mathtt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \mathtt{HomMat2D}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat2D, use hom_mat2d_scale_local.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Sx** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the x-axis.
Default: 2
Suggested values: Sx ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 16}
Restriction: Sx != 0

▷ **Sy** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the y-axis.
Default: 2
Suggested values: Sy ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 16}
Restriction: Sy != 0

▷ **Px** (input_control) . . . . . point.x ⇝ *real* / integer
Fixed point of the transformation (x coordinate).

hom_mat2d_scale_local

Module

Foundation

hom_mat2d_scale_local (: : HomMat2D, Sx, Sy : HomMat2DScale)

Add a scaling to a homogeneous 2D transformation matrix.

hom_mat2d_scale_local adds a scaling by the scale factors Sx and Sy to the homogeneous 2D transformation matrix HomMat2D and returns the resulting matrix in HomMat2DScale. The scaling is described by a 2×2 scaling matrix $\mathbf{S}$. In contrast to hom_mat2d_scale, it is performed relative to the local coordinate system, i.e., the coordinate system described by HomMat2D; this corresponds to the following chain of transformation matrices:

$$\text{HomMat2DScale} = \text{HomMat2D} \cdot \begin{bmatrix} & \mathbf{S} & & 0 \\ & & & 0 \\ 0 & & 0 & 1 \end{bmatrix} \qquad \mathbf{S} = \begin{bmatrix} \text{Sx} & 0 \\ 0 & \text{Sy} \end{bmatrix}$$

The fixed point of the transformation is the origin of the local coordinate system, i.e., this point remains unchanged when transformed using HomMat2DScale.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Sx** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the x-axis.
Default: 2
Suggested values: Sx ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 16}
Restriction: Sx != 0

▷ **Sy** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the y-axis.
Default: 2
Suggested values: Sy ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 16}
Restriction: Sy != 0

▷ **HomMat2DScale** (output_control) . . . . . hom_mat2d ⇝ *real*
Output transformation matrix.

Result

hom_mat2d_scale_local returns 2 (H_MSG_TRUE) if both scale factors are not 0. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

hom_mat2d_scale

Module

Foundation

hom_mat2d_slant (: : HomMat2D, Theta, Axis, Px, Py : HomMat2DSlant)

Add a slant to a homogeneous 2D transformation matrix.

hom_mat2d_slant adds a slant by the angle Theta to the homogeneous 2D transformation matrix HomMat2D and returns the resulting matrix in HomMat2DSlant. A slant is an affine transformation in which one coordinate axis remains fixed, while the other coordinate axis is rotated counterclockwise by an angle Theta. The parameter Axis determines which coordinate axis is slanted. For Axis = *'x'*, the x-axis is slanted and the y-axis remains fixed, while for Axis = *'y'* the y-axis is slanted and the x-axis remains fixed. The slanting is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chains of transformation matrices:

$$\texttt{Axis} = 'x': \quad \texttt{HomMat2DSlant} = \begin{bmatrix} \cos(\texttt{Theta}) & 0 & 0 \\ \sin(\texttt{Theta}) & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D}$$

$$\texttt{Axis} = 'y': \quad \texttt{HomMat2DSlant} = \begin{bmatrix} 1 & -\sin(\texttt{Theta}) & 0 \\ 0 & \cos(\texttt{Theta}) & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D}$$

The point (Px,Py) is the fixed point of the transformation, i.e., this point remains unchanged when transformed using HomMat2DSlant. To obtain this behavior, first a translation is added to the input transformation matrix that moves the fixed point onto the origin of the global coordinate system. Then, the slant is added, and finally a translation that moves the fixed point back to its original position. This corresponds to the following chain of transformations for Axis = *'x'*:

$$\texttt{HomMat2DSlant} = \begin{bmatrix} 1 & 0 & +\texttt{Px} \\ 0 & 1 & +\texttt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \cos(\texttt{Theta}) & 0 & 0 \\ \sin(\texttt{Theta}) & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & -\texttt{Px} \\ 0 & 1 & -\texttt{Py} \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat2D, use hom_mat2d_slant_local.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
Input transformation matrix.

▷ **Theta** (input_control) ..... angle.rad ⇝ *real* / integer
Slant angle.
Default: 0.78
Suggested values: Theta ∈ {0.1, 0.2, 0.3, 0.4, 0.78, 1.57, 3.14}
Value range: 0 ≤ Theta ≤ 6.28318530718

▷ **Axis** (input_control) ..... string ⇝ *string*
Coordinate axis that is slanted.
Default: 'x'
List of values: Axis ∈ {'x', 'y'}

▷ **Px** (input_control) ..... point.x ⇝ *real* / integer
Fixed point of the transformation (x coordinate).
Default: 0
Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Py** (input_control) ..... point.y ⇝ *real* / integer
Fixed point of the transformation (y coordinate).
Default: 0
Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **HomMat2DSlant** (output_control) . . . . . hom_mat2d ⇝ *real*
Output transformation matrix.

Result

If the parameters are valid, the operator `hom_mat2d_slant` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

`hom_mat2d_slant_local`

Module

Foundation

hom_mat2d_slant_local (: : HomMat2D, Theta, Axis : HomMat2DSlant)

Add a slant to a homogeneous 2D transformation matrix.

`hom_mat2d_slant_local` adds a slant by the angle `Theta` to the homogeneous 2D transformation matrix `HomMat2D` and returns the resulting matrix in `HomMat2DSlant`. A slant is an affine transformation in which one coordinate axis remains fixed, while the other coordinate axis is rotated counterclockwise by an angle `Theta`. The parameter `Axis` determines which coordinate axis is slanted. For `Axis` = *'x'*, the x-axis is slanted and the y-axis remains fixed, while for `Axis` = *'y'* the y-axis is slanted and the x-axis remains fixed. In contrast to `hom_mat2d_slant`, the slanting is performed relative to the local coordinate system, i.e., the coordinate system described by `HomMat2D`; this corresponds to the following chains of transformation matrices:

$$\texttt{Axis} = 'x': \quad \texttt{HomMat2DSlant} = \texttt{HomMat2D} \cdot \begin{bmatrix} \cos(\texttt{Theta}) & 0 & 0 \\ \sin(\texttt{Theta}) & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\texttt{Axis} = 'y': \quad \texttt{HomMat2DSlant} = \texttt{HomMat2D} \cdot \begin{bmatrix} 1 & -\sin(\texttt{Theta}) & 0 \\ 0 & \cos(\texttt{Theta}) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

The fixed point of the transformation is the origin of the local coordinate system, i.e., this point remains unchanged when transformed using `HomMat2DSlant`.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (`Row`,`Column`). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

Parameters

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*

hom_mat2d_slant

Module

Foundation

hom_mat2d_to_affine_par (: : HomMat2D : Sx, Sy, Phi, Theta, Tx, Ty)

Compute the affine transformation parameters from a homogeneous 2D transformation matrix.

hom_mat2d_to_affine_par computes the affine transformation parameters corresponding to the homogeneous 2D transformation matrix HomMat2D. The parameters Sx and Sy determine how the transformation scales the original x- and y-axes, respectively. The two scaling factors are always positive. The angle Theta describes whether the transformed coordinate axes are orthogonal (Theta = 0) or slanted. If $|\text{Theta}| > \pi/2$, the transformation contains a reflection. The angle Phi determines the rotation of the transformed x-axis with respect to the original x-axis. The parameters Tx and Ty determine the translation of the two coordinate systems. The matrix HomMat2D can be constructed from the six transformation parameters by the following operator sequence:

```
hom_mat2d_identity(HomMat2DIdentity)
hom_mat2d_scale(HomMat2DIdentity, Sx, Sy, 0, 0, HomMat2DScale)
hom_mat2d_slant(HomMat2DScale, Theta, 'y', 0, 0, HomMat2DSlant)
hom_mat2d_rotate(HomMat2DSlant, Phi, 0, 0, HomMat2DRotate)
hom_mat2d_translate(HomMat2DRotate, Tx, Ty, HomMat2D)
```

This is equivalent to the following chain of transformation matrices:

$$\mathtt{HomMat2D} = \begin{bmatrix} 1 & 0 & +\mathtt{Tx} \\ 0 & 1 & +\mathtt{Ty} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \cos(\mathtt{Phi}) & -\sin(\mathtt{Phi}) & 0 \\ \sin(\mathtt{Phi}) & \cos(\mathtt{Phi}) & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & -\sin(\mathtt{Theta}) & 0 \\ 0 & \cos(\mathtt{Theta}) & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathtt{Sx} & 0 & 0 \\ 0 & \mathtt{Sy} & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Parameters

- ▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
  Input transformation matrix.
- ▷ **Sx** (output_control) . . . . . real ⇝ *real*
  Scaling factor along the x direction.
- ▷ **Sy** (output_control) . . . . . real ⇝ *real*
  Scaling factor along the y direction.
- ▷ **Phi** (output_control) . . . . . angle.rad ⇝ *real*
  Rotation angle.
- ▷ **Theta** (output_control) . . . . . angle.rad ⇝ *real*
  Slant angle.
- ▷ **Tx** (output_control) . . . . . point.x ⇝ *real*
  Translation along the x direction.
- ▷ **Ty** (output_control) . . . . . point.y ⇝ *real*
  Translation along the y direction.

Result

If the matrix HomMat2D is non-degenerate and represents an affine transformation (i.e., not a projective transformation), hom_mat2d_to_affine_par returns 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

hom_mat2d_translate, hom_mat2d_scale, hom_mat2d_rotate, hom_mat2d_slant

Module

Foundation

hom_mat2d_translate (: : HomMat2D, Tx, Ty : HomMat2DTranslate)

Add a translation to a homogeneous 2D transformation matrix.

hom_mat2d_translate adds a translation by the vector $\mathbf{T}$ = (Tx,Ty) to the homogeneous 2D transformation matrix HomMat2D and returns the resulting matrix in HomMat2DTranslate. The translation is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chain of transformation matrices:

$$\texttt{HomMat2DTranslate} = \begin{bmatrix} 1 & 0 & \\ 0 & 1 & \mathbf{T} \\ 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat2D} \qquad \mathbf{T} = \begin{pmatrix} \texttt{Tx} \\ \texttt{Ty} \end{pmatrix}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat2D, use hom_mat2d_translate_local.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & tc \\ rd & re & tf \\ 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, tc, rd, re, tf]. However, it is also possible to process full 3×3 matrices, which represent a projective 2D transformation.

hom_mat3d_project (: : HomMat3D, PrincipalPointRow, PrincipalPointCol, Focus : HomMat2D)

Project an affine 3D transformation matrix to a 2D projective transformation matrix.

hom_mat3d_project calculates a homogeneous projection matrix from a homogeneous 3×4 transformation matrix describing an affine transformation in 3D. The result can be used to project a plane, in particular a plane containing an image. The projection matrix defines a projective transformation between two (two-dimensional) planes.

This can be used to create perspective distortions, which occur in a projection of a plane rotated around an axis other than the z axis. Usually, however, projective transformations are determined from point correspondences (see vector_to_proj_hom_mat2d, hom_vector_to_proj_hom_mat2d, and proj_match_points_ransac).

Matrices for rotation, scale, and translation can be constructed using the operators hom_mat3d_identity, hom_mat3d_scale, hom_mat3d_rotate, hom_mat3d_translate and pose_to_hom_mat3d.

Note that for 3D transformations the x-axis represents the column axis while the y-axis represents the row axis (see also Calibration) while in `projective_trans_image`, the first row of `HomMat2D` contains the transformation of the row axis and the second row contains the transformation of the column axis of the image.

The point (`PrincipalPointRow`, `PrincipalPointCol`) is the principal point of the projection and the point (`PrincipalPointRow`, `PrincipalPointCol`, *0*) can thus be interpreted as the position of the camera in a virtual three-dimensional space. The direction of view is along the positive z-axis.

In this virtual space the plane containing the input image as well as the image plane are located at $z =$ `Focus`, which is `Focus` pixels away form the camera. As a result, using the identity matrix as the input matrix `HomMat3D` leads to a matrix `HomMat2D` which also represents the identity in 2D.

Consequently, the parameter `Focus` is the "focal distance" of the virtual camera used and its unit is pixels. Its value influences the degree of perspective distortions. The same input matrix at a bigger focal distance results in weaker distortions than at a low focal distance.

Let H be the affine 3D matrix with elements h_{ij}, $(r, c) =$ (`PrincipalPointRow`, `PrincipalPointCol`) and $f =$ `Focus`.

Then the projective transformation matrix is calculated as follows: First, a 3×4 projection matrix is calculated as:

$$Q = \begin{pmatrix} f & 0 & c \\ 0 & f & r \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 & 0 & -c \\ 0 & 1 & 0 & -r \\ 0 & 0 & 1 & 0 \end{pmatrix} \cdot \begin{pmatrix} h_{11} & h_{12} & h_{13} & h_{14} \\ h_{21} & h_{22} & h_{23} & h_{24} \\ h_{31} & h_{32} & h_{33} & h_{34} \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Since the image of a plane containing points $(x, y, f, 1)^T$ is to be calculated the last two columns of Q can be joined:

$$R = \begin{pmatrix} r_{11} & r_{12} & r_{13} \\ r_{21} & r_{22} & r_{23} \\ r_{31} & r_{32} & r_{33} \end{pmatrix} = \begin{pmatrix} q_{11} & q_{12} & f \cdot q_{13} + q_{14} \\ q_{21} & q_{22} & f \cdot r_{23} + q_{24} \\ q_{31} & q_{32} & f \cdot r_{33} + q_{34} \end{pmatrix} = Q \cdot \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & f \\ 0 & 0 & 1 \end{pmatrix}$$

Finally, the columns and rows of R are swapped in a way that the first row of P contains the transformation of the row coordinates and the second row contains the transformation of the column coordinates so that P can be used directly in `projective_trans_image`:

$$P = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot R \cdot \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The overall transformation can be written as:

$$P = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} f & 0 & c \\ 0 & f & r \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 & 0 & -c \\ 0 & 1 & 0 & -r \\ 0 & 0 & 1 & 0 \end{pmatrix} \cdot H \cdot \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & f \\ 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Parameters

▷ **`HomMat3D`** (input_control) ..... hom_mat3d ⇝ *real*
3 × 4 3D transformation matrix.

▷ **`PrincipalPointRow`** (input_control) ..... point.y ⇝ *real* / integer
Row coordinate of the principal point.
Default: 256
Suggested values: `PrincipalPointRow` ∈ {16, 32, 64, 128, 240, 256, 512}

▷ **`PrincipalPointCol`** (input_control) ..... point.x ⇝ *real* / integer
Column coordinate of the principal point.
Default: 256
Suggested values: `PrincipalPointCol` ∈ {16, 32, 64, 128, 256, 320, 512}

▷ **Focus** (input_control) ..... number ⇝ *real* / integer
Focal length in pixels.
Default: 256
Suggested values: Focus ∈ {1, 2, 5, 256, 32768}

▷ **HomMat2D** (output_control) ..... hom_mat2d ⇝ *real*
Homogeneous projective transformation matrix.

Module

Foundation

hom_vector_to_proj_hom_mat2d (: : Px, Py, Pw, Qx, Qy, Qw, Method : HomMat2D)

Compute a homogeneous transformation matrix using given point correspondences.

hom_vector_to_proj_hom_mat2d determines the homogeneous projective transformation matrix HomMat2D that optimally fulfills the following equations given by at least 4 point correspondences

$$\mathtt{HomMat2D} \cdot \begin{pmatrix} \mathtt{Px} \\ \mathtt{Py} \\ \mathtt{Pw} \end{pmatrix} = \begin{pmatrix} \mathtt{Qx} \\ \mathtt{Qy} \\ \mathtt{Qw} \end{pmatrix}$$

If fewer than 4 pairs of points (Px, Py, Pw), (Qx, Qy, Qw) are given, there exists no unique solution, if exactly 4 pairs are supplied the matrix HomMat2D transforms them in exactly the desired way, and if there are more than 4 point pairs given, hom_vector_to_proj_hom_mat2d seeks to minimize the transformation error. To achieve such a minimization, two different algorithms are available. The algorithm to use can be chosen using the parameter Method. For conventional geometric problems Method=*'normalized_dlt'* usually yields better results. However, if one of the coordinates Qw or Pw equals *0*, Method=*'dlt'* must be chosen.

In contrast to vector_to_proj_hom_mat2d, hom_vector_to_proj_hom_mat2d uses homogeneous coordinates for the points, and hence points at infinity (Pw = *0* or Qw = *0*) can be used to determine the transformation. If finite points are used, typically Pw and Qw are set to *1*. In this case, vector_to_proj_hom_mat2d can also be used. vector_to_proj_hom_mat2d has the advantage that one additional optimization method can be used and that the covariances of the points can be taken into account. If the correspondence between the points has not been determined, proj_match_points_ransac should be used to determine the correspondence as well as the transformation.

If the points to transform are specified in standard image coordinates, their *row* coordinates must be passed in Px and their *column* coordinates in Py. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain

a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Furthermore, it should be noted that if a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, it is assumed that the origin of the coordinate system of the homogeneous transformation matrix lies in the upper left corner of a pixel. The image processing operators that return point coordinates, however, assume a coordinate system in which the origin lies in the center of a pixel. Therefore, to obtain a consistent homogeneous transformation matrix, 0.5 must be added to the point coordinates before computing the transformation.

Parameters

▷ **Px** (input_control) . . . . . number-array ⇝ *real* / integer
Input points 1 (x coordinate).

▷ **Py** (input_control) . . . . . number-array ⇝ *real* / integer
Input points 1 (y coordinate).

▷ **Pw** (input_control) . . . . . number-array ⇝ *real* / integer
Input points 1 (w coordinate).

▷ **Qx** (input_control) . . . . . number-array ⇝ *real*
Input points 2 (x coordinate).

▷ **Qy** (input_control) . . . . . number-array ⇝ *real*
Input points 2 (y coordinate).

▷ **Qw** (input_control) . . . . . number-array ⇝ *real*
Input points 2 (w coordinate).

▷ **Method** (input_control) . . . . . string ⇝ *string*
Estimation algorithm.
Default: 'normalized_dlt'
List of values: `Method` ∈ {'normalized_dlt', 'dlt'}

▷ **HomMat2D** (output_control) . . . . . hom_mat2d ⇝ *real*
Homogeneous projective transformation matrix.

Calibration

point_line_to_hom_mat2d (: : TransformationType, Px, Py, L1x, L1y, L2x, L2y : HomMat2D)

Approximate an affine transformation from point-to-line correspondences.

point_line_to_hom_mat2d approximates an affine transformation from point-to-line correspondences and returns it as the homogeneous transformation matrix HomMat2D (see hom_mat2d_to_affine_par for the content of the homogeneous transformation matrix).

The points are passed in the tuples (Px,Py). Their corresponding lines are specified as two points on the line, which are passed in (L1x,L1y) and (L2x,L2y). Corresponding points and lines must be at the same index positions in these tuples.

The type of transformation to be approximated is determined with TransformationType. Each type of transformation requires a certain minimum number of point-to-line correspondences, as described in the following table:

TransformationType	Type of transformation	Minimum number of correspondences
'translation'	translation	2
'rigid'	rigid transformation	3
'similarity'	similarity transformation	4
'aniso'	anisotropic similarity transformation	5
'affine'	general affine transformation	6

The types of transformations that are supported can be described as follows:

'translation': A translation, i.e., a transformation that can be obtained as follows:

```
hom_mat2d_identity(HomMat2D)
hom_mat2d_translate(HomMat2D, Tx, Ty, HomMat2D)
```

This means that

$$\begin{aligned} \texttt{HomMat2D} &= \begin{bmatrix} 1 & 0 & \\ 0 & 1 & \mathbf{T} \\ 0 & 0 & 1 \end{bmatrix} \\ &= \mathbf{H}(\mathbf{T}) \end{aligned}$$

where $\mathbf{T}$ is the translation vector.

'rigid': A rigid transformation, i.e., a transformation that can be obtained as follows:

```
hom_mat2d_identity(HomMat2D)
hom_mat2d_rotate(HomMat2D, Phi, 0, 0, HomMat2D)
hom_mat2d_translate(HomMat2D, Tx, Ty, HomMat2D)
```

This means that

$$\begin{aligned} \texttt{HomMat2D} &= \begin{bmatrix} \mathbf{R} & \mathbf{T} \\ 0\,0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & \\ 0 & 1 & \mathbf{T} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & 0 \\ & 0 \\ 0\,0 & 1 \end{bmatrix} \\ &= \mathbf{H}(\mathbf{T}) \cdot \mathbf{H}(\mathbf{R}) \end{aligned}$$

where $\mathbf{R}$ is a rotation matrix corresponding to the rotation angle Phi and $\mathbf{T}$ is the translation vector.

'similarity': A similarity transformation, i.e., a transformation that can be obtained as follows (note the identical scale factors in hom_mat2d_scale):

```
hom_mat2d_identity(HomMat2D)
hom_mat2d_scale(HomMat2D, S, S, 0, 0, HomMat2D)
hom_mat2d_rotate(HomMat2D, Phi, 0, 0, HomMat2D)
hom_mat2d_translate(HomMat2D, Tx, Ty, HomMat2D)
```

This means that

$$\begin{aligned}\texttt{HomMat2D} &= \begin{bmatrix} \mathbf{R}\cdot\mathbf{S} & \mathbf{T} \\ 0\;0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & \\ 0 & 1 & \mathbf{T} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & & 0 \\ & & 0 \\ 0\;0 & & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{S} & & 0 \\ & & 0 \\ 0\;0 & & 1 \end{bmatrix} \\ &= \mathbf{H}(\mathbf{T}) \cdot \mathbf{H}(\mathbf{R}) \cdot \mathbf{H}(\mathbf{S})\end{aligned}$$

where $\mathbf{S}$ is a scaling matrix with identical scaling `S` in the x and y directions, $\mathbf{R}$ is a rotation matrix corresponding to the rotation angle `Phi`, and $\mathbf{T}$ is the translation vector.

'aniso': An anisotropic similarity transformation, i.e., a transformation that can be obtained as follows (note the different scale factors in `hom_mat2d_scale`):

```
hom_mat2d_identity(HomMat2D)
hom_mat2d_scale(HomMat2D, Sx, Sy, 0, 0, HomMat2D)
hom_mat2d_rotate(HomMat2D, Phi, 0, 0, HomMat2D)
hom_mat2d_translate(HomMat2D, Tx, Ty, HomMat2D)
```

This means that

$$\begin{aligned}\texttt{HomMat2D} &= \begin{bmatrix} \mathbf{R}\cdot\mathbf{S} & \mathbf{T} \\ 0\;0 & 1 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 & \\ 0 & 1 & \mathbf{T} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & & 0 \\ & & 0 \\ 0\;0 & & 1 \end{bmatrix} \cdot \begin{bmatrix} s_x & 0 & 0 \\ 0 & s_y & 0 \\ 0 & 0 & 1 \end{bmatrix} \\ &= \mathbf{H}(\mathbf{T}) \cdot \mathbf{H}(\mathbf{R}) \cdot \mathbf{H}(\mathbf{S})\end{aligned}$$

where $\mathbf{S}$ is a scaling matrix with non-identical scaling `Sx` and `Sy` in the x and y directions, $\mathbf{R}$ is a rotation matrix corresponding to the rotation angle `Phi`, and $\mathbf{T}$ is the translation vector.

'affine': A general affine transformation, i.e., a transformation that can be obtained as follows:

```
hom_mat2d_identity(HomMat2D)
hom_mat2d_scale(HomMat2D, Sx, Sy, 0, 0, HomMat2D)
hom_mat2d_slant(HomMat2D, Theta, 'y', 0, 0, HomMat2D)
hom_mat2d_rotate(HomMat2D, Phi, 0, 0, HomMat2D)
hom_mat2d_translate(HomMat2D, Tx, Ty, HomMat2D)
```

This means that

$$\texttt{HomMat2D} = \begin{bmatrix} h_{1,1} & h_{1,2} & h_{1,3} \\ h_{2,1} & h_{2,2} & h_{2,3} \\ 0 & 0 & 1 \end{bmatrix}$$

where $h_{1,1}$–$h_{2,3}$ are arbitrary numbers.

The transformation is computed by minimizing the sum of the squared distances of the points (`Px`,`Py`) transformed with the computed transformation to the lines given by (`L1x`,`L1y`) and (`L2x`,`L2y`). The lines are regarded as lines with infinite extent. This means that the points (`Px`,`Py`) transformed with the transformation `HomMat2D` may not lie "between" (`L1x`,`L1y`) and (`L2x`,`L2y`). An exception to this rule occurs for rigid and anisotropic similarity transformations that are determined from the minimum number of point-to-line correspondences (3 and 5, respectively). In this case, there are in general two possible solutions that both yield an error of 0. The algorithm returns the solution for which the transformed points lie as close as possible to the line *segments* given by (`L1x`,`L1y`) and (`L2x`,`L2y`). If a unique solution is desired, one additional point-to-line correspondence should be used (i.e., 4 or 6, respectively).

`HomMat2D` can be used directly with operators that transform data using affine transformations, e.g., `affine_trans_image`.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or

any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Furthermore, it should be noted that if a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, it is assumed that the origin of the coordinate system of the homogeneous transformation matrix lies in the upper left corner of a pixel. The image processing operators that return point coordinates, however, assume a coordinate system in which the origin lies in the center of a pixel. Therefore, to obtain a consistent homogeneous transformation matrix, 0.5 must be added to the point coordinates before computing the transformation.

Parameters

- ▷ **TransformationType** (input_control) ..... string ⇝ *string*
  Type of the transformation to compute.
  Default: 'rigid'
  List of values: TransformationType ∈ {'translation', 'rigid', 'similarity', 'aniso', 'affine'}
- ▷ **Px** (input_control) ..... point.x-array ⇝ *real*
  X coordinates of the original points.
- ▷ **Py** (input_control) ..... point.y-array ⇝ *real*
  Y coordinates of the original points.
- ▷ **L1x** (input_control) ..... point.x-array ⇝ *real*
  X coordinates of the first point on the corresponding line.
- ▷ **L1y** (input_control) ..... point.y-array ⇝ *real*
  Y coordinates of the first point on the corresponding line.
- ▷ **L2x** (input_control) ..... point.x-array ⇝ *real*
  X coordinates of the second point on the corresponding line.
- ▷ **L2y** (input_control) ..... point.y-array ⇝ *real*
  Y coordinates of the second point on the corresponding line.
- ▷ **HomMat2D** (output_control) ..... hom_mat2d ⇝ *real*
  Output transformation matrix.

Example

```
* Use point_line_to_hom_mat2d for alignment.
* Read the reference image.
read_image (Image, ReferenceFileName)
* Set up the metrology model with four lines.  Four lines are used
* since this is the minimum number of point-to-line correspondences
* that results in a unique rigid transformation.
Row1 := [RowB1,RowB2,RowB3,RowB4]

Module

Foundation

projective_trans_pixel (: : HomMat2D, Row, Col : RowTrans, ColTrans)

Project pixel coordinates using a homogeneous projective transformation matrix.

projective_trans_pixel applies the homogeneous projective transformation matrix HomMat2D to all input pixels (Row,Col) and returns an array of output pixels (RowTrans,ColTrans). The transformation is described by the homogeneous transformation matrix given in HomMat2D.

The difference between projective_trans_pixel and projective_trans_point_2d lies in the used coordinate system: projective_trans_pixel uses a coordinate system with origin in the upper left corner of the image, while projective_trans_point_2d uses the standard image coordinate system, whose origin lies in the middle of the upper left pixel and which is also used by operators like area_center.

projective_trans_pixel corresponds to the following steps (input and output points as homogeneous vectors):

$$\begin{pmatrix} \mathtt{RTrans} \\ \mathtt{CTrans} \\ \mathtt{WTrans} \end{pmatrix} = \mathtt{HomMat2D} \cdot \begin{pmatrix} \mathtt{Row} \\ \mathtt{Col} \\ 1 \end{pmatrix}$$

$$\begin{pmatrix} \mathtt{RowTrans} \\ \mathtt{ColTrans} \end{pmatrix} = \begin{pmatrix} \frac{\mathtt{RTrans}}{\mathtt{WTrans}} \\ \frac{\mathtt{CTrans}}{\mathtt{WTrans}} \end{pmatrix}$$

If a point at infinity (WTrans $= 0$) is created by the transformation, an error is returned.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- ▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
  Homogeneous projective transformation matrix.
- ▷ **Row** (input_control) . . . . . point.x(-array) ⇝ *real* / integer
  Input pixel(s) (row coordinate).
  Default: 64
  Suggested values: Row ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **Col** (input_control) . . . . . point.y(-array) ⇝ *real* / integer
  Input pixel(s) (column coordinate).
  Default: 64
  Suggested values: Col ∈ {0, 16, 32, 64, 128, 256, 512, 1024}
- ▷ **RowTrans** (output_control) . . . . . point.x(-array) ⇝ *real*
  Output pixel(s) (row coordinate).
- ▷ **ColTrans** (output_control) . . . . . point.y(-array) ⇝ *real*
  Output pixel(s) (column coordinate).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

projective_trans_point_2d (: : HomMat2D, Px, Py, Pw : Qx, Qy, Qw)

Project a homogeneous 2D point using a projective transformation matrix.

projective_trans_point_2d applies the homogeneous projective transformation matrix HomMat2D to all homogeneous input points (Px,Py,Pw) and returns an array of homogeneous output points (Qx,Qy,Qw). The transformation is described by the homogeneous transformation matrix given in HomMat2D. This corresponds to the following equation (input and output points as homogeneous vectors):

$$\begin{pmatrix} Qx \\ Qy \\ Qw \end{pmatrix} = HomMat2D \cdot \begin{pmatrix} Px \\ Py \\ Pw \end{pmatrix}$$

To transform the homogeneous coordinates to Euclidean coordinates, they have to be divided by Qw:

$$\begin{pmatrix} Ex \\ Ey \end{pmatrix} = \begin{pmatrix} \frac{Qx}{Qw} \\ \frac{Qy}{Qw} \end{pmatrix}$$

If the points to transform are specified in standard image coordinates, their *row* coordinates must be passed in Px and their *column* coordinates in Py. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

Parameters

- ▷ **HomMat2D** (input_control) . . . hom_mat2d ⇝ *real*
  Homogeneous projective transformation matrix.
- ▷ **Px** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (x coordinate).
- ▷ **Py** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (y coordinate).
- ▷ **Pw** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (w coordinate).
- ▷ **Qx** (output_control) . . . number(-array) ⇝ *real*
  Output point (x coordinate).
- ▷ **Qy** (output_control) . . . number(-array) ⇝ *real*
  Output point (y coordinate).
- ▷ **Qw** (output_control) . . . number(-array) ⇝ *real*
  Output point (w coordinate).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Module

Foundation

serialize_hom_mat2d (: : HomMat2D : SerializedItemHandle)

Serialize a homogeneous 2D transformation matrix.

serialize_hom_mat2d serializes the data of a homogeneous 2D transformation matrix (see fwrite_serialized_item for an introduction of the basic principle of serialization). The transformation matrix is defined by the handle HomMat2D. The serialized transformation matrix is returned by the handle SerializedItemHandle and can be deserialized by deserialize_hom_mat2d.

Parameters

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Transformation matrix.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_hom_mat2d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_hom_mat2d

Module

Foundation

vector_angle_to_rigid (: : Row1, Column1, Angle1, Row2, Column2, Angle2 : HomMat2D)

Compute a rigid affine transformation from points and angles.

vector_angle_to_rigid computes a rigid affine transformation, i.e., a transformation consisting of a rotation and a translation, from a point correspondence and two corresponding angles and returns it as the homogeneous transformation matrix HomMat2D. The matrix consists of 2 components: a rotation matrix $\mathbf{R}$ and a translation vector $\mathbf{T}$ (also see hom_mat2d_rotate and hom_mat2d_translate):

$$\mathtt{HomMat2D} = \begin{bmatrix} \mathbf{R} & \mathbf{T} \\ 0\,0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & \\ 0 & 1 & \mathbf{T} \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & 0 \\ 0\,0 & 1 \end{bmatrix} = \mathbf{H}(\mathbf{T}) \cdot \mathbf{H}(\mathbf{R})$$

The coordinates of the original point are passed in (Row1,Column1), while the corresponding angle is passed in Angle1. The coordinates of the transformed point are passed in (Row2,Column2), while the corresponding angle is passed in Angle2. The following equation describes the transformation of the point using homogeneous vectors:

$$\begin{pmatrix} \mathtt{Row2} \\ \mathtt{Column2} \\ 1 \end{pmatrix} = \mathtt{HomMat2D} \cdot \begin{pmatrix} \mathtt{Row1} \\ \mathtt{Column1} \\ 1 \end{pmatrix}$$

In particular, the operator vector_angle_to_rigid is useful to construct a rigid affine transformation from the results of the matching operators (e.g., find_ncc_model), which transforms a reference image to the current image or (if the parameters are passed in reverse order) from the current image to the reference image.

HomMat2D can be used directly with operators that transform data using affine transformations, e.g., affine_trans_image.

Parameters

- ▷ **Row1** (input_control) . . . . . point.y ⇝ *real* / integer
  Row coordinate of the original point.
- ▷ **Column1** (input_control) . . . . . point.x ⇝ *real* / integer
  Column coordinate of the original point.
- ▷ **Angle1** (input_control) . . . . . angle.rad ⇝ *real* / integer
  Angle of the original point.
- ▷ **Row2** (input_control) . . . . . point.y ⇝ *real* / integer
  Row coordinate of the transformed point.
- ▷ **Column2** (input_control) . . . . . point.x ⇝ *real* / integer
  Column coordinate of the transformed point.
- ▷ **Angle2** (input_control) . . . . . angle.rad ⇝ *real* / integer
  Angle of the transformed point.
- ▷ **HomMat2D** (output_control) . . . . . hom_mat2d ⇝ *real*
  Output transformation matrix.

Example

```
read_image (Image, 'face_masks/face_mask_01')
* Prepare NCC matching.
gen_rectangle2 (ROI, 616.5, 708.5, rad(-82.4054), 50, 35)
reduce_domain (Image, ROI, ImageReduced)
create_ncc_model (ImageReduced, 'auto', rad(0), rad(360), 'auto',\
                  'use_polarity', ModelID)
read_image (SearchImage, 'face_masks/face_mask_02')
find_ncc_model (SearchImage, ModelID, rad(0), rad(360), 0.7, 1, 0.5,\
                'true', 0, Row, Column, Angle, Score)
get_ncc_model_region (ModelRegion, ModelID)
gen_contour_region_xld (ModelRegion, ModelContours, 'border_holes')
* Create transformation matrix for found match.
vector_angle_to_rigid (0, 0, 0, Row, Column, Angle, HomMat2D)
affine_trans_contour_xld (ModelContours, ContoursAffineTrans, HomMat2D)
```

vector_field_to_hom_mat2d (VectorField : : : HomMat2D)

Approximate an affine map from a displacement vector field.

vector_field_to_hom_mat2d approximates an affine map from the displacement vector field VectorField. The affine map is returned in HomMat2D.

If the displacement vector field has been computed from the original image I_{orig} and the second image I_{res}, the internally stored transformation matrix (see affine_trans_image) contains a map that describes how to transform the first image I_{orig} to the second image I_{res}. Note that the VectorField must be in relative coordinates as returned by optical_flow_mg.

Parameters

▷ **VectorField** (input_object) . . . . . singlechannelimage ⇝ *object :* vector_field
Input image.

▷ **HomMat2D** (output_control) . . . . . hom_mat2d ⇝ *real*
Output transformation matrix.

Alternatives

vector_to_hom_mat2d

Module

Foundation

vector_to_aniso (: : Px, Py, Qx, Qy : HomMat2D)

Approximate an anisotropic similarity transformation from point correspondences.

vector_to_aniso approximates an anisotropic similarity transformation, i.e., a transformation consisting of a rotation, a non-uniform scaling, and a translation, from at least three point correspondences and returns it as the homogeneous transformation matrix HomMat2D. The matrix consists of 3 components: a scaling matrix $\mathbf{S}$ with non-identical scaling in the x and y directions, a rotation matrix $\mathbf{R}$, and a translation vector $\mathbf{T}$ (also see hom_mat2d_scale, hom_mat2d_rotate, and hom_mat2d_translate):

$$\texttt{HomMat2D} = \begin{bmatrix} \mathbf{R}\cdot\mathbf{S} & \mathbf{T} \\ 0\ \ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & \mathbf{T} \\ 0 & 1 & \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & & 0 \\ & & 0 \\ 0\,0 & & 1 \end{bmatrix} \cdot \begin{bmatrix} s_x & 0 & 0 \\ 0 & s_y & 0 \\ 0 & 0 & 1 \end{bmatrix} = \mathbf{H}(\mathbf{T})\cdot\mathbf{H}(\mathbf{R})\cdot\mathbf{H}(\mathbf{S})$$

The point correspondences are passed in the tuples (Px,Py) and (Qx,Qy), where corresponding points must be at the same index positions in the tuples. The transformation is always overdetermined. Therefore, the returned transformation is the transformation that minimizes the distances between the original points (Px,Py) and the transformed points (Qx,Qy), as described in the following equation (points as homogeneous vectors):

$$\sum_i \left\| \begin{pmatrix} \texttt{Qx}[i] \\ \texttt{Qy}[i] \\ 1 \end{pmatrix} - \texttt{HomMat2D} \cdot \begin{pmatrix} \texttt{Px}[i] \\ \texttt{Py}[i] \\ 1 \end{pmatrix} \right\|^2 = \text{minimum}$$

HomMat2D can be used directly with operators that transform data using affine transformations, e.g., affine_trans_image.

In an anisotropic similarity transformation, as defined above, the points are first scaled and then rotated. Sometimes, a transformation in which the points are first rotated and then scaled is useful. This kind of transformation can be computed with vector_to_aniso by passing the point correspondences in the opposite order, i.e., the points (Px,Py) are passed in the parameters (Qx,Qy) and vice versa. The resulting transformation must then be inverted with hom_mat2d_invert.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Furthermore, it should be noted that if a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, it is assumed that the origin of the coordinate system of the homogeneous transformation matrix lies in the upper left corner of a pixel. The image processing operators that return point coordinates, however, assume a coordinate system in which the origin lies in the center of a pixel. Therefore, to obtain a consistent homogeneous transformation matrix, 0.5 must be added to the point coordinates before computing the transformation.

Parameters

- ▷ **Px** (input_control) ..... point.x-array ⇝ *real*
  X coordinates of the original points.
- ▷ **Py** (input_control) ..... point.y-array ⇝ *real*
  Y coordinates of the original points.
- ▷ **Qx** (input_control) ..... point.x-array ⇝ *real*
  X coordinates of the transformed points.
- ▷ **Qy** (input_control) ..... point.y-array ⇝ *real*
  Y coordinates of the transformed points.
- ▷ **HomMat2D** (output_control) ..... hom_mat2d ⇝ *real*
  Output transformation matrix.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

vector_to_hom_mat2d (: : Px, Py, Qx, Qy : HomMat2D)

Approximate an affine transformation from point correspondences.

vector_to_hom_mat2d approximates an affine transformation from at least three point correspondences and returns it as the homogeneous transformation matrix HomMat2D (see hom_mat2d_to_affine_par for the content of the homogeneous transformation matrix).

The point correspondences are passed in the tuples (Px,Py) and (Qx,Qy), where corresponding points must be at the same index positions in the tuples. If more than three point correspondences are passed, the transformation is overdetermined. In this case, the returned transformation is the transformation that minimizes the distances between the input points (Px,Py) and the transformed points (Qx,Qy), as described in the following equation (points as homogeneous vectors):

$$\sum_i \left\| \begin{pmatrix} \mathtt{Qx}[i] \\ \mathtt{Qy}[i] \\ 1 \end{pmatrix} - \mathtt{HomMat2D} \cdot \begin{pmatrix} \mathtt{Px}[i] \\ \mathtt{Py}[i] \\ 1 \end{pmatrix} \right\|^2 = \text{minimum}$$

HomMat2D can be used directly with operators that transform data using affine transformations, e.g., affine_trans_image.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Module

Foundation

vector_to_proj_hom_mat2d (: : Px, Py, Qx, Qy, Method, CovXX1, CovYY1, CovXY1, CovXX2, CovYY2, CovXY2 : HomMat2D, Covariance)

Compute a projective transformation matrix using given point correspondences.

vector_to_proj_hom_mat2d determines the homogeneous projective transformation matrix HomMat2D that optimally fulfills the following equations given by at least 4 point correspondences

$$\mathtt{HomMat2D} \cdot \begin{pmatrix} \mathtt{Px} \\ \mathtt{Py} \\ 1 \end{pmatrix} = \begin{pmatrix} \mathtt{Qx} \\ \mathtt{Qy} \\ 1 \end{pmatrix}.$$

If fewer than 4 pairs of points (Px,Py), (Qx,Qy) are given, there exists no unique solution, if exactly 4 pairs are supplied the matrix HomMat2D transforms them in exactly the desired way, and if there are more than 4 point pairs given, vector_to_proj_hom_mat2d seeks to minimize the transformation error. To achieve such a minimization, several different algorithms are available. The algorithm to use can be chosen using the parameter Method. Method=*'dlt'* uses a fast and simple, but also rather inaccurate error estimation algorithm while Method=*'normalized_dlt'* offers a good compromise between speed and accuracy. Finally, Method=*'gold_standard'* performs a mathematically optimal but slower optimization.

If *'gold_standard'* is used and the input points have been obtained from an operator like points_foerstner, which provides a covariance matrix for each of the points, which specifies the accuracy of the points, this can be taken into account by using the input parameters CovYY1, CovXX1, CovXY1 for the points in the first image and CovYY2, CovXX2, CovXY2 for the points in the second image. The covariances are symmetric 2×2 matrices. CovXX1/CovXX2 and CovYY1/CovYY2 are a list of diagonal entries while CovXY1/CovXY2 contains the non-diagonal entries which appear twice in a symmetric matrix. If a different Method than *'gold_standard'* is used or the covariances are unknown the covariance parameters can be left empty.

In contrast to hom_vector_to_proj_hom_mat2d, points at infinity cannot be used to determine the transformation in vector_to_proj_hom_mat2d. If this is necessary, hom_vector_to_proj_hom_mat2d must be used. If the correspondence between the points has not been determined, proj_match_points_ransac should be used to determine the correspondence as well as the transformation.

If the points to transform are specified in standard image coordinates, their *row* coordinates must be passed in Px and their *column* coordinates in Py. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Furthermore, it should be noted that if a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, it is assumed that the origin of the coordinate system of the homogeneous transformation matrix lies in the upper left corner of a pixel. The image processing operators that return point coordinates, however, assume a coordinate system in which the origin lies in the center of a pixel. Therefore, to obtain a consistent homogeneous transformation matrix, 0.5 must be added to the point coordinates before computing the transformation.

Parameters

Calibration

vector_to_proj_hom_mat2d_distortion (: : Points1Row, Points1Col, Points2Row, Points2Col, CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2, ImageWidth, ImageHeight, Method : HomMat2D, Kappa, Error)

Compute a projective transformation matrix and the radial distortion coefficient using given image point correspondences.

vector_to_proj_hom_mat2d_distortion determines the projective transformation matrix HomMat2D and the radial distortion coefficient Kappa (κ) from given point correspondences (Points1Row,Points1Col), (Points2Row,Points2Col) that optimally fulfill the following equation:

$$\begin{pmatrix} r_2 \\ c_2 \\ 1 \end{pmatrix} = \text{HomMat2D} \cdot \begin{pmatrix} r_1 \\ c_1 \\ 1 \end{pmatrix}.$$

Here, (r_1, c_1) and (r_2, c_2) denote image points that are obtained by undistorting the input image points with the division model (see Calibration):

$$r = \frac{\tilde{r}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)} \qquad c = \frac{\tilde{c}}{1 + \kappa(\tilde{r}^2 + \tilde{c}^2)}$$

Here, $(\tilde{r}_1, \tilde{c}_1) = (\text{Points1Row} - 0.5(\text{ImageHeight} - 1), \text{Points1Col} - 0.5(\text{ImageWidth} - 1))$ and $(\tilde{r}_2, \tilde{c}_2) = (\text{Points2Row} - 0.5(\text{ImageHeight} - 1), \text{Points2Col} - 0.5(\text{ImageWidth} - 1))$ denote the distorted image points, specified relative to the image center. Thus, vector_to_proj_hom_mat2d_distortion assumes that the principal point of the camera, i.e., the center of the radial distortions, lies at the center of the image. Note that the images from which the points (Points1Row,Points1Col) and (Points2Row,Points2Col) are extracted have to be obtained with the same camera.

The returned Kappa can be used to construct camera parameters that can be used to rectify images or points (see change_radial_distortion_cam_par, change_radial_distortion_image, and change_radial_distortion_points):

$$\begin{aligned} \text{CamPar} = [&'\textit{area\_scan\_telecentric\_division}', 1.0, \text{Kappa}, 1.0, 1.0, 0.5(\text{ImageWidth} - 1), \\ &0.5(\text{ImageHeight} - 1), \text{ImageWidth}, \text{ImageHeight}] \end{aligned}$$

The minimum number of required point correspondences is five. vector_to_proj_hom_mat2d_distortion seeks to minimize the transformation error between the point correspondences based on the above equations. To achieve such a minimization, two different algorithms are available. The algorithm to use can be chosen using the parameter Method. For Method = *'linear'*, a linear algorithm that minimizes an algebraic error based on the above equations is used. This algorithm is very fast and returns accurate results for small to moderate noise of the point coordinates and for most distortions (except for small distortions). For Method = *'gold_standard'*, a mathematically optimal but slower optimization is used, which minimizes the geometric reprojection error. In general, it is preferable to use Method = *'gold_standard'*.

If *'gold_standard'* is used, the covariances of the image points (CovRR1, CovRC1, CovCC1, CovRR2, CovRC2, CovCC2) can be incorporated into the computation. They can be provided, for example, by the operator points_foerstner. If the point covariances are unknown, which is the default, empty tuples are passed. In this case, the optimization algorithm internally assumes uniform and equal covariances for all points. If *'linear'* is used, the covariances are ignored and the covariance parameters can be left empty.

The value Error indicates the overall quality of the optimization procedure and is the mean symmetric euclidean distance in pixels between the points and their corresponding transformed points.

If the correspondence between the points has not been determined, proj_match_points_distortion_ransac or proj_match_points_distortion_ransac_guided should be used to determine the correspondence as well as the transformation.

Attention

It should be noted that if a homogeneous transformation matrix is used to transform images, regions, XLD contours,

or any other data that has been extracted from images, it is assumed that the origin of the coordinate system of the homogeneous transformation matrix lies in the upper left corner of a pixel. The image processing operators that return point coordinates, however, assume a coordinate system in which the origin lies in the center of a pixel. Therefore, to obtain a consistent homogeneous transformation matrix, 0.5 must be added to the point coordinates before computing the transformation.

Parameters

Column coordinate variance of the points in image 1.
Default: []

▷ **CovRR2** (input_control) . . . . . number-array ⇝ *real* / integer
Row coordinate variance of the points in image 2.
Default: []

▷ **CovRC2** (input_control) . . . . . number-array ⇝ *real* / integer
Covariance of the points in image 2.
Default: []

▷ **CovCC2** (input_control) . . . . . number-array ⇝ *real* / integer
Column coordinate variance of the points in image 2.
Default: []

▷ **ImageWidth** (input_control) . . . . . integer ⇝ *integer*
Width of the images from which the points were extracted.
Restriction: ImageWidth > 0

▷ **ImageHeight** (input_control) . . . . . integer ⇝ *integer*
Height of the images from which the points were extracted.
Restriction: ImageHeight > 0

▷ **Method** (input_control) . . . . . string ⇝ *string*
Estimation algorithm.
Default: 'gold_standard'
List of values: `Method` ∈ {'linear', 'gold_standard'}

▷ **HomMat2D** (output_control) . . . . . hom_mat2d ⇝ *real*
Homogeneous projective transformation matrix.

▷ **Kappa** (output_control) . . . . . real ⇝ *real*
Computed radial distortion coefficient.

▷ **Error** (output_control) . . . . . real ⇝ *real*
Root-Mean-Square transformation error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

vector_to_rigid (: : Px, Py, Qx, Qy : HomMat2D)

Approximate a rigid affine transformation from point correspondences.

vector_to_rigid approximates a rigid affine transformation, i.e., a transformation consisting of a rotation and a translation, from at least two point correspondences and returns it as the homogeneous transformation matrix HomMat2D. The matrix consists of 2 components: a rotation matrix $\mathbf{R}$ and a translation vector $\mathbf{T}$ (also see hom_mat2d_rotate and hom_mat2d_translate):

$$\texttt{HomMat2D} = \begin{bmatrix} \mathbf{R} & \mathbf{T} \\ 0\,0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & \mathbf{T} \\ 0 & 1 & \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & 0 \\ & 0 \\ 0\,0 & 1 \end{bmatrix} = \mathbf{H}(\mathbf{T}) \cdot \mathbf{H}(\mathbf{R})$$

The point correspondences are passed in the tuples (Px, Py) and (Qx,Qy), where corresponding points must be at the same index positions in the tuples. The transformation is always overdetermined. Therefore, the returned transformation is the transformation that minimizes the distances between the original points (Px,Py) and the transformed points (Qx,Qy), as described in the following equation (points as homogeneous vectors):

$$\sum_i \left\| \begin{pmatrix} \texttt{Qx}[i] \\ \texttt{Qy}[i] \\ 1 \end{pmatrix} - \texttt{HomMat2D} \cdot \begin{pmatrix} \texttt{Px}[i] \\ \texttt{Py}[i] \\ 1 \end{pmatrix} \right\|^2 = \text{minimum}$$

HomMat2D can be used directly with operators that transform data using affine transformations, e.g., affine_trans_image.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain

a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Furthermore, it should be noted that if a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, it is assumed that the origin of the coordinate system of the homogeneous transformation matrix lies in the upper left corner of a pixel. The image processing operators that return point coordinates, however, assume a coordinate system in which the origin lies in the center of a pixel. Therefore, to obtain a consistent homogeneous transformation matrix, 0.5 must be added to the point coordinates before computing the transformation.

Parameters

- ▷ **Px** (input_control) . . . . . point.x-array ⇝ *real*
  X coordinates of the original points.
- ▷ **Py** (input_control) . . . . . point.y-array ⇝ *real*
  Y coordinates of the original points.
- ▷ **Qx** (input_control) . . . . . point.x-array ⇝ *real*
  X coordinates of the transformed points.
- ▷ **Qy** (input_control) . . . . . point.y-array ⇝ *real*
  Y coordinates of the transformed points.
- ▷ **HomMat2D** (output_control) . . . . . hom_mat2d ⇝ *real*
  Output transformation matrix.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

vector_to_similarity (: : Px, Py, Qx, Qy : HomMat2D)

Approximate an similarity transformation from point correspondences.

vector_to_similarity approximates a similarity transformation, i.e., a transformation consisting of a uniform scaling, a rotation, and a translation, from at least two point correspondences and returns it as the homogeneous transformation matrix HomMat2D. The matrix consists of 3 components: a scaling matrix $\mathbf{S}$ with identical scaling in the x and y directions, a rotation matrix $\mathbf{R}$, and a translation vector $\mathbf{T}$ (also see hom_mat2d_scale, hom_mat2d_rotate, and hom_mat2d_translate):

$$\mathtt{HomMat2D} = \begin{bmatrix} \mathbf{R}\cdot\mathbf{S} & \mathbf{T} \\ 0\ \ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & \mathbf{T} \\ 0 & 1 & \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R} & 0 \\ & 0 \\ 0\ \ 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{S} & 0 \\ & 0 \\ 0\ \ 0 & 1 \end{bmatrix} = \mathbf{H}(\mathbf{T}) \cdot \mathbf{H}(\mathbf{R}) \cdot \mathbf{H}(\mathbf{S})$$

The point correspondences are passed in the tuples (Px, Py) and (Qx,Qy), where corresponding points must be at the same index positions in the tuples. If more than two point correspondences are passed, the transformation is overdetermined. In this case, the returned transformation is the transformation that minimizes the distances between the original points (Px,Py) and the transformed points (Qx,Qy), as described in the following equation (points as homogeneous vectors):

$$\sum_i \left\| \begin{pmatrix} \texttt{Qx}[i] \\ \texttt{Qy}[i] \\ 1 \end{pmatrix} - \texttt{HomMat2D} \cdot \begin{pmatrix} \texttt{Px}[i] \\ \texttt{Py}[i] \\ 1 \end{pmatrix} \right\|^2 = \text{minimum}$$

HomMat2D can be used directly with operators that transform data using affine transformations, e.g., affine_trans_image.

Attention

It should be noted that homogeneous transformation matrices refer to a general right-handed mathematical coordinate system. If a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, the row coordinates of the transformation must be passed in the x coordinates, while the column coordinates must be passed in the y coordinates. Consequently, the order of passing row and column coordinates follows the usual order (Row,Column). This convention is essential to obtain a right-handed coordinate system for the transformation of iconic data, and consequently to ensure in particular that rotations are performed in the correct mathematical direction.

Furthermore, it should be noted that if a homogeneous transformation matrix is used to transform images, regions, XLD contours, or any other data that has been extracted from images, it is assumed that the origin of the coordinate system of the homogeneous transformation matrix lies in the upper left corner of a pixel. The image processing operators that return point coordinates, however, assume a coordinate system in which the origin lies in the center of a pixel. Therefore, to obtain a consistent homogeneous transformation matrix, 0.5 must be added to the point coordinates before computing the transformation.

Parameters

- ▷ **Px** (input_control) ..... point.x-array ⇝ *real*
  X coordinates of the original points.
- ▷ **Py** (input_control) ..... point.y-array ⇝ *real*
  Y coordinates of the original points.
- ▷ **Qx** (input_control) ..... point.x-array ⇝ *real*
  X coordinates of the transformed points.
- ▷ **Qy** (input_control) ..... point.y-array ⇝ *real*
  Y coordinates of the transformed points.
- ▷ **HomMat2D** (output_control) ..... hom_mat2d ⇝ *real*
  Output transformation matrix.

27.2 3D Transformations

affine_trans_point_3d (: : HomMat3D, Px, Py, Pz : Qx, Qy, Qz)

Apply an arbitrary affine 3D transformation to points.

affine_trans_point_3d applies an arbitrary affine 3D transformation, i.e., scaling, rotation, and translation, to the input points (Px,Py,Pz) and returns the resulting points in (Qx, Qy,Qz). The affine transformation is described by the homogeneous transformation matrix given in HomMat3D. This corresponds to the following equation (input and output points as homogeneous vectors):

$$\begin{pmatrix} Qx \\ Qy \\ Qz \\ 1 \end{pmatrix} = HomMat3D \cdot \begin{pmatrix} Px \\ Py \\ Pz \\ 1 \end{pmatrix}$$

The transformation matrix can be created using the operators hom_mat3d_identity, hom_mat3d_scale, hom_mat3d_rotate, hom_mat3d_translate, etc., or be the result of pose_to_hom_mat3d.

For example, if HomMat3D corresponds to a rigid transformation, i.e., if it consists of a rotation and a translation, the points are transformed as follows:

$$\begin{pmatrix} Qx \\ Qy \\ Qz \\ 1 \end{pmatrix} = \begin{bmatrix} \mathbf{R} & \mathbf{T} \\ 0\,0\,0 & 1 \end{bmatrix} \cdot \begin{pmatrix} Px \\ Py \\ Pz \\ 1 \end{pmatrix} = \begin{pmatrix} \mathbf{R} \cdot \begin{pmatrix} Px \\ Py \\ Pz \end{pmatrix} + \mathbf{T} \\ 1 \end{pmatrix}$$

Parameters

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Input transformation matrix.

▷ **Px** (input_control) . . . . . point3d.x(-array) ⇝ *real* / integer
Input point(s) (x coordinate).
Default: 64
Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Py** (input_control) . . . . . point3d.y(-array) ⇝ *real* / integer
Input point(s) (y coordinate).
Default: 64
Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Pz** (input_control) . . . . . point3d.z(-array) ⇝ *real* / integer
Input point(s) (z coordinate).
Default: 64
Suggested values: Pz ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Qx** (output_control) . . . . . point3d.x(-array) ⇝ *real*
Output point(s) (x coordinate).

▷ **Qy** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Output point(s) (y coordinate).

▷ **Qz** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Output point(s) (z coordinate).

Result

If the parameters are valid, the operator affine_trans_point_3d returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

hom_mat3d_translate, hom_mat3d_translate_local, hom_mat3d_scale, hom_mat3d_scale_local, hom_mat3d_rotate, hom_mat3d_rotate_local

Possible Successors

hom_mat3d_translate, hom_mat3d_translate_local, hom_mat3d_scale, hom_mat3d_scale_local, hom_mat3d_rotate, hom_mat3d_rotate_local

Module

Foundation

deserialize_hom_mat3d (: : SerializedItemHandle : HomMat3D)

Deserialize a serialized homogeneous 3D transformation matrix.

deserialize_hom_mat3d deserializes a homogeneous 3D transformation matrix, that was serialized by serialize_hom_mat3d (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized transformation matrix is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created transformation matrix with the handle HomMat3D.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **HomMat3D** (output_control) ..... hom_mat3d ⇝ *real*
Transformation matrix.

Result

If the parameters are valid, the operator deserialize_hom_mat3d returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_hom_mat3d

Module

Foundation

hom_mat3d_compose (: : HomMat3DLeft,
HomMat3DRight : HomMat3DCompose)

Multiply two homogeneous 3D transformation matrices.

hom_mat3d_compose composes a new 3D transformation matrix by multiplying the two input matrices:

$$\texttt{HomMat3DCompose} = \texttt{HomMat3DLeft} \cdot \texttt{HomMat3DRight}$$

For example, if the two input matrices correspond to rigid transformations, i.e., to transformations consisting of a rotation and a translation, the resulting matrix is calculated as follows:

$$\texttt{HomMat3DCompose} = \begin{bmatrix} \mathbf{R}_l & \mathbf{T}_l \\ 0\,0\,0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R}_r & \mathbf{T}_r \\ 0\,0\,0 & 1 \end{bmatrix} = \begin{bmatrix} \mathbf{R}_l \cdot \mathbf{R}_r & \mathbf{R}_l \cdot \mathbf{T}_r + \mathbf{T}_l \\ 0 \quad 0 \quad 0 & 1 \end{bmatrix}$$

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & rc & td \\ re & rf & rg & th \\ ri & rj & rk & tl \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, rc, td, re, rf, rg, th, ri, rj, rk, tl]. However, it is also possible to process full 4×4 matrices, which represent a projective 4D transformation.

Parameters

▷ **HomMat3DLeft** (input_control) . . . . . hom_mat3d ⇝ *real*
Left input transformation matrix.

▷ **HomMat3DRight** (input_control) . . . . . hom_mat3d ⇝ *real*
Right input transformation matrix.

▷ **HomMat3DCompose** (output_control) . . . . . hom_mat3d ⇝ *real*
Output transformation matrix.

Result

If the parameters are valid, the operator `hom_mat3d_compose` returns `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`hom_mat3d_compose`, `hom_mat3d_translate`, `hom_mat3d_translate_local`, `hom_mat3d_scale`, `hom_mat3d_scale_local`, `hom_mat3d_rotate`, `hom_mat3d_rotate_local`, `pose_to_hom_mat3d`

Possible Successors

`hom_mat3d_compose`, `hom_mat3d_translate`, `hom_mat3d_translate_local`, `hom_mat3d_scale`, `hom_mat3d_scale_local`, `hom_mat3d_rotate`, `hom_mat3d_rotate_local`

Alternatives

`pose_compose`, `dual_quat_compose`

See also

`affine_trans_point_3d`, `hom_mat3d_identity`, `hom_mat3d_rotate`, `hom_mat3d_translate`, `pose_to_hom_mat3d`, `hom_mat3d_to_pose`

Module

Foundation

hom_mat3d_determinant (: : HomMat3D : Determinant)

Compute the determinant of a homogeneous 3D transformation matrix.

`hom_mat3d_determinant` computes the determinant of the homogeneous 3D transformation matrix given by `HomMat3D` and returns it in `Determinant`.

Parameters

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Input transformation matrix.

▷ **Determinant** (output_control) . . . . . real ⇝ *real*
Determinant of the input matrix.

Result

`hom_mat3d_determinant` always returns `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

hom_mat3d_translate, hom_mat3d_translate_local, hom_mat3d_scale, hom_mat3d_scale_local, hom_mat3d_rotate, hom_mat3d_rotate_local, vector_to_hom_mat3d

Module

Foundation

hom_mat3d_identity (: : : HomMat3DIdentity)

Generate the homogeneous transformation matrix of the identical 3D transformation.

hom_mat3d_identity generates the homogeneous transformation matrix HomMat3DIdentity describing the identical 3D transformation:

$$\text{HomMat3DIdentity} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is not stored because it is identical for all homogeneous matrices that describe an affine transformation. Thus, HomMat3DIdentity is stored as the tuple [1,0,0,0,0,1,0,0,0,0,1,0].

Parameters

▷ **HomMat3DIdentity** (output_control) ..... hom_mat3d ⇝ *real*
Transformation matrix.

Result

hom_mat3d_identity always returns 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

hom_mat3d_translate, hom_mat3d_translate_local, hom_mat3d_scale, hom_mat3d_scale_local, hom_mat3d_rotate, hom_mat3d_rotate_local

Alternatives

pose_to_hom_mat3d

Module

Foundation

hom_mat3d_invert (: : HomMat3D : HomMat3DInvert)

Invert a homogeneous 3D transformation matrix.

hom_mat3d_invert inverts the homogeneous 3D transformation matrix given by HomMat3D. The resulting matrix is returned in HomMat3DInvert.

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & rc & td \\ re & rf & rg & th \\ ri & rj & rk & tl \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, rc, td, re, rf, rg, th, ri, rj, rk, tl]. However, it is also possible to process full 4×4 matrices, which represent a projective 4D transformation.

Parameters

▷ **HomMat3D** (input_control) ..... hom_mat3d ⇝ *real*
Input transformation matrix.

▷ **HomMat3DInvert** (output_control) ..... hom_mat3d ⇝ *real*
Output transformation matrix.

Result

hom_mat3d_invert returns 2 (H_MSG_TRUE) if the parameters are valid and the input matrix is invertible. Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

hom_mat3d_rotate (: : HomMat3D, Phi, Axis, Px, Py, Pz : HomMat3DRotate)

Add a rotation to a homogeneous 3D transformation matrix.

hom_mat3d_rotate adds a rotation by the angle Phi around the axis passed in the parameter Axis to the homogeneous 3D transformation matrix HomMat3D and returns the resulting matrix in HomMat3DRotate. The axis can be specified by passing the strings 'x', 'y', or 'z', or by passing a vector [x,y,z] as a tuple.

The rotation is described by a 3×3 rotation matrix $\mathbf{R}$. It is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chain of transformation matrices:

Axis = *'x'*:

$$\text{HomMat3DRotate} = \begin{bmatrix} & & & 0 \\ & \mathbf{R}_x & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \text{HomMat3D} \qquad \mathbf{R}_x = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\text{Phi}) & -\sin(\text{Phi}) \\ 0 & \sin(\text{Phi}) & \cos(\text{Phi}) \end{bmatrix}$$

Axis = *'y'*:

$$\texttt{HomMat3DRotate} = \begin{bmatrix} & & & 0 \\ & \mathbf{R}_y & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat3D} \qquad \mathbf{R}_y = \begin{bmatrix} \cos(\texttt{Phi}) & 0 & \sin(\texttt{Phi}) \\ 0 & 1 & 0 \\ -\sin(\texttt{Phi}) & 0 & \cos(\texttt{Phi}) \end{bmatrix}$$

Axis = *'z'*:

$$\texttt{HomMat3DRotate} = \begin{bmatrix} & & & 0 \\ & \mathbf{R}_z & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat3D} \qquad \mathbf{R}_z = \begin{bmatrix} \cos(\texttt{Phi}) & -\sin(\texttt{Phi}) & 0 \\ \sin(\texttt{Phi}) & \cos(\texttt{Phi}) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Axis = *[x,y,z]*:

$$\texttt{HomMat3DRotate} = \begin{bmatrix} & & & 0 \\ & \mathbf{R}_a & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat3D} \qquad \mathbf{R}_a = \mathbf{u} \cdot \mathbf{u}^{\mathrm{T}} + cos(\texttt{Phi}) \cdot (\mathbf{I} - \mathbf{u} \cdot \mathbf{u}^{\mathrm{T}}) + sin(\texttt{Phi}) \cdot \mathbf{S}$$

$$\mathbf{u} = \frac{\texttt{Axis}}{\|\texttt{Axis}\|} = \begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} \qquad \mathbf{I} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \qquad \mathbf{S} = \begin{bmatrix} 0 & -z' & y' \\ z' & 0 & -x' \\ -y' & x' & 0 \end{bmatrix}$$

The point (Px,Py,Pz) is the fixed point of the transformation, i.e., this point remains unchanged when transformed using HomMat3DRotate. To obtain this behavior, first a translation is added to the input transformation matrix that moves the fixed point onto the origin of the global coordinate system. Then, the rotation is added, and finally a translation that moves the fixed point back to its original position. This corresponds to the following chain of transformations:

$$\texttt{HomMat3DRotate} = \begin{bmatrix} 1 & 0 & 0 & +\texttt{Px} \\ 0 & 1 & 0 & +\texttt{Py} \\ 0 & 0 & 1 & +\texttt{Pz} \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} & & & 0 \\ & \mathbf{R} & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & 0 & -\texttt{Px} \\ 0 & 1 & 0 & -\texttt{Py} \\ 0 & 0 & 1 & -\texttt{Pz} \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \texttt{HomMat3D}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat3D, use hom_mat3d_rotate_local.

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & rc & td \\ re & rf & rg & th \\ ri & rj & rk & tl \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, rc, td, re, rf, rg, th, ri, rj, rk, tl]. However, it is also possible to process full 4×4 matrices, which represent a projective 4D transformation.

Parameters

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Input transformation matrix.

▷ **Phi** (input_control) . . . . . angle.rad ⇝ *real* / integer
Rotation angle.
Default: 0.78
Suggested values: Phi ∈ {0.1, 0.2, 0.3, 0.4, 0.78, 1.57, 3.14}
Value range: 0 ≤ Phi ≤ 6.28318530718

▷ **Axis** (input_control) . . . . . string(-array) ⇝ *string* / real / integer
Axis, to be rotated around.
Default: 'x'
Suggested values: Axis ∈ {'x', 'y', 'z'}

▷ **Px** (input_control) . . . . . point3d.x ⇝ *real* / integer
Fixed point of the transformation (x coordinate).
Default: 0
Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Py** (input_control) . . . . . point3d.y ⇝ *real* / integer
Fixed point of the transformation (y coordinate).
Default: 0
Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Pz** (input_control) . . . . . point3d.z ⇝ *real* / integer
Fixed point of the transformation (z coordinate).
Default: 0
Suggested values: Pz ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **HomMat3DRotate** (output_control) . . . . . hom_mat3d ⇝ *real*
Output transformation matrix.

Result

If the parameters are valid, the operator hom_mat3d_rotate returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

hom_mat3d_rotate_local (: : HomMat3D, Phi, Axis : HomMat3DRotate)

Add a rotation to a homogeneous 3D transformation matrix.

hom_mat3d_rotate_local adds a rotation by the angle Phi around the axis passed in the parameter Axis to the homogeneous 3D transformation matrix HomMat3D and returns the resulting matrix in HomMat3DRotate. The axis can be specified by passing the strings 'x', 'y', or 'z', or by passing a vector [x,y,z] as a tuple.

The rotation is described by a 3×3 rotation matrix $\mathbf{R}$. In contrast to hom_mat3d_rotate, it is performed relative to the local coordinate system, i.e., the coordinate system described by HomMat3D; this corresponds to the following chain of transformation matrices:

Axis = *'x'*:

$$\text{HomMat3DRotate} = \text{HomMat3D} \cdot \begin{bmatrix} & & & 0 \\ & \mathbf{R}_x & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad \mathbf{R}_x = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(\text{Phi}) & -\sin(\text{Phi}) \\ 0 & \sin(\text{Phi}) & \cos(\text{Phi}) \end{bmatrix}$$

Axis = 'y':

$$\texttt{HomMat3DRotate} = \texttt{HomMat3D} \cdot \begin{bmatrix} & & & 0 \\ & \mathbf{R}_y & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad \mathbf{R}_y = \begin{bmatrix} \cos(\texttt{Phi}) & 0 & \sin(\texttt{Phi}) \\ 0 & 1 & 0 \\ -\sin(\texttt{Phi}) & 0 & \cos(\texttt{Phi}) \end{bmatrix}$$

Axis = 'z':

$$\texttt{HomMat3DRotate} = \texttt{HomMat3D} \cdot \begin{bmatrix} & & & 0 \\ & \mathbf{R}_z & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad \mathbf{R}_z = \begin{bmatrix} \cos(\texttt{Phi}) & -\sin(\texttt{Phi}) & 0 \\ \sin(\texttt{Phi}) & \cos(\texttt{Phi}) & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

@

Axis = [x,y,z]:

$$\texttt{HomMat3DRotate} = \texttt{HomMat3D} \cdot \begin{bmatrix} & & & 0 \\ & \mathbf{R}_a & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad \mathbf{R}_a = \mathbf{u} \cdot \mathbf{u}^{\mathrm{T}} + cos(\texttt{Phi}) \cdot (\mathbf{I} - \mathbf{u} \cdot \mathbf{u}^{\mathrm{T}}) + sin(\texttt{Phi}) \cdot \mathbf{S}$$

$$\mathbf{u} = \frac{\texttt{Axis}}{\|\texttt{Axis}\|} = \begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} \qquad \mathbf{I} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \qquad \mathbf{S} = \begin{bmatrix} 0 & -z' & y' \\ z' & 0 & -x' \\ -y' & x' & 0 \end{bmatrix}$$

The fixed point of the transformation is the origin of the local coordinate system, i.e., this point remains unchanged when transformed using HomMat3DRotate.

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & rc & td \\ re & rf & rg & th \\ ri & rj & rk & tl \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, rc, td, re, rf, rg, th, ri, rj, rk, tl]. However, it is also possible to process full 4×4 matrices, which represent a projective 4D transformation.

Parameters

- ▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
  Input transformation matrix.
- ▷ **Phi** (input_control) . . . . . angle.rad ⇝ *real* / integer
  Rotation angle.
  Default: 0.78
  Suggested values: Phi ∈ {0.1, 0.2, 0.3, 0.4, 0.78, 1.57, 3.14}
  Value range: 0 ≤ Phi ≤ 6.28318530718
- ▷ **Axis** (input_control) . . . . . string(-array) ⇝ *string* / real / integer
  Axis, to be rotated around.
  Default: 'x'
  Suggested values: Axis ∈ {'x', 'y', 'z'}
- ▷ **HomMat3DRotate** (output_control) . . . . . hom_mat3d ⇝ *real*
  Output transformation matrix.

Result

If the parameters are valid, the operator hom_mat3d_rotate_local returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

hom_mat3d_scale (: : HomMat3D, Sx, Sy, Sz, Px, Py, Pz : HomMat3DScale)

Add a scaling to a homogeneous 3D transformation matrix.

hom_mat3d_scale adds a scaling by the scale factors Sx, Sy, and Sz to the homogeneous 3D transformation matrix HomMat3D and returns the resulting matrix in HomMat3DScale. The scaling is described by a 3×3 scaling matrix $\mathbf{S}$. It is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chain of transformation matrices:

$$\mathtt{HomMat3DScale} = \begin{bmatrix} & & 0 \\ & \mathbf{S} & 0 \\ & & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \mathtt{HomMat3D} \qquad \mathbf{S} = \begin{bmatrix} \mathtt{Sx} & 0 & 0 \\ 0 & \mathtt{Sy} & 0 \\ 0 & 0 & \mathtt{Sz} \end{bmatrix}$$

The point (Px,Py,Pz) is the fixed point of the transformation, i.e., this point remains unchanged when transformed using HomMat3DScale. To obtain this behavior, first a translation is added to the input transformation matrix that moves the fixed point onto the origin of the global coordinate system. Then, the scaling is added, and finally a translation that moves the fixed point back to its original position. This corresponds to the following chain of transformations:

$$\mathtt{HomMat3DScale} = \begin{bmatrix} 1 & 0 & 0 & +\mathtt{Px} \\ 0 & 1 & 0 & +\mathtt{Py} \\ 0 & 0 & 1 & +\mathtt{Pz} \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} & & 0 \\ & \mathbf{S} & 0 \\ & & 0 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & 0 & -\mathtt{Px} \\ 0 & 1 & 0 & -\mathtt{Py} \\ 0 & 0 & 1 & -\mathtt{Pz} \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \mathtt{HomMat3D}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat3D, use hom_mat3d_scale_local.

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & rc & td \\ re & rf & rg & th \\ ri & rj & rk & tl \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, rc, td, re, rf, rg, th, ri, rj, rk, tl]. However, it is also possible to process full 4×4 matrices, which represent a projective 4D transformation.

Parameters

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Input transformation matrix.

▷ **Sx** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the x-axis.
Default: 2
Suggested values: Sx ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 112}
Restriction: Sx != 0

▷ **Sy** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the y-axis.
Default: 2
Suggested values: Sy ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 112}
Restriction: Sy != 0

▷ **Sz** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the z-axis.
Default: 2
Suggested values: Sz ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 112}
Restriction: Sz != 0

▷ **Px** (input_control) . . . . . point3d.x ⇝ *real* / integer
Fixed point of the transformation (x coordinate).
Default: 0
Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Py** (input_control) . . . . . point3d.y ⇝ *real* / integer
Fixed point of the transformation (y coordinate).
Default: 0
Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Pz** (input_control) . . . . . point3d.z ⇝ *real* / integer
Fixed point of the transformation (z coordinate).
Default: 0
Suggested values: Pz ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **HomMat3DScale** (output_control) . . . . . hom_mat3d ⇝ *real*
Output transformation matrix.

Result

hom_mat3d_scale returns 2 (H_MSG_TRUE) if all three scale factors are not 0. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

hom_mat3d_scale_local (: : HomMat3D, Sx, Sy, Sz : HomMat3DScale)

Add a scaling to a homogeneous 3D transformation matrix.

hom_mat3d_scale_local adds a scaling by the scale factors Sx, Sy, and Sz to the homogeneous 3D transformation matrix HomMat3D and returns the resulting matrix in HomMat3DScale. The scaling is described by a 3×3 scaling matrix $\mathbf{S}$. In contrast to hom_mat3d_scale, it is performed relative to the local coordinate system, i.e., the coordinate system described by HomMat3D; this corresponds to the following chain of transformation matrices:

$$\texttt{HomMat3DScale} = \texttt{HomMat3D} \cdot \begin{bmatrix} & & & 0 \\ & \mathbf{S} & & 0 \\ & & & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \qquad \mathbf{S} = \begin{bmatrix} \texttt{Sx} & 0 & 0 \\ 0 & \texttt{Sy} & 0 \\ 0 & 0 & \texttt{Sz} \end{bmatrix}$$

The fixed point of the transformation is the origin of the local coordinate system, i.e., this point remains unchanged when transformed using HomMat3DScale.

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & rc & td \\ re & rf & rg & th \\ ri & rj & rk & tl \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, rc, td, re, rf, rg, th, ri, rj, rk, tl]. However, it is also possible to process full 4×4 matrices, which represent a projective 4D transformation.

Parameters

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Input transformation matrix.

▷ **Sx** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the x-axis.
Default: 2
Suggested values: Sx ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 112}
Restriction: Sx != 0

▷ **Sy** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the y-axis.
Default: 2
Suggested values: Sy ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 112}
Restriction: Sy != 0

▷ **Sz** (input_control) . . . . . number ⇝ *real* / integer
Scale factor along the z-axis.
Default: 2
Suggested values: Sz ∈ {0.125, 0.25, 0.5, 1, 2, 4, 8, 112}
Restriction: Sz != 0

▷ **HomMat3DScale** (output_control) . . . . . hom_mat3d ⇝ *real*
Output transformation matrix.

Result

hom_mat3d_scale_local returns 2 (H_MSG_TRUE) if all three scale factors are not 0. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

hom_mat3d_to_pose (: : HomMat3D : Pose)

Convert a homogeneous transformation matrix into a 3D pose.

hom_mat3d_to_pose converts a homogeneous transformation matrix into the corresponding 3D pose with type code 0. For details about 3D poses and the corresponding transformation matrices please refer to create_pose.

A typical application of hom_mat3d_to_pose is that a 3D pose was converted into a homogeneous transformation matrix to further transform it, e.g., with hom_mat3d_rotate or hom_mat3d_translate, and now must be converted back into a pose to use it as input for operators like image_points_to_world_plane.

Attention

hom_mat3d_to_pose only supports rigid transformations in HomMat3D. For non-rigid transformations, the operator attempts to return a pose that is close to HomMat3D. If HomMat3D deviates significantly from a rigid transformation, the generated pose may also deviate significantly from HomMat3D.

Parameters

▷ **HomMat3D** (input_control) ..... hom_mat3d ⇝ *real*
Homogeneous transformation matrix.

▷ **Pose** (output_control) ..... pose ⇝ *real* / integer
Equivalent 3D pose.
Number of elements: 7

Example

```
* Calibrate camera.
calibrate_cameras (CalibDataID,Error)
* Get reference pose (pose 2 of calibration object 0).
get_calib_data (CalibDataID, 'calib_obj_pose',\
                [0,2], 'pose', ObjInCameraPose)
*  Convert pose to homogeneous transformation matrix.
pose_to_hom_mat3d(ObjInCameraPose, cam_H_cal)
*  Rotate it 90 degrees around its y-axis to obtain a world coordinate system
*  whose y- and z-axis lie in the plane of the calibration plate while the
*  x-axis point 'upwards': cam_H_w = cam_H_cal * RotY(90).
hom_mat3d_identity(HomMat3DIdent)
hom_mat3d_rotate(HomMat3DIdent, rad(90), 'y', 0, 0, 0, \
                 HomMat3DRotateY)
hom_mat3d_compose(cam_H_cal, HomMat3DRotateY, cam_H_w)
* Convert transformed matrix back to pose.
hom_mat3d_to_pose (cam_H_w, Pose)
```

Result

hom_mat3d_to_pose returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Predecessors

hom_mat3d_rotate, hom_mat3d_translate, hom_mat3d_invert

Possible Successors

Module

Foundation

hom_mat3d_translate (: : HomMat3D, Tx, Ty, Tz : HomMat3DTranslate)

Add a translation to a homogeneous 3D transformation matrix.

hom_mat3d_translate adds a translation by the vector $\mathbf{T} = (\mathtt{Tx},\mathtt{Ty},\mathtt{Tz})$ to the homogeneous 3D transformation matrix HomMat3D and returns the resulting matrix in HomMat3DTranslate. The translation is performed relative to the global (i.e., fixed) coordinate system; this corresponds to the following chain of transformation matrices:

$$\mathtt{HomMat3DTranslate} = \begin{bmatrix} 1 & 0 & 0 & \\ 0 & 1 & 0 & \mathbf{T} \\ 0 & 0 & 1 & \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \mathtt{HomMat3D} \qquad \mathbf{T} = \begin{pmatrix} \mathtt{Tx} \\ \mathtt{Ty} \\ \mathtt{Tz} \end{pmatrix}$$

To perform the transformation in the local coordinate system, i.e., the one described by HomMat3D, use hom_mat3d_translate_local.

Attention

Note that homogeneous matrices are stored row-by-row as a tuple; the last row is usually not stored because it is identical for all homogeneous matrices that describe an affine transformation. For example, the homogeneous matrix

$$\begin{bmatrix} ra & rb & rc & td \\ re & rf & rg & th \\ ri & rj & rk & tl \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

is stored as the tuple [ra, rb, rc, td, re, rf, rg, th, ri, rj, rk, tl]. However, it is also possible to process full 4×4 matrices, which represent a projective 4D transformation.

Parameters

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Input transformation matrix.

▷ **Tx** (input_control) . . . . . point3d.x ⇝ *real* / integer
Translation along the x-axis.
Default: 64
Suggested values: Tx ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Ty** (input_control) . . . . . point3d.y ⇝ *real* / integer
Translation along the y-axis.
Default: 64
Suggested values: Ty ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Tz** (input_control) . . . . . point3d.z ⇝ *real* / integer
Translation along the z-axis.
Default: 64
Suggested values: Tz ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **HomMat3DTranslate** (output_control) . . . . . hom_mat3d ⇝ *real*
Output transformation matrix.

Result

If the parameters are valid, the operator hom_mat3d_translate returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

point_pluecker_line_to_hom_mat3d (: : TransformationType, PointX, PointY, PointZ, LineDirectionX, LineDirectionY, LineDirectionZ, LineMomentX, LineMomentY, LineMomentZ : HomMat3D)

Approximate a 3D affine transformation from 3D point-to-line correspondences.

point_pluecker_line_to_hom_mat3d approximates a 3D affine transformation from 3D point-to-line correspondences and returns it as the homogeneous transformation matrix HomMat3D. The input tuples must be of same length and determine at least 3 point-to-line correspondences. The corresponding points and lines must be at the same index positions in the tuples. The points are given by (PointX, PointY, PointZ). The lines are given by their Plücker coordinates $\mathbf{L}$ (LineDirectionX, LineDirectionY, LineDirectionZ) and $\mathbf{M}$ (LineMomentX, LineMomentY, LineMomentZ) For the definition of Plücker coordinates, see "Solution Guide III-C - 3D Vision".

The type of the 3D transformation to compute is specified with TransformationType. For TransformationType = *'rigid'*, a rigid 3D transformation (a rotation and a translation) is computed. This is the only transformation type that is supported at the moment.

Note that for the minimum number of 3 correspondences, up to 8 valid solutions are possible. point_pluecker_line_to_hom_mat3d returns an arbitrarily chosen valid solution in this case. If a unique solution is desired, at least 4 correspondences should be specified. Furthermore, note that no well-defined solution exists if all lines are parallel. In this case, point_pluecker_line_to_hom_mat3d returns an error.

The returned transformation minimizes the sum of the squared orthogonal distances of the points transformed with HomMat3D from their corresponding lines (see distance_point_pluecker_line).

HomMat3D can be used directly with operators that transform 3D data using affine transformations, e.g., affine_trans_point_3d. To transform lines given in Plücker coordinates, the operator dual_quat_trans_line_3d can be used. Here, HomMat3D must be converted into a pose using hom_mat3d_to_pose, the pose must be inverted using pose_invert and then converted into a dual quaternion using pose_to_dual_quat.

Parameters

▷ **TransformationType** (input_control) ..... string ⇝ *string*
Type of the transformation to compute.
Default: 'rigid'
List of values: TransformationType ∈ {'rigid'}

▷ **PointX** (input_control) ..... point3d.x-array ⇝ *real*
X coordinate of the original points.

▷ **PointY** (input_control) ..... point3d.y-array ⇝ *real*
Y coordinate of the original points.

▷ **PointZ** (input_control) ..... point3d.z-array ⇝ *real*
Z coordinate of the original points.

▷ **LineDirectionX** (input_control) ..... point3d.x-array ⇝ *real* / integer
X component of the direction vector of the corresponding line.

▷ **LineDirectionY** (input_control) ..... point3d.y-array ⇝ *real* / integer
Y component of the direction vector of the corresponding line.

▷ **LineDirectionZ** (input_control) ..... point3d.z-array ⇝ *real* / integer
Z component of the direction vector of the corresponding line.

▷ **LineMomentX** (input_control) ..... point3d.x-array ⇝ *real* / integer
X component of the moment vector of the corresponding line.

▷ **LineMomentY** (input_control) ..... point3d.y-array ⇝ *real* / integer
Y component of the moment vector of the corresponding line.

▷ **LineMomentZ** (input_control) . . . . . point3d.z-array ⇝ *real* / integer
Z component of the moment vector of the corresponding line.

▷ **HomMat3D** (output_control) . . . . . hom_mat3d ⇝ *real*
Output transformation matrix.

Example

```
* In this example, we assume that correspondences between points
* (PX, PY, PZ) and Plücker lines (LX, LY, LZ) - (MX, MY, MZ) have
* already been computed.
point_pluecker_line_to_hom_mat3d ('rigid', PX, PY, PZ, LX, LY, LZ, \
                                  MX, MY, MZ, HomMat3D)
hom_mat3d_to_pose (HomMat3D, Pose)
* Compute the residual errors in 3D space, i.e., the distance of the
* points (PX, PY, PZ) transformed by HomMat3D from the lines.
affine_trans_point_3d (HomMat3D, PX, PY, PZ, TPX, TPY, TPZ)
distance_point_pluecker_line (TPX, TPY, TPZ, LX, LY, LZ, \
                              MX, MY, MZ, D)
* The same distance can also be computed by transforming the lines
* instead of the points.  Here, the inverse pose must be used.
pose_invert (Pose, PoseInv)
pose_to_dual_quat (PoseInv, DualQuat)
dual_quat_trans_line_3d (DualQuat, 'moment', LX, LY, LZ, MX, MY, MZ, \
                         TLX, TLY, TLZ, TMX, TMY, TMZ)
distance_point_pluecker_line (PX, PY, PZ, TLX, TLY, TLZ, \
                              TMX, TMY, TMZ, D)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

pose_to_hom_mat3d (: : Pose : HomMat3D)

Convert a 3D pose into a homogeneous transformation matrix.

pose_to_hom_mat3d converts a 3D pose Pose, e.g., the external camera parameters, into the equivalent homogeneous transformation matrix HomMat3D. For details about 3D poses and the corresponding transformation matrices please refer to create_pose.

A typical application of pose_to_hom_mat3d is that you want to further transform the pose, e.g., rotate or translate it using hom_mat3d_rotate or hom_mat3d_translate. In case of the external camera parameters, this can be necessary if the calibration plate cannot be placed such that its coordinate system coincides with the desired world coordinate system.

Parameters

▷ **Pose** (input_control) . . . . . pose ⇝ *real* / integer
3D pose.
Number of elements: 7

▷ **HomMat3D** (output_control) . . . . . hom_mat3d ⇝ *real*
Equivalent homogeneous transformation matrix.

Example

```
* Calibrate camera.
calibrate_cameras (CalibDataID,Error)
* Get reference pose (pose 2 of calibration object 0).
get_calib_data (CalibDataID, 'calib_obj_pose',\
                [0,2], 'pose', ObjInCameraPose)
*  Convert pose to homogeneous transformation matrix.
pose_to_hom_mat3d(ObjInCameraPose, cam_H_cal)
*  Rotate it 90 degrees around its y-axis to obtain a world coordinate system
*  whose y- and z-axis lie in the plane of the calibration plate while the
*  x-axis point 'upwards': cam_H_w = cam_H_cal * RotY(90).
hom_mat3d_identity(HomMat3DIdent)
hom_mat3d_rotate(HomMat3DIdent, rad(90), 'y', 0, 0, 0, \
                 HomMat3DRotateY)
hom_mat3d_compose(cam_H_cal, HomMat3DRotateY, cam_H_w)
* Convert transformed matrix back to pose.
hom_mat3d_to_pose (cam_H_w, Pose)
```

Result

`pose_to_hom_mat3d` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`camera_calibration`, `read_pose`

Possible Successors

Module

Foundation

projective_trans_hom_point_3d (: : HomMat3D, Px, Py, Pz, Pw : Qx, Qy, Qz, Qw)

Project a homogeneous 3D point using a projective transformation matrix.

`projective_trans_hom_point_3d` applies the homogeneous projective transformation matrix `HomMat3D` to all homogeneous input points (`Px`,`Py`,`Pz`,`Pw`) and returns an array of homogeneous output

points (Qx,Qy,Qz,Qw). The transformation is described by the homogeneous transformation matrix given in HomMat3D. This corresponds to the following equation (input and output points as homogeneous vectors):

$$\begin{pmatrix} Qx \\ Qy \\ Qz \\ Qw \end{pmatrix} = HomMat3D \cdot \begin{pmatrix} Px \\ Py \\ Pz \\ Pw \end{pmatrix}$$

To transform the homogeneous coordinates to Euclidean coordinates, they must be divided by Qw:

$$\begin{pmatrix} Ex \\ Ey \\ Ez \end{pmatrix} = \begin{pmatrix} \frac{Qx}{Qw} \\ \frac{Qy}{Qw} \\ \frac{Qz}{Qw} \end{pmatrix}$$

This can be achieved directly by calling projective_trans_point_3d. Thus, projective_trans_hom_point_3d is primarily useful for transforming points or point sets for which the resulting points might lie in the plane at infinity, i.e., points that potentially have Qw = 0, for which the above division cannot be performed.

Parameters

- ▷ **HomMat3D** (input_control) . . . hom_mat3d ⇝ *real*
  Homogeneous projective transformation matrix.
- ▷ **Px** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (x coordinate).
- ▷ **Py** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (y coordinate).
- ▷ **Pz** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (z coordinate).
- ▷ **Pw** (input_control) . . . number(-array) ⇝ *real* / integer
  Input point (w coordinate).
- ▷ **Qx** (output_control) . . . number(-array) ⇝ *real*
  Output point (x coordinate).
- ▷ **Qy** (output_control) . . . number(-array) ⇝ *real*
  Output point (y coordinate).
- ▷ **Qz** (output_control) . . . number(-array) ⇝ *real*
  Output point (z coordinate).
- ▷ **Qw** (output_control) . . . number(-array) ⇝ *real*
  Output point (w coordinate).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

vector_to_hom_mat3d

Alternatives

projective_trans_point_3d

Module

Foundation

projective_trans_point_3d (: : HomMat3D, Px, Py, Pz : Qx, Qy, Qz)

Project a 3D point using a projective transformation matrix.

projective_trans_point_3d applies the homogeneous projective transformation matrix HomMat3D to all input points (Px,Py,Pz) and returns an array of output points (Qx,Qy,Qz). The transformation is described by the homogeneous transformation matrix given in HomMat3D. This corresponds to the following equations (input and output points as homogeneous vectors):

$$\begin{pmatrix} Tx \\ Ty \\ Tz \\ Tw \end{pmatrix} = \texttt{HomMat3D} \cdot \begin{pmatrix} \texttt{Px} \\ \texttt{Py} \\ \texttt{Pz} \\ 1 \end{pmatrix}$$

projective_trans_point_3d then transforms the homogeneous coordinates to Euclidean coordinates by dividing them by Tw:

$$\begin{pmatrix} \texttt{Qx} \\ \texttt{Qy} \\ \texttt{Qz} \end{pmatrix} = \begin{pmatrix} \frac{Tx}{Tw} \\ \frac{Ty}{Tw} \\ \frac{Tz}{Tw} \end{pmatrix}$$

If a point in the plane at infinity ($Tw = 0$) is created by the transformation, an error is returned. If this is undesired, projective_trans_hom_point_3d can be used.

Parameters

- ▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
  Homogeneous projective transformation matrix.
- ▷ **Px** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input point (x coordinate).
- ▷ **Py** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input point (y coordinate).
- ▷ **Pz** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input point (z coordinate).
- ▷ **Qx** (output_control) . . . . . number(-array) ⇝ *real*
  Output point (x coordinate).
- ▷ **Qy** (output_control) . . . . . number(-array) ⇝ *real*
  Output point (y coordinate).
- ▷ **Qz** (output_control) . . . . . number(-array) ⇝ *real*
  Output point (z coordinate).

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Possible Predecessors

vector_to_hom_mat3d

Alternatives

projective_trans_hom_point_3d

Module

Foundation

serialize_hom_mat3d (: : HomMat3D : SerializedItemHandle)

Serialize a homogeneous 3D transformation matrix.

serialize_hom_mat3d serializes the data of a homogeneous 3D transformation matrix (see fwrite_serialized_item for an introduction of the basic principle of serialization). The transformation matrix is defined by the handle HomMat3D. The serialized transformation matrix is returned by the handle SerializedItemHandle and can be deserialized by deserialize_hom_mat3d.

Parameters

▷ **HomMat3D** (input_control) . . . . . hom_mat3d ⇝ *real*
Transformation matrix.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator `serialize_hom_mat3d` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`fwrite_serialized_item`, `send_serialized_item`, `deserialize_hom_mat3d`

Module

Foundation

vector_to_hom_mat3d (: : TransformationType, Px, Py, Pz, Qx, Qy, Qz : HomMat3D)

Approximate a 3D transformation from point correspondences.

`vector_to_hom_mat3d` approximates an affine or projective 3D transformation from point correspondences and returns it as the homogeneous transformation matrix `HomMat3D`.

The type of the 3D transformation to compute is specified with `TransformationType`. For `TransformationType` = *'rigid'*, a rigid 3D transformation (a rotation and a translation), for `TransformationType` = *'similarity'*, a 3D similarity transformation (a uniform scaling, a rotation, and a translation), for `TransformationType` = *'affine'* a general affine 3D transformation, and for `TransformationType` = *'projective'* a projective 3D transformation is computed.

The minimum required number of point correspondences is 3 for `TransformationType` = *'rigid'*, 3 for `TransformationType` = *'similarity'*, 4 for `TransformationType` = *'affine'*, and 5 for `TransformationType` = *'projective'*.

The point correspondences are passed in the tuples (`Px`,`Py`,`Pz`) and (`Qx`,`Qy`,`Qz`), where corresponding points must be at the same index positions in the tuples. If more than the minimum number of point correspondences are passed, the transformation is overdetermined. In this case, the returned transformation is the transformation that minimizes the distances between the transformed input points (`Px`,`Py`,`Pz`) and the points (`Qx`,`Qy`,`Qz`), as described in the following equation (points as homogeneous vectors):

$$\sum_i \left\| \begin{pmatrix} \mathtt{Qx}[i] \\ \mathtt{Qy}[i] \\ \mathtt{Qz}[i] \\ 1 \end{pmatrix} - \mathtt{HomMat3D} \cdot \begin{pmatrix} \mathtt{Px}[i] \\ \mathtt{Py}[i] \\ \mathtt{Pz}[i] \\ 1 \end{pmatrix} \right\|^2 = \text{minimum}$$

`HomMat3D` can be used directly with operators that transform 3D data using affine transformations, e.g., `affine_trans_point_3d`.

Parameters

▷ **TransformationType** (input_control) . . . . . string ⇝ *string*
Type of the transformation to compute.
Default: 'rigid'
List of values: `TransformationType` ∈ {'rigid', 'similarity', 'affine', 'projective'}

▷ **Px** (input_control) . . . . . point3d.x-array ⇝ *real*
X coordinates of the original points.

▷ **Py** (input_control) . . . . . point3d.y-array ⇝ *real*
Y coordinates of the original points.
▷ **Pz** (input_control) . . . . . point3d.z-array ⇝ *real*
Z coordinates of the original points.
▷ **Qx** (input_control) . . . . . point3d.x-array ⇝ *real*
X coordinates of the transformed points.
▷ **Qy** (input_control) . . . . . point3d.x-array ⇝ *real*
Y coordinates of the transformed points.
▷ **Qz** (input_control) . . . . . point3d.z-array ⇝ *real*
Z coordinates of the transformed points.
▷ **HomMat3D** (output_control) . . . . . hom_mat3d ⇝ *real*
Output transformation matrix.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

27.3 Dual Quaternions

This chapter contains operators for handling dual quaternions.

Introduction to Dual Quaternions

A dual quaternion $\hat{q} = q_r + \varepsilon q_d$ consists of the two quaternions q_r and q_d, where q_r is the real part, q_d is the dual part, and ε is the dual unit number ($\varepsilon^2 = 0$). Each quaternion $q = w + ix + jy + kz$ consists of the scalar part w and the vector part $\mathbf{v} = (x, y, z)$, where $(1, i, j, k)$ are the basis elements of the quaternion vector space.

For information how dual quaternions can be used for the description of rigid 3D transformations and their relation to Plücker coordinates, see "Solution Guide III-C - 3D Vision".

Representing Dual Quaternions in HALCON

In HALCON, a dual quaternion is represented by a tuple with eight values $[w_r, x_r, y_r, z_r, w_d, x_d, y_d, z_d]$, where w_r and $\mathbf{v}_r = (x_r, y_r, z_r)$ are the scalar and the vector part of the real part and w_d and $\mathbf{v}_d = (x_d, y_d, z_d)$ are the scalar and the vector part of the dual part.

deserialize_dual_quat (: : SerializedItemHandle : DualQuaternion)

Deserialize a serialized dual quaternion.

deserialize_dual_quat deserializes a dual quaternion that was serialized by serialize_dual_quat (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized dual quaternion is defined by the handle SerializedItemHandle. The deserialized values are stored in DualQuaternion.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **DualQuaternion** (output_control) ..... dual_quaternion ⇝ *real* / integer
Dual quaternion.

Result

If the parameters are valid, the operator `deserialize_dual_quat` returns the value `2` (`H_MSG_TRUE`). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`fread_serialized_item`, `receive_serialized_item`, `serialize_quat`

Possible Successors

`dual_quat_to_hom_mat3d`, `dual_quat_to_pose`, `dual_quat_compose`

Module

Foundation

dual_quat_compose (: : DualQuaternionLeft,
DualQuaternionRight : DualQuaternionComposed)

Multiply two dual quaternions.

The operator `dual_quat_compose` multiplies the two dual quaternions `DualQuaternionLeft` and `DualQuaternionRight` and returns the product in `DualQuaternionComposed`.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "`Solution Guide III-C - 3D Vision`".

The multiplication of the dual quaternions $\hat{p}$ and $\hat{q}$ is $\hat{p}\hat{q} = p_r q_r + \varepsilon(p_r q_d + p_d q_r)$.

For the multiplication of quaternions see `quat_compose`.

Note that the multiplication of two dual quaternions is not commutative, i.e., $\hat{p}\hat{q} \neq \hat{q}\hat{p}$.

If `DualQuaternionLeft` and `DualQuaternionRight` are unit dual quaternions and, hence, represent 3D rigid transformations, their multiplication corresponds to the multiplication of their corresponding homogeneous transformation matrices. Consequently, `dual_quat_compose` can be used to concatenate two 3D rigid transformations analogously to `pose_compose` or `hom_mat3d_compose`.

Parameters

▷ **DualQuaternionLeft** (input_control) ..... dual_quaternion(-array) ⇝ *real*
Left dual quaternion.

▷ **DualQuaternionRight** (input_control) ..... dual_quaternion(-array) ⇝ *real*
Right dual quaternion.

▷ **DualQuaternionComposed** (output_control) ..... dual_quaternion(-array) ⇝ *real*
Product of the dual quaternions.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

screw_to_dual_quat

Possible Successors

dual_quat_to_hom_mat3d, dual_quat_to_pose, dual_quat_to_screw

Alternatives

pose_compose, hom_mat3d_compose

See also

dual_quat_interpolate, pose_to_dual_quat, dual_quat_normalize, dual_quat_conjugate, serialize_dual_quat, deserialize_dual_quat, dual_quat_trans_line_3d, dual_quat_trans_point_3d, quat_compose

Module

Foundation

dual_quat_conjugate (
: : DualQuaternion : DualQuaternionConjugate)

Conjugate a dual quaternion.

The operator dual_quat_conjugate computes the conjugation DualQuaternionConjugate of the input dual quaternion DualQuaternion.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

The conjugation of a dual quaternion $\hat{q} = q_r + \varepsilon q_d$ is given by $\bar{\hat{q}} = \bar{q}_r + \varepsilon \bar{q}_d$, where $\bar{q}_r$ and $\bar{q}_d$ are the conjugations of the quaternions q_r and q_d.

For the conjugation of quaternions see quat_conjugate.

If DualQuaternion is a unit dual quaternion and, hence, represents a 3D rigid transformation, its inverse is its conjugate, i.e., $\hat{q}^{-1} = \bar{\hat{q}}$. Consequently, DualQuaternionConjugate represents the inverse 3D rigid transformation of DualQuaternion. Therefore, dual_quat_conjugate can be used to invert a 3D rigid transformation analogously to pose_invert or hom_mat3d_invert.

Parameters

▷ **DualQuaternion** (input_control) ..... dual_quaternion(-array) ⇝ *real*
Dual quaternion.

▷ **DualQuaternionConjugate** (output_control) ..... dual_quaternion(-array) ⇝ *real*
Conjugate of the dual quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

dual_quat_compose, pose_to_dual_quat, screw_to_dual_quat

Possible Successors

dual_quat_compose, dual_quat_to_hom_mat3d, dual_quat_to_screw, dual_quat_interpolate, dual_quat_to_pose

Alternatives

pose_invert, hom_mat3d_invert

See also

dual_quat_normalize, serialize_dual_quat, deserialize_dual_quat, dual_quat_trans_line_3d, dual_quat_trans_point_3d, quat_conjugate

Module

Foundation

dual_quat_interpolate (: : DualQuaternionStart, DualQuaternionEnd, InterpPos : DualQuaternionInterpolated)

Interpolate two dual quaternions.

The operator dual_quat_interpolate interpolates the two dual quaternions DualQuaternionStart and DualQuaternionEnd at the interpolation position InterpPos.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

For interpolations, the position InterpPos must lie within the interval $[0, 1]$. However, values outside this interval are also possible, which then correspond to an extrapolation. For InterpPos $= 0$, the interpolated dual quaternion DualQuaternionInterpolated corresponds to DualQuaternionStart. For InterpPos $= 1$, the interpolated dual quaternion DualQuaternionInterpolated corresponds to DualQuaternionEnd.

The interpolation is performed by using screw linear interpolation (ScLERP). If both DualQuaternionStart and DualQuaternionEnd are unit dual quaternions, DualQuaternionInterpolated will be a unit dual quaternion as well. Hence, dual_quat_interpolate can be used to smoothly interpolate between two 3D rigid transformations.

Note that the interpolation of the rotation parts of DualQuaternionStart and DualQuaternionEnd is performed identically to the interpolation of quaternions, i.e., the screw angle is interpolated linearly (see quat_interpolate). The interpolation of the translation part is done by linearly interpolating the screw translation.

It is possible to pass a tuple of values for InterpPos. In this case, a tuple of interpolated DualQuaternionInterpolated is returned, one for each value in InterpPos. This is more efficient than calling dual_quat_interpolate multiple times with a single value for InterpPos.

Parameters

▷ **DualQuaternionStart** (input_control) ..... dual_quaternion ⇝ *real*
Dual quaternion as the start point of the interpolation.

▷ **DualQuaternionEnd** (input_control) ..... dual_quaternion ⇝ *real*
Dual quaternion as the end point of the interpolation.

▷ **InterpPos** (input_control) ..... real(-array) ⇝ *real*
Interpolation parameter.
Default: 0.5
Suggested values: InterpPos ∈ {0.0, 0.25, 0.5, 0.75, 1.0}

▷ **DualQuaternionInterpolated** (output_control) ..... dual_quaternion(-array) ⇝ *real*
Interpolated dual quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

pose_to_dual_quat, screw_to_dual_quat, dual_quat_normalize

Possible Successors

dual_quat_to_hom_mat3d, dual_quat_to_pose, dual_quat_to_screw

See also

dual_quat_compose, dual_quat_conjugate, serialize_dual_quat, deserialize_dual_quat, dual_quat_trans_line_3d, dual_quat_trans_point_3d, quat_interpolate

Module

Foundation

dual_quat_normalize (: : DualQuaternion : DualQuaternionNormalized)

Normalize a dual quaternion.

The operator dual_quat_normalize normalizes the input dual quaternion DualQuaternion and returns the normalized dual quaternion, which is also called a unit dual quaternion, in DualQuaternionNormalized.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

The norm of a unit dual quaternion $\hat{q} = q_r + \varepsilon q_d$ is 1, i.e., $\hat{q}\bar{\hat{q}} = 1$. This is equivalent to the following two conditions:

$$\begin{aligned} \|q_r\| = q_r \bar{q}_r &= 1 \\ q_r \bar{q}_d + \bar{q}_r q_d &= 0, \end{aligned}$$

where $\bar{q}$ represents the conjugate quaternion of q (see quat_conjugate).

A 3D rigid transformation can be represented by a unit dual quaternion.

Attention

If the norm of the real part of DualQuaternion is 0, dual_quat_normalize returns the error code 9310 (H_ERR_DQ_ZERO_NORM) because in this case no normalization is possible.

Parameters

- ▷ **DualQuaternion** (input_control) ..... dual_quaternion(-array) ⇝ *real*
  Unit dual quaternion.
- ▷ **DualQuaternionNormalized** (output_control) ..... dual_quaternion(-array) ⇝ *real*
  Normalized dual quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

dual_quat_to_hom_mat3d (: : DualQuaternion : HomMat3D)

Convert a unit dual quaternion into a homogeneous transformation matrix.

The operator dual_quat_to_hom_mat3d converts a unit dual quaternion DualQuaternion, which represents a 3D rigid transformation, into its corresponding homogeneous transformation matrix HomMat3D.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

The rotation part of HomMat3D is computed from the real part of the dual quaternion, as described in quat_to_hom_mat3d. The translation part $\mathbf{T}$ of HomMat3D is computed from the real and dual part of $\hat{q} = q_r + \varepsilon q_d$:

$$\begin{aligned} p &= q_d q_r \\ \mathbf{T} &= 2.0\mathbf{v}_p, \end{aligned}$$

where $\mathbf{v}_p$ is the vector part of the quaternion p.

Attention

HomMat3D will only be a valid rigid transformation matrix if DualQuaternion is a unit dual quaternion.

Parameters

▷ **DualQuaternion** (input_control) ..... dual_quaternion ⇝ *real*
Unit dual quaternion.

▷ **HomMat3D** (output_control) ..... hom_mat3d ⇝ *real*
Transformation matrix.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

dual_quat_to_screw (: : DualQuaternion, ScrewFormat : AxisDirectionX, AxisDirectionY, AxisDirectionZ, AxisMomentOrPointX, AxisMomentOrPointY, AxisMomentOrPointZ, Rotation, Translation)

Convert a unit dual quaternion into a screw.

The operator dual_quat_to_screw converts the input unit dual quaternion DualQuaternion, which represents a 3D rigid transformation, into the parameters of the corresponding screw.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

If ScrewFormat is set to *'moment'*, these parameters are returned in the corresponding parameters AxisDirectionX, AxisDirectionY, AxisDirectionZ, AxisMomentOrPointX, AxisMomentOrPointY, AxisMomentOrPointZ, Rotation, and Translation.

For convenience reasons, it is also possible to query the point on the screw axis that is closest to the origin instead of the moment of the screw axis. For this, ScrewFormat must be set to *'point'*. In this case, the coordinates of the point are returned in AxisMomentOrPointX, AxisMomentOrPointY, and AxisMomentOrPointZ.

Attention

dual_quat_to_screw assumes that the input DualQuaternion is a unit dual quaternion, and hence represents a 3D rigid transformation. Otherwise the returned screw parameters are not meaningful. Further note that

the screw axis for an identity transformation, i.e., no rotation and no translation, is undefined. In this case L is arbitrarily set to $(1, 0, 0)^T$.

Parameters

▷ **DualQuaternion** (input_control) . . . . . dual_quaternion ⇝ *real*
Unit dual quaternion.

▷ **ScrewFormat** (input_control) . . . . . string ⇝ *string*
Format of the screw parameters.
Default: 'moment'
List of values: ScrewFormat ∈ {'moment', 'point'}

▷ **AxisDirectionX** (output_control) . . . . . point3d.x ⇝ *real*
X component of the direction vector of the screw axis.

▷ **AxisDirectionY** (output_control) . . . . . point3d.y ⇝ *real*
Y component of the direction vector of the screw axis.

▷ **AxisDirectionZ** (output_control) . . . . . point3d.z ⇝ *real*
Z component of the direction vector of the screw axis.

▷ **AxisMomentOrPointX** (output_control) . . . . . point3d.x ⇝ *real*
X component of the moment vector or a point on the screw axis.

▷ **AxisMomentOrPointY** (output_control) . . . . . point3d.y ⇝ *real*
Y component of the moment vector or a point on the screw axis.

▷ **AxisMomentOrPointZ** (output_control) . . . . . point3d.z ⇝ *real*
Z component of the moment vector or a point on the screw axis.

▷ **Rotation** (output_control) . . . . . angle.rad ⇝ *real*
Rotation angle in radians.

▷ **Translation** (output_control) . . . . . real ⇝ *real*
Translation.

Execution Information

dual_quat_trans_line_3d (: : DualQuaternion, LineFormat, LineDirectionX, LineDirectionY, LineDirectionZ, LineMomentOrPointX, LineMomentOrPointY, LineMomentOrPointZ : TransLineDirectionX, TransLineDirectionY, TransLineDirectionZ, TransLineMomentOrPointX, TransLineMomentOrPointY, TransLineMomentOrPointZ)

Transform a 3D line with a unit dual quaternion.

The operator dual_quat_trans_line_3d transforms a 3D line that is represented by its Plücker coordinates by a 3D rigid transformation that is given by the unit dual quaternion DualQuaternion.

For a brief introduction to dual quaternions, Plücker coordinates and the used notation, see "Solution Guide III-C - 3D Vision".

If LineFormat is set to *'moment'*, the moment of the line must be passed in LineMomentOrPointX, LineMomentOrPointY, and LineMomentOrPointZ.

If LineFormat is set to *'point'*, instead of the moment an arbitrary point on the line can be passed in LineMomentOrPointX, LineMomentOrPointY, and LineMomentOrPointZ.

The parameters of the transformed line are returned in TransLineDirectionX, TransLineDirectionY, TransLineDirectionZ, TransLineMomentOrPointX, TransLineMomentOrPointY, and TransLineMomentOrPointZ in the format that was specified in LineFormat. If LineFormat is set to *'point'*, the point on the line that is closest to the origin of the coordinate system is returned.

Attention

dual_quat_trans_line_3d returns meaningful results only if DualQuaternion is a unit dual quaternion and the length of the line direction is 1.

Parameters

- ▷ **DualQuaternion** (input_control) . . . . . dual_quaternion ⇝ *real* / integer
  Unit dual quaternion representing the transformation.
- ▷ **LineFormat** (input_control) . . . . . string ⇝ *string*
  Format of the line parameters.
  Default: 'moment'
  List of values: LineFormat ∈ {'moment', 'point'}
- ▷ **LineDirectionX** (input_control) . . . . . point3d.x(-array) ⇝ *real* / integer
  X component of the direction vector of the line.
- ▷ **LineDirectionY** (input_control) . . . . . point3d.y(-array) ⇝ *real* / integer
  Y component of the direction vector of the line.
- ▷ **LineDirectionZ** (input_control) . . . . . point3d.z(-array) ⇝ *real* / integer
  Z component of the direction vector of the line.
- ▷ **LineMomentOrPointX** (input_control) . . . . . point3d.x(-array) ⇝ *real* / integer
  X component of the moment vector or a point on the line.
- ▷ **LineMomentOrPointY** (input_control) . . . . . point3d.y(-array) ⇝ *real* / integer
  Y component of the moment vector or a point on the line.
- ▷ **LineMomentOrPointZ** (input_control) . . . . . point3d.z(-array) ⇝ *real* / integer
  Z component of the moment vector or a point on the line.
- ▷ **TransLineDirectionX** (output_control) . . . . . point3d.x(-array) ⇝ *real* / integer
  X component of the direction vector of the transformed line.
- ▷ **TransLineDirectionY** (output_control) . . . . . point3d.y(-array) ⇝ *real* / integer
  Y component of the direction vector of the transformed line.
- ▷ **TransLineDirectionZ** (output_control) . . . . . point3d.z(-array) ⇝ *real* / integer
  Z component of the direction vector of the transformed line.
- ▷ **TransLineMomentOrPointX** (output_control) . . . . . point3d.x(-array) ⇝ *real* / integer
  X component of the moment vector or a point on the transformed line.
- ▷ **TransLineMomentOrPointY** (output_control) . . . . . point3d.y(-array) ⇝ *real* / integer
  Y component of the moment vector or a point on the transformed line.
- ▷ **TransLineMomentOrPointZ** (output_control) . . . . . point3d.z(-array) ⇝ *real* / integer
  Z component of the moment vector or a point on the transformed line.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

dual_quat_trans_point_3d (: : DualQuaternion, Px, Py, Pz : Tx, Ty, Tz)

Transform a 3D point with a unit dual quaternion.

The operator dual_quat_trans_point_3d transforms a 3D point (Px, Py, Pz) by a 3D rigid transformation that is given by the unit dual quaternion DualQuaternion and returns the transformed 3D point in (Tx, Ty, Tz).

For a brief introduction to dual quaternions, see "Solution Guide III-C - 3D Vision".

Attention

dual_quat_trans_point_3d returns meaningful results only if DualQuaternion is a unit dual quaternion.

Parameters

▷ **DualQuaternion** (input_control) . . . . . dual_quaternion ⇝ *real* / integer
Unit dual quaternion representing the transformation.

▷ **Px** (input_control) . . . . . point3d.x(-array) ⇝ *real* / integer
Input point(s) (x coordinate).
Default: 64
Suggested values: Px ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Py** (input_control) . . . . . point3d.y(-array) ⇝ *real* / integer
Input point(s) (y coordinate).
Default: 64
Suggested values: Py ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Pz** (input_control) . . . . . point3d.z(-array) ⇝ *real* / integer
Input point(s) (z coordinate).
Default: 64
Suggested values: Pz ∈ {0, 16, 32, 64, 128, 256, 512, 1024}

▷ **Tx** (output_control) . . . . . point3d.x(-array) ⇝ *real*
Output point(s) (x coordinate).

▷ **Ty** (output_control) . . . . . point3d.y(-array) ⇝ *real*
Output point(s) (y coordinate).

▷ **Tz** (output_control) . . . . . point3d.z(-array) ⇝ *real*
Output point(s) (z coordinate).

Example

```
* dual_quat_trans_point_3d (DualQuat, Px, Py, Pz, Tx, Ty, Tz)
* is equivalent to the following code:
dual_quat_to_hom_mat3d (DualQuat, HomMat3D)
affine_trans_point_3d (HomMat3D, Px, Py, Pz, Tx, Ty, Tz)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

screw_to_dual_quat (: : ScrewFormat, AxisDirectionX, AxisDirectionY, AxisDirectionZ, AxisMomentOrPointX, AxisMomentOrPointY, AxisMomentOrPointZ, Rotation, Translation : DualQuaternion)

Convert a screw into a dual quaternion.

The operator screw_to_dual_quat converts the screw parameters to the unit dual quaternion DualQuaternion, which represents a 3D rigid transformation.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

A screw is described by the direction of the screw axis $\mathbf{L} = (L_x, L_y, L_z)^T$ with $\|\mathbf{L}\| = 1$, the moment of the screw axis $\mathbf{M} = (M_x, M_y, M_z)^T$ with $\mathbf{L} \cdot \mathbf{M} = 0$, the screw angle θ, and the screw translation d.

If ScrewFormat is set to *'moment'*, these parameters can be passed in the corresponding parameters AxisDirectionX, AxisDirectionY, AxisDirectionZ, AxisMomentOrPointX, AxisMomentOrPointY, AxisMomentOrPointZ, Rotation, and Translation.

For convenience reasons, it is also possible to specify an arbitrary point on the screw axis instead of the moment of the screw axis. For this, ScrewFormat must be set to *'point'* and the coordinates of the points must be passed in AxisMomentOrPointX, AxisMomentOrPointY, and AxisMomentOrPointZ.

Attention

screw_to_dual_quat assumes that the direction vector of the screw axis has length 1, i.e., $\sqrt{L_x^2 + L_y^2 + L_z^2} = 1$. Otherwise the returned dual quaternion is not meaningful.

Parameters

- ▷ **ScrewFormat** (input_control) ..... string ⇝ *string*
  Format of the screw parameters.
  Default: 'moment'
  List of values: ScrewFormat ∈ {'moment', 'point'}
- ▷ **AxisDirectionX** (input_control) ..... point3d.x ⇝ *real* / integer
  X component of the direction vector of the screw axis.
- ▷ **AxisDirectionY** (input_control) ..... point3d.y ⇝ *real* / integer
  Y component of the direction vector of the screw axis.
- ▷ **AxisDirectionZ** (input_control) ..... point3d.z ⇝ *real* / integer
  Z component of the direction vector of the screw axis.
- ▷ **AxisMomentOrPointX** (input_control) ..... point3d.x ⇝ *real* / integer
  X component of the moment vector or a point on the screw axis.
- ▷ **AxisMomentOrPointY** (input_control) ..... point3d.y ⇝ *real* / integer
  Y component of the moment vector or a point on the screw axis.
- ▷ **AxisMomentOrPointZ** (input_control) ..... point3d.z ⇝ *real* / integer
  Z component of the moment vector or a point on the screw axis.
- ▷ **Rotation** (input_control) ..... angle.rad ⇝ *real* / integer
  Rotation angle in radians.
- ▷ **Translation** (input_control) ..... real ⇝ *real* / integer
  Translation.

▷ **DualQuaternion** (output_control) . . . . . dual_quaternion ⇝ *real* / integer
Dual quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

serialize_dual_quat (: : DualQuaternion : SerializedItemHandle)

Serialize a dual quaternion.

serialize_dual_quat serializes the data of the DualQuaternion (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized dual quaternion is returned by the handle SerializedItemHandle and can be deserialized by deserialize_dual_quat.

Parameters

▷ **DualQuaternion** (input_control) . . . . . dual_quaternion ⇝ *real* / integer
Dual quaternion.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_dual_quat returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

27.4 Misc

convert_point_3d_cart_to_spher (: : X, Y, Z, EquatPlaneNormal, ZeroMeridian : Longitude, Latitude, Radius)

Convert Cartesian coordinates of a 3D point to spherical coordinates.

The operator convert_point_3d_cart_to_spher converts Cartesian coordinates of a 3D point, which are given in X, Y, and Z, into spherical coordinates. The spherical coordinates are returned in Longitude, Latitude, and Radius. The Longitude is returned in the range $[-\pi, +\pi]$ while the Latitude is returned in the range $[-\pi/2, +\pi/2]$. Furthermore, the latitude of the north pole is $\pi/2$, and hence, the latitude of the south pole is $-\pi/2$.

The orientation of the spherical coordinate system with respect to the Cartesian coordinate system can be specified with the parameters EquatPlaneNormal and ZeroMeridian.

EquatPlaneNormal determines the normal of the equatorial plane (longitude == 0) pointing to the north pole (positive latitude) and may take the following values:

'x': The equatorial plane is the yz plane. The positive x axis points to the north pole.

'-x': The equatorial plane is the yz plane. The positive x axis points to the south pole.

'y': The equatorial plane is the xz plane. The positive y axis points to the north pole.

'-y': The equatorial plane is the xz plane. The positive y axis points to the south pole.

'z': The equatorial plane is the xy plane. The positive z axis points to the north pole.

'-z': The equatorial plane is the xy plane. The positive z axis points to the south pole.

The position of the zero meridian can be specified with the parameter ZeroMeridian. For this, the coordinate axis (lying in the equatorial plane) that points to the zero meridian must be passed. The following values for ZeroMeridian are valid:

'x': The *positive* x axis points in the direction of the zero meridian.

'-x': The *negative* x axis points in the direction of the zero meridian.

'y': The *positive* y axis points in the direction of the zero meridian.

'-y': The *negative* y axis points in the direction of the zero meridian.

'z': The *positive* z axis points in the direction of the zero meridian.

'-z': The *negative* z axis points in the direction of the zero meridian.

Only reasonable combinations of EquatPlaneNormal and ZeroMeridian are permitted, i.e., the normal of the equatorial plane must not be parallel to the direction of the zero meridian. For example, the combination EquatPlaneNormal='y' and ZeroMeridian='-y' is not permitted.

Note that in order to guarantee a consistent conversion back from spherical to Cartesian coordinates by using convert_point_3d_spher_to_cart, the same values must be passed for EquatPlaneNormal and ZeroMeridian as were passed to convert_point_3d_cart_to_spher.

The operator convert_point_3d_cart_to_spher can be used, for example, to convert a given camera position into spherical coordinates. If multiple camera positions are converted in this way, one obtains a pose range (in spherical coordinates), which can be passed to create_shape_model_3d in order to create a 3D shape model.

Parameters

▷ **X** (input_control) ..... real(-array) ⇝ *real*
X coordinate of the 3D point.

▷ **Y** (input_control) ..... real(-array) ⇝ *real*
Y coordinate of the 3D point.

▷ **Z** (input_control) ..... real(-array) ⇝ *real*
Z coordinate of the 3D point.

▷ **EquatPlaneNormal** (input_control) ..... string ⇝ *string*
Normal vector of the equatorial plane (points to the north pole).
Default: '-y'
List of values: EquatPlaneNormal ∈ {'x', 'y', 'z', '-x', '-y', '-z'}

▷ **ZeroMeridian** (input_control) ..... string ⇝ *string*
Coordinate axis in the equatorial plane that points to the zero meridian.
Default: '-z'
List of values: ZeroMeridian ∈ {'x', 'y', 'z', '-x', '-y', '-z'}

▷ **Longitude** (output_control) ..... angle.rad(-array) ⇝ *real*
Longitude of the 3D point.

▷ **Latitude** (output_control) ..... angle.rad(-array) ⇝ *real*
Latitude of the 3D point.

▷ **Radius** (output_control) ..... real(-array) ⇝ *real*
Radius of the 3D point.

Result

If the parameters are valid, the operator convert_point_3d_cart_to_spher returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

create_shape_model_3d, find_shape_model_3d

convert_point_3d_spher_to_cart

Module

3D Metrology

convert_point_3d_spher_to_cart (: : Longitude, Latitude, Radius, EquatPlaneNormal, ZeroMeridian : X, Y, Z)

Convert spherical coordinates of a 3D point to Cartesian coordinates.

The operator convert_point_3d_spher_to_cart converts the spherical coordinates of a 3D point, which are given in Longitude, Latitude, and Radius, into the Cartesian coordinates X, Y, and Z. The spherical coordinates Longitude and Latitude must be specified in radians. Furthermore, the Latitude must be within the range $[-\pi/2, +\pi/2]$, where the latitude of the north pole is $\pi/2$, and hence, the latitude of the south pole is $-\pi/2$.

The orientation of the spherical coordinate system with respect to the Cartesian coordinate system can be specified with the parameters EquatPlaneNormal and ZeroMeridian.

EquatPlaneNormal determines the normal of the equatorial plane (longitude == 0) pointing to the north pole (positive latitude) and may take the following values:

'x': The equatorial plane is the yz plane. The positive x axis points to the north pole.

'-x': The equatorial plane is the yz plane. The positive x axis points to the south pole.

'y': The equatorial plane is the xz plane. The positive y axis points to the north pole.

'-y': The equatorial plane is the xz plane. The positive y axis points to the south pole.

'z': The equatorial plane is the xy plane. The positive z axis points to the north pole.

'-z': The equatorial plane is the xy plane. The positive z axis points to the south pole.

The position of the zero meridian can be specified with the parameter ZeroMeridian. For this, the coordinate axis (lying in the equatorial plane) that points to the zero meridian must be passed. The following values for ZeroMeridian are valid:

'x': The *positive* x axis points in the direction of the zero meridian.

'-x': The *negative* x axis points in the direction of the zero meridian.

'y': The *positive* y axis points in the direction of the zero meridian.

'-y': The *negative* y axis points in the direction of the zero meridian.

'z': The *positive* z axis points in the direction of the zero meridian.

'-z': The *negative* z axis points in the direction of the zero meridian.

Only reasonable combinations of `EquatPlaneNormal` and `ZeroMeridian` are permitted, i.e., the normal of the equatorial plane must not be parallel to the direction of the zero meridian. For example, the combination `EquatPlaneNormal`='*y*' and `ZeroMeridian`='*-y*' is not permitted.

Note that in order to guarantee a consistent conversion back from Cartesian to spherical coordinates by using `convert_point_3d_cart_to_spher`, the same values must be passed for `EquatPlaneNormal` and `ZeroMeridian` as were passed to `convert_point_3d_spher_to_cart`.

The operator `convert_point_3d_spher_to_cart` can be used, for example, to convert a camera position that is given in spherical coordinates into Cartesian coordinates. The result can then be utilized to create a complete camera pose by passing the Cartesian coordinates to `create_cam_pose_look_at_point`.

Parameters

- ▷ **`Longitude`** (input_control) ..... angle.rad(-array) ⇝ *real*
  Longitude of the 3D point.
- ▷ **`Latitude`** (input_control) ..... angle.rad(-array) ⇝ *real*
  Latitude of the 3D point.
  Restriction: - pi / 2 <= Latitude && Latitude <= pi / 2
- ▷ **`Radius`** (input_control) ..... real(-array) ⇝ *real*
  Radius of the 3D point.
- ▷ **`EquatPlaneNormal`** (input_control) ..... string ⇝ *string*
  Normal vector of the equatorial plane (points to the north pole).
  Default: '-y'
  List of values: `EquatPlaneNormal` ∈ {'x', 'y', 'z', '-x', '-y', '-z'}
- ▷ **`ZeroMeridian`** (input_control) ..... string ⇝ *string*
  Coordinate axis in the equatorial plane that points to the zero meridian.
  Default: '-z'
  List of values: `ZeroMeridian` ∈ {'x', 'y', 'z', '-x', '-y', '-z'}
- ▷ **`X`** (output_control) ..... real(-array) ⇝ *real*
  X coordinate of the 3D point.
- ▷ **`Y`** (output_control) ..... real(-array) ⇝ *real*
  Y coordinate of the 3D point.
- ▷ **`Z`** (output_control) ..... real(-array) ⇝ *real*
  Z coordinate of the 3D point.

Result

If the parameters are valid, the operator `convert_point_3d_spher_to_cart` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

27.5 Poses

A pose describes a rigid 3D transformation, i.e., a transformation consisting of an arbitrary translation and rotation. In HALCON, a pose is a tuple with 7 parameters: 3 parameters specifying the translation (`TransX`, `TransY`, and `TransZ`), 3 parameters describing the rotation (`RotX`, `RotY`, and `RotZ`). The last parameter codes the order of the translations and the rotations (as well as the direction of rotation). Further information about these parameters can be found in the documentation of `create_pose` and in the "`Solution Guide III-C - 3D Vision`".

3D poses can be interpreted in two ways: First, to describe the position and orientation of one coordinate system relative to another (e.g., the pose of a part's coordinate system relative to the camera coordinate system - in short: the pose of the part relative to the camera). Following the second interpretation, a pose describes how coordinates can be transformed between two coordinate systems (e.g., to transform points from part coordinates into camera coordinates).

A pose that transforms point coordinates from coordinate system 1 ($cs1$) to coordinate system 2 ($cs2$) is denoted as ${}^{cs2}\mathbf{P}_{cs1}$. The corresponding transformation of a point given in $cs1$ ($\mathbf{p}^{cs1}$) into $cs2$ ($\mathbf{p}^{cs2}$) is denoted as

$$\mathbf{p}^{cs2} = {}^{cs2}\mathbf{P}_{cs1} \cdot \mathbf{p}^{cs1}.$$

It should be noted that not the pose (as a tuple) but the transformation described by this pose is used for the multiplication and the above notation is only used for readability. Hence, the pose ${}^{cs2}\mathbf{P}_{cs1}$ describes the rigid transformation that is represented by the homogeneous transformation matrix $\mathbf{H}({}^{cs2}\mathbf{P}_{cs1}) = {}^{cs2}\mathbf{H}_{cs1}$ (see, e.g., the documentation of `create_pose` for further details)

$$\begin{pmatrix} \mathbf{p}^{cs2} \\ 1 \end{pmatrix} = {}^{cs2}\mathbf{H}_{cs1} \cdot \begin{pmatrix} \mathbf{p}^{cs1} \\ 1 \end{pmatrix}.$$

Consequently, the pose ${}^{cs2}\mathbf{P}_{cs1}$ describes the transformation of points from $cs1$ into $cs2$. Furthermore, as mentioned above, it also describes the transformation of the coordinate system itself, however, in reverse order: Thus, ${}^{cs2}\mathbf{P}_{cs1}$ describes how coordinate system 2 must be transformed to obtain coordinate system 1, and hence, the pose of coordinate system 2 relative to system 1.

With this notation, poses can easily concatenated like homogeneous matrices, e.g.,

$${}^{cs2}\mathbf{P}_{cs0} = {}^{cs2}\mathbf{P}_{cs1} \cdot {}^{cs1}\mathbf{P}_{cs0}.$$

Such a concatenation can be done using e.g., `pose_compose`.

`convert_pose_type` (: : `PoseIn`, `OrderOfTransform`, `OrderOfRotation`, `ViewOfTransform` : `PoseOut`)

Change the representation type of a 3D pose.

`convert_pose_type` converts the 3D pose `PoseIn` into a 3D pose `PoseOut` with a different representation type. See `create_pose` for details about 3D poses, their representation types, and the meaning of the parameters `OrderOfTransform`, `OrderOfRotation`, and `ViewOfTransform`.

Note that `convert_pose_type` only changes the representation of a 3D pose, but not the rigid transformation described by the pose.

Parameters

▷ **`PoseIn`** (input_control) ..... pose ⇝ *real* / integer
Original 3D pose.
Number of elements: 7

▷ **`OrderOfTransform`** (input_control) ..... string ⇝ *string*
Order of rotation and translation.
Default: 'Rp+T'
Suggested values: `OrderOfTransform` ∈ {'Rp+T', 'R(p-T)'}

▷ **OrderOfRotation** (input_control) ..... string ⇝ *string*
Meaning of the rotation values.
Default: 'gba'
Suggested values: OrderOfRotation ∈ {'gba', 'abg', 'rodriguez'}

▷ **ViewOfTransform** (input_control) ..... string ⇝ *string*
View of transformation.
Default: 'point'
Suggested values: ViewOfTransform ∈ {'point', 'coordinate_system'}

▷ **PoseOut** (output_control) ..... pose ⇝ *real* / integer
3D transformation.
Number of elements: 7

Example

```
* Define a pose.
create_pose (0.1, 0.1, 0.1, 90, 90, 90, 'Rp+T', 'gba', 'point', Pose)
* Convert pose to a pose with desired semantic.
convert_pose_type (Pose, 'Rp+T', 'abg', 'point', Pose2)
```

Result

convert_pose_type returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

create_pose, hom_mat3d_to_pose, camera_calibration, hand_eye_calibration

Possible Successors

write_pose

create_pose, get_pose_type, write_pose, read_pose

Module

Foundation

create_pose (: : TransX, TransY, TransZ, RotX, RotY, RotZ, OrderOfTransform, OrderOfRotation, ViewOfTransform : Pose)

Create a 3D pose.

create_pose creates the 3D pose Pose. A pose describes a rigid 3D transformation, i.e., a transformation consisting of an arbitrary translation and rotation, with 6 parameters: TransX, TransY, and TransZ specify the translation along the x-, y-, and z-axis, respectively, while RotX, RotY, and RotZ describe the rotation.

3D poses are typically used in two ways: First, to describe the position and orientation of one coordinate system relative to another (e.g., the pose of a part's coordinate system relative to the camera coordinate system - in short: the pose of the part relative to the camera) and secondly, to describe how coordinates can be transformed between two coordinate systems (e.g., to transform points from part coordinates into camera coordinates).

Representation of orientation (rotation)

A 3D rotation around an arbitrary axis can be represented by 3 parameters in multiple ways. HALCON lets you choose between three of them with the parameter OrderOfRotation: If you pass the value *'gba'*, the rotation is described by the following chain of rotations around the three axes (see hom_mat3d_rotate for the content for the rotation matrices $\mathbf{R}_x$, $\mathbf{R}_y$, and $\mathbf{R}_z$):

$$\mathbf{R}_{gba} = \mathbf{R}_x(\texttt{RotX}) \cdot \mathbf{R}_y(\texttt{RotY}) \cdot \mathbf{R}_z(\texttt{RotZ})$$

$\mathbf{R}_{gba}$ is referred to as the Yaw-Pitch-Roll convention in the literature. Please note that you can "read" this chain in two ways: If you start from the right, the rotations are always performed relative to the global (i.e., fixed or "old") coordinate system. Thus, $\mathbf{R}_{gba}$ can be read as follows: First rotate around the z-axis, then around the "old" y-axis, and finally around the "old" x-axis. In contrast, if you read from the left to the right, the rotations are performed relative to the local (i.e., "new") coordinate system. Then, $\mathbf{R}_{gba}$ corresponds to the following: First rotate around the x-axis, the around the "new" y-axis, and finally around the "new(est)" z-axis.

Reading $\mathbf{R}_{gba}$ from right to left corresponds to the following sequence of operator calls:

```
hom_mat3d_identity(HomMat3DIdent)
hom_mat3d_rotate(HomMat3DIdent, RotZ, 'z', 0, 0, 0, HomMat3DRotZ)
hom_mat3d_rotate(HomMat3DRotZ, RotY, 'y', 0, 0, 0, HomMat3DRotYZ)
hom_mat3d_rotate(HomMat3DRotYZ, RotX, 'x', 0, 0, 0, HomMat3DXYZ)
```

In contrast, reading from left to right corresponds to the following operator sequence:

```
hom_mat3d_identity(HomMat3DIdent)
hom_mat3d_rotate_local(HomMat3DIdent, RotX, 'x', HomMat3DRotX)
hom_mat3d_rotate_local(HomMat3DRotX, RotY, 'y', HomMat3DRotXY)
hom_mat3d_rotate_local(HomMat3DRotXY, RotZ, 'z', HomMat3DXYZ)
```

When passing *'abg'* in `OrderOfRotation`, the rotation corresponds to the following chain:

$$\mathbf{R}_{abg} = \mathbf{R}_z(\texttt{RotZ}) \cdot \mathbf{R}_y(\texttt{RotY}) \cdot \mathbf{R}_x(\texttt{RotX})$$

$\mathbf{R}_{abg}$ is referred to as the Roll-Pitch-Yaw convention in the literature.

If you pass *'rodriguez'* in `OrderOfRotation`, the rotation parameters `RotX`, `RotY`, and `RotZ` are interpreted as the x-, y-, and z-component of the so-called Rodriguez rotation vector. The direction of the vector defines the (arbitrary) axis of rotation. The length of the vector usually defines the rotation angle with positive orientation. Here, a variation of the Rodriguez vector is used, where the length of the vector defines the tangent of half the rotation angle:

$$\mathbf{R}_{rodriguez} \quad = \quad rotate\ around \quad \begin{pmatrix} \texttt{RotX} \\ \texttt{RotY} \\ \texttt{RotZ} \end{pmatrix} \quad by \quad 2 \cdot \arctan(\sqrt{\texttt{RotX}^2 + \texttt{RotY}^2 + \texttt{RotZ}^2})$$

Please note that these 3D poses can be ambiguous, meaning a homogeneous transformation matrix can have several pose representations. For example, for $\mathbf{R}_{gba}$ with $b = \pm 90$ the following poses correspond to the same homogeneous transformation matrix:

```
create_pose(0, 0, 0, 30, 90, 54, 'Rp+T', 'gba', 'point', Pose1)
create_pose(0, 0, 0, 17, 90, 67, 'Rp+T', 'gba', 'point', Pose2)
```

If this leads to problems, you can instead use homogeneous transformation matrices or quaternions (`axis_angle_to_quat`) to represent rotations.

Corresponding homogeneous transformation matrix

You can obtain the homogeneous transformation matrix corresponding to a pose with the operator `pose_to_hom_mat3d`. In the standard definition, this is the following homogeneous transformation matrix which can be split into two separate matrices, one for the translation ($\mathbf{H}(\mathbf{T})$) and one for the rotation ($\mathbf{H}(\mathbf{R})$):

$$\mathbf{H}_{pose} = \begin{bmatrix} \mathbf{R} & \mathbf{T} \\ 0\,0\,0 & 1 \end{bmatrix} = \begin{bmatrix} \mathbf{R}(\texttt{RotX},\texttt{RotY},\texttt{RotZ}) & \begin{matrix}\texttt{TransX}\\ \texttt{TransY}\\ \texttt{TransZ}\end{matrix} \\ \begin{matrix}0 & 0 & 0\end{matrix} & 1 \end{bmatrix} =$$

$$= \begin{bmatrix} 1 & 0 & 0 & \texttt{TransX} \\ 0 & 1 & 0 & \texttt{TransY} \\ 0 & 0 & 1 & \texttt{TransZ} \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R}(\texttt{RotX},\texttt{RotY},\texttt{RotZ}) & \begin{matrix}0\\0\\0\end{matrix} \\ \begin{matrix}0 & 0 & 0\end{matrix} & 1 \end{bmatrix} = \mathbf{H}(\mathbf{T}) \cdot \mathbf{H}(\mathbf{R})$$

Transformation of coordinates

The following equation describes how a point can be transformed from coordinate system 1 (*cs*1) into coordinate system 2 (*cs*2) with a pose, or more exactly, with the corresponding homogeneous transformation matrix ${}^{cs2}\mathbf{H}_{cs1}$ (input and output points as homogeneous vectors, see also `affine_trans_point_3d`). Note that to transform points from *cs*1 into *cs*2, you use the transformation matrix that describes the pose of *cs*1 relative to *cs*2.

$$\begin{pmatrix} \mathbf{p}^{cs2} \\ 1 \end{pmatrix} = {}^{cs2}\mathbf{H}_{cs1} \cdot \begin{pmatrix} \mathbf{p}^{cs1} \\ 1 \end{pmatrix} = \begin{pmatrix} \mathbf{R}(\texttt{RotX},\texttt{RotY},\texttt{RotZ}) \cdot \mathbf{p}^{cs1} + \begin{pmatrix} \texttt{TransX} \\ \texttt{TransY} \\ \texttt{TransZ} \end{pmatrix} \\ 1 \end{pmatrix}$$

This corresponds to the following operator calls:

```
pose_to_hom_mat3d(PoseOf1In2, HomMat3DFrom1In2)
affine_trans_point_3d(HomMat3DFrom1In2, P1X, P1Y, P1Z, P2X, P2Y,
P2Z)
```

Non-standard pose definitions

So far, we described the standard pose definition. To create such poses, you select the (default) values *'Rp+T'* for the parameter `OrderOfTransform` and *'point'* for `ViewOfTransform`. By specifying other values for these parameters, you can create non-standard poses types which we describe briefly below. Please note that these representation types are only supported for backwards compatibility; we strongly recommend to use the standard types.

If you select *'R(p-T)'* for `OrderOfTransform`, the created pose corresponds to the following chain of transformations, i.e., the sequence of rotation and translation is reversed and the translation is negated:

$$\mathbf{H}_{R(p-T)} = \begin{bmatrix} \mathbf{R}(\texttt{RotX},\texttt{RotY},\texttt{RotZ}) & \begin{matrix}0\\0\\0\end{matrix} \\ \begin{matrix}0 & 0 & 0\end{matrix} & 1 \end{bmatrix} \cdot \begin{bmatrix} 1 & 0 & 0 & -\texttt{TransX} \\ 0 & 1 & 0 & -\texttt{TransY} \\ 0 & 0 & 1 & -\texttt{TransZ} \\ 0 & 0 & 0 & 1 \end{bmatrix} = \mathbf{H}(\mathbf{R}) \cdot \mathbf{H}(-\mathbf{T})$$

If you select *'coordinate_system'* for `ViewOfTransform`, the sequence of transformations remains constant, but the rotation angles are negated. Please note that, contrary to its name, this is not equivalent to transforming a coordinate system!

$$\mathbf{H}_{coordinate\_system} = \begin{bmatrix} 1 & 0 & 0 & \texttt{TransX} \\ 0 & 1 & 0 & \texttt{TransY} \\ 0 & 0 & 1 & \texttt{TransZ} \\ 0 & 0 & 0 & 1 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{R}(-\texttt{RotX},-\texttt{RotY},-\texttt{RotZ}) & \begin{matrix}0\\0\\0\end{matrix} \\ \begin{matrix}0 & 0 & 0\end{matrix} & 1 \end{bmatrix}$$

Returned data structure

The created 3D pose is returned in `Pose` which is a tuple of length seven. The first three elements hold the translation parameters `TransX`, `TransY`, and `TransZ`, followed by the rotation parameters `RotX`, `RotY`, and `RotZ`. The last element codes the representation type of the pose that you selected with the parameters `OrderOfTransform`, `OrderOfRotation`, and `ViewOfTransform`. The following table lists the possible combinations. As already noted, we recommend to use only the representation types with `OrderOfTransform` = *'Rp+T'* and `ViewOfTransform` = *'point'* (codes 0, 2, and 4).

OrderOfTransform	OrderOfRotation	ViewOfTransform	Code
'Rp+T'	*'gba'*	*'point'*	0
'Rp+T'	*'abg'*	*'point'*	2
'Rp+T'	*'rodriguez'*	*'point'*	4
'Rp+T'	*'gba'*	*'coordinate_system'*	1
'Rp+T'	*'abg'*	*'coordinate_system'*	3
'Rp+T'	*'rodriguez'*	*'coordinate_system'*	5
'R(p-T)'	*'gba'*	*'point'*	8
'R(p-T)'	*'abg'*	*'point'*	10
'R(p-T)'	*'rodriguez'*	*'point'*	12
'R(p-T)'	*'gba'*	*'coordinate_system'*	9
'R(p-T)'	*'abg'*	*'coordinate_system'*	11
'R(p-T)'	*'rodriguez'*	*'coordinate_system'*	13

You can convert poses into other representation types using `convert_pose_type` and query the type using `get_pose_type`.

Parameters

▷ **`TransX`** (input_control) . . . . . real ⇝ *real*
Translation along the x-axis (in [m]).
Default: 0.1
Suggested values: `TransX` ∈ {-1.0, -0.75, -0.5, -0.25, -0.2, -0.1, -0.5, -0.25, -0.125, -0.01, 0.0, 0.01, 0.125, 0.25, 0.5, 0.1, 0.2, 0.25, 0.5, 0.75, 1.0}

▷ **`TransY`** (input_control) . . . . . real ⇝ *real*
Translation along the y-axis (in [m]).
Default: 0.1
Suggested values: `TransY` ∈ {-1.0, -0.75, -0.5, -0.25, -0.2, -0.1, -0.5, -0.25, -0.125, -0.01, 0.0, 0.01, 0.125, 0.25, 0.5, 0.1, 0.2, 0.25, 0.5, 0.75, 1.0}

▷ **`TransZ`** (input_control) . . . . . real ⇝ *real*
Translation along the z-axis (in [m]).
Default: 0.1
Suggested values: `TransZ` ∈ {-1.0, -0.75, -0.5, -0.25, -0.2, -0.1, -0.5, -0.25, -0.125, -0.01, 0.0, 0.01, 0.125, 0.25, 0.5, 0.1, 0.2, 0.25, 0.5, 0.75, 1.0}

▷ **`RotX`** (input_control) . . . . . real ⇝ *real*
Rotation around x-axis or x component of the Rodriguez vector (in [°] or without unit).
Default: 90.0
Suggested values: `RotX` ∈ {0.0, 90.0, 180.0, 270.0}
Value range: 0 ≤ `RotX` ≤ 360

▷ **`RotY`** (input_control) . . . . . real ⇝ *real*
Rotation around y-axis or y component of the Rodriguez vector (in [°] or without unit).
Default: 90.0
Suggested values: `RotY` ∈ {0.0, 90.0, 180.0, 270.0}
Value range: 0 ≤ `RotY` ≤ 360

▷ **`RotZ`** (input_control) . . . . . real ⇝ *real*
Rotation around z-axis or z component of the Rodriguez vector (in [°] or without unit).
Default: 90.0
Suggested values: `RotZ` ∈ {0.0, 90.0, 180.0, 270.0}
Value range: 0 ≤ `RotZ` ≤ 360

▷ **`OrderOfTransform`** (input_control) . . . . . string ⇝ *string*
Order of rotation and translation.
Default: 'Rp+T'
Suggested values: `OrderOfTransform` ∈ {'Rp+T', 'R(p-T)'}

▷ **`OrderOfRotation`** (input_control) . . . . . string ⇝ *string*
Meaning of the rotation values.
Default: 'gba'
Suggested values: `OrderOfRotation` ∈ {'gba', 'abg', 'rodriguez'}

▷ **ViewOfTransform** (input_control) ..... string ⇝ *string*
View of transformation.
Default: 'point'
Suggested values: ViewOfTransform ∈ {'point', 'coordinate_system'}

▷ **Pose** (output_control) ..... pose ⇝ *real* / integer
3D pose.
Number of elements: 7

Example

```
* Create a pose.
create_pose (0.1, 0.2, 0.3, 40, 50, 60, 'Rp+T', 'gba', 'point', Pose)
```

Result

create_pose returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

pose_to_hom_mat3d, write_pose, camera_calibration, hand_eye_calibration

Alternatives

read_pose, hom_mat3d_to_pose

Module

Foundation

deserialize_pose (: : SerializedItemHandle : Pose)

Deserialize a serialized pose.

deserialize_pose deserializes a pose, that was serialized by serialize_pose (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized pose is defined by the handle SerializedItemHandle. The deserialized values are stored in an automatically created pose with the handle Pose.

Parameters

▷ **SerializedItemHandle** (input_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **Pose** (output_control) ..... pose ⇝ *real* / integer
3D pose.
Number of elements: 7

Result

If the parameters are valid, the operator deserialize_pose returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_pose

Module

Foundation

dual_quat_to_pose (: : DualQuaternion : Pose)

Convert a dual quaternion to a 3D pose.

The operator dual_quat_to_pose converts the input DualQuaternion into its corresponding 3D Pose.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

Multiple dual quaternions can be passed in DualQuaternion, in which case a pose is returned for each of them.

Attention

dual_quat_to_pose assumes that the input DualQuaternion is a unit dual quaternion, and hence represents a 3D rigid transformation. Otherwise the returned pose is not meaningful.

Parameters

▷ **DualQuaternion** (input_control) . . . . . dual_quaternion(-array) ⇝ *real*
Unit dual quaternion.

▷ **Pose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
3D pose.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_circle_pose (Contour : : CameraParam, Radius, OutputType : Pose1, Pose2)

Determine the 3D pose of a circle from its perspective 2D projection.

Each ellipse in an image can be interpreted as the perspective projection of a circle into the image. In fact, for a given radius of the circle, there exist two differently oriented circles in 3D that result in the same projection. get_circle_pose determines the 3D positions and orientations of these two circles. First, each Contour is approximated by an ellipse. Then, based on the internal camera parameters (CameraParam) and the radius of the circle in 3D (Radius), the 3D positions and orientations (Pose1,Pose2) are determined in camera coordinates.

Depending on the value of the parameter OutputType, the position and orientation is returned as a 3D pose (OutputType = *'pose'*) or in the form of the center of the 3D circle and the normal vector of the plane in which the circle lies (OutputType = *'center_normal'*). In the former case, the angle for the rotation around the z axis is set to zero, because it cannot be determined. In the latter case, the first three elements of the output parameters Pose1 and Pose2 contain the position of the center of the circle. The following three elements contain the normal vector. The normal vectors are normalized and oriented such that they point away from the optical center which is the origin of the camera coordinate system. If OutputType is set to *'center_normal'*, the output parameters Pose1 and Pose2 contain only six elements which describe the position and orientation of the circle instead of the seven elements of the 3D pose that are returned if OutputType is set to *'pose'*.

If more than one contour is passed in Contour, Radius must either contain a tuple that contains a value for each contour or only one value which is then used for all contours. The resulting positions and orientations are stored one after another in Pose1 and Pose2, i.e., Pose1 and Pose2 contain first the pose or the position and the normal vector of the first contour, followed by the respective values for the second contour and so on.

Attention

The accuracy of the determined poses depends heavily on the accuracy of the extracted contours. The extraction of curved edges using relatively large filter masks leads to a slightly shifted edge position. Edge extraction approaches that are based on the first derivative of the image function (e.g., edges_sub_pix) yield edges that are shifted towards the center of curvature, i.e., extracted ellipses will be slightly to small. Approaches that are based on the second derivative of the image function (laplace_of_gauss followed by zero_crossing_sub_pix) result in edges that are shifted away from the center of curvature, i.e., extracted ellipses will be slightly too large.

These effects increase with the curvature of the edge and with the size of the filter mask that is used for the edge extraction. Therefore, to achieve high accuracy, the ellipses should appear large in the image and the filter parameter should be chosen such that small filter masks are used (see info_edges).

Parameters

- ▷ **Contour** (input_object) . . . . . xld(-array) ⇝ *object*
  Contours to be examined.
- ▷ **CameraParam** (input_control) . . . . . campar ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **Radius** (input_control) . . . . . number(-array) ⇝ *real*
  Radius of the circle in object space.
  Number of elements: Radius == Contour || Radius == 1
  Restriction: Radius > 0.0
- ▷ **OutputType** (input_control) . . . . . string ⇝ *string*
  Type of output parameters.
  Default: 'pose'
  List of values: OutputType ∈ {'pose', 'center_normal'}
- ▷ **Pose1** (output_control) . . . . . real-array ⇝ *real* / integer
  3D pose of the first circle.
  Number of elements: Pose1 == 7 * Contour || Pose1 == 6 * Contour
- ▷ **Pose2** (output_control) . . . . . real-array ⇝ *real* / integer
  3D pose of the second circle.
  Number of elements: Pose2 == 7 * Contour || Pose2 == 6 * Contour

Result

get_circle_pose returns 2 (H_MSG_TRUE) if all parameter values are correct and the position of the circle has been determined successfully. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

3D Metrology

get_pose_type (: : Pose : OrderOfTransform, OrderOfRotation, ViewOfTransform)

Get the representation type of a 3D pose.

With get_pose_type, the representation type of the 3D pose Pose can be queried. See create_pose for details about 3D poses, their representation types, and the meaning of the parameters OrderOfTransform, OrderOfRotation, and ViewOfTransform.

Parameters

▷ **Pose** (input_control) . . . . . pose ⇝ *real / integer*
3D pose.
Number of elements: 7

▷ **OrderOfTransform** (output_control) . . . . . string ⇝ *string*
Order of rotation and translation.

▷ **OrderOfRotation** (output_control) . . . . . string ⇝ *string*
Meaning of the rotation values.

▷ **ViewOfTransform** (output_control) . . . . . string ⇝ *string*
View of transformation.

Result

create_pose returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_rectangle_pose (Contour : : CameraParam, Width, Height, WeightingMode, ClippingFactor : Pose, CovPose, Error)

Determine the 3D pose of a rectangle from its perspective 2D projection

A rectangle in space is projected as a general quadrangle into the image. get_rectangle_pose determines the Pose of the rectangle from this projection (Contour).

The algorithm works as follows: First, Contour is segmented into four line segments and their intersections are considered as corners of the contour. The corners together with the internal camera parameters (CameraParam) and the rectangle size in meters (Width, Height) are used for an initial estimation of the rectangle pose. Then, the final Pose is refined with a non-linear optimization by minimizing the geometrical distance of the contour points from the back projection of the rectangle in the image.

The operator supports only area scan pinhole (projective) cameras. An error is returned if CameraParam specifies a line scan or a telecentric camera (see also Calibration).

Width and Height specify the size of the rectangle in x and y dimensions, respectively, in its coordinate system. The origin of this coordinate system is in the center of the rectangle. The z axis points away from the camera.

The arguments WeightingMode and ClippingFactor can be used to damp the impact of outliers on the algorithm. If WeightingMode is set to *'tukey'* or *'huber'*, the contour points are weighted based on the approach of Tukey or Huber respectively. In such a case a robust error statistics is used to estimate the standard deviation of the distances of the contour points from the backprojected rectangle excluding outliers. The parameter ClippingFactor (a scaling factor for the standard deviation) controls the amount of damping outliers: The smaller the value chosen for ClippingFactor the more outliers are detected. See a discussion about the properties of the different weighting modes in fit_line_contour_xld. Note that, unlike by fit_line_contour_xld, for the rectangle pose estimation the approach of Huber is recommended.

Output

The resulting Pose is of code 0 (see create_pose) and represents the pose of the center of the rectangle. You can compute the pose of the corners of the rectangle as follows:

```
set_origin_pose(Pose, Width/2, -Height/2, 0, PoseCorner1)
set_origin_pose(Pose, Width/2, Height/2, 0, PoseCorner2)
set_origin_pose(Pose, -Width/2, Height/2, 0, PoseCorner3)
set_origin_pose(Pose, -Width/2, -Height/2, 0, PoseCorner4)
```

A rectangle is symmetric with respect to its x, y, and z axis and one and the same contour can represent a rectangle in 4 different poses. The angles in Pose are normalized to be in the range $[-90; 90]$ degrees and the rest of the 4 possible poses can be computed by combining flips around the corresponding axis:

```
* NOTE: the following code works ONLY for pose of code 0
* as it is returned by get_rectangle_pose
*
* flip around z-axis
PoseFlippedZ := Pose
PoseFlippedZ[5] := PoseFlippedZ[5]+180
* flip around y-axis
PoseFlippedY := Pose
PoseFlippedY[4] := PoseFlippedY[4]+180
PoseFlippedY[5] := -PoseFlippedY[5]
* flip around x-axis
PoseFlippedX := Pose
PoseFlippedX[3] := PoseFlippedX[3]+180
PoseFlippedX[4] := -PoseFlippedX[4]
PoseFlippedX[5] := -PoseFlippedX[5]
```

Note that if the rectangle is a square (Width == Height) the number of alternative poses is 8.

If more than one contour are given in Contour, a corresponding tuple of values for both Width and Height has to be provided as well. Yet, if only one value is provided for each of these arguments, then this value is applied for each processed contour. A pose is estimated for each processed contour and all poses are concatenated in Pose (see the example below).

Accuracy of the pose

The accuracy of the estimated pose depends on the following three factors:

- ratio Width/Height
- length of the projected contour

- degree of perspective distortion of the contour

In order to achieve an accurate pose estimation, there are three corresponding criteria that should be considered:

The **ratio** Width/Height should fulfill

$$\frac{1}{3} < \texttt{Width}/\texttt{Height} < 3$$

For a rectangular object deviating from this criterion, its longer side dominates the determination of its pose. This causes instability in the estimation of the angle around the longer rectangle's axis. In the extreme case when one of the dimensions is 0, the rectangle is in fact a line segment, whose pose cannot be estimated.

Secondly, the **lengths of each side of the contour** should be at least 20 pixels. An error is returned if a side of the contour is less than 5 pixels long.

Thirdly, the more the contour appears **projectively distorted**, the more stable the algorithm works. Therefore, the pose of a rectangle tilted with respect to the image plane can be estimated accurately, whereas the pose of an rectangle parallel to the image plane of the camera could be unstable. This is further discussed in the next paragraph. Additionally, there is a rule of thumb that ensures projective distortion: the rectangle should be placed in space such that its size in x and y dimension in the camera coordinate system should not be less than $1/10th$ of its distance from the camera in z direction.

get_rectangle_pose provides two measures for the accuracy of the estimated Pose. Error is the average pixel error between the contour points and the modeled rectangle backprojected on the image. If Error is exceeding 0.5, this is an indication that the algorithm did not converge properly, and the resulting Pose should not be used. CovPose contains 36 entries representing the 6×6 covariance matrix of the first 6 entries of Pose. The above mentioned case of instability of the angle about the longer rectangle's axis be detected by checking that the absolute values of the variances and covariances of the rotations around the x and y axis (CovPose[21],CovPose[28], and CovPose[22] == CovPose[27]) do not exceed 0.05. Further, unusually increased values of any of the covariances and especially of the variances (the 6 values on the diagonal of CovPose with indices 0, 7, 14, 21, 28 and 35, respectively) indicate a poor quality of Pose.

Parameters

- ▷ **Contour** (input_object) ..... xld(-array) ⇝ *object*
  Contour(s) to be examined.
- ▷ **CameraParam** (input_control) ..... campar ⇝ *real* / integer / string
  Internal camera parameters.
- ▷ **Width** (input_control) ..... number(-array) ⇝ *real*
  Width of the rectangle in meters.
  Restriction: Width > 0
- ▷ **Height** (input_control) ..... number(-array) ⇝ *real*
  Height of the rectangle in meters.
  Restriction: Height > 0
- ▷ **WeightingMode** (input_control) ..... string ⇝ *string*
  Weighting mode for the optimization phase.
  Default: 'nonweighted'
  List of values: WeightingMode ∈ {'nonweighted', 'huber', 'tukey'}
- ▷ **ClippingFactor** (input_control) ..... number ⇝ *real*
  Clipping factor for the elimination of outliers (typical: *1.0* for *'huber'* and *3.0* for *'tukey'*).
  Default: 2.0
  Suggested values: ClippingFactor ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
  Restriction: ClippingFactor > 0
- ▷ **Pose** (output_control) ..... pose(-array) ⇝ *real* / integer
  3D pose of the rectangle.
  Number of elements: Pose == 7 * Contour
- ▷ **CovPose** (output_control) ..... number-array ⇝ *real*
  Covariances of the pose values.
  Number of elements: CovPose == 36 * Contour
- ▷ **Error** (output_control) ..... number-array ⇝ *real*
  Root-mean-square value of the final residual error.
  Number of elements: Error == Contour

Example

```
* Process an image with several rectangles of the same size appearing
* as light objects.
RectWidth := 0.04
RectHeight := 0.025
gen_cam_par_area_scan_division (0.014, 830, 4.58e-006, 4.65e-006, \
                                509, 488, 800, 800, CameraParam)
read_image (Image, 'barcode/ean13/tea_box_01')
* Find light objects in the image.
mean_image (Image, ImageMean, 201, 201)
dyn_threshold (Image, ImageMean, Region, 5, 'light')
* Fill gaps in the objects.
fill_up (Region, RegionFillUp)
* Extract rectangular contours.
connection (RegionFillUp, ConnectedRegions)
select_shape (ConnectedRegions, SelectedRegions, ['area','rectangularity'], \
              'and', [50000,0.9], [640000,1])
boundary (SelectedRegions, RegionBorder, 'inner')
dilation_circle (RegionBorder, RegionDilation, 3.5)
* NOTE: for a real application, this step might require some additional
*       pre- or postprocessing.
reduce_domain (Image, RegionDilation, ImageReduced)
edges_sub_pix (ImageReduced, Edges, 'canny', 1, 20, 40)
* Get the pose of all contours found.
get_rectangle_pose (Edges, CameraParam, RectWidth, RectHeight, 'huber', 2, \
                    Poses, CovPose, Error)
NumPoses := |Poses|/7
for I := 0 to NumPoses-1 by 1
  Pose := Poses[I*7:I*7+6]
  * Use the Pose here.
  * ...
endfor
```

Result

`get_rectangle_pose` returns `2` (`H_MSG_TRUE`) if all parameter values are correct and the position of the rectangle has been determined successfully. If the provided contour(s) cannot be segmented as a quadrangle `get_rectangle_pose` returns H_ERR_FIT_QUADRANGLE. If further necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

pose_average (: : Poses, Weights, Mode, SigmaT, SigmaR : AveragePose, Quality)

Compute the average of a set of poses.

pose_average computes the average rotation and translation of the poses passed in Poses, and returns this average pose in AveragePose. The poses can be weighted using the parameter Weights. If an empty tuple is passed as weight, all poses have the same influence on the result. Otherwise, a tuple that contains one positive weight per pose needs to be passed. A higher weight leads to a higher influence of that pose on the average.

pose_average supports two modes for averaging the poses, which can be selected with the parameter Mode. *'direct'* selects a direct computation of the average, where the translation and rotation are averaged independently from each other. *'iterative'* uses the average pose computed by the *'direct'* method as initial value for an iterative method, which computes the local mode of the poses. The iterative method is slower than the direct method. However, it returns more accurate poses especially in the presence of outlier poses, as such outliers are downweighted automatically.

For the iterative method, the relative weight of the translation and the rotation can be set with the parameters SigmaT and SigmaR, respectively. Both values can be set to *'auto'*, in which case they are automatically estimated. In this case, SigmaT is set to the spread of the translations of the poses, and SigmaR is set to a constant value. Both values describe the expected spread of the translation and the rotation, and influence the weighting of the poses. For the direct method, both parameters are ignored.

A measure of the quality of the computed pose is returned in Quality. Quality contains a tuple with four elements, which describe the average and maximum deviation of the passed poses from the returned average pose AveragePose. The order of the values is: Root-Mean-Square error of the translation, Root-Mean-Square error of the rotation, maximum translation and maximum rotation deviation. The weights passed in Weights are used in the Root-Mean-Square errors of translation and rotation, but not for the last two quality measures.

Parameters

▷ **Poses** (input_control) . . . . . pose-array ⇝ *integer*
Set of poses of which the average if computed.

▷ **Weights** (input_control) . . . . . number-array ⇝ *real* / integer
Empty tuple, or one weight per pose.
Default: []
Restriction: Weights > 0 && length(Weights) == 0 || length(Weights) == length(Poses) / 7

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Averaging mode.
Default: 'iterative'
List of values: Mode ∈ {'direct', 'iterative'}

▷ **SigmaT** (input_control) . . . . . number ⇝ *real* / integer / string
Weight of the translation.
Default: 'auto'
Suggested values: SigmaT ∈ {'auto', 0.1, 1, 100}

▷ **SigmaR** (input_control) . . . . . number ⇝ *real* / integer / string
Weight of the rotation.
Default: 'auto'
Suggested values: SigmaR ∈ {'auto', 0.1, 1, 10}

▷ **AveragePose** (output_control) . . . . . pose ⇝ *real* / integer
Weighted mean of the poses.

▷ **Quality** (output_control) . . . . . number-array ⇝ *real*
Deviation of the mean from the input poses.
Assertion: length(Quality) == 4

Result

If the parameters are valid, the operator pose_average returns 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Module

Foundation

pose_compose (: : PoseLeft, PoseRight : PoseCompose)

Combine 3D poses given in two tuples.

pose_compose combines the poses in the tuples, PoseLeft and PoseRight. If both tuples contain the same number of poses, the corresponding elements of both tuples are composed. Otherwise, either tuple PoseLeft or PoseRight must contain only one pose. In this case, the composition is performed for each pose of the longer tuple with the single pose of the other tuple. For each composition, the poses are interpreted as transformations of coordinate systems. The poses in tuple PoseCompose are therefore the result of applying the corresponding poses in PoseLeft and PoseRight in sequence.

First, the respective poses in PoseLeft and PoseRight are transformed into the corresponding homogeneous transformation matrices $\mathbf{H}_1$ and $\mathbf{H}_2$. $\mathbf{H}_1$ is then multiplied with $\mathbf{H}_2$. The resulting matrix $\mathbf{H}_1 \cdot \mathbf{H}_2$ is converted into a pose and returned at the corresponding index in tuple PoseCompose.

If the respective poses in PoseLeft and PoseRight have different types, the default pose type 0 ('Rp+T', 'gba', 'point') is returned. Otherwise, the returned poses have the same types as the poses used for their composition.

Parameters

▷ **PoseLeft** (input_control) . . . . . pose(-array) ⇝ *real* / integer
Tuple containing the left poses.

▷ **PoseRight** (input_control) . . . . . pose(-array) ⇝ *real* / integer
Tuple containing the right poses.

▷ **PoseCompose** (output_control) . . . . . pose(-array) ⇝ *real* / integer
Tuple containing the returned poses.

Result

pose_compose returns 2 (H_MSG_TRUE) if all parameters are valid. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Foundation

pose_invert (: : Pose : PoseInvert)

Invert each pose in a tuple of 3D poses.

pose_invert inverts each pose of the given tuple Pose by transforming it into the corresponding homogeneous transformation matrix $\mathbf{H}$ and inverting this matrix. The resulting matrix is converted into a pose. This pose is returned at the respective index in the tuple PoseInvert. The returned poses have the same types as the original poses.

Parameters

▷ **Pose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
Tuple of 3D poses.

▷ **PoseInvert** (output_control) . . . . . pose(-array) ⇝ *real* / integer
Tuple of inverted 3D poses.

Result

pose_invert returns 2 (H_MSG_TRUE) if all parameters are valid. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

Module

Foundation

pose_to_dual_quat (: : Pose : DualQuaternion)

Convert a 3D pose to a unit dual quaternion.

The operator pose_to_dual_quat converts the input Pose into its corresponding unit dual quaternion DualQuaternion.

For a brief introduction to dual quaternions, the used notation, and the relationship between dual quaternions and screws, see "Solution Guide III-C - 3D Vision".

Because $\hat{q}$ and $-\hat{q}$ represent the same rigid transformation, the sign of the resulting dual quaternion DualQuaternion is chosen such that the scalar part of the real part is ≥ 0.

Multiple poses can be passed in Pose, in which case a unit dual quaternion is returned for each of them.

Parameters

▷ **Pose** (input_control) . . . . . pose(-array) ⇝ *real* / integer
3D pose.

▷ **DualQuaternion** (output_control) . . . . . dual_quaternion(-array) ⇝ *real*
Unit dual quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

pose_to_quat (: : Pose : Quaternion)

Convert the rotational part of a 3D pose to a quaternion.

The operator pose_to_quat converts the rotation of the input 3D pose Pose into its corresponding quaternion Quaternion. Note that the translation of Pose is ignored. Multiple poses can be passed in Pose, in which case a quaternion is returned for each of them.

Parameters

- ▷ **Pose** (input_control) ..... pose(-array) ⇝ *real* / integer
  3D Pose.
- ▷ **Quaternion** (output_control) ..... quaternion(-array) ⇝ *real*
  Rotation quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

proj_hom_mat2d_to_pose (: : Homography, CameraMatrix, Method : Pose)

Compute a pose out of a homography describing the relation between world and image coordinates.

proj_hom_mat2d_to_pose computes a pose out of a homography Homography that describes the relation between 2D world- (unit meters) and 2D image coordinates. The homography can be obtained by the use of vector_to_proj_hom_mat2d. To compute a pose, a camera matrix (obtained by cam_par_to_cam_mat,

for example) has to be passed in CameraMatrix. By setting the Parameter Method, it is possible to choose which computation algorithm is used. Currently a direct decomposition (Method = 'decomposition') and a singular value decomposition based method (Method = 'decomposition_svd') are supported. In general due to numeric reasons, the direct decomposition method returns more stable results.

The subsequent calls of vector_to_proj_hom_mat2d and proj_hom_mat2d_to_pose are similar to vector_to_pose for 2D objects, whereas no refinement due to redundancy is possible.

Parameters

- ▷ **Homography** (input_control) . . . . . hom_mat2d ⇝ *real*
  The homography from world- to image coordinates.
- ▷ **CameraMatrix** (input_control) . . . . . hom_mat2d ⇝ *real*
  The camera calibration matrix K.
- ▷ **Method** (input_control) . . . . . string ⇝ *string*
  Type of pose computation.
  Default: 'decomposition'
  List of values: Method ∈ {'decomposition', 'decomposition_svd'}
- ▷ **Pose** (output_control) . . . . . pose ⇝ *real* / integer
  Pose of the 2D object.

Result

proj_hom_mat2d_to_pose returns 2 (H_MSG_TRUE) if all parameter values are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

quat_to_pose (: : Quaternion : Pose)

Convert a quaternion into the corresponding 3D pose.

The operator quat_to_pose converts the input quaternion Quaternion into its corresponding 3D pose Pose. Note that the translation of Pose is zero in any case.

Parameters

- ▷ **Quaternion** (input_control) . . . . . quaternion ⇝ *real*
  Rotation quaternion.
- ▷ **Pose** (output_control) . . . . . pose ⇝ *real* / integer
  3D Pose.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

read_pose (: : PoseFile : Pose)

Read a 3D pose from a text file.

read_pose is used to read the 3D pose Pose from a text file with the name PoseFile. The default HALCON file extension for the 3D pose is 'dat'.

A pose describes a rigid 3D transformation, i.e., a transformation consisting of an arbitrary translation and rotation, with 6 parameters, three for the translation, three for the rotation. With a seventh parameter different pose types can be indicated (see create_pose).

A suitable file can be generated by the operator write_pose and looks like the following:

```
\# 3D POSE PARAMETERS: rotation and translation

\# Used representation type:
f 0

\# Rotation angles [deg] or Rodriguezvector:
r -17.8134 1.83816 0.288092

\# Translation vector (x y z [m]):
t 0.280164 0.150644 1.7554
```

Parameters

▷ **PoseFile** (input_control) . . . . . filename.read ⇝ *string*
File name of the external camera parameters.
Default: 'campose.dat'
Suggested values: PoseFile ∈ {'campose.dat', 'campose_initial.dat', 'campose_final.dat'}
File extension: .dat

▷ **Pose** (output_control) . . . . . pose ⇝ *real* / integer
3D pose.
Number of elements: 7

Result

read_pose returns 2 (H_MSG_TRUE) if all parameter values are correct and the file has been read successfully. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_cam_par

Possible Successors

pose_to_hom_mat3d, camera_calibration, disp_caltab, sim_caltab

See also

create_pose, find_marks_and_pose, camera_calibration, disp_caltab, sim_caltab, write_pose, pose_to_hom_mat3d, hom_mat3d_to_pose

Module

Foundation

serialize_pose (: : Pose : SerializedItemHandle)

Serialize a pose.

serialize_pose serializes the data of a pose (see fwrite_serialized_item for an introduction of the basic principle of serialization). The same data that is written in a file by write_pose is converted to a serialized item. The pose is defined by the handle Pose. The serialized pose is returned by the handle SerializedItemHandle and can be deserialized by deserialize_pose.

Parameters

▷ **Pose** (input_control) ..... pose ⇝ *real / integer*
3D pose.
Number of elements: 7

▷ **SerializedItemHandle** (output_control) ..... serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_pose returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_pose

Module

Foundation

set_origin_pose (: : PoseIn, DX, DY, DZ : PoseNewOrigin)

Translate the origin of a 3D pose.

set_origin_pose translates the origin of the 3D pose PoseIn by the vector given by DX, DY, and DZ and returns the result in PoseNewOrigin. Note that the translation is performed relative to the local coordinate system of the pose itself. For example, if PoseIn describes the pose of an object in camera coordinates, PoseNewOrigin is obtained by translating the object's coordinate system by DX along its own x-axis (and so on for the other axes) and not along the x-axis of the camera coordinate system. This corresponds to the following chain of transformations:

$$\mathtt{PoseNewOrigin} = \mathtt{PoseIn} \cdot \begin{bmatrix} 1 & 0 & 0 & \begin{pmatrix} \mathtt{DX} \\ \mathtt{DY} \\ \mathtt{DZ} \end{pmatrix} \\ 0 & 1 & 0 & \\ 0 & 0 & 1 & \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Thus, set_origin_pose is a shortcut for the following sequence of operator calls:

```
pose_to_hom_mat3d(PoseIn, HomMat3DIn)
hom_mat3d_translate_local(HomMat3DIn, DX, DY, DZ,
HomMat3DNewOrigin)
hom_mat3d_to_pose(HomMat3DNewOrigin, PoseNewOrigin)
```

A typical application of this operator when defining a world coordinate system by placing the standard calibration plate on the plane of measurements. In this case, the external camera parameters returned by `camera_calibration` correspond to a coordinate system that lies above the measurement plane, because the coordinate system of the calibration plate is located on its surface and the plate has a certain thickness. To correct the pose, call `set_origin_pose` with the translation vector (0,0,D), where D is the thickness of the calibration plate.

Parameters

- ▷ **`PoseIn`** (input_control) . . . . . pose ⇝ *real* / integer
  original 3D pose.
  Number of elements: 7
- ▷ **`DX`** (input_control) . . . . . real ⇝ *real*
  translation of the origin in x-direction.
  Default: 0
- ▷ **`DY`** (input_control) . . . . . real ⇝ *real*
  translation of the origin in y-direction.
  Default: 0
- ▷ **`DZ`** (input_control) . . . . . real ⇝ *real*
  translation of the origin in z-direction.
  Default: 0
- ▷ **`PoseNewOrigin`** (output_control) . . . . . pose ⇝ *real* / integer
  new 3D pose after applying the translation.
  Number of elements: 7

Result

`set_origin_pose` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

vector_to_pose (: : WorldX, WorldY, WorldZ, ImageRow, ImageColumn, CameraParam, Method, QualityType : Pose, Quality)

Compute an absolute pose out of point correspondences between world and image coordinates.

The operator `vector_to_pose` computes a pose out of at least three or four (depending on `Method`) point correspondences of 3D world coordinates (`WorldX`, `WorldY`, `WorldZ`), given in meters, and 2D image coordinates (`ImageRow`, `ImageColumn`), given in pixels, as well as the internal camera parameters (`CameraParam`).

Thereby the pose (the external camera parameters) is in the form ${}^{ccs}\mathbf{P}_{wcs}$, where *ccs* denotes the camera coordinate system and *wcs* the world coordinate system (see Transformations / Poses and "Solution Guide III-C - 3D Vision").

Parameter Method

By setting the parameter Method, it is possible to choose what kind of algorithm is used for the pose computation.

Methods supported for **perspective area scan cameras**:

Method	*When to use*	*Minimum number of point correspondences*
'analytic' [1]	Default method for general cases	4
'iterative' [2]	If only three or four point correspondences are used or if the world points are close to being planar	3
'planar_analytic' [4]	If the world points lie in a horizontal plane (WorldZ = 0)	4

The numbers in square brackets in the table above refer to the publications the implementations of the corresponding methods are based on.

Methods supported for **telecentric area or line scan cameras**:

Method	*When to use*	*Minimum number of point correspondences*
'telecentric' [3]	Default method for general cases	4
'telecentric_robust' [3]	For very ill-posed point configurations where Quality has an unlikely large value	4
'telecentric_planar' [3]	If the world points lie in a horizontal plane (WorldZ = 0)	3
'telecentric_planar_robust' [3]	For very ill-posed point configurations where the world points lie in a horizontal plane (WorldZ = 0) and Quality has an unlikely large value	3

The numbers in square brackets in the table above refer to the publications the implementations of the corresponding methods are based on.

Methods supported for **perspective line scan cameras**:

Method	*When to use*	*Minimum number of point correspondences*
'line_scan'	Default method for general cases	3

Parameters CameraParam and Quality

All methods need the inner camera parameters obtained from camera_calibration to solve the pose estimation problem. They must be passed in CameraParam.

The user can specify in QualityType one or more quality measures of the pose to be evaluated. The resulting quality evaluations are returned concatenated in Quality. Currently, only *'error'* is supported. It corresponds to the root-mean-square error in pixels of the projected 3D world coordinates.

General Remarks

If a method for planar world points is chosen, all world points are assumed to lie in the plane WorldZ = 0. Therefore, the z-component of the world coordinates can be left empty (WorldZ = *[]*) since only 2D correspondences are used in this case.

For telecentric cameras, the translation in *z* obviously cannot be determined. It is set to *0* in Pose.

For planar world points and telecentric cameras, there are always two possible equivalent poses. This ambiguity can only be resolved by some additional knowledge. `vector_to_pose` returns an arbitrary solution of the two possible solutions in this case. The other solution can be calculated easily by replacing the values of α and β in `Pose` by $360 - \alpha$ and $360 - \beta$.

For perspective line scan cameras, the call to `vector_to_pose` corresponds to the following operator sequence:

```
get_line_of_sight(ImageRow, ImageColumn, CameraParam, PX, PY, PZ,
QX, QY, QZ)
points_to_pluecker_line(PX, PY, PZ, QX, QY, QZ, LX, LY, LZ, MX,
MY, MZ)
point_pluecker_line_to_hom_mat3d('rigid', WorldX, WorldY, WorldZ,
LX, LY, LZ, MX, MY, MZ, HomMat3D)
hom_mat3d_to_pose(HomMat3D, Pose)
```

In contrast to the methods for other camera types, an error in 3D space is minimized in this case (see `point_pluecker_line_to_hom_mat3d`). However, like for all other methods, the quality evaluation is performed in pixels. If it is essential that a pixel error is optimized, this can be done as shown in the example below.

Attention

The method *'analytic'* only allows a maximum number of 32767 point correspondences.

Parameters

- ▷ **`WorldX`** (input_control) ..... number-array ⇝ *real* / integer
  X-Component of world coordinates.
  Number of elements: WorldX >= 4
- ▷ **`WorldY`** (input_control) ..... number-array ⇝ *real* / integer
  Y-Component of world coordinates.
  Number of elements: WorldY == WorldX
- ▷ **`WorldZ`** (input_control) ..... number-array ⇝ *real* / integer
  Z-Component of world coordinates.
  Number of elements: WorldZ == WorldX || WorldZ == 0
- ▷ **`ImageRow`** (input_control) ..... number-array ⇝ *real* / integer
  Row-Component of image coordinates.
  Number of elements: ImageRow == WorldX
- ▷ **`ImageColumn`** (input_control) ..... number-array ⇝ *real* / integer
  Column-Component of image coordinates.
  Number of elements: ImageColumn == WorldX
- ▷ **`CameraParam`** (input_control) ..... campar ⇝ *real* / integer / string
  The inner camera parameters from camera calibration.
- ▷ **`Method`** (input_control) ..... string ⇝ *string*
  Kind of algorithm
  Default: 'iterative'
  List of values: `Method` ∈ {'iterative', 'analytic', 'planar_analytic', 'telecentric', 'telecentric_robust', 'telecentric_planar', 'telecentric_planar_robust', 'line_scan'}
- ▷ **`QualityType`** (input_control) ..... string(-array) ⇝ *string*
  Type of pose quality to be returned in Quality.
  Default: 'error'
  List of values: `QualityType` ∈ {'error'}
- ▷ **`Pose`** (output_control) ..... pose ⇝ *real* / integer
  Pose.
- ▷ **`Quality`** (output_control) ..... number(-array) ⇝ *real* / integer
  Pose quality.

Example

```
* Optimize the pixel error line scan cameras. We assume that the
```

```
* point correspondences (Row, Col) - (PX, PY, PZ) have already been
* computed and the internal camera parameters CamParam have already
* been calibrated.
vector_to_pose (PX, PY, PZ, Row, Col, CamParam, 'line_scan', \
                'error', PoseObjectSpace, RMS)
* Use PoseObjectSpace as the starting value for a camera calibration
* that only optimizes the pose.
create_calib_data ('calibration_object', 1, 1, CalibDataID)
set_calib_data_cam_param (CalibDataID, 0, [], CamParam)
set_calib_data_calib_object (CalibDataID, 0, [PX, PY, PZ])
set_calib_data (CalibDataID, 'camera', 0, \
                'excluded_settings', 'params')
set_calib_data_observ_points (CalibDataID, 0, 0, 0, Row, Col, \
                              'all', PoseObjectSpace)
calibrate_cameras (CalibDataID, Error)
get_calib_data (CalibDataID, 'calib_obj_pose', [0, 0], 'pose', Pose)
clear_calib_data (CalibDataID)
* As an alternative, the following one-line code can be used.
camera_calibration (PX, PY, PZ, Row, Col, CamParam, PoseObjectSpace, \
                    'pose', _, Pose, Error)
```

Result

`vector_to_pose` returns `2` (`H_MSG_TRUE`) if all parameter values are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Calibration

write_pose (: : Pose, PoseFile :)

Write a 3D pose to a text file.

`write_pose` is used to write a 3D pose `Pose` into a text file with the name `PoseFile`. The default HALCON file extension for the 3D pose is ’dat’.

A pose describes a rigid 3D transformation, i.e., a transformation consisting of an arbitrary translation and rotation, with 6 parameters, three for the translation, three for the rotation. With a seventh parameter different pose types can be indicated (see `create_pose`).

A file generated by `write_pose` looks like the following:

```
\# 3D POSE PARAMETERS: rotation and translation

\# Used representation type:
f 0

\# Rotation angles [deg] or Rodriguez vector:
r -17.8134 1.83816 0.288092

\# Translation vector (x y z [m]):
t 0.280164 0.150644 1.7554
```

Parameters

▷ **Pose** (input_control) . . . . . pose ⇝ *real* / integer
3D pose.
Number of elements: 7

▷ **PoseFile** (input_control) . . . . . filename.write ⇝ *string*
File name of the external camera parameters.
Default: 'campose.dat'
Suggested values: PoseFile ∈ {'campose.dat', 'campose_initial.dat', 'campose_final.dat'}
File extension: .dat

Example

```
* Perform hand-eye calibration.
calibrate_hand_eye (CalibDataID, Errors)
* Query the camera parameters and the poses.
get_calib_data (CalibDataID, 'camera', 0, 'params', CamParam)
* Get poses computed by the hand eye calibration.
get_calib_data (CalibDataID, 'camera', 0, 'base_in_cam_pose', BaseInCamPose)
get_calib_data (CalibDataID, 'calib_obj', 0,\
                'obj_in_tool_pose', ObjInToolPose)
* Store the camera parameters to file.
write_cam_par (CamParam, DataNameStart + 'final_campar.dat')
* Save the hand eye calibration results to file.
write_pose (BaseInCamPose, DataNameStart + 'final_pose_cam_base.dat')
write_pose (ObjInToolPose, DataNameStart + 'final_pose_tool_calplate.dat')
```

Result

write_pose returns 2 (H_MSG_TRUE) if all parameter values are correct and the file has been written successfully. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

27.6 Quaternions

axis_angle_to_quat (: : AxisX, AxisY, AxisZ, Angle : Quaternion)

Create a rotation quaternion.

Quaternions are an extension of the complex numbers. The set of quaternions is given by $\{x_0 + x_1 * i + x_2 * j + x_3 * k | x_0, x_1, x_2, x_3 \in R\}$. In HALCON, quaternions are represented by a tuple containing four elements: $[x_0, x_1, x_2, x_3]$.

Unit quaternions can be used to describe rotations. A quaternion is a unit quaternion if its norm is 1. A counter-clockwise rotation around an unit vector v (AxisX, AxisY, AxisZ) by an angle a (Angle) can be described by the unit quaternion $q = (cos(a/2), sin(a/2)v)$.

The operator axis_angle_to_quat can be used to create such a quaternion. To rotate a point using Quaternion use the operator quat_rotate_point_3d.

Note that two rotations can be concatenated using the operator quat_compose. Further, you can use a rotation quaternion to set the orientation of the 3D plot in set_paint.

Attention

The operator axis_angle_to_quat does not check whether the vector (AxisX, AxisY, AxisZ) is of unit length (i.e. of length 1). If this is not the case, Quaternion will be no valid rotation quaternion.

Parameters

- ▷ **AxisX** (input_control) ..... real ⇝ *real* / integer
  X component of the rotation axis.
- ▷ **AxisY** (input_control) ..... real ⇝ *real* / integer
  Y component of the rotation axis.
- ▷ **AxisZ** (input_control) ..... real ⇝ *real* / integer
  Z component of the rotation axis.
- ▷ **Angle** (input_control) ..... real ⇝ *real* / integer
  Rotation angle in radians.
- ▷ **Quaternion** (output_control) ..... quaternion ⇝ *real* / integer
  Rotation quaternion.

Example

```
** Normalize a vector and create a rotation quaternion
Length := sqrt(AxisX*AxisX+AxisY*AxisY+AxisZ*AxisZ)
AxisX := AxisX/Length
AxisY := AxisY/Length
AxisZ := AxisZ/Length
axis_angle_to_quat (AxisX, AxisY, AxisZ, rad(90), Quaternion)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

quat_to_hom_mat3d, quat_to_pose, quat_rotate_point_3d, quat_compose

See also

quat_normalize, quat_conjugate, quat_interpolate, screw_to_dual_quat

Module

Foundation

deserialize_quat (: : SerializedItemHandle : Quaternion)

Deserialize a serialized quaternion.

deserialize_quat deserializes a quaternion, that was serialized by serialize_quat (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized quaternion is defined by the handle SerializedItemHandle. The deserialized values are stored in Quaternion.

Parameters

▷ **SerializedItemHandle** (input_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

▷ **Quaternion** (output_control) . . . . . quaternion ⇝ *real* / integer
Quaternion.

Result

If the parameters are valid, the operator deserialize_quat returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fread_serialized_item, receive_serialized_item, serialize_quat

Possible Successors

quat_to_hom_mat3d, quat_to_pose, quat_rotate_point_3d, quat_compose

Module

Foundation

quat_compose (: : QuaternionLeft,
QuaternionRight : QuaternionComposed)

Multiply two quaternions.

The operator quat_compose multiplies the two quaternions QuaternionLeft and QuaternionRight and returns the result in QuaternionComposed.

A quaternion x is given by $x = x_0 + x_1 i + x_2 j + x_3 k$. In HALCON, a quaternion is represented by a four value tuple: $[x_0, x_1, x_2, x_3]$.

The product of two quaternions x and y is defined as:

$$\begin{aligned} xy \quad = \quad & (x_0y_0 - x_1y_1 - x_2y_2 - x_3y_3) + \\ & (x_0y_1 + x_1y_0 + x_2y_3 - x_3y_2)i + \\ & (x_0y_2 - x_1y_3 + x_2y_0 + x_3y_1)j + \\ & (x_0y_3 + x_1y_2 - x_2y_1 + x_3y_0)k \end{aligned}$$

As a consequence, the multiplication of two quaternions is not commutative, i.e. $xy \neq yx$.

Parameters

▷ **QuaternionLeft** (input_control) . . . . . quaternion ⇝ *real*
Left quaternion.

▷ **QuaternionRight** (input_control) . . . . . quaternion ⇝ *real*
Right quaternion.

▷ **QuaternionComposed** (output_control) . . . . . quaternion ⇝ *real*
Product of the input quaternions.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

axis_angle_to_quat

Possible Successors

quat_to_hom_mat3d, quat_to_pose, quat_rotate_point_3d

See also

axis_angle_to_quat, quat_to_hom_mat3d, quat_rotate_point_3d, quat_normalize, quat_conjugate, dual_quat_compose

Module

Foundation

quat_conjugate (: : Quaternion : ConjugatedQuaternion)

Generate the conjugation of a quaternion.

The operator quat_conjugate generates the conjugation ConjugatedQuaternion of the input quaternion Quaternion.

The conjugation of a quaternion $q = x_0 + x_1 i + x_2 j + x_3 k$ is given by $\bar{q} = x_0 - x_1 i - x_2 j - x_3 k$.

Parameters

▷ **Quaternion** (input_control) ..... quaternion ⇝ *real*
Input quaternion.

▷ **ConjugatedQuaternion** (output_control) ..... quaternion ⇝ *real*
Conjugated quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

axis_angle_to_quat

Module

Foundation

quat_interpolate (: : QuaternionStart, QuaternionEnd, InterpPos : QuaternionInterpolated)

Interpolation of two quaternions.

The operator quat_interpolate interpolates the two quaternions QuaternionStart and QuaternionEnd at the interpolation position InterpPos. This position must lie within the interval $[0, 1]$. In the case of InterpPos $= 0$, the interpolated quaternion QuaternionInterpolated

corresponds to QuaternionStart. In the case of InterpPos = 1, the interpolated quaternion QuaternionInterpolated corresponds to QuaternionEnd.

The interpolation is done using spherical linear interpolation. As a consequence if both QuaternionStart and QuaternionEnd are rotation quaternions, QuaternionInterpolated will be a rotation quaternion as well. Further, if InterpPos is increased at constant speed, a point on the unit sphere that is rotated using QuaternionInterpolated travels with constant speed on an arc on the unit sphere.

Parameters

- ▷ **QuaternionStart** (input_control) . . . quaternion ⇝ *real*
  Start quaternion.
- ▷ **QuaternionEnd** (input_control) . . . quaternion ⇝ *real*
  End quaternion.
- ▷ **InterpPos** (input_control) . . . real-array ⇝ *real*
  Interpolation parameter.
  Default: 0.5
  Suggested values: InterpPos ∈ {0.0, 0.25, 0.5, 0.75, 1.0}
- ▷ **QuaternionInterpolated** (output_control) . . . quaternion ⇝ *real*
  Interpolated quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

axis_angle_to_quat, quat_normalize

Possible Successors

quat_to_hom_mat3d, quat_rotate_point_3d, quat_to_pose

See also

quat_rotate_point_3d, quat_conjugate, quat_compose, dual_quat_interpolate

Module

Foundation

quat_normalize (: : Quaternion : NormalizedQuaternion)

Normalize a quaternion.

The operator quat_normalize scales the input quaternion Quaternion such that its norm is 1. The result is returned in NormalizedQuaternion.

Parameters

- ▷ **Quaternion** (input_control) . . . quaternion ⇝ *real*
  Input quaternion.
- ▷ **NormalizedQuaternion** (output_control) . . . quaternion ⇝ *real*
  Normalized quaternion.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

axis_angle_to_quat

Possible Successors

quat_to_hom_mat3d, quat_rotate_point_3d

See also

axis_angle_to_quat, quat_interpolate, quat_compose, quat_conjugate, dual_quat_to_hom_mat3d

Module

Foundation

quat_rotate_point_3d (: : Quaternion, Px, Py, Pz : Qx, Qy, Qz)

Perform a rotation by a unit quaternion.

Given a rotation quaternion (e.g., generated by axis_angle_to_quat), the operator quat_rotate_point_3d can be used to rotate a 3D point (Px, Py, Pz). The rotated point is returned in (Qx, Qy, Qz).

The rotation of a point x by an unit quaternion q is given by

$x' = qx\bar{q}$.

$\bar{q}$ corresponds to the conjugation of a quaternion q (see quat_conjugate). Note that x will be transformed into quaternion form to perform the rotation. This is done by setting the real part to zero and the three imaginary components to the three components of x.

Attention

The operator quat_rotate_point_3d does not check whether Quaternion is a unit quaternion. If Quaternion is not a unit quaternion, the result of this operator is not defined.

Parameters

- ▷ **Quaternion** (input_control) . . . quaternion ⇝ *real*
  Rotation quaternion.
- ▷ **Px** (input_control) . . . real ⇝ *real*
  X coordinate of the point to be rotated.
- ▷ **Py** (input_control) . . . real ⇝ *real*
  Y coordinate of the point to be rotated.
- ▷ **Pz** (input_control) . . . real ⇝ *real*
  Z coordinate of the point to be rotated.
- ▷ **Qx** (output_control) . . . real ⇝ *real*
  X coordinate of the rotated point.
- ▷ **Qy** (output_control) . . . real ⇝ *real*
  Y coordinate of the rotated point.
- ▷ **Qz** (output_control) . . . real ⇝ *real*
  Z coordinate of the rotated point.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

axis_angle_to_quat

Module

Foundation

quat_to_hom_mat3d (: : Quaternion : RotationMatrix)

Convert a quaternion into the corresponding rotation matrix.

The operator quat_to_hom_mat3d converts a unit quaternion Quaternion into its corresponding rotation matrix RotationMatrix.

The RotationMatrix for a quaternion $x = x_0 + x_1 i + x_2 j + x_3 k$ is given by:

$$\begin{pmatrix} x_0^2 + x_1^2 - x_2^2 - x_3^2 & 2x_1x_2 - 2x_0x_3 & 2x_0x_2 + 2x_1x_3 \\ 2x_0x_3 + 2x_1x_2 & x_0^2 - x_1^2 + x_2^2 - x_3^2 & 2x_2x_3 - 2x_0x_1 \\ 2x_1x_3 - 2x_0x_2 & 2x_0x_1 + 2x_2x_3 & x_0^2 - x_1^2 - x_2^2 + x_3^2 \end{pmatrix}$$

Attention

RotationMatrix will only be a valid rotation matrix if Quaternion is a unit quaternion.

Parameters

▷ **Quaternion** (input_control) . . . . . quaternion ⇝ *real*
Rotation quaternion.

▷ **RotationMatrix** (output_control) . . . . . hom_mat3d ⇝ *real*
Rotation matrix.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

axis_angle_to_quat, quat_rotate_point_3d, quat_to_pose, quat_normalize, quat_conjugate, quat_interpolate

Module

Foundation

serialize_quat (: : Quaternion : SerializedItemHandle)

Serialize a quaternion.

serialize_quat serializes the data of the Quaternion (see fwrite_serialized_item for an introduction of the basic principle of serialization). The serialized quaternion is returned by the handle SerializedItemHandle and can be deserialized by deserialize_quat.

Parameters

▷ **Quaternion** (input_control) . . . . . quaternion ⇝ *real* / integer
Quaternion.

▷ **SerializedItemHandle** (output_control) . . . . . serialized_item ⇝ *handle*
Handle of the serialized item.

Result

If the parameters are valid, the operator serialize_quat returns the value 2 (H_MSG_TRUE). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

axis_angle_to_quat

Possible Successors

fwrite_serialized_item, send_serialized_item, deserialize_quat

Module

Chapter 28

Tuple

To learn more about the basic concept of tuples in HALCON you can also see the example program `halcon_basic_concepts.hdev`.

28.1 Arithmetic

tuple_abs (: : T : Abs)

Compute the absolute value of a tuple.

`tuple_abs` computes the absolute value of the input tuple `T`. The absolute value of an integer number is again an integer number. The absolute value of a floating point number is a floating point number. The absolute value of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_abs`, which can be used in an expression in the following syntax:

```
Abs := abs(T)
```

Parameters

- ▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **Abs** (output_control) . . . . . number(-array) ⇝ *real* / integer
  Absolute value of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_fabs`

Module

Foundation

tuple_acos (: : T : ACos)

Compute the arccosine of a tuple.

tuple_acos computes the arccosine of the input tuple T. The arccosine is always returned as a floating point number in ACos. The angles in ACos are represented in radians. The arccosine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_acos, which can be used in an expression in the following syntax:

```
ACos := acos(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.
Restriction: -1 <= T <= 1

▷ **ACos** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Arccosine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_asin, tuple_atan, tuple_atan2

See also

tuple_cos, tuple_cosh, tuple_acosh

Module

Foundation

tuple_acosh (: : T : Acosh)

Compute the inverse hyperbolic cosine of a tuple.

tuple_acosh computes the inverse hyperbolic cosine of the input tuple T. The inverse hyperbolic cosine is always returned as a floating point number in Acosh. The inverse hyperbolic cosine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_acosh, which can be used in an expression in the following syntax:

```
Acosh := acosh(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Acosh** (output_control) . . . . . number(-array) ⇝ *real*
Inverse hyperbolic cosine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_asinh, tuple_atanh

See also

tuple_cosh, tuple_cos, tuple_acos

Module

Foundation

tuple_add (: : S1, S2 : Sum)

Add two tuples.

tuple_add computes the sum of the input tuples S1 and S2. If both tuples have the same length the corresponding elements of both tuples are added. Otherwise, either S1 or S2 must have length 1. In this case, the addition is performed for each element of the longer tuple with the single element of the other tuple. If two integer numbers are added, the result is again an integer number. If a floating point number is added to another number, the result is a floating point number. If two strings are added, the addition corresponds to a string concatenation. If a number and a string are added, the number is converted to a string first. Thus, the addition also corresponds to a string concatenation in this case.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_add, which can be used in an expression in the following syntax:

```
Sum := S1 + S2
```

The + operation corresponds to a string concatenation if S1 and S2 contain strings.

Parameters

- ▷ **S1** (input_control) ..... tuple(-array) ⇝ *real* / integer / string
  Input tuple 1.
- ▷ **S2** (input_control) ..... tuple(-array) ⇝ *real* / integer / string
  Input tuple 2.
- ▷ **Sum** (output_control) ..... tuple(-array) ⇝ *real* / integer / string
  Sum of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sub

See also

tuple_cumul

Module

Foundation

tuple_asin (: : T : ASin)

Compute the arcsine of a tuple.

tuple_asin computes the arcsine of the input tuple T. The arcsine is always returned as a floating point number in ASin. The angles in ASin are represented in radians. The arcsine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_asin`, which can be used in an expression in the following syntax:

```
ASin := asin(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.
Restriction: -1 <= T <= 1

▷ **ASin** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Arcsine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_acos`, `tuple_atan`, `tuple_atan2`

See also

`tuple_sin`, `tuple_sinh`, `tuple_asinh`

Module

Foundation

tuple_asinh (: : T : Asinh)

Compute the inverse hyperbolic sine of a tuple.

`tuple_asinh` computes the inverse hyperbolic sine of the input tuple `T`. The inverse hyperbolic sine is always returned as a floating point number in `Asinh`. The inverse hyperbolic sine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_asinh`, which can be used in an expression in the following syntax:

```
Asinh := asinh(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Asinh** (output_control) . . . . . number(-array) ⇝ *real*
Inverse hyperbolic sine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_acosh, tuple_atanh

See also

tuple_asin, tuple_sin, tuple_asin

Module

Foundation

tuple_atan (: : T : ATan)

Compute the arctangent of a tuple.

tuple_atan computes the arctangent of the input tuple T. The arctangent is always returned as a floating point number in ATan. The angles in ATan are represented in radians. The arctangent of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_atan, which can be used in an expression in the following syntax:

```
ATan := atan(T)
```

Parameters

- ▷ **T** (input_control) ..... number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **ATan** (output_control) ..... angle.rad(-array) ⇝ *real*
  Arctangent of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_atan2, tuple_asin, tuple_acos

See also

tuple_tan, tuple_tanh, tuple_atanh

Module

Foundation

tuple_atan2 (: : Y, X : ATan)

Compute the arctangent of a tuple for all four quadrants.

tuple_atan2 computes the arctangent of the input tuples Y/X while treating all four quadrants correctly. The arctangent is always returned as a floating point number in ATan. The angles in ATan are represented in radians. The arctangent of a string is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_atan2, which can be used in an expression in the following syntax:

```
ATan := atan2(Y, X)
```

Parameters

▷ **Y** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple of the y-values.

▷ **X** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple of the x-values.

▷ **ATan** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Arctangent of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_atan, tuple_asin, tuple_acos

See also

tuple_tan, tuple_tanh

Module

Foundation

tuple_atanh (: : T : Atanh)

Compute the inverse hyperbolic tangent of a tuple.

tuple_atanh computes the inverse hyperbolic tangent of the input tuple T. The inverse hyperbolic tangent is always returned as a floating point number in Atanh. The inverse hyperbolic tangent of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_atanh, which can be used in an expression in the following syntax:

```
Atanh := atanh(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Atanh** (output_control) . . . . . number(-array) ⇝ *real*
Inverse hyperbolic tangent of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_asinh, tuple_acosh

See also

tuple_tanh, tuple_tan, tuple_atan, tuple_atan2

Module

Foundation

tuple_cbrt (: : T : Cbrt)

Compute the cube root of a tuple.

tuple_cbrt computes the cube root of the input tuple T. The cube root is always returned as a floating point number. The cube root of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_cbrt, which can be used in an expression in the following syntax:

```
Cbrt := cbrt(T)
```

Parameters

- ▷ **T** (input_control) . . . number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **Cbrt** (output_control) . . . number(-array) ⇝ *real*
  Cube root of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_pow

See also

tuple_sqrt

Module

Foundation

tuple_ceil (: : T : Ceil)

Compute the ceiling function of a tuple.

tuple_ceil computes the ceiling function of the input tuple T, i.e., the smallest integer greater than or equal to T. The ceiling function is always returned as a floating point number. The ceiling function of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_ceil, which can be used in an expression in the following syntax:

```
Ceil := ceil(T)
```

Parameters

- ▷ **T** (input_control) . . . number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **Ceil** (output_control) . . . number(-array) ⇝ *real*
  Ceiling function of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

tuple_cos (: : T : Cos)

Compute the cosine of a tuple.

tuple_cos computes the cosine of the input tuple T. The cosine is always returned as a floating point number in Cos. The angles in T are represented in radians. The cosine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_cos, which can be used in an expression in the following syntax:

```
Cos := cos(T)
```

Parameters

▷ **T** (input_control) ..... angle.rad(-array) ⇝ *real* / integer
Input tuple.

▷ **Cos** (output_control) ..... number(-array) ⇝ *real*
Cosine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sin, tuple_tan

See also

tuple_acos, tuple_cosh, tuple_acosh

Module

Foundation

tuple_cosh (: : T : Cosh)

Compute the hyperbolic cosine of a tuple.

tuple_cosh computes the hyperbolic cosine of the input tuple T. The hyperbolic cosine is always returned as a floating point number in Cosh. The hyperbolic cosine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_cosh, which can be used in an expression in the following syntax:

```
Cosh := cosh(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Cosh** (output_control) . . . . . number(-array) ⇝ *real*
Hyperbolic cosine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sinh, tuple_tanh

See also

tuple_acosh, tuple_cos, tuple_acos

Module

Foundation

tuple_cumul (: : Tuple : Cumul)

Calculate the cumulative sums of a tuple.

tuple_cumul returns the different cumulative sums of the corresponding elements of the input tuple Tuple, i.e. the i-th element of the result tuple Cumul is the sum of the first i elements of the input tuple Tuple. For example, if Tuple contains the values [1,2,3,4], the output tuple Cumul will contain the values [1,3,6,10]. All elements of Tuple must be numbers (integer or floating point numbers). Each element of the result tuple Cumul will contain a floating point number if at least one element of the calculation is a floating point number. If all elements of the calculation are integer numbers the resulting sum in Cumul will also be an integer number.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_cumul, which can be used in an expression in the following syntax:

```
Cumul := cumul(Tuple)
```

Parameters

▷ **Tuple** (input_control) . . . . . number(-array) ⇝ *integer* / real
Input tuple.

▷ **Cumul** (output_control) . . . . . number(-array) ⇝ *real* / integer
Cumulative sum of the corresponding tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sum

See also

tuple_min2, tuple_max2, tuple_add

Module

Foundation

tuple_deg (: : Rad : Deg)

Convert a tuple from radians to degrees.

tuple_deg converts the input tuple Rad from radians to degrees. The result is always returned as a floating point number. The conversion of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_deg, which can be used in an expression in the following syntax:

```
Deg := deg(Rad)
```

Parameters

▷ **Rad** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Deg** (output_control) . . . . . number(-array) ⇝ *real*
Input tuple in degrees.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

tuple_rad

Module

Foundation

tuple_div (: : Q1, Q2 : Quot)

Divide two tuples.

tuple_div computes the quotient of the input tuples Q1 and Q2. If both tuples have the same length the corresponding elements of both tuples are divided. Otherwise, either Q1 or Q2 must have length 1. In this case, the division is performed for each element of the longer tuple with the single element of the other tuple. If two integer numbers are divided, the result is again an integer number. If one of the operands is a floating point number, the result is a floating point number. The division of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_div, which can be used in an expression in the following syntax:

```
Quot := Q1 / Q2
```

Parameters

▷ **Q1** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 1.

▷ **Q2** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 2.
Restriction: Q2 != 0

▷ **Quot** (output_control) . . . . . number(-array) ⇝ *real* / integer
Quotient of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_mult

Module

Foundation

tuple_erf (: : T : Erf)

Compute the error function of a tuple.

tuple_erf computes the error function of the input tuple T. The error function is defined as:

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt.$$

The value of the error function is always returned as a floating point number in Erf. The error function of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_erf, which can be used in an expression in the following syntax:

```
Erf := erf(T)
```

Parameters

▷ **T** (input_control) ..... number(-array) ⇝ *real* / integer
Input tuple.

▷ **Erf** (output_control) ..... number(-array) ⇝ *real*
Value of the error function of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_erfc

See also

tuple_exp

Module

Foundation

tuple_erfc (: : T : Erfc)

Compute the complementary error function of a tuple.

tuple_erfc computes the complementary error function of the input tuple T. The complementary error function is defined as $1 - \mathrm{erf}(x)$ (for the definition of $\mathrm{erf}(x)$ see tuple_erf). The value of the complementary error function is always returned as a floating point number in Erfc. The complementary error function of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_erfc, which can be used in an expression in the following syntax:

```
Erfc := erfc(T)
```

Parameters

▷ **T** (input_control) . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Erfc** (output_control) . . . number(-array) ⇝ *real*
Value of the complementary error function of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_erf

See also

tuple_exp

Module

Foundation

tuple_exp (: : T : Exp)

Compute the exponential of a tuple.

tuple_exp computes the exponential of the input tuple T. The exponential is always returned as a floating point number. The exponential of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_exp, which can be used in an expression in the following syntax:

```
Exp := exp(T)
```

Parameters

▷ **T** (input_control) . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Exp** (output_control) . . . number(-array) ⇝ *real*
Exponential of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Alternatives

tuple_exp2, tuple_exp10, tuple_pow

See also

tuple_log, tuple_log2, tuple_log10

Module

Foundation

tuple_exp10 (: : T : Exp)

Compute the base 10 exponential of a tuple.

tuple_exp10 computes the base 10 exponential of the input tuple T. The exponential is always returned as a floating point number. The exponential of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_exp10, which can be used in an expression in the following syntax:

```
Exp := exp10(T)
```

Parameters

▷ **T** (input_control) ..... number(-array) ⇝ *real* / integer
Input tuple.

▷ **Exp** (output_control) ..... number(-array) ⇝ *real*
Base 10 exponential of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_exp, tuple_exp2, tuple_pow

See also

tuple_log, tuple_log2, tuple_log10

Module

Foundation

tuple_exp2 (: : T : Exp)

Compute the base 2 exponential of a tuple.

tuple_exp2 computes the base 2 exponential of the input tuple T. The exponential is always returned as a floating point number. The exponential of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_exp2, which can be used in an expression in the following syntax:

```
Exp := exp2(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Exp** (output_control) . . . . . number(-array) ⇝ *real*
Base 2 exponential of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_exp, tuple_exp10, tuple_pow

See also

tuple_log, tuple_log2, tuple_log10

Module

Foundation

tuple_fabs (: : T : Abs)

Compute the absolute value of a tuple (as floating point numbers).

tuple_fabs computes the absolute value of the input tuple T. In contrast to tuple_abs, the absolute value is always returned as a floating point number by tuple_fabs. The absolute value of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_fabs, which can be used in an expression in the following syntax:

```
Abs := fabs(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Abs** (output_control) . . . . . number(-array) ⇝ *real*
Absolute value of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_abs

Module

Foundation

tuple_floor (: : T : Floor)

Compute the floor function of a tuple.

tuple_floor computes the floor function of the input tuple T, i.e., the largest integer less than or equal to T. The floor function is always returned as a floating point number. The floor function of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_floor, which can be used in an expression in the following syntax:

```
Floor := floor(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Floor** (output_control) . . . . . number(-array) ⇝ *real*
Floor function of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_ceil

Module

Foundation

tuple_fmod (: : T1, T2 : Fmod)

Calculate the remainder of the floating point division of two tuples.

tuple_fmod computes the remainder of the floating point division of the input tuples T1/T2. If both tuples have the same length the division is performed for the corresponding elements of both tuples. Otherwise, either T1 or T2 must have length 1. In this case, the division is performed for each element of the longer tuple with the single element of the other tuple. The result is always a floating point number. The division of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_fmod, which can be used in an expression in the following syntax:

```
Fmod := fmod(T1, T2)
```

Parameters

▷ **T1** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 1.

▷ **T2** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 2.
Restriction: T2 != 0.0

▷ **Fmod** (output_control) . . . . . number(-array) ⇝ *real*
Remainder of the division of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_mod

See also

tuple_floor, tuple_ceil

Module

Foundation

tuple_hypot (: : T1, T2 : Hypot)

Calculate the hypotenuse of two tuples.

tuple_hypot computes the hypotenuse $\sqrt{T1^2 + T2^2}$ of the input tuples. The calculation is performed without undue arithmetic overflow or underflow during the intermediate steps of the calculation. If both tuples have the same length, the hypotenuse is applied to the corresponding elements of both tuples. Otherwise, either T1 or T2 must have length 1. In this case, the hypotenuse is calculated for each element of the longer tuple with the single element of the other tuple. The result is always a floating point number. The hypotenuse of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_hypot, which can be used in an expression in the following syntax:

```
Hypot := hypot(T1, T2)
```

Parameters

▷ **T1** (input_control) . . . number(-array) ⇝ *real* / integer
Input tuple 1.

▷ **T2** (input_control) . . . number(-array) ⇝ *real* / integer
Input tuple 2.

▷ **Hypot** (output_control) . . . number(-array) ⇝ *real*
Hypotenuse of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sqrt

See also

tuple_mult, tuple_add

Module

Foundation

tuple_ldexp (: : T1, T2 : Ldexp)

Calculate the ldexp function of two tuples.

tuple_ldexp computes the ldexp function of the input tuples, i.e., $T1 \cdot 2^{floor(T2)}$. If both tuples have the same length the operation is performed for the corresponding elements of both tuples. Otherwise, either T1 or T2 must

have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The result is always a floating point number. The ldexp function of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_ldexp`, which can be used in an expression in the following syntax:

```
Ldexp := ldexp(T1, T2)
```

Parameters

- ▷ **T1** (input_control) . . . number(-array) ⇝ *real* / integer
  Input tuple 1.
- ▷ **T2** (input_control) . . . number(-array) ⇝ *real* / integer
  Input tuple 2.
- ▷ **Ldexp** (output_control) . . . number(-array) ⇝ *real*
  Ldexp function of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`tuple_exp`

Module

Foundation

tuple_lgamma (: : T : LogGamma)

Compute the logarithm of the absolute value of the gamma function of a tuple.

`tuple_lgamma` computes the logarithm of the absolute value of the gamma function of the input tuple `T` (for the definition of the gamma function, see `tuple_tgamma`). It is defined for every real number except for nonpositive integers. The logarithm of the absolute value of the gamma function is always returned as a floating point number in `LogGamma`. The logarithm of the absolute value of the gamma function of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_lgamma`, which can be used in an expression in the following syntax:

```
LogGamma := lgamma(T)
```

Parameters

- ▷ **T** (input_control) . . . number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **LogGamma** (output_control) . . . number(-array) ⇝ *real*
  Logarithm of the absolute value of the gamma function of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Alternatives

tuple_tgamma

Module

Foundation

tuple_log (: : T : Log)

Compute the natural logarithm of a tuple.

tuple_log computes the natural logarithm of the input tuple T. The natural logarithm is always returned as a floating point number. The natural logarithm of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_log, which can be used in an expression in the following syntax:

```
Log := log(T)
```

Parameters

▷ **T** (input_control) ..... number(-array) ⇝ *real* / integer
Input tuple.
Restriction: T > 0

▷ **Log** (output_control) ..... number(-array) ⇝ *real*
Natural logarithm of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_log2, tuple_log10

tuple_exp, tuple_exp2, tuple_exp10, tuple_pow

Module

Foundation

tuple_log10 (: : T : Log)

Compute the base 10 logarithm of a tuple.

tuple_log10 computes the base 10 logarithm of the input tuple T. The logarithm is always returned as a floating point number. The logarithm of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_log10, which can be used in an expression in the following syntax:

```
Log := log10(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.
Restriction: T > 0

▷ **Log** (output_control) . . . . . number(-array) ⇝ *real*
Base 10 logarithm of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_log, tuple_log2

See also

tuple_exp, tuple_exp2, tuple_exp10, tuple_pow

Module

Foundation

tuple_log2 (: : T : Log)

Compute the base 2 logarithm of a tuple.

tuple_log2 computes the base 2 logarithm of the input tuple T. The logarithm is always returned as a floating point number. The logarithm of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_log2, which can be used in an expression in the following syntax:

```
Log := log2(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.
Restriction: T > 0

▷ **Log** (output_control) . . . . . number(-array) ⇝ *real*
Base 2 logarithm of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_log, tuple_log10

tuple_exp, tuple_exp2, tuple_exp10, tuple_pow

Module

Foundation

tuple_max2 (: : T1, T2 : Max2)

Calculate the elementwise maximum of two tuples.

tuple_max2 returns the elementwise maximum of the input tuples T1 and T2 in the output tuple Max2. If both tuples have the same length the corresponding elements of both tuples are compared. Otherwise, either T1 or T2 must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. If the corresponding elements of the two tuples have the same type, it is allowed to mix strings with numerical values.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_max2, which can be used in an expression in the following syntax:

```
Max2 := max2(T1, T2)
```

Parameters

- ▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string
  Input tuple 1.
- ▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string
  Input tuple 2.
- ▷ **Max2** (output_control) . . . . . tuple(-array) ⇝ *real* / integer / string
  Elementwise maximum of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

tuple_min2, tuple_min, tuple_max, tuple_cumul

Module

Foundation

tuple_min2 (: : T1, T2 : Min2)

Calculate the elementwise minimum of two tuples.

tuple_min2 returns the elementwise minimum of the input tuples T1 and T2 in the output tuple Min2. If both tuples have the same length the corresponding elements of both tuples are compared. Otherwise, either T1 or T2 must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. If the corresponding elements of the two tuples have the same type, it is allowed to mix strings with numerical values.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_min2, which can be used in an expression in the following syntax:

```
Min2 := min2(T1, T2)
```

Parameters

▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Input tuple 1.

▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Input tuple 2.

▷ **Min2** (output_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Elementwise minimum of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`tuple_max2`, `tuple_min`, `tuple_max`

Module

Foundation

tuple_mod (: : T1, T2 : Mod)

Calculate the remainder of the integer division of two tuples.

`tuple_mod` returns the remainder of the integer division of the input tuples `T1`/`T2` in the output tuple `Mod`. If both tuples have the same length the division is performed for the corresponding elements of both tuples. Otherwise, either `T1` or `T2` must have length 1. In this case, the division is performed for each element of the longer tuple with the single element of the other tuple. The result is always an integer number. The division of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_mod`, which can be used in an expression in the following syntax:

```
Mod := T1 % T2
```

Parameters

▷ **T1** (input_control) . . . . . number(-array) ⇝ *integer*
Input tuple 1.

▷ **T2** (input_control) . . . . . number(-array) ⇝ *integer*
Input tuple 2.
Restriction: T2 != 0

▷ **Mod** (output_control) . . . . . number(-array) ⇝ *integer*
Remainder of the division of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

`tuple_fmod`, `tuple_div`

Module

Foundation

tuple_mult (: : P1, P2 : Prod)

Multiply two tuples.

tuple_mult computes the product of the input tuples P1 and P2. If both tuples have the same length the corresponding elements of both tuples are multiplied. Otherwise, either P1 or P2 must have length 1. In this case, the multiplication is performed for each element of the longer tuple with the single element of the other tuple. If two integer numbers are multiplied, the result is again an integer number. If one of the operands is a floating point number, the result is a floating point number. The multiplication of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_mult, which can be used in an expression in the following syntax:

```
Prod := P1 * P2
```

Parameters

- ▷ **P1** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input tuple 1.
- ▷ **P2** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input tuple 2.
- ▷ **Prod** (output_control) . . . . . number(-array) ⇝ *real* / integer
  Product of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_div

Module

Foundation

tuple_neg (: : T : Neg)

Negate a tuple.

tuple_neg computes the negation of the input tuple T, i.e., Neg = −T. The negation of an integer number is again an integer number. The negation of a floating point number is a floating point number. The negation of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_neg, which can be used in an expression in the following syntax:

```
Neg := -T
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Neg** (output_control) . . . . . number(-array) ⇝ *real* / integer
Negation of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

tuple_pow (: : T1, T2 : Pow)

Calculate the power function of two tuples.

`tuple_pow` computes the power function of the input tuples $T1^{T2}$. If both tuples have the same length the power function is applied to the corresponding elements of both tuples. Otherwise, either `T1` or `T2` must have length 1. In this case, the power function is performed for each element of the longer tuple with the single element of the other tuple. The result is always a floating point number. The power function of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_pow`, which can be used in an expression in the following syntax:

```
Pow := pow(T1, T2)
```

Parameters

▷ **T1** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 1.

▷ **T2** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 2.

▷ **Pow** (output_control) . . . . . number(-array) ⇝ *real*
Power function of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_exp`

See also

`tuple_log`, `tuple_log10`

Module

Foundation

tuple_rad (: : Deg : Rad)

Convert a tuple from degrees to radians.

tuple_rad converts the input tuple Deg from degrees to radians. The result is always returned as a floating point number. The conversion of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_rad, which can be used in an expression in the following syntax:

```
Rad := rad(Deg)
```

Parameters

▷ **Deg** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Rad** (output_control) . . . . . number(-array) ⇝ *real*
Input tuple in radians.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

tuple_deg

Module

Foundation

tuple_sgn (: : T : Sgn)

Calculate the sign of a tuple.

tuple_sgn calculates the sign of the elements of the input tuple T and returns them as integer numbers (-1,0,1) in the output tuple Sgn. The calculation of the sign of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sgn, which can be used in an expression in the following syntax:

```
Sgn := sgn(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Sgn** (output_control) . . . . . number(-array) ⇝ *integer*
Signs of the input tuple as integer numbers.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

tuple_sin (: : T : Sin)

Compute the sine of a tuple.

tuple_sin computes the sine of the input tuple T. The sine is always returned as a floating point number in Sin. The angles in T are represented in radians. The sine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sin, which can be used in an expression in the following syntax:

```
Sin := sin(T)
```

Parameters

- ▷ **T** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **Sin** (output_control) . . . . . number(-array) ⇝ *real*
  Sine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_cos, tuple_tan

See also

tuple_asin, tuple_sinh, tuple_asinh

Module

Foundation

tuple_sinh (: : T : Sinh)

Compute the hyperbolic sine of a tuple.

tuple_sinh computes the hyperbolic sine of the input tuple T. The hyperbolic sine is always returned as a floating point number in Sinh. The hyperbolic sine of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sinh, which can be used in an expression in the following syntax:

```
Sinh := sinh(T)
```

Parameters

- ▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **Sinh** (output_control) . . . . . number(-array) ⇝ *real*
  Hyperbolic sine of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_cosh, tuple_tanh

See also

tuple_asinh, tuple_sin, tuple_asin

Module

Foundation

tuple_sqrt (: : T : Sqrt)

Compute the square root of a tuple.

tuple_sqrt computes the square root of the input tuple T. The square root is always returned as a floating point number. The square root of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sqrt, which can be used in an expression in the following syntax:

```
Sqrt := sqrt(T)
```

Parameters

▷ **T** (input_control) ..... number(-array) ⇝ *real* / integer
Input tuple.
Restriction: T >= 0

▷ **Sqrt** (output_control) ..... number(-array) ⇝ *real*
Square root of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_pow

See also

tuple_cbrt, tuple_hypot

Module

Foundation

tuple_sub (: : D1, D2 : Diff)

Subtract two tuples.

tuple_sub computes the difference of the input tuples D1 and D2. If both tuples have the same length the corresponding elements of both tuples are subtracted. Otherwise, either D1 or D2 must have length 1. In this case, the subtraction is performed for each element of the longer tuple with the single element of the other tuple. If two integer numbers are subtracted, the result is again an integer number. If one of the operands is a floating point number, the result is a floating point number. The subtraction of strings is not allowed.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_sub`, which can be used in an expression in the following syntax:

```
Diff := D1 - D2
```

Parameters

▷ **D1** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 1.

▷ **D2** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple 2.

▷ **Diff** (output_control) . . . . . number(-array) ⇝ *real* / integer
Difference of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_add`

Module

Foundation

tuple_tan (: : T : Tan)

Compute the tangent of a tuple.

`tuple_tan` computes the tangent of the input tuple `T`. The tangent is always returned as a floating point number in `Tan`. The angles in `T` are represented in radians. The tangent of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_tan`, which can be used in an expression in the following syntax:

```
Tan := tan(T)
```

Parameters

▷ **T** (input_control) . . . . . angle.rad(-array) ⇝ *real* / integer
Input tuple.

▷ **Tan** (output_control) . . . . . number(-array) ⇝ *real*
Tangent of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_sin`, `tuple_cos`

See also

`tuple_atan`, `tuple_atan2`, `tuple_tanh`, `tuple_atanh`

Module

Foundation

tuple_tanh (: : T : Tanh)

Compute the hyperbolic tangent of a tuple.

tuple_tanh computes the hyperbolic tangent of the input tuple T. The hyperbolic tangent is always returned as a floating point number in Tanh. The hyperbolic tangent of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_tanh, which can be used in an expression in the following syntax:

```
Tanh := tanh(T)
```

Parameters

- ▷ **T** (input_control) . . . number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **Tanh** (output_control) . . . number(-array) ⇝ *real*
  Hyperbolic tangent of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sinh, tuple_cosh

See also

tuple_atanh, tuple_tan, tuple_atan, tuple_atan2

Module

Foundation

tuple_tgamma (: : T : Gamma)

Compute the gamma function of a tuple.

tuple_tgamma computes the gamma function of the input tuple T. The gamma function is defined as:

$$\Gamma(x) = \int_0^\infty t^{x-1} e^{-t} dt.$$

It is defined for every real number except for nonpositive integers. For nonnegative integer m, it holds that

$$\Gamma(m+1) = m!$$

and, more generally, for all x:

$$\Gamma(x+1) = x\Gamma(x).$$

The value of the gamma function is always returned as a floating point number in Gamma. The gamma function of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_tgamma`, which can be used in an expression in the following syntax:

```
Gamma := tgamma(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Gamma** (output_control) . . . . . number(-array) ⇝ *real*
Value of the gamma function of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_lgamma`

Module

Foundation

28.2 Bit Operations

tuple_band (: : T1, T2 : BAnd)

Compute the bitwise and of two tuples.

`tuple_band` computes the bitwise and of the input tuples `T1` and `T2`. If both tuples have the same length the operation is performed on the corresponding elements of both tuples. Otherwise, either `T1` or `T2` must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_band`, which can be used in an expression in the following syntax:

```
BAnd := T1 band T2
```

Parameters

▷ **T1** (input_control) . . . . . integer(-array) ⇝ *integer*
Input tuple 1.

▷ **T2** (input_control) . . . . . integer(-array) ⇝ *integer*
Input tuple 2.

▷ **BAnd** (output_control) . . . . . integer(-array) ⇝ *integer*
Binary and of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_bor, tuple_bxor, tuple_bnot

See also

tuple_and, tuple_or, tuple_xor, tuple_not

Module

Foundation

tuple_bnot (: : T : BNot)

Compute the bitwise not of a tuple.

tuple_bnot computes the bitwise not of the input tuple T. The input tuple must contain only integer numbers.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_bnot, which can be used in an expression in the following syntax:

```
BNot := bnot T
```

Parameters

- ▷ **T** (input_control) ..... integer(-array) ⇝ *integer*
  Input tuple.
- ▷ **BNot** (output_control) ..... integer(-array) ⇝ *integer*
  Binary not of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_band, tuple_bor, tuple_bxor

See also

tuple_and, tuple_or, tuple_xor, tuple_not

Module

Foundation

tuple_bor (: : T1, T2 : BOr)

Compute the bitwise or of two tuples.

tuple_bor computes the bitwise or of the input tuples T1 and T2. If both tuples have the same length the operation is performed on the corresponding elements of both tuples. Otherwise, either T1 or T2 must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_bor, which can be used in an expression in the following syntax:

```
BOr := T1 bor T2
```

Parameters

▷ **T1** (input_control) . . . integer(-array) ⇝ *integer*
Input tuple 1.
▷ **T2** (input_control) . . . integer(-array) ⇝ *integer*
Input tuple 2.
▷ **BOr** (output_control) . . . integer(-array) ⇝ *integer*
Binary or of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_band, tuple_bxor, tuple_bnot

See also

tuple_and, tuple_or, tuple_xor, tuple_not

Module

Foundation

tuple_bxor (: : T1, T2 : BXor)

Compute the bitwise exclusive or of two tuples.

tuple_bxor computes the bitwise exclusive or of the input tuples T1 and T2. If both tuples have the same length the operation is performed on the corresponding elements of both tuples. Otherwise, either T1 or T2 must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_bxor, which can be used in an expression in the following syntax:

```
BXor := T1 bxor T2
```

Parameters

▷ **T1** (input_control) . . . integer(-array) ⇝ *integer*
Input tuple 1.
▷ **T2** (input_control) . . . integer(-array) ⇝ *integer*
Input tuple 2.
▷ **BXor** (output_control) . . . integer(-array) ⇝ *integer*
Binary exclusive or of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_band, tuple_bor, tuple_bnot

See also

tuple_and, tuple_or, tuple_xor, tuple_not

Module

Foundation

tuple_lsh (: : T, Shift : Lsh)

Shift a tuple bitwise to the left.

tuple_lsh shifts the tuple T bitwise to the left by Shift places. If no overflow occurs, this operation is equivalent to a multiplication by 2^{Shift}. If T is negative, the result depends on the hardware. If Shift is negative or larger than 32, the result is undefined. If both tuples have the same length the corresponding elements of both tuples are shifted. Otherwise, either T or Shift must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_lsh, which can be used in an expression in the following syntax:

```
Lsh := lsh(T, Shift)
```

Parameters

- ▷ **T** (input_control) ..... integer(-array) ⇝ *integer*
  Input tuple.
- ▷ **Shift** (input_control) ..... integer(-array) ⇝ *integer*
  Number of places to shift the input tuple.
- ▷ **Lsh** (output_control) ..... integer(-array) ⇝ *integer*
  Shifted input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_mult

See also

tuple_rsh

Module

Foundation

tuple_rsh (: : T, Shift : Rsh)

Shift a tuple bitwise to the right.

tuple_rsh shifts the tuple T bitwise to the right by Shift places. This operation is equivalent to a division by 2^{Shift}. If T is negative, the result depends on the hardware. If Shift is negative or larger than 32, the result is undefined. If both tuples have the same length the corresponding elements of both tuples are shifted. Otherwise, either T or Shift must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuple

If any of the input tuples is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_rsh, which can be used in an expression in the following syntax:

```
Rsh := rsh(T, Shift)
```

Parameters

▷ **T** (input_control) . . . . . integer(-array) ⇝ *integer*
Input tuple.
▷ **Shift** (input_control) . . . . . integer(-array) ⇝ *integer*
Number of places to shift the input tuple.
▷ **Rsh** (output_control) . . . . . integer(-array) ⇝ *integer*
Shifted input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_div

Module

Foundation

28.3 Comparison

tuple_equal (: : T1, T2 : Equal)

Test whether two tuples are equal.

tuple_equal tests whether the two input tuples T1 and T2 are equal by comparing the tuples elementwise. Two tuples are equal, if they have got the same number of elements and if their elements are equal. Two tuple elements are equal, if they are both (integer or floating point) numbers or both are strings and contain the same value.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_equal, which can be used in an expression in the following syntax:

Equal := T1 == T2 or Equal := T1 = T2

Parameters

▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 1.
▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 2.
▷ **Equal** (output_control) . . . . . integer ⇝ *integer*
Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_not_equal, tuple_less, tuple_greater, tuple_less_equal, tuple_greater_equal, tuple_equal_elem, tuple_not_equal_elem, tuple_less_elem, tuple_greater_elem, tuple_less_equal_elem, tuple_greater_equal_elem

Module

Foundation

tuple_equal_elem (: : T1, T2 : Equal)

Test, whether two tuples are elementwise equal.

`tuple_equal_elem` tests whether the two input tuples `T1` and `T2` are elementwise equal. If both tuples have the same length, the corresponding elements of both tuples are compared. Otherwise, either `T1` or `T2` must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. Two tuple elements are equal if they are both (integer or floating point) numbers or both are strings and contain the same value.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_equal_elem`, which can be used in an expression in the following syntax:

`Equal := T1 [==] T2` or `Equal := T1 [=] T2`

Parameters

- ▷ **T1** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple 1.
- ▷ **T2** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple 2.
- ▷ **Equal** (output_control) ..... integer(-array) ⇝ *integer*
  Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

Module

Foundation

tuple_greater (: : T1, T2 : Greater)

Test whether a tuple is greater than another tuple.

`tuple_greater` tests whether the input tuple `T1` is greater than `T2`. A tuple `T1` is said to be greater than a tuple `T2`, if `T1` has been found to be greater when comparing it elementwise to `T2` or if the first $min(|T1|, |T2|)$ elements are equal and `T1` has got more elements than `T2`.

With the elementwise comparison, the elements of `T1` and `T2` are compared one by one. If the two elements are equal, the next pair of elements will be examined. If the element of `T1` is greater than that from `T2`, the result is 1 and the comparison will be aborted. If the element of `T1` is less than that from `T2`, the result is 0 and the comparison will be aborted. If all elements have been tested and if all were equal, the result is 0.

As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise `tuple_greater` returns an error.

Exception: Empty input tuples

If one input tuple is empty and the other is not, the tuple that is not empty is considered greater than the empty one.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_greater`, which can be used in an expression in the following syntax:

```
Greater := T1 > T2
```

Parameters

▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 1.

▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 2.

▷ **Greater** (output_control) . . . . . integer ⇝ *integer*
Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_greater_equal`, `tuple_less`, `tuple_less_equal`, `tuple_equal`, `tuple_not_equal`, `tuple_equal_elem`, `tuple_not_equal_elem`, `tuple_less_elem`, `tuple_greater_elem`, `tuple_less_equal_elem`, `tuple_greater_equal_elem`

Module

Foundation

tuple_greater_elem (: : T1, T2 : Greater)

Test, whether a tuple is elementwise greater than another tuple.

`tuple_greater_elem` tests elementwise whether the input tuple `T1` is greater than `T2`. If both tuples have the same length, the corresponding elements of both tuples are compared. Otherwise, either `T1` or `T2` must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise `tuple_greater_elem` returns an error.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_greater_elem`, which can be used in an expression in the following syntax:

```
Greater := T1 [>] T2
```

Parameters

▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 1.

▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 2.

▷ **Greater** (output_control) . . . . . integer(-array) ⇝ *integer*
Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Alternatives

Module

Foundation

tuple_greater_equal (: : T1, T2 : Greatereq)

Test whether a tuple is greater or equal to another tuple.

tuple_greater_equal tests whether the input tuple T1 is greater or equal to T2. A tuple T1 is said to be greater or equal to a tuple T2, if T1 is not less than T2. A tuple T1 is said to be less than a tuple T2, if T1 has been found to be less when comparing it elementwise to T2 or if the first $min(|T1|, |T2|)$ elements are equal and T1 has got less elements than T2.

With the elementwise comparison, the elements of T1 and T2 are compared one by one. If the two elements are equal, the next pair of elements will be examined. If the element of T1 is greater than that from T2, the result is 1 and the comparison will be aborted. If the element of T1 is less than that from T2, the result is 0 and the comparison will be aborted. If all elements have been tested and if all were equal, the result is 1.

As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise tuple_greater_equal returns an error.

Exception: Empty input tuples

If one input tuple is empty and the other is not, the tuple that is not empty is considered greater than the empty one.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_greater_equal, which can be used in an expression in the following syntax:

```
Greatereq := T1 >= T2
```

Parameters

- ▷ **T1** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple 1.
- ▷ **T2** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple 2.
- ▷ **Greatereq** (output_control) ..... integer ⇝ *integer*
  Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

Module

Foundation

tuple_greater_equal_elem (: : T1, T2 : Greatereq)

Test, whether a tuple is elementwise greater or equal to another tuple.

tuple_greater_equal_elem tests elementwise whether the input tuple T1 is greater than or equal to T2. If both tuples have the same length, the corresponding elements of both tuples are compared. Otherwise, either T1 or T2 must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise tuple_greater_equal_elem returns an error.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_greater_equal_elem, which can be used in an expression in the following syntax:

```
Greatereq := T1 [>=] T2
```

Parameters

- ▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple 1.
- ▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple 2.
- ▷ **Greatereq** (output_control) . . . . . integer(-array) ⇝ *integer*
  Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_equal_elem, tuple_not_equal_elem, tuple_less_elem, tuple_greater_elem, tuple_less_equal_elem, tuple_equal, tuple_not_equal, tuple_less, tuple_greater, tuple_less_equal, tuple_greater_equal

Module

Foundation

tuple_less (: : T1, T2 : Less)

Test whether a tuple is less than another tuple.

tuple_less tests whether the input tuple T1 is less than T2. A tuple T1 is said to be less than a tuple T2, if T1 has been found to be less when comparing it elementwise to T2 or if the first $min(|T1|, |T2|)$ elements are equal and T1 has got less elements than T2.

With the elementwise comparison, the elements of T1 and T2 are compared one by one. If the two elements are equal, the next pair of elements will be examined. If the element of T1 is less than that from T2, the result is 1 and the comparison will be aborted. If the element of T1 is greater than that from T2, the result is 0 and the comparison will be aborted. If all elements have been tested and if all were equal, the result is 0.

As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise tuple_less returns an error.

Exception: Empty input tuples

If one input tuple is empty and the other is not, the tuple that is empty is considered less than the one that is not empty.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_less, which can be used in an expression in the following syntax:

```
Less := T1 < T2
```

Parameters

▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 1.

▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 2.

▷ **Less** (output_control) . . . . . integer ⇝ *integer*
Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_less_equal, tuple_greater, tuple_greater_equal, tuple_equal, tuple_not_equal, tuple_equal_elem, tuple_not_equal_elem, tuple_less_elem, tuple_greater_elem, tuple_less_equal_elem, tuple_greater_equal_elem

Module

Foundation

tuple_less_elem (: : T1, T2 : Less)

Test, whether a tuple is elementwise less than another tuple.

tuple_less_elem tests elementwise whether the input tuple T1 is less than T2. If both tuples have the same length, the corresponding elements of both tuples are compared. Otherwise, either T1 or T2 must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise tuple_less_elem returns an error.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_less_elem, which can be used in an expression in the following syntax:

```
Less := T1 [<] T2
```

Parameters

▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 1.

▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple 2.

▷ **Less** (output_control) . . . . . integer(-array) ⇝ *integer*
Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_equal_elem, tuple_not_equal_elem, tuple_greater_elem, tuple_less_equal_elem, tuple_greater_equal_elem, tuple_equal, tuple_not_equal, tuple_less, tuple_greater, tuple_less_equal, tuple_greater_equal

Module

Foundation

tuple_less_equal (: : T1, T2 : Lesseq)

Test whether a tuple is less or equal to another tuple.

tuple_less_equal tests whether the input tuple T1 is less or equal to T2. A tuple T1 is said to be less or equal to a tuple T2, if T1 is not greater than T2. A tuple T1 is said to be greater than a tuple T2, if T1 has been found to be greater when comparing it elementwise to T2 or if the first $min(|T1|, |T2|)$ elements are equal and T1 has got more elements than T2.

With the elementwise comparison, the elements of T1 and T2 are compared one by one. If the two elements are equal, the next pair of elements will be examined. If the element of T1 is less than that from T2, the result is 1 and the comparison will be aborted. If the element of T1 is greater than that from T2, the result is 0 and the comparison will be aborted. If all elements have been tested and if all were equal, the result is 1.

As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise tuple_less_equal returns an error.

Exception: Empty input tuples

If one input tuple is empty and the other is not, the tuple that is empty is considered less than the one that is not empty.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_less_equal, which can be used in an expression in the following syntax:

```
Lesseq := T1 <= T2
```

Parameters

- ▷ **T1** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple 1.
- ▷ **T2** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple 2.
- ▷ **Lesseq** (output_control) ..... integer ⇝ *integer*
  Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_less, tuple_greater, tuple_greater_equal, tuple_equal, tuple_not_equal, tuple_equal_elem, tuple_not_equal_elem, tuple_less_elem, tuple_greater_elem, tuple_less_equal_elem, tuple_greater_equal_elem

Module

Foundation

tuple_less_equal_elem (: : T1, T2 : Lesseq)

Test, whether a tuple is elementwise less or equal to another tuple.

tuple_less_equal_elem tests elementwise whether the input tuple T1 is less than or equal to T2. If both tuples have the same length, the corresponding elements of both tuples are compared. Otherwise, either T1 or T2 must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. As a precondition for comparing the tuples elementwise two corresponding elements must either both be (integer or floating point) numbers or both be strings. Otherwise tuple_less_equal_elem returns an error.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_less_equal_elem, which can be used in an expression in the following syntax:

```
Lesseq := T1 [<=] T2
```

Parameters

- ▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple 1.
- ▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple 2.
- ▷ **Lesseq** (output_control) . . . . . integer(-array) ⇝ *integer*
  Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_equal_elem, tuple_not_equal_elem, tuple_greater_elem, tuple_less_elem, tuple_greater_equal_elem, tuple_equal, tuple_not_equal, tuple_less, tuple_greater, tuple_less_equal, tuple_greater_equal

Module

Foundation

tuple_not_equal (: : T1, T2 : Nequal)

Test whether two tuples are not equal.

tuple_not_equal tests whether the two input tuples T1 and T2 are not equal. Two tuples are not equal, if they consist of a different number of elements or if they differ when compared elementwise. Two tuple elements differ, if they are of types that may not be compared (e.g., one string and one integer) or if they differ in their values.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_not_equal, which can be used in an expression in the following syntax:

```
Nequal := T1 != T2
```
or
```
Nequal := T1 # T2
```

Parameters

- ▷ **T1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple 1.
- ▷ **T2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple 2.
- ▷ **Nequal** (output_control) . . . . . integer ⇝ *integer*
  Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_equal, tuple_less, tuple_greater, tuple_less_equal, tuple_greater_equal, tuple_equal_elem, tuple_not_equal_elem, tuple_less_elem, tuple_greater_elem, tuple_less_equal_elem, tuple_greater_equal_elem

Module

Foundation

tuple_not_equal_elem (: : T1, T2 : Nequal)

Test, whether two tuples are elementwise not equal.

tuple_not_equal_elem tests whether the two input tuples T1 and T2 are elementwise not equal. If both tuples have the same length, the corresponding elements of both tuples are compared. Otherwise, either T1 or T2 must have length 1. In this case, the comparison is performed for each element of the longer tuple with the single element of the other tuple. Two tuple elements differ if they are of types that may not be compared (e.g., one string and one integer) or if they differ in their values.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_not_equal_elem, which can be used in an expression in the following syntax:

Nequal := T1 [!=] T2 or Nequal := T1 [#] T2

Parameters

▷ **T1** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
Input tuple 1.

▷ **T2** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
Input tuple 2.

▷ **Nequal** (output_control) ..... integer(-array) ⇝ *integer*
Result of the comparison of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

Module

Foundation

28.4 Conversion

handle_to_integer (: : Handle : CastedHandle)

Convert a handle into an integer.

It is not recommended to use this operator in HDevelop. This operator is only provided for reasons of backward compatibility.

handle_to_integer converts the handle Handle into an integer representation and returns it in CastedHandle.

If the legacy handle mode is disabled (the default), the ownership of the handle is not transferred. Once all instances of the handle, such as in the tuple Handle, were overwritten, the handle and its content will be destroyed and CastedHandle will become invalid. In that case, if CastedHandle should be passed to code parts that run in legacy handle mode, a reference to the original Handle must be kept in order to avoid clearing the handle.

If the legacy handle mode is enabled, the ownership of the handle is transferred. The handle must then be cleared using clear_handle or the clear operator of the corresponding semantic type of the handle.

Attention

It is not recommended to use this operator in HDevelop. It is solely provided to enable backward compatibility with legacy code.

Parameters

▷ **Handle** (input_control) ..... handle(-array) ⇝ *handle*
The handle to be cast.

▷ **CastedHandle** (output_control) ..... pointer(-array) ⇝ *integer*
The handle cast to an integer value.

Result

If the parameters are valid, the operator handle_to_integer returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

integer_to_handle

Module

Foundation

integer_to_handle (: : IntegerHandle : Handle)

Convert an integer into a handle.

It is not recommended to use this operator in HDevelop. This operator is only provided for reasons of backward compatibility.

integer_to_handle converts the integer IntegerHandle, that represents a handle, to a handle of type HANDLE_PAR and returns it in Handle. This allows to convert handles created in code parts where the legacy handle mode is enabled into proper handles.

If the legacy handle mode is disabled (the default), the ownership of the handle is transferred onto the handle. In this case, the handle will automatically be cleared once all references to that handle, such as in the tuple Handle, are overwritten. In that case, if the original IntegerHandle should continue to be used, a reference to the returned Handle must be kept in order to avoid clearing the handle.

If the legacy handle mode is enabled, the returned value will again be an integer. Additionally, the handle must then be cleared using clear_handle or the clear operator of the corresponding semantic type of the handle.

Attention

It is not recommended to use this operator in HDevelop. This operator is solely provided to enable backward compatibility with legacy code.

Parameters

▷ **IntegerHandle** (input_control) . . . . . pointer(-array) ⇝ *integer*
The handle as integer.

▷ **Handle** (output_control) . . . . . handle(-array) ⇝ *handle*
The handle as handle.

Result

If the parameters are valid, the operator `integer_to_handle` returns the value `2` (`H_MSG_TRUE`). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

See also

`handle_to_integer`

Module

Foundation

tuple_chr (: : T : Chr)

Convert a tuple of integer numbers into strings.

`tuple_chr` converts the input tuple `T`, consisting of integer numbers, into a tuple of strings, each of length 1. When the encoding used in the HALCON library is UTF-8 (see `set_system ('filename_encoding', 'utf8')`) and the string operators are set to work by code points (see `set_system('tuple_string_operator_mode', 'codepoint')`), which is the default for both, the operator accepts Unicode character codes and returns strings with the appropriate UTF-8 representations of the characters. When the HALCON library encoding is set to *'locale'* or the string operator mode is *'byte'*, the operator accepts only numbers between 0 and 256. In that case the operator `tuple_chr` returns strings with one byte length each, where the input number is set as ANSI code. See also Tuple / String Operations for a more detailed description of the different modes and further encoding issues.

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_chr`, which can be used in an expression in the following syntax:

```
Chr := chr(T)
```

Parameters

▷ **T** (input_control) . . . . . integer(-array) ⇝ *integer*
Input tuple with Unicode character codes or ANSI codes.
Restriction: 0 <= T

▷ **Chr** (output_control) . . . . . string(-array) ⇝ *string*
Output tuple with strings built from the character codes in the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_chrt

See also

tuple_ord, tuple_ords

Module

Foundation

tuple_chrt (: : T : Chrt)

Convert a tuple of integer numbers into strings.

tuple_chrt converts the input tuple T, consisting of integer numbers, into a tuple of strings and integer numbers (where only the number 0 is passed as number to the output). All other numbers are converted to characters that are concatenated to one string up to the next 0 in the input tuple. When the encoding used in the HALCON library is UTF-8 (see set_system('filename_encoding', 'utf8')) and the string operators are set to work by code points (see set_system('tuple_string_operator_mode', 'codepoint')), which is the default for both, the operator interprets the input numbers as Unicode character codes and transforms them to the appropriate UTF-8 representations of the characters. When the HALCON library encoding is set to *'locale'* or the string operator mode is *'byte'*, the operator accepts only numbers between 0 and 256. In that case they are interpreted as ANSI codes from which the output string has to be built byte by byte. In that mode it is not checked whether the byte sequences will build valid characters according to the current string encoding. See also Tuple / String Operations for a more detailed description of the different modes and further encoding issues.

The operator tries to pack as many input numbers into one string as possible. If the number 0 occurs in the input tuple T, the current string is terminated and the number 0 is added to the output tuple. If in the input tuple more numbers follow, a new string is started. This operator can be used to convert data read with read_serial into strings. This approach allows also to read bytes with the value 0.

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_chrt, which can be used in an expression in the following syntax:

```
Chrt := chrt(T)
```

Parameters

▷ **T** (input_control) ..... integer(-array) ⇝ *integer*
Input tuple with integer numbers.
Restriction: 0 <= T

▷ **Chrt** (output_control) ..... string(-array) ⇝ *string* / integer
Output tuple with strings that are separated by the number 0.

Example

```
read_serial (SerialHandle, 100, Data)
tuple_chrt (Data, Strings)
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_chr

See also

tuple_ord, tuple_ords, read_serial

Module

Foundation

tuple_int (: : T : Int)

Convert a tuple into a tuple of integer numbers.

tuple_int converts the input tuple T into a tuple of integer numbers by truncating T. The conversion of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_int, which can be used in an expression in the following syntax:

```
Int := int(T)
```

Parameters

- ▷ **T** (input_control) ..... number(-array) ⇝ *real* / integer
  Input tuple.
- ▷ **Int** (output_control) ..... number(-array) ⇝ *integer*
  Result of the conversion into integer numbers.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_round

Module

Foundation

tuple_number (: : T : Number)

Convert a tuple (of strings) into a tuple of numbers.

tuple_number converts the input tuple T into a tuple of numbers. If the input tuple contains numbers, they are simply copied into the output tuple. Strings are converted into the appropriate type of number (integer or floating point numbers) or are copied as strings if they do not represent a number. Note that strings starting with 0x are interpreted as hexadecimal numbers, and strings starting with 0 as octal numbers. For example, the string '20' is converted to the integer 20, '020' to 16, and '0x20' to 32.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

Exception: Out of range integers

If the input tuple contains strings with integers that cannot be represented as Hlong (32-bit signed integer for 32-bit HALCON, 64-bit signed integer for 64-bit HALCON), an exception is raised.

String padding

If tuple_number converts a string to a number, the same string with added leading and/or trailing spaces will be converted to the same number. Example: number('55.6') == 55.6 and number(' 55.6 ') == 55.6

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_number, which can be used in an expression in the following syntax:

```
Number := number(T)
```

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *string* / real / integer
Input tuple.

▷ **Number** (output_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Input tuple as numbers.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

tuple_is_number, tuple_string

Module

Foundation

tuple_ord (: : T : Ord)

Convert a tuple of strings of length 1 into a tuple of integer numbers.

tuple_ord converts the input tuple T, which may only contain strings of length 1, into a tuple of integer numbers. When the encoding used in the HALCON library is UTF-8 (see set_system ('filename_encoding', 'utf8')) and the string operators are set to work by code points (see set_system('tuple_string_operator_mode', 'codepoint')), which is the default for both, the operator accepts the UTF-8 representation of a Unicode character (code point) and returns the appropriate Unicode character code. When the HALCON library encoding is set to *'locale'* or the string operator mode is *'byte'*, the operator accepts only a single byte for each input string. In that case the operator tuple_ord returns the ANSI code of the input byte as integer number between 0 and 256. See also Tuple / String Operations for a more detailed description of the different modes and further encoding issues.

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_ord, which can be used in an expression in the following syntax:

```
Ord := ord(T)
```

Parameters

▷ **T** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with strings of length 1.

▷ **Ord** (output_control) . . . . . integer(-array) ⇝ *integer*
Output tuple with Unicode character codes or ANSI codes of the characters passed in the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_ords

tuple_chr, tuple_chrt

Module

Foundation

tuple_ords (: : T : Ords)

Convert a tuple of strings into a tuple of integer numbers.

tuple_ords converts the input tuple T, which may only contain strings and integer numbers, into a tuple of integer numbers. When the encoding used in the HALCON library is UTF-8 (see set_system('filename_encoding', 'utf8')) and the string operators are set to work by code points (see set_system('tuple_string_operator_mode', 'codepoint')), which is the default for both, the operator returns for the input strings the appropriate Unicode character codes. When the HALCON library encoding is set to *'locale'* or the string operator mode is *'byte'*, the operator returns the ANSI code for every byte of the input string. In that mode, the result may depend on the currently used code page for strings that contain non-ASCII characters. See also Tuple / String Operations for a more detailed description of the different modes and further encoding issues.

The character codes of the individual strings are written to the output according to their order within the string and within the tuple. Integer numbers are simply copied to an appropriate position in the output tuple. This operator can be used to prepare outputs with write_serial. In particular, a byte with value 0 can be written by inserting the integer number 0 into T.

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_ords, which can be used in an expression in the following syntax:

```
Ords := ords(T)
```

Parameters

- ▷ **T** (input_control) ..... string(-array) ⇝ *string* / integer
  Input tuple with strings.
- ▷ **Ords** (output_control) ..... integer(-array) ⇝ *integer*
  Output tuple with the Unicode character codes or ANSI codes of the input string.

Example

```
tuple_ords (['String 1', 0, 'String 2', 0], Data)
write_serial (SerialHandle, Data)
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_ord

See also

tuple_chr, tuple_chrt, write_serial

Module

Foundation

tuple_real (: : T : Real)

Convert a tuple into a tuple of floating point numbers.

tuple_real converts the input tuple T into a tuple of floating point numbers. The conversion of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_real, which can be used in an expression in the following syntax:

```
Real := real(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Real** (output_control) . . . . . number(-array) ⇝ *real*
Input tuple as floating point numbers.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

tuple_round (: : T : Round)

Convert a tuple into a tuple of integer numbers.

tuple_round converts the input tuple T into a tuple of integer numbers by rounding T to the nearest integer. The conversion of a string is not allowed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_round, which can be used in an expression in the following syntax:

```
Round := round(T)
```

Parameters

▷ **T** (input_control) . . . . . number(-array) ⇝ *real* / integer
Input tuple.

▷ **Round** (output_control) . . . . . number(-array) ⇝ *integer*
Result of the rounding.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_int

Module

Foundation

tuple_string (: : T, Format : String)

Convert a tuple into a tuple of strings.

tuple_string converts numbers into strings or modifies strings. The operator has two parameters: T is the number or string that has to be converted. Format specifies the conversion.

In the following, first some examples for the use of tuple_string are given and then, the structure of the Format string is explained in detail.

Examples

Examples for the conversion of numbers into strings:

T (Input)	Format (Input)	String (Output)
23	'10.2f'	' 23.00'
23	'-10.2f'	'23.00 '
4	'.7f'	'4.0000000'
1234.56789	'+10.3f'	' +1234.568'
255	'x'	'ff'
255	'X'	'FF'
0xff	'.5d'	'00255'

Examples for the modification of strings:

T (Input)	Format (Input)	String (Output)
'total'	'10s'	' total'
'total'	'-10s'	'total '
'total'	'-10.3s'	'tot '

Format string

The Format string consists of the following four parts:

```
<flags><field width>.<precision><conversion characters>
```

flags Zero or more flags, in any order, which modify the meaning of the conversion specification. Flags may consist of the following characters:

- **-** The result of the conversion is left justified within the field.
- **+** The result of a signed conversion always begins with a sign, + or −.
- <**space**> If the first character of a signed conversion is not a sign, a space character is prefixed to the result. This means that if the space flag (<space>) and + flag both appear, the space flag is ignored.
- **#** The value is to be converted to an "alternate form". For d and s conversions, this flag has no effect. For o conversion (see below), it increases the precision to force the first digit of the result to be a zero. For x or X conversion (see below), a non- zero result has 0x or 0X prefixed to it. For e, E, f, g, and G conversions, the result always contains a radix character, even if no digits follow the radix character. For g and G conversions, trailing zeros are not removed from the result, contrary to usual behavior.
- **0** The value should be zero padded. For d, o, u, x, X, e, E, f, F, g, and G conversions, the converted value is padded on the left with zeros rather than blanks. If the 0 and − flags both appear, the 0 flag is ignored. If a precision is given with a numeric conversion (d, o, u, x, and X), the 0 flag is ignored. For other conversions, the behavior is undefined.

field width An optional string of decimal digits to specify a minimum field width. For an output field, if the converted value has fewer characters than the field width, it is padded on the left (or right, if the left-adjustment flag, - has been given) to the field width.

precision The precision specifies the minimum number of digits to appear for the `d`, `o`, `x`, or `X` conversions (the field is padded with leading zeros), the number of digits to appear after the radix character for the `e` and `f` conversions, the maximum number of significant digits for the `g` conversion, or the maximum number of characters to be printed from a string in `s` conversion. The precision takes the form of a period **.** followed by a decimal digit string. A null digit string is treated as a zero.

conversion characters A conversion character indicates the type of conversion to be applied:

d,u,o,x,X The integer argument is printed in signed decimal (`d`), unsigned decimal (`u`), unsigned octal (`o`), or unsigned hexadecimal notation (`x` and `X`). The `x` conversion uses the numbers and letters `0123456789abcdef`, and the `X` conversion uses the numbers and letters `0123456789ABCDEF`. The precision component of the argument specifies the minimum number of digits to appear. If the value being converted can be represented in fewer digits than the specified minimum, it is expanded with leading zeroes. The default precision is 1. The result of converting a zero value with a precision of 0 is no characters.

f The floating-point number argument is printed in decimal notation in the style `[-]dddrddd`, where the number of digits after the radix character, `r`, is equal to the precision specification. If the precision is omitted from the argument, six digits are output; if the precision is explicitly 0, no radix appears.

e,E The floating-point-number argument is printed in the style `[-]d.ddde±dd`, where there is one digit before the radix character, and the number of digits after it is equal to the precision. When the precision is missing, six digits are produced; if the precision is 0, no radix character appears. The `E` conversion character produces a number with `E` introducing the exponent instead of `e`. The exponent always contains at least two digits. However, if the value to be printed requires an exponent greater than two digits, additional exponent digits are printed as necessary.

g,G The floating-point-number argument is printed in style `f` or `e` (or in style `E` in the case of a `G` conversion character), with the precision specifying the number of significant digits. The style used depends on the value converted; style `e` is used only if the exponent resulting from the conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the result. A radix character appears only if it is followed by a digit.

s The argument is taken to be a string, and characters from the string are printed until the end of the string or the number of characters indicated by the precision specification of the argument is reached. If the precision is omitted from the argument, it is interpreted as infinite and all characters up to the end of the string are printed.

b Similar to the `s` conversion specifier, except that the string can contain backslash-escape sequences which are then converted to the characters they represent.

In no case does a nonexistent or insufficient field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result.

Exception: Empty input tuple

If any of the input tuples is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_string`, which can be used in an expression in the following syntax:

```
String := T $ Format
```

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Input tuple.

▷ **Format** (input_control) . . . . . string ⇝ *string*
Format string.

▷ **String** (output_control) . . . . . string(-array) ⇝ *string*
Input tuple converted to strings.

Example

```
*
* '     23.00'
tuple_string (23, '10.2f', String)
String := 23$'10.2f'
*
* '23.00     '
tuple_string (23, '-10.2f', String)
String := 23$'-10.2f'
*
* '4.0000000'
tuple_string (4, '.7f', String)
String := 4$'.7f'
*
* ' +1234.568'
tuple_string (1234.56789, '+10.3f', String)
String := 1234.56789$'+10.3f'
*
* 'ff'
tuple_string (255, 'x', String)
String := 255$'x'
*
* 'FF'
tuple_string (255, 'X', String)
String := 255$'X'
*
* '00255'
tuple_string (0xff, '.5d', String)
String := 0xff$'.5d'
*
* '     total'
tuple_string ('total', '10s', String)
String := 'total'$'10s'
*
* 'total     '
tuple_string ('total', '-10s', String)
String := 'total'$'-10s'
*
* 'tot       '
tuple_string ('total', '-10.3s', String)
String := 'total'$'-10.3s'
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sub

Module

Foundation

28.5 Creation

clear_handle (: : Handle :)

Clear the content of a handle.

clear_handle clears the content of the handle contained in Handle. The handle is left in a cleared state afterwards. Attempts to use it in any other operator will raise an error.

Usually, handles are automatically cleared once all references in all tuples are overwritten. clear_handle can be used to clear a handle at a specific time, even if there are still references to it.

This operator can be used to clear handles of any type instead of the more specialized operators, such as clear_matrix or clear_shape_model.

Parameters

▷ **Handle** (input_control) ..... tuple(-array) ⇝ *handle*
Handle to clear.

Result

If the parameters are valid, the operator clear_handle returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- Handle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

See also

tuple_is_valid_handle

Module

Foundation

tuple_concat (: : T1, T2 : Concat)

Concatenate two tuples to a new one.

tuple_concat concatenates the input tuples T1 and T2 to a new tuple Concat. The first elements of Concat conform to the elements of T1 and the remaining elements of Concat conform to those of T2.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_concat, which can be used in an expression in the following syntax:

```
Concat := [T1, T2]
```

Parameters

▷ **T1** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
Input tuple 1.

▷ **T2** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
Input tuple 2.

▷ **Concat** (output_control) ..... tuple(-array) ⇝ *integer* / real / string
Concatenation of input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_gen_const, tuple_str_bit_select, tuple_select, tuple_str_first_n, tuple_str_last_n, tuple_substr

See also

tuple_remove

Module

Foundation

tuple_constant (: : Name : Value)

Generate a tuple with the value of a HDevelop language constant.

tuple_constant generates a new tuple with the value of a HDevelop language constant.

Attention

H_INT64_MIN and H_INT64_MAX will both produce an error if 32-bit HALCON is being used, as they cannot be represented in the then 32-bit integer used in tuples.

H_INT_MIN and H_INT_MAX will produce different values depending on whether HALCON 32- or 64-bit is being used.

Parameters

▷ **Name** (input_control) ..... tuple ⇝ *string*
The name of the HDevelop language constant as string.
Default: 'H_INT32_MIN'
List of values: Name ∈ {'H_INT_MIN', 'H_INT_MAX', 'H_INT32_MIN', 'H_INT32_MAX', 'H_INT64_MIN', 'H_INT64_MAX', 'H_FLOAT32_MIN', 'H_FLOAT32_MAX', 'H_FLOAT32_MIN_POSITIVE', 'H_FLOAT32_EPSILON', 'H_FLOAT64_MIN', 'H_FLOAT64_MAX', 'H_FLOAT64_MIN_POSITIVE', 'H_FLOAT64_EPSILON', 'H_FLOAT_INFINITY', 'H_FLOAT_NEG_INFINITY', 'H_FLOAT_NAN', 'HNULL', 'H_MSG_TRUE', 'H_MSG_FALSE', 'H_MSG_VOID', 'H_MSG_FAIL', 'H_TYPE_INT', 'H_TYPE_REAL', 'H_TYPE_STRING', 'H_TYPE_HANDLE', 'H_TYPE_MIXED', 'H_TYPE_ANY', 'true', 'false'}

▷ **Value** (output_control) ..... tuple ⇝ *integer* / real / handle
The value of the constant.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

tuple_gen_const (: : Length, Const : Newtuple)

Generate a tuple of a specific length and initialize its elements.

tuple_gen_const generates a new tuple in Newtuple. The input parameter Length determines the number of elements for the new tuple. Thus, Length may only consist of a single number. If Length contains a floating point number, this may only represent an integer value (without fraction). The data type and value of each element of the new generated tuple is determined by the input parameter Const that may only consist of a single element. All elements in Newtuple have got the same data type and value as the single element in Const.

Exception: Empty input tuples

If any of the input tuples is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_gen_const`, which can be used in an expression in the following syntax:

```
Newtuple := gen_tuple_const(Length, Const)
```

Parameters

- ▷ **Length** (input_control) . . . . . number ⇝ *integer* / real
  Length of tuple to generate.
- ▷ **Const** (input_control) . . . . . tuple ⇝ *integer* / real / string / handle
  Constant for initializing the tuple elements.
- ▷ **Newtuple** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  New Tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_str_bit_select`, `tuple_select`, `tuple_str_first_n`, `tuple_str_last_n`, `tuple_concat`, `tuple_insert`, `tuple_replace`, `tuple_gen_sequence`

See also

`tuple_rand`

Module

Foundation

tuple_gen_sequence (: : Start, End, Step : Sequence)

Generate a tuple with a sequence of equidistant values.

`tuple_gen_sequence` generates a new tuple `Sequence` with a sequence of equidistant values:

[Start, Start + Step, Start + 2*Step, ... End]

`Step` must not be zero and the sign of (`End` - `Start`) must be equal to the sign of `Step`. The last entry of `Sequence` may actually be less than `End`, if (`End` - `Start`) is not divisible by `Step` without remainder.

Exception: Empty input tuples

If any of the input tuples is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_gen_sequence`, which can be used in an expression in the following syntax:

```
Sequence := [Start:Step:End]
```

An alternative syntax is `Sequence := [Start:End]`, where `Step` defaults to *1*.

Parameters

- ▷ **Start** (input_control) . . . . . number ⇝ *integer* / real
  Start value of the tuple.
- ▷ **End** (input_control) . . . . . number ⇝ *integer* / real
  Maximum value for the last entry.
- ▷ **Step** (input_control) . . . . . number ⇝ *integer* / real
  Increment value.
- ▷ **Sequence** (output_control) . . . . . number(-array) ⇝ *integer* / real
  The resulting sequence.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_str_bit_select, tuple_select, tuple_str_first_n, tuple_str_last_n, tuple_concat, tuple_insert, tuple_replace, tuple_gen_const

See also

tuple_rand

Module

Foundation

tuple_rand (: : Length : Rand)

Return a tuple of random numbers between 0 and 1.

tuple_rand returns a tuple of random numbers distributed uniformly in the interval [0,1). The parameter Length specifies the length of the output tuple, i.e., how many random numbers are generated.

The random numbers are generated using the C function "drand48()". See the parameter *'seed_rand'* of set_system for information on the used random seed.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_rand, which can be used in an expression in the following syntax:

```
Rand := rand(Length)
```

Parameters

▷ **Length** (input_control) ..... number ⇝ *integer*
Length of tuple to generate.

▷ **Rand** (output_control) ..... number(-array) ⇝ *real*
Tuple of random numbers.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

See also

tuple_gen_const

Module

Foundation

tuple_repeat (: : Tuple, Num : Result)

Repeat a tuple.

tuple_repeat repeats Tuple Num times and returns them with Result. Thus, Result contains Num times more elements than Tuple. For example, the first Num elements of Result are element-wise equal to the elements of Tuple. Num must be positive and integer (also for type real). If Num is equal to 0, an empty tuple is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_repeat`, which can be used in an expression in the following syntax:

```
Result := rep(Tuple, Num)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **Num** (input_control) . . . . . integer ⇝ *integer* / real
Number of repetitions.

▷ **Result** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Tuple with multiple copies.

Example

```
tuple_repeat (['a', 'b', 'c'], 2, Result)
* Returns ['a', 'b', 'c', 'a', 'b', 'c']
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_gen_const`, `tuple_concat`

See also

`tuple_repeat_elem`

Module

Foundation

tuple_repeat_elem (: : Tuple, Num : Result)

Repeat the elements of a tuple.

`tuple_repeat_elem` repeats each element of `Tuple` `Num` times and returns them with `Result`. Thus, `Result` contains `Num` times more elements than `Tuple`. For example, the first `Num` elements of `Result` are equal to the first element of `Tuple`. `Num` must be positive and integer (also for type `real`). If `Num` is equal to 0, an empty tuple is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_repeat_elem`, which can be used in an expression in the following syntax:

```
Result := rep_elem(Tuple, Num)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **Num** (input_control) . . . . . integer ⇝ *integer* / real
Number of repetitions.

▷ **Result** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Tuple with repeated elements.

Example

```
tuple_repeat_elem (['a', 'b', 'c'], 2, Result)
* Returns ['a', 'a', 'b', 'b', 'c', 'c']
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_concat, tuple_gen_const

28.6 Data Containers

copy_dict (: : DictHandle, GenParamName, GenParamValue : CopiedDictHandle)

Copy a dictionary.

copy_dict creates a deep copy (i.e., all contained handles and iconic objects are deep copied) of the dictionary DictHandle in the dictionary CopiedDictHandle.

If DictHandle contains a handle that can not be copied or that has been freed already, an exception is raised per default. This behavior is controlled by GenParamName *'raise_error_if_content_not_serializable'*, and the corresponding GenParamValue can take the following values:

'true': The default: Errors are raised and the copy process aborted.

'low_level': Only low level errors are raised. Instead of the handle concerned an empty handle is copied in CopiedDictHandle and the copy process will be continued. The behavior regarding HALCON low level errors is determined by *'do_low_error'* in set_system.

'false': The errors are suppressed. Instead of the handle concerned an empty handle is copied in CopiedDictHandle and the copy process will be continued.

Parameters

▷ **DictHandle** (input_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'raise_error_if_content_not_serializable'}

▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false', 'low_level'}

▷ **CopiedDictHandle** (output_control) . . . . . dict ⇝ *handle*
Copied dictionary handle.
Number of elements: CopiedDictHandle == 1

Result

If the parameters are valid, the operator `copy_dict` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`read_dict`, `deserialize_handle`, `create_dict`

Possible Successors

`write_dict`

See also

`read_dict`, `write_dict`, `serialize_handle`, `deserialize_handle`

Module

Foundation

`create_dict` (: : : DictHandle)

Create a new empty dictionary.

`create_dict` creates a new empty dictionary and returns it in `DictHandle`.

The dictionary serves as an associative array-like container allowing to store an arbitrary number of values associated with unique keys (integers or strings). Each key can refer either to a tuple or to an iconic object. These are stored in the dictionary using `set_dict_tuple` or `set_dict_object`, respectively, from where they can be retrieved again using `get_dict_tuple` or `get_dict_object`.

The data stored in the dictionary is always a copy of the original data, being it control parameters or objects. The original data can thus be reused immediately after the `set_dict_tuple` or `set_dict_object` calls. The following particularities apply:

- Objects: The copy is a reference, as in `copy_obj`. In particular, changes made using the operators `set_grayval` or `overpaint_region` affect the object stored in the dictionary as well.
- Handles: Storing any handle in the dictionary will copy the handle value, but not the resource behind the handle.

Multiple threads can add, retrieve and remove keys concurrently as long as every thread accesses a different key. As an exception to this rule, multiple threads can retrieve the same key from a dictionary simultaneously.

HDevelop In-line Operation

HDevelop provides an in-line operation for `create_dict`, which can be used in an expression in the following syntax:

```
DictHandle := dict{}
```

Parameters

▷ **DictHandle** (output_control) ..... dict ⇝ *handle*
Handle of the newly created dictionary.
Number of elements: DictHandle == 1

Example

```
Dicts := []
for idx := 0 to 4 by 1
  create_dict (DictHandle)
  Dicts[idx] := DictHandle
endfor
* ...
```

Result

Returns 2 (H_MSG_TRUE) unless a resource allocation error occurs.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

set_dict_tuple, set_dict_object

set_dict_tuple, get_dict_tuple, set_dict_object, get_dict_object, get_dict_param

Module

Foundation

dict_to_json (: : DictHandle, GenParamName, GenParamValue : JsonString)

Transform a dictionary into a JSON string.

dict_to_json transforms the dictionary passed in DictHandle into a JSON string and returns that string in JsonString.

Several optional parameters can be set that control the creation of the JSON strings. Those parameters can be set via GenParamName and GenParamValue and are described in the documentation of write_dict:

- *'raise_error_if_content_not_serializable'*,
- *'compact_json'*,
- *'use_json_arrays'*.

dict_to_json can transform several dictionaries at once. For this, DictHandle must contain a tuple of dictionaries. The output JsonString will then contain one string per input dictionary.

Parameters

▷ **DictHandle** (input_control) . . . . . dict(-array) ⇝ *handle*
Dictionary handle.

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'compact_json', 'raise_error_if_content_not_serializable', 'use_json_arrays'}

▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
Suggested values: GenParamValue ∈ {'true', 'false'}

▷ **JsonString** (output_control) . . . . . string(-array) ⇝ *string*
String in JSON format.

Example

```
dict_to_json (dict{foo: 'bar', bar: [0:2]}, [], [], JSONString)
```

Result

If the parameters are valid, the operator `dict_to_json` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_dict`, `read_dict`, `json_to_dict`

Possible Successors

`json_to_dict`

Alternatives

`read_dict`, `create_dict`

See also

`json_to_dict`, `read_dict`, `write_dict`, `serialize_handle`, `deserialize_handle`, `copy_dict`

Module

Foundation

get_dict_object (: Object : DictHandle, Key :)

Retrieve an object associated with the key from the dictionary.

`get_dict_object` retrieves an object associated with the `Key` from the dictionary denoted by the `DictHandle`. The object has to be previously stored to the dictionary using `set_dict_object`.

The operator returns the data in the parameter `Object`. The iconic object is copied by the operation. Therefore, clearing or reusing the dictionary object afterwards will not have any side-effect on the returned iconic object.

If the given `Key` is not present in the dictionary or if the data associated with the key is not an object, `get_dict_object` fails. Presence of keys and information about the data associated with the key can be verified using `get_dict_param`.

HDevelop In-line Operation

HDevelop provides an in-line operation for `get_dict_object`, which can be used in an expression in the following syntax:

- Dynamic syntax:
  `Object := DictHandle.['Key']`
- Static syntax:
  `Object := DictHandle.Key`

Parameters

▷ **Object** (output_object) ..... object(-array) ⇝ *object*
Object value retrieved from the dictionary.

▷ **DictHandle** (input_control) ..... dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **Key** (input_control) ..... string ⇝ *string* / integer
Key string.
Number of elements: Key == 1
Restriction: length(Key) > 0

Example

```
* ...
get_dict_param (Dict, 'key_exists', ['simple_string','foo','my_image'], \
                KeysPresence)
get_dict_param (Dict, 'key_data_type', ['simple_string','my_image'], \
                KeysType)
get_dict_object (Image, Dict, 'my_image')
```

Result

If the operation succeeds, `get_dict_object` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key), the required key not found in the dictionary or other than object data associated with given key.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`set_dict_object`

Module

Foundation

get_dict_param (: : DictHandle, GenParamName, Key : GenParamValue)

Query dictionary parameters or information about a dictionary.

`get_dict_param` queries current values of dictionary parameters or other information about the dictionary status.

With each call of `get_dict_param`, only a single parameter value can be queried. However, there are two types of parameters/queries:

- Parameters/queries applicable to the entire dictionary. In this case no keys must be specified, the parameter `Key` must be an empty tuple.
- Parameters/queries applicable to the individual keys. In this case a list of keys must be specified in the parameter `Key`. The keys are processed in the same order as specified in the `Key` parameter.

Key-independent (global) parameter names:

'keys': Queries all the keys stored in the dictionary, no matter whether they are associated with tuple or object data. The list of keys is reported as a string tuple via `GenParamValue`. For this query the parameter `Key` must be an empty tuple.

Currently supported key-specific parameter names are:

'key_exists': Reports *1* if the given key is stored in the dictionary, *0* otherwise. The results are reported via `GenParamValue`, one value for each key.

'key_data_type': Reports *'tuple'* for keys associated with tuple data within the dictionary (the data can be retrieved using `get_dict_tuple`). Reports *'object'* for keys associated with object data (the data can be retrieved using `get_dict_object`). The results are reported via `GenParamValue`, one value for each key. This parameter is useful to decide dynamically whether to use `get_dict_tuple` or `get_dict_object` to get the data of a specific key.

Parameters

▷ **`DictHandle`** (input_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **`GenParamName`** (input_control) . . . . . attribute.name ⇝ *string*
Names of the dictionary parameters or info queries.
Number of elements: GenParamName == GenParamValue
Default: 'keys'
List of values: `GenParamName` ∈ {'keys', 'key_exists', 'key_data_type'}

▷ **`Key`** (input_control) . . . . . string(-array) ⇝ *string* / integer
Dictionary keys the parameter/query should be applied to (empty for `GenParamName` = *'keys'*).
Default: []

▷ **`GenParamValue`** (output_control) . . . . . attribute.value(-array) ⇝ *string* / integer / real
Values of the dictionary parameters or info queries.

Example

```
get_dict_param (Dict, 'keys', [], AllKeys)
get_dict_param (Dict, 'key_data_type', AllKeys, KeysType)
```

Result

If all the operator parameters, and the specified keys are valid, `get_dict_param` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`create_dict`

See also

`create_dict`, `set_dict_tuple`, `get_dict_tuple`, `set_dict_object`, `get_dict_object`, `remove_dict_key`

Module

Foundation

`get_dict_tuple ( : : DictHandle, Key : Tuple )`

Retrieve a tuple associated with the key from the dictionary.

`get_dict_tuple` retrieves a tuple associated with the `Key` from the dictionary denoted by the `DictHandle`. The tuple has to be previously stored to the dictionary using `set_dict_tuple`.

The operator returns the data in the parameter `Tuple`. The data including strings is copied by the operation, the dictionary can thus be immediately reused.

If the given `Key` is not present in the dictionary or if the data associated with the key is not a tuple, `get_dict_tuple` fails. Presence of keys and information about the data associated with the key can be verified using `get_dict_param`.

Obtaining the values for multiple keys at once is only possible if for each of those keys, the dictionary contains a tuple with a single element.

HDevelop In-line Operation

HDevelop provides an in-line operation for `get_dict_tuple`, which can be used in an expression in the following syntax:

- Dynamic syntax:
  `Tuple := DictHandle.['Key']`
- Static syntax:
  `Tuple := DictHandle.Key`

Parameters

▷ **`DictHandle`** (input_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **`Key`** (input_control) . . . . . string(-array) ⇝ *string* / integer
Key string.

▷ **`Tuple`** (output_control) . . . . . tuple(-array) ⇝ *string* / integer / real
Tuple value retrieved from the dictionary.

Example

```
* ...
get_dict_param (Dict, 'key_exists', ['simple_string','foo','my_image'], \
                KeysPresence)
get_dict_param (Dict, 'key_data_type', ['simple_string','my_image'], \
                KeysType)
get_dict_tuple (Dict, 'simple_string', TupleString)
*
* Access multiple keys, if their tuple all have length 1
get_dict_tuple (Dict, ['key1','key2','key3'], MultipleValues)
```

Result

If the operation succeeds, `get_dict_tuple` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key), the required key not found in the dictionary, or other than tuple data associated with given key.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

json_to_dict (: : JsonString, GenParamName, GenParamValue : DictHandle)

Transform a JSON string into a dictionary.

json_to_dict transforms the string passed in JsonString, which must be valid JSON, into a dictionary and returns the handle of the dictionary in DictHandle.

Several optional parameters can be set that control the values of JSON constants. Those parameters can be set via GenParamName and GenParamValue and are described in the documentation of read_dict.

json_to_dict can transform several strings at once. For this, JsonString must contain a tuple of strings. The output DictHandle will then contain one dictionary per input string.

Parameters

- ▷ **JsonString** (input_control) . . . . . string(-array) ⇝ *string*
  String in JSON format.
  Default: ['"key":"value"']
- ▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
  Name of the generic parameter.
  Default: []
  List of values: GenParamName ∈ {'json_value_true', 'json_value_false', 'json_value_null', 'convert_json_arrays_to'}
- ▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
  Value of the generic parameter.
  Default: []
  Suggested values: GenParamValue ∈ {0, 1, 'HNULL', 'true', 'false', 'dict', 'tuple', 'tuple_if_possible'}
- ▷ **DictHandle** (output_control) . . . . . dict(-array) ⇝ *handle*
  Dictionary handle.

Example

```
json_to_dict ('{"capacity": "medium", "image_height": 1024, "image_width":
1024}', [], [], DictHandle)
```

Result

If the parameters are valid, the operator json_to_dict returns the value 2 (H_MSG_TRUE). If necessary an exception is raised. This is especially the case if JsonString does not contain valid JSON.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Successors

write_dict, copy_dict

Alternatives

read_dict, create_dict

See also

read_dict, write_dict, serialize_handle, deserialize_handle

Module

Foundation

read_dict (: : FileName, GenParamName, GenParamValue : DictHandle)

Read a dictionary from a file.

read_dict reads a dictionary from the file FileName and returns the handle of the dictionary in DictHandle.

The operator supports the following file formats:

'hdict': Binary HALCON format for dictionaries. Files with this format can be written by write_dict. The default file extension for this format is 'hdict'.

'json': JSON (JavaScript Object Notation) file format. The default file extension for this format is 'json'.

If the given file does not exist, the operator attempts to find the file by appending the default file extensions to the filename. The file type is automatically recognized based on the file content and the file ending (which have to be consistent).

A set of additional optional parameters can be set. The names and values of the parameters are passed in GenParamName and GenParamValue, respectively. Some of the optional parameters can only be set for a certain file type. The following values for GenParamName are possible:

'json_value_true', *'json_value_false'*, *'json_value_null'*: Set the values that are used for JSON primitives. Valid JSON primitives are 'true', 'false', and 'null'. When encountering such a primitive in a JSON file, the corresponding value in the read dictionary is set to the value defined with these parameters. The value passed in GenParamValue must be a tuple of length 1.

The default values for primitives are *1* for 'true', *0* for 'false', and *'HNULL'* for 'null'. These parameters only have an effect when reading a JSON file.

'convert_json_arrays_to': This parameter controls which HALCON-internal data type is used to represent JSON arrays. Possible values for GenParamValue are:

'dict' **(default):** JSON arrays are converted into HALCON-Dictionaries with consecutive integer keys starting at *0*. This is always possible, even if the JSON array contains further JSON arrays. However, using dictionaries might require more memory than storing the same data in HALCON tuples.

'tuple': JSON arrays are converted into HALCON tuples. If this is not possible, for example if an array contains an array, an exception is raised.

'tuple_if_possible': JSON arrays are converted into HALCON tuples if possible, and into HALCON dictionaries otherwise.

Note that when using this option, the structure of the returned dictionary can change even if the JSON data follows the same schema. For example, an array of 2D point coordinates of the form *'"pt": [[1,2], [3,4]]'* would be converted into an outer dictionary which contains two tuples. However, if under the same schema no points are contained in the array, the corresponding entry in the JSON of the form *'"pt": []'* would be converted into a tuple instead of a dictionary. Code using the read dictionary must be prepared to deal with this kind of change in types.

Parameters

▷ **FileName** (input_control) . . . . . filename.read ⇝ *string*
File name.
File extension: .hdict, .json

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'json_value_true', 'json_value_false', 'json_value_null', 'convert_json_arrays_to'}

▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
Suggested values: GenParamValue ∈ {0, 1, 'HNULL', 'true', 'false', 'dict', 'tuple', 'tuple_if_possible'}

▷ **DictHandle** (output_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

Result

If the parameters are valid, the operator read_dict returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator returns a handle. Note that the state of an instance of this handle type may be changed by specific operators even though the handle is used as an input parameter by those operators.

Possible Predecessors

write_dict

Alternatives

json_to_dict, create_dict

Module

Foundation

remove_dict_key (: : DictHandle, Key :)

Remove keys from a dictionary.

remove_dict_key removes the keys specified in Key from the dictionary passed in DictHandle and releases all the (tuple or object) data associated with those keys.

If an error occurs while processing one or more keys (in particular if a key is invalid), the operator attempts to continue removing as many keys as possible before reporting an appropriate failure.

Parameters

▷ **DictHandle** (input_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **Key** (input_control) . . . . . string(-array) ⇝ *string* / integer
Key to remove.
Restriction: length(Key) > 0

Example

```
* Remove all keys
get_dict_param (Dict, 'keys', [], Keys)
remove_dict_key (Dict, Keys)
```

Result

If all the operator parameters are valid, remove_dict_key returns 2 (H_MSG_TRUE). Otherwise an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DictHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_dict

Possible Successors

get_dict_param

See also

create_dict, set_dict_tuple, get_dict_tuple, set_dict_object, get_dict_object, get_dict_param

Module

Foundation

set_dict_object (Object : : DictHandle, Key :)

Add a key/object pair to the dictionary.

set_dict_object stores an object associated with a key in the dictionary. The dictionary is denoted by the DictHandle parameter.

Object is copied by the operation and can thus be immediately reused. Thereby the object data is copied in HALCON's object database, meaning the new object contains a reference to Object, see copy_obj.

Both an empty object or an object tuple are considered as a valid value that can be associated with the key. If any data (tuple or object) was already associated with given key (Key), the old data is destroyed by set_dict_object and replaced by Object.

The Key has to be a string or an integer. Strings are treated case sensitive.

The object data for the given key can be retrieved again from the dictionary using get_dict_object.

HDevelop In-line Operation

HDevelop provides an in-line operation for set_dict_object, which can be used in an expression in the following syntax:

- Dynamic syntax:
  DictHandle.['Key'] := Object
- Static syntax:
  DictHandle.Key := Object

Parameters

▷ **Object** (input_object) ..... object(-array) ⇝ *object*
Object to be associated with the key.

▷ **DictHandle** (input_control) ..... dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **Key** (input_control) ..... string ⇝ *string* / integer
Key string.
Number of elements: Key == 1
Restriction: length(Key) > 0

Example

```
create_dict (Dict)
read_image (Image, 'filename')
set_dict_object (Image, Dict, 'my_image')
```

Result

If the operation succeeds, set_dict_object returns 2 (H_MSG_TRUE). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key) or resource allocation error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DictHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Possible Predecessors

create_dict

Possible Successors

set_dict_object, set_dict_tuple

Alternatives

set_dict_tuple

See also

create_dict, set_dict_tuple, get_dict_tuple, get_dict_object, remove_dict_key, get_dict_param

Module

Foundation

set_dict_tuple (: : DictHandle, Key, Tuple :)

Add a key/tuple pair to the dictionary.

set_dict_tuple stores a tuple associated with a key in the dictionary. The dictionary is denoted by the DictHandle parameter.

Tuple including strings is copied by the operation, and can thus be immediately reused. An empty tuple is considered as a valid value that can be associated with the key. If any data (tuple or object) was already associated with given key (Key), the old data is destroyed by set_dict_tuple and replaced by Tuple.

The Key has to be a string or an integer. Strings are treated case sensitive.

The tuple data for the given key can be retrieved again from the dictionary using get_dict_tuple.

set_dict_tuple allows setting the values of multiple keys with a single call. In this case, the length of Tuple must either be equal to the number of keys or *1*. In the first case, Tuple is split into segments of length *1*, one for each key. In the second case, if Tuple has length *1*, that one value is associated with each key. If no keys are passed, the values in Tuple are ignored. The following table summarizes the possible combinations of number of keys and values, where N is an arbitrary non-negative integer:

Length of Key	Length of Tuple	Effect
N	1	Value in Tuple is associated with all keys
1	N	Associate Tuple with Key
N	N	Associate tuples of length *1* with each passed key

HDevelop In-line Operation

HDevelop provides an in-line operation for set_dict_tuple, which can be used in an expression in the following syntax:

- Dynamic syntax:
  ```
  DictHandle.['Key'] := ['The answer', 42]
  ```
- Static syntax:
  ```
  DictHandle.Key := ['The answer', 42]
  ```

Attention

If the tuple contains any handles only the handle values are copied by the operation, not the resources behind those handles (no deep copy is created).

Parameters

▷ **DictHandle** (input_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **Key** (input_control) . . . . . string(-array) ⇝ *string* / integer
Key string.

▷ **Tuple** (input_control) . . . . . tuple-array ⇝ *string* / integer / real / handle
Tuple value to be associated with the key.

Example

```
create_dict (Dict)
set_dict_tuple (Dict, 'simple_integer', 27)
set_dict_tuple (Dict, 'simple_string', 'Hello world')
set_dict_tuple (Dict, 'mixed_tuple', ['The answer', 42])
set_dict_tuple (Dict, 0, 'This is zero')
```

Result

If the operation succeeds, `set_dict_tuple` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters (handle or key) or resource allocation error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DictHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

set_dict_tuple_at (: : DictHandle, Key, Index, Value :)

Assignment of one or several values to one or several tuple elements in a dictionary

`set_dict_tuple_at` assigns a single value to one or several elements of a tuple, or it assigns a number of values elementwise to the specified elements of a tuple that is stored in `DictHandle` under the key `Key`. The operator allows to efficiently replace parts of a tuple stored in a dictionary without first reading the previous values from the dictionary.

If the dictionary does not yet contain a tuple under the given key, or if the given key maps to an iconic value, a new tuple is created and stored under the given key. In the latter case, the iconic object previously stored under that key is removed from the dictionary.

If the passed indices are out of the current range of the tuple stored in the dictionary, the tuple length is increased and the new values are initialized to a default value.

The `Key` has to be a string or an integer. Strings are treated case sensitive. The `Index` parameter can be any expression that evaluates to any number of positive integer values. The `Value` parameter must evaluate to exactly one value or to the same number of indices that are provided via the `Index` parameter.:

The tuple data for the given key can be retrieved again from the dictionary using `get_dict_tuple`.

Attention

Note that if `Value` contains any handles, only the handle values are copied by the operation, not the resources behind those handles.

Parameters

▷ **`DictHandle`** (input_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **`Key`** (input_control) . . . . . string ⇝ *string* / integer
Key string.
Number of elements: Key == 1
Restriction: length(Key) > 0

▷ **`Index`** (input_control) . . . . . integer-array ⇝ *integer*
Indices of the elements that have to be replaced by the new value(s).
Default: 0
Suggested values: `Index` ∈ {0, 1, 2, 3, 4, 5, 6}
Minimum increment: 1

▷ **`Value`** (input_control) . . . . . tuple-array ⇝ *string* / integer / real / handle
Value(s) that is to be assigned.

Example

```
Dict := dict{}
Dict.some_key := 27

set_dict_tuple_at (Dict, 'some_key', 1, 5)
* Dict.some_key is now [27, 5]

* Alternative TRIAS syntax
Dict.some_key[0] := 66
* Dict.some_key is now [66, 5]
```

Result

If the operation succeeds, `set_dict_tuple_at` returns `2` (`H_MSG_TRUE`). Otherwise an exception is raised. Possible error conditions include invalid parameters or resource allocation error.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

This operator modifies the state of the following input parameter:

- DictHandle

During execution of this operator, access to the value of this parameter must be synchronized if it is used across multiple threads.

Module

Foundation

write_dict (: : DictHandle, FileName, GenParamName, GenParamValue :)

Write a dictionary to a file.

write_dict writes the dictionary denoted by the DictHandle to the file FileName.

The operator supports the file formats *'hdict'* and *'json'* (see read_dict). The format is selected based on the filename ending or by using the generic parameter *'file_type'* (see below). If neither is conclusive or set, the file is written as *'hdict'*.

Note that due to restrictions of the *'json'*-format, some information contained in dictionaries can not be stored in that file format. This includes iconic objects and handles that are not dictionaries. By default, write_dict will return an error if the dictionary contains such an item. This behavior can be changed using the generic parameter *'raise_error_if_content_not_serializable'* (see below).

A set of additional optional parameters can be set. The names and values of the parameters are passed in GenParamName and GenParamValue, respectively. Some of the optional parameters can only be set for a certain file type. The following values for GenParamName are possible:

'raise_error_if_content_not_serializable': If DictHandle contains an item that can not be serialized, an exception is raised per default. This behavior is controlled by this parameter, for which GenParamValue can take the following values:

- *'true'*: The default behavior, errors are raised.
- *'false'*: The errors are suppressed. Depending on the file type an empty handle (*'hdict'*) or no entry at all (*'json'*) are written in place of the non serializable item.
- *'low_level'*: The file output is the same as for *'false'*. Additionally, low level errors are raised if non-serializable items are encountered. The behavior regarding HALCON low level errors is determined by *'do_low_error'* in set_system.

'file_type': Sets the file type to be used. The corresponding entry in GenParamValue must be set to *'hdict'* (default) or *'json'*. If this parameter is not set, the file type is determined based on the ending of the file name. If that ending is not conclusive, the default *'hdict'* is used.

'compact_json': Controls if JSON files are written in a compact format without additional whitespace, or human-readable with newlines and indentation. In both cases the file will contain the same information. The corresponding entry in GenParamValue must be set to *'true'* (default) or *'false'*.

'use_json_arrays': Controls if write_dict should convert dictionaries into native JSON arrays where possible. For this, the dictionaries must only contain ascending integer keys starting at zero. The corresponding entry in GenParamValue must be set to *'true'* (default) or *'false'*.

Parameters

▷ **DictHandle** (input_control) . . . . . dict ⇝ *handle*
Dictionary handle.
Number of elements: DictHandle == 1

▷ **FileName** (input_control) . . . . . filename.write ⇝ *string*
File name.
File extension: .hdict

▷ **GenParamName** (input_control) . . . . . attribute.name(-array) ⇝ *string*
Name of the generic parameter.
Default: []
List of values: GenParamName ∈ {'file_type', 'raise_error_if_content_not_serializable', 'compact_json', 'use_json_arrays'}

▷ **GenParamValue** (input_control) . . . . . attribute.name(-array) ⇝ *string* / integer / real
Value of the generic parameter.
Default: []
Suggested values: GenParamValue ∈ {'hdict', 'json', 'true', 'false', 'low_level'}

Result

If the parameters are valid, the operator write_dict returns the value 2 (H_MSG_TRUE). If necessary an exception is raised.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

read_dict, deserialize_handle, create_dict

Possible Successors

read_dict, create_dict

See also

read_dict, serialize_handle, deserialize_handle, dict_to_json

Module

Foundation

28.7 Element Order

tuple_inverse (: : Tuple : Inverted)

Invert a tuple.

tuple_inverse inverts the input tuple Tuple. Thus, Inverted contains the same elements as Tuple but with the reverse order.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_inverse, which can be used in an expression in the following syntax:

```
Inverted := inverse(Tuple)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Inverted** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Inverted input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sort, tuple_sort_index

Module

Foundation

tuple_sort (: : Tuple : Sorted)

Sort the elements of a tuple in ascending order.

tuple_sort sorts all elements of Tuple in ascending order and returns the result with Sorted. As a precondition the single elements of Tuple must be comparable. Thus, Tuple must either exclusively consist of strings or it must only contain (integer or floating point) numbers. In the latter case integers and floating point numbers may be mixed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sort, which can be used in an expression in the following syntax:

```
Sorted := sort(Tuple)
```

Parameters

▷ **Tuple** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Sorted** (output_control) ..... tuple(-array) ⇝ *integer* / real / string
Sorted tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

tuple_sort_index, tuple_inverse

Module

Foundation

tuple_sort_index (: : Tuple : Indices)

Sort the elements of a tuple and return the indices of the sorted tuple.

tuple_sort_index sorts all elements of Tuple in ascending order and returns the indices of the elements of the sorted tuple (in relation to the input tuple Tuple) with Indices. As a precondition the single elements of Tuple must be comparable. Thus, Tuple must either exclusively consist of strings or it must only contain (integer or floating point) numbers. In the latter case integers and floating point numbers may be mixed.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sort_index, which can be used in an expression in the following syntax:

```
Indices := sort_index(Tuple)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Indices** (output_control) . . . . . integer(-array) ⇝ *integer*
Sorted tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sort, tuple_inverse

Module

Foundation

28.8 Features

get_handle_object (: Object : Handle, Key :)

Retrieve an object associated with a key from a handle.

get_handle_object retrieves an iconic object associated with the Key from Handle and returns it in Object. The list of keys supported by a handle can be queried with get_handle_param.

Note that this operator is provided only for implementing generic debug and inspection mechanisms. The keys returned for certain handle types can change without notice. Additionally, some handle types might not be supported by this operator. Also, this operator is not optimized for performance. To obtain more reliable information about a handle in a program, it is strongly recommended to use the operators specialized for the particular handle type, such as get_object_model_3d_params, get_generic_shape_model_param etc.

Parameters

▷ **Object** (output_object) . . . . . object(-array) ⇝ *object*
Iconic value of the key.

▷ **Handle** (input_control) . . . . . handle ⇝ *handle*
Handle of which to get the key.

▷ **Key** (input_control) . . . . . string ⇝ *string* / integer
Key to get.

Result

If the parameters are valid, the operator get_handle_object returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

get_handle_tuple

See also

get_handle_param

Module

Foundation

get_handle_param (: : Handle, GenParamName, Key : GenParamValue)

Return information about a handle.

get_handle_param returns details about Handle in GenParamValue. It provides a generic mechanism for inspecting and debugging handles of any type by returning keys of that handle that can later be queried using get_handle_tuple and get_handle_object.

Note that this operator is provided only for implementing generic debug and inspection mechanisms. The keys returned for certain handle types can change without notice. Additionally, some handle types might not be supported by this operator. Also, this operator is not optimized for performance. To obtain more reliable information about a handle in a program, it is strongly recommended to use the operators specialized for the particular handle type, such as get_object_model_3d_params, get_generic_shape_model_param etc.

Depending on the value of GenParamName, the following values can be queried:

'keys': Returns a list of keys that this handle supports in GenParamValue. Each key contains either a tuple or an iconic object. For this query, the parameter Key must be empty. Note that due to the generic nature of this operator, some of the returned keys might not be valid for the particular handle. In this case, get_handle_tuple or get_handle_object will return an error for those keys.

'key_data_type': Returns the data type of Key. The type is returned in GenParamValue and is either *'tuple'* or *'object'*. Depending on the type, the key's corresponding value can be queried with get_handle_tuple or get_handle_object, respectively.

Parameters

▷ **Handle** (input_control) . . . . . handle ⇝ *handle*
Handle of which to get the parameter.

▷ **GenParamName** (input_control) . . . . . string ⇝ *string*
Parameter to get.
Default: 'keys'
List of values: GenParamName ∈ {'keys', 'key_data_type'}

▷ **Key** (input_control) . . . . . string(-array) ⇝ *string*
Optional key.
Default: []

▷ **GenParamValue** (output_control) . . . . . tuple(-array) ⇝ *string* / integer / real
Returned value.

Result

If the parameters are valid, the operator get_handle_param returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

clear_handle, get_handle_tuple, get_handle_object

See also

get_handle_tuple, get_handle_object

Module

Foundation

get_handle_tuple (: : Handle, Key : Tuple)

Retrieve a tuple associated with a key from a handle.

get_handle_tuple retrieves a tuple associated with the Key from Handle and returns it in Tuple. The list of keys supported by a handle can be queried with get_handle_param.

Note that this operator is provided only for implementing generic debug and inspection mechanisms. The keys returned for certain handle types can change without notice. Additionally, some handle types might not be supported by this operator. Also, this operator is not optimized for performance. To obtain more reliable information about a handle in a program, it is strongly recommended to use the operators specialized for the particular handle type, such as get_object_model_3d_params, get_generic_shape_model_param etc.

Parameters

▷ **Handle** (input_control) . . . . . handle ⇝ *handle*
Handle of which to get the key.

▷ **Key** (input_control) . . . . . string ⇝ *string* / integer
Key to get.
Number of elements: Key == 1
Restriction: length(Key) > 0

▷ **Tuple** (output_control) . . . . . tuple(-array) ⇝ *string* / integer / real
Control value of the key.

Result

If the parameters are valid, the operator get_handle_tuple returns the value 2 (H_MSG_TRUE). If the handle is invalid or does not support the given key, or if the key references an iconic object instead of a tuple, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

get_handle_param

Alternatives

get_handle_object

See also

get_handle_param, get_handle_object

Module

Foundation

tuple_deviation (: : Tuple : Deviation)

Return the standard deviation of the elements of a tuple.

tuple_deviation calculates the standard deviation of all elements of the input tuple Tuple. It returns the deviation as a floating point number in the output parameter Deviation. The input tuple may only consist of numbers (integer or floating point numbers).

Exception: Empty input tuple

If the input tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_deviation, which can be used in an expression in the following syntax:

```
Deviation := deviation(Tuple)
```

Parameters

▷ **Tuple** (input_control) . . . . . number(-array) ⇝ *integer* / real
Input tuple.

▷ **Deviation** (output_control) . . . . . number(-array) ⇝ *real*
Standard deviation of tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_mean, tuple_sum, tuple_min, tuple_max, tuple_length, tuple_median

Module

Foundation

tuple_histo_range (: : Tuple, Min, Max, NumBins : Histo, BinSize)

Calculate the value distribution of a tuple within a certain value range.

tuple_histo_range calculates the value distribution Histo of the Tuple within the value range [Min, Max]. The values for Min and Max are rounded down to the next integer if all entries of the Tuple are of type integer. The value range is divided into NumBins bins of the same size, which is returned in BinSize. If a value lies between two bins the value is assigned to the smaller bin. If the Tuple has entries of type real $\texttt{BinSize} = \frac{\texttt{Max}-\texttt{Min}}{\texttt{NumBins}}$. If all entries are of type integer the size of a bin is computed with $\texttt{BinSize} = \frac{\texttt{Max}-\texttt{Min}+1}{\texttt{NumBins}}$.

Exception: Empty input tuples

If any of the input tuples is empty, an exception is raised.

Attention

If all the data of the Tuple are of type integer the value of BinSize may cause the following effects: For $\texttt{BinSize} > 1$ multiple consecutive numbers are assigned to the same bin. If BinSize is no integer the numbers are distributed uneven among the bins, e.g., for $\texttt{BinSize} = 1.5$ the first and second number are assigned to the first bin, the third number is assigned to the second bin, and the fourth and fifth number are assigned to the third bin. This becomes noticeable in several peeks in the histogram Histo. If $\texttt{BinSize} < 1$ some classes are not assigned by any number, e.g., for $\texttt{BinSize} = 0.5$ the first number is assigned to the first bin and the second number is assigned to the third bin. The histogram Histo shows some gaps, which resembles the structure of a comb.

If the Tuple has entries of type real and $\texttt{Min} = \texttt{Max}$, all entries of the corresponding value are assigned only to the first bin.

Parameters

▷ **Tuple** (input_control) . . . . . number-array ⇝ *real* / integer
Input tuple.

▷ **Min** (input_control) . . . . . number ⇝ *real* / integer
Minimum value.

▷ **Max** (input_control) . . . . . number ⇝ *real* / integer
Maximum value.
Restriction: Max >= Min

▷ **NumBins** (input_control) . . . . . integer ⇝ *integer*
Number of bins.
Restriction: NumBins >= 1

▷ **Histo** (output_control) . . . . . histogram(-array) ⇝ *integer*
Histogram to be calculated.

▷ **BinSize** (output_control) . . . . . real ⇝ *real*
Bin size.

Result

If the parameters are valid, the operator `tuple_histo_range` returns the value `2` (`H_MSG_TRUE`). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`create_funct_1d_array`

See also

`gray_histo`, `gray_histo_abs`, `gray_histo_range`

Module

Foundation

tuple_length (: : Tuple : Length)

Return the number of elements of a tuple.

`tuple_length` returns the number of elements of the input tuple `Tuple`.

Exception: Empty input tuple

If the input tuple is empty, the operator returns 0.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_length`, which can be used in an expression in the following syntax:

```
Length := |Tuple|
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Length** (output_control) . . . . . integer ⇝ *integer*
Number of elements of input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_min`, `tuple_max`, `tuple_mean`, `tuple_deviation`, `tuple_sum`, `tuple_median`

See also

`tuple_type`

Module

Foundation

tuple_max (: : Tuple : Max)

Return the maximal element of a tuple.

tuple_max returns the maximal element of all elements of the input tuple Tuple. All elements of Tuple either have to be strings or numbers (integer or floating point numbers). It is not allowed to mix strings with numerical values. The result parameter Max will contain a floating point number, if at least one element of Tuple is a floating point number. If all elements of Tuple are integer numbers the resulting maximum in Max will also be an integer number.

Exception: Empty input tuple

If the input tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_max, which can be used in an expression in the following syntax:

```
Max := max(Tuple)
```

Parameters

- ▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple.
- ▷ **Max** (output_control) . . . . . tuple(-array) ⇝ *real* / integer / string
  Maximal element of the input tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_min, tuple_mean, tuple_deviation, tuple_sum, tuple_length, tuple_median

See also

tuple_max2, tuple_min2

Module

Foundation

tuple_mean (: : Tuple : Mean)

Return the mean value of a tuple of numbers.

tuple_mean returns the mean value of all elements of the input tuple Tuple as a floating point number in the output parameter Mean. The input tuple may only consist of numbers (integer or floating point numbers).

Exception: Empty input tuple

If the input tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_mean, which can be used in an expression in the following syntax:

```
Mean := mean(Tuple)
```

Parameters

- ▷ **Tuple** (input_control) . . . . . number(-array) ⇝ *integer* / real
  Input tuple.
- ▷ **Mean** (output_control) . . . . . number ⇝ *real*
  Mean value of tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_deviation, tuple_sum, tuple_min, tuple_max, tuple_length, tuple_median

Module

Foundation

tuple_median (: : Tuple : Median)

Return the median of the elements of a tuple.

tuple_median calculates the median of all elements of the input tuple Tuple and returns it in the output parameter Median. The input tuple may only consist of numbers (integer or floating point numbers). The median is defined as the element with rank n/2 (see tuple_select_rank).

Note that for an even number of input elements, this will return the upper median, not the arithmetic median. To calculate the arithmetic median, you can use tuple_select_rank to select the upper and lower median values and then calculate the arithmetic mean of both values.

Exception: Empty input tuple

If the input tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_median, which can be used in an expression in the following syntax:

```
Median := median(Tuple)
```

Parameters

▷ **Tuple** (input_control) ..... number(-array) ⇝ *integer* / real
Input tuple.

▷ **Median** (output_control) ..... number ⇝ *integer* / real
Median of the tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_select_rank

See also

tuple_mean, tuple_min, tuple_max

Module

Foundation

tuple_min (: : Tuple : Min)

Return the minimal element of a tuple.

tuple_min returns the minimal element of all elements of the input tuple Tuple. All elements of Tuple either have to be strings or numbers (integer or floating point numbers). It is not allowed to mix strings with numerical

values. The result parameter Min will contain a floating point number, if at least one element of Tuple is a floating point number. If all elements of Tuple are integer numbers the resulting minimum in Min will also be an integer number.

Exception: Empty input tuple

If the input tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_min, which can be used in an expression in the following syntax:

```
Min := min(Tuple)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Min** (output_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Minimal element of the input tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_max, tuple_mean, tuple_deviation, tuple_sum, tuple_length, tuple_median

See also

tuple_max2, tuple_min2

Module

Foundation

tuple_sum (: : Tuple : Sum)

Return the sum of all elements of a tuple.

tuple_sum returns the sum of all elements of the input tuple Tuple. All elements of Tuple either have to be strings or numbers (integer or floating point numbers). It is not allowed to mix strings with numerical values. The result parameter Sum will contain a floating point number, if at least one element of Tuple is a floating point number. If all elements of Tuple are integer numbers the resulting sum will also be an integer number. If Tuple contains strings, the concatenation will be used for building the sum.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sum, which can be used in an expression in the following syntax:

```
Sum := sum(Tuple)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Sum** (output_control) . . . . . tuple(-array) ⇝ *real* / integer / string
Sum of tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_mean, tuple_deviation, tuple_min, tuple_max, tuple_length, tuple_median

tuple_cumul

Module

Foundation

28.9 Logical Operations

tuple_and (: : T1, T2 : And)

Compute the logical and of two tuples.

tuple_and computes the logical and of the input tuples T1 and T2. If both tuples have the same length the operation is performed on the corresponding elements of both tuples. Otherwise, either T1 or T2 must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuples

If any of the input tuples is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_and, which can be used in an expression in the following syntax:

```
And := T1 and T2
```

Parameters

▷ **T1** (input_control) ..... integer(-array) ⇝ *integer*
Input tuple 1.

▷ **T2** (input_control) ..... integer(-array) ⇝ *integer*
Input tuple 2.

▷ **And** (output_control) ..... integer(-array) ⇝ *integer*
Logical and of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_or, tuple_xor, tuple_not

See also

tuple_band, tuple_bor, tuple_bxor, tuple_bnot

Module

Foundation

tuple_not (: : T : Not)

Compute the logical not of a tuple.

tuple_not computes the logical not of the input tuple T. The input tuple must contain only integer numbers.

Exception: Empty input tuple

If the input tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_not`, which can be used in an expression in the following syntax:

```
Not := not T1
```

Parameters

▷ **T** (input_control) . . . integer(-array) ⇝ *integer*
Input tuple.

▷ **Not** (output_control) . . . integer(-array) ⇝ *integer*
Binary not of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_and`, `tuple_or`, `tuple_xor`

See also

`tuple_band`, `tuple_bor`, `tuple_bxor`, `tuple_bnot`

Module

Foundation

tuple_or (: : T1, T2 : Or)

Compute the logical or of two tuples.

`tuple_or` computes the logical or of the input tuples `T1` and `T2`. If both tuples have the same length the operation is performed on the corresponding elements of both tuples. Otherwise, either `T1` or `T2` must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuples

If any of the input tuples is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_or`, which can be used in an expression in the following syntax:

```
Or := T1 or T2
```

Parameters

▷ **T1** (input_control) . . . integer(-array) ⇝ *integer*
Input tuple 1.

▷ **T2** (input_control) . . . integer(-array) ⇝ *integer*
Input tuple 2.

▷ **Or** (output_control) . . . integer(-array) ⇝ *integer*
Logical or of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Alternatives

tuple_and, tuple_xor, tuple_not

See also

tuple_band, tuple_bor, tuple_bxor, tuple_bnot

Module

Foundation

tuple_xor (: : T1, T2 : Xor)

Compute the logical exclusive or of two tuples.

tuple_xor computes the logical exclusive or of the input tuples T1 and T2. If both tuples have the same length the operation is performed on the corresponding elements of both tuples. Otherwise, either T1 or T2 must have length 1. In this case, the operation is performed for each element of the longer tuple with the single element of the other tuple. The input tuples must contain only integer numbers.

Exception: Empty input tuples

If any of the input tuples is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_xor, which can be used in an expression in the following syntax:

```
Xor := T1 xor T2
```

Parameters

▷ **T1** (input_control) ..... integer(-array) ⇝ *integer*
Input tuple 1.

▷ **T2** (input_control) ..... integer(-array) ⇝ *integer*
Input tuple 2.

▷ **Xor** (output_control) ..... integer(-array) ⇝ *integer*
Binary exclusive or of the input tuples.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_and, tuple_or, tuple_not

tuple_band, tuple_bor, tuple_bxor, tuple_bnot

Module

Foundation

28.10 Manipulation

tuple_insert (: : Tuple, Index, InsertTuple : Extended)

Inserts one or more elements into a tuple at index.

tuple_insert inserts the elements of the tuple InsertTuple at index into the tuple Tuple and returns them in the tuple Extended. In this context Index determines the start index of the elements and InsertTuple

the values to insert. Successive values of Tuple will be positioned after the inserted values of InsertTuple. The parameter Index must contain a single integer value (any floating point number must represent an integer value without fraction). Indices of tuple elements start at 0. Therefore, the first tuple element has got the index 0. If Index contains the length of Tuple as index, InsertTuple will be appended. The length of the result tuple Extended is always the sum of the two input tuples Tuple and InsertTuple. For example, if Tuple contains the values [0,1,0,1,0,1], the Index contains the value [3] and the InsertTuple contains the values [2,2,2], then the output tuple Extended will contain the values [0,1,0,2,2,2,1,0,1]. It is allowed to mix strings and numbers in the input tuples Tuple and InsertTuple.

Exception: Empty input tuples

If any of the input tuples is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_insert, which can be used in an expression in the following syntax:

```
Extended := insert(Tuple, Index, InsertTuple)
```

Parameters

- ▷ **Tuple** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple.
- ▷ **Index** (input_control) ..... integer ⇝ *integer*
  Start index of elements to be inserted.
- ▷ **InsertTuple** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Element(s) to insert at index.
- ▷ **Extended** (output_control) ..... tuple-array ⇝ *integer* / real / string
  Tuple with inserted elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_concat, tuple_replace, tuple_gen_const

See also

tuple_remove

Module

Foundation

tuple_remove (: : Tuple, Index : Reduced)

Remove elements from a tuple.

tuple_remove removes one or more elements from the tuple Tuple and returns the rest in the tuple Reduced. Index determines the indices of the elements to remove. Thus, Index may only contain integer values (any floating point number within Index must represent an integer value without fraction). Note that indices of tuple elements start at 0, i.e. the first tuple element has got the index 0. Duplicates and indices out of range are ignored.

Exception: Empty input tuple

If Tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_remove, which can be used in an expression in the following syntax:

```
Reduced := remove(Tuple, Index)
```

Parameters

- ▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple.
- ▷ **Index** (input_control) . . . . . integer(-array) ⇝ *integer*
  Indices of the elements to remove.
- ▷ **Reduced** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Reduced tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_first_n, tuple_last_n, tuple_str_bit_select, tuple_concat, tuple_insert, tuple_replace

See also

tuple_select, tuple_select_mask

Module

Foundation

tuple_replace (: : Tuple, Index, ReplaceTuple : Replaced)

Replaces one or more elements of a tuple.

tuple_replace replaces one or more elements of the input tuple Tuple and returns them with Replaced. At this, Index determines the indices of the elements and ReplaceTuple the corresponding values to replace. The parameter Index must contain one or more integer values (any floating point number must represent an integer value without fraction). Indices of tuple elements start at 0. Therefore, the first tuple element has got the index 0. If ReplaceTuple contains only one value, this value will be replaced at all indices of Index. If a value of Index is greater than the length of the input tuple Tuple, Replaced will be extended accordingly and initialized with zeros. For example, if Tuple contains [1], Index contains the values [2,4], and ReplaceTuple contains the values [3,5], Replaced will be [1,0,3,0,5].

It is allowed to mix strings and numbers in the input tuples Tuple and ReplaceTuple.

Exception: Empty input tuples

If either Index or ReplaceTuple is empty and the other is not, an exception is raised. If both are empty, the output tuple Replaced corresponds to the input Tuple. If both are empty, but the input Tuple is not, the empty tuple will be extended as described above.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_replace, which can be used in an expression in the following syntax:

```
Replaced := replace(Tuple, Index, ReplaceTuple)
```

Parameters

- ▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Input tuple.
- ▷ **Index** (input_control) . . . . . integer(-array) ⇝ *integer*
  Index/Indices of elements to be replaced.
- ▷ **ReplaceTuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
  Element(s) to replace.
- ▷ **Replaced** (output_control) . . . . . tuple-array ⇝ *integer* / real / string
  Tuple with replaced elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_select, tuple_first_n, tuple_last_n, tuple_select_mask, tuple_str_bit_select, tuple_concat, tuple_select_rank

See also

tuple_remove, tuple_insert

Module

Foundation

28.11 Selection

tuple_find (: : Tuple, ToFind : Indices)

Return the indices of all occurrences of a tuple within another tuple.

tuple_find searches Tuple sequentially for all occurrences of the values of the second tuple ToFind and returns the indices in Indices (in relation to the first input tuple Tuple). For example, if Tuple contains the values [3,4,5,6,1,2,3,4,0] and ToFind contains the values [3,4], the output tuple Indices will contain the values [0,6]. If the first tuple does not contain the second tuple as a subtuple, tuple_find returns -1 in Indices. It is allowed to mix strings and numbers in the input tuples.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_find, which can be used in an expression in the following syntax:

```
Indices := find(Tuple, ToFind)
```

Parameters

▷ **Tuple** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
Input tuple to examine.

▷ **ToFind** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
Input tuple with values to find.

▷ **Indices** (output_control) ..... integer(-array) ⇝ *integer*
Indices of the occurrences of the values to find in the tuple to examine.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_find_first, tuple_find_last, tuple_sort, tuple_inverse, tuple_equal_elem

Module

Foundation

tuple_find_first (: : Tuple, ToFind : Index)

Return the index of the first occurrence of a tuple within another tuple.

tuple_find_first searches forward through Tuple for the first occurrence of the values of the second tuple ToFind and returns the Index (in relation to the first input tuple Tuple). For example, if Tuple contains the values [3,4,5,6,1,2,3,4,0] and ToFind contains the values [3,4], the output Index is 0. If the first tuple does not contain the second tuple as a subtuple, tuple_find_first returns -1 in Index. It is allowed to mix strings and numbers in the input tuples.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_find_first, which can be used in an expression in the following syntax:

```
Index := find_first(Tuple, ToFind)
```

Parameters

- ▷ **Tuple** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple to examine.
- ▷ **ToFind** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple with values to find.
- ▷ **Index** (output_control) ..... integer ⇝ *integer*
  Index of the first occurrence of the values to find.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_find, tuple_find_last, tuple_sort, tuple_equal_elem

Module

Foundation

tuple_find_last (: : Tuple, ToFind : Index)

Return the index of the last occurrence of a tuple within another tuple.

tuple_find_last searches backward through Tuple for the first occurrence of the values of the second tuple ToFind and returns the Index (in relation to the first input tuple Tuple). For example, if Tuple contains the values [3,4,5,6,1,2,3,4,0] and ToFind contains the values [3,4], the output Index is 6. If the first tuple does not contain the second tuple as a subtuple, tuple_find_last returns -1 in Index. It is allowed to mix strings and numbers in the input tuples.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_find_last, which can be used in an expression in the following syntax:

```
Index := find_last(Tuple, ToFind)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple to examine.
▷ **ToFind** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple with values to find.
▷ **Index** (output_control) . . . . . integer ⇝ *integer*
Index of the last occurrence of the values to find.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_find, tuple_find_first, tuple_sort, tuple_equal_elem

Module

Foundation

tuple_first_n (: : Tuple, Index : Selected)

Select the first elements of a tuple up to the index "n".

tuple_first_n selects the first elements of Tuple up to the index Index and returns them in Selected. Indices of tuple elements start at 0, that means, the first tuple element has got the index 0. In total, Index+1 elements are returned.

Index must contain a single integer value (or a floating point number that represents an integer value without fraction).

Exception: Empty input tuple

If Tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_first_n, which can be used in an expression in the following syntax:

```
Selected := firstn(Tuple, Index)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.
▷ **Index** (input_control) . . . . . integer ⇝ *integer*
Index of the last element to select.
▷ **Selected** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Selected tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_last_n, tuple_select, tuple_str_bit_select, tuple_concat, tuple_select_mask

See also

tuple_remove

Module

Foundation

tuple_last_n (: : Tuple, Index : Selected)

Select all elements from index "n" to the end of a tuple.

Starting with the "n-th" element of the tuple Tuple, tuple_last_n selects every element of Tuple and returns it with Selected. Thus, Selected contains all elements of Tuple from index "n" up to the last element of Tuple (including the element at position "n"). The index "n" is determined by the input parameter Index. Thus, Index must contain a single integer value (if Index consists of a floating point number, this must represent an integer value without fraction). Indices of tuple elements start at 0, that means, the first tuple element has got the index 0.

Exception: Empty input tuple

If Tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_last_n, which can be used in an expression in the following syntax:

```
Selected := lastn(Tuple, Index)
```

Parameters

- ▷ **Tuple** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple.
- ▷ **Index** (input_control) ..... integer ⇝ *integer*
  Index of the first element to select.
- ▷ **Selected** (output_control) ..... tuple(-array) ⇝ *integer* / real / string
  Selected tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_first_n, tuple_select, tuple_str_bit_select, tuple_concat, tuple_select_mask

See also

tuple_remove

Module

Foundation

tuple_select (: : Tuple, Index : Selected)

Select single elements of a tuple.

tuple_select selects one or more single elements of the tuple Tuple and returns them with Selected. At this, Index determines the indices of the elements to select. Thus, Index may only contain integer values (any floating point number within Index must represent an integer value without fraction). Indices of tuple elements start at 0, that means, the first tuple element has got the index 0.

Exception: Empty input tuples

If Tuple is empty, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_select, which can be used in an expression in the following syntax:

```
Selected := Tuple[Index]
```

```
Selected := subset(Tuple, Index)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Index** (input_control) . . . . . integer(-array) ⇝ *integer*
Indices of the elements to select.

▷ **Selected** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Selected tuple element.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_first_n, tuple_last_n, tuple_str_bit_select, tuple_concat, tuple_select_range, tuple_select_rank

See also

tuple_remove

Module

Foundation

tuple_select_mask (: : Tuple, Mask : Selected)

Select in mask specified elements of a tuple.

tuple_select_mask selects one or more single elements of the tuple Tuple and returns them with Selected. For every element Mask determines the corresponding element to select. If the value is greater than 0, the appropriate element is selected. Thus the length of the two input tuples has to be equal and Mask may only contain integer or float values.

Exception: Empty input tuples

If both input tuples are empty, the operator returns an empty tuple. If only one of the input tuples is empty and the other is not, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_select_mask, which can be used in an expression in the following syntax:

```
Selected := select_mask(Tuple, Mask)
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Mask** (input_control) . . . . . integer(-array) ⇝ *integer*
> 0 specifies the elements to select.

▷ **Selected** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Selected tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_first_n, tuple_last_n, tuple_str_bit_select, tuple_concat, tuple_select, tuple_select_range, tuple_select_rank

See also

tuple_remove

Module

Foundation

tuple_select_range (: : Tuple, Leftindex, Rightindex : Selected)

Select several elements of a tuple.

tuple_select_range selects several consecutive elements of the input tuple Tuple and returns them with Selected. At this, Leftindex determines the index of the first element and Rightindex determines the index of the last element to select. Thus, both parameters Leftindex and Rightindex must contain a single integer value (any floating point number must represent an integer value without fraction). Indices of tuple elements start at 0, that means, the first tuple element has got the index 0. The result tuple Selected contains every element from the tuple Tuple that has got an index between Leftindex and Rightindex (including the elements at position Leftindex and Rightindex). If the indices are equal, only one element is selected. In addition, it is possible that the right index is Leftindex - 1. In this case and if the left or right index are valid an empty tuple is returned. Hence, the index Rightindex must be greater or equal to Leftindex - 1.

Exception: Empty input tuples

If Leftindex and Rightindex are empty tuples, the operator returns an empty tuple. If only one of those parameters or Tuple is an empty tuple, an exception is raised.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_select_range, which can be used in an expression in the following syntax:

```
Selected := Tuple[Leftindex:Rightindex]
```

Parameters

- ▷ **Tuple** (input_control) ..... tuple(-array) ⇝ *integer* / real / string
  Input tuple.
- ▷ **Leftindex** (input_control) ..... integer(-array) ⇝ *integer*
  Index of first element to select.
- ▷ **Rightindex** (input_control) ..... integer(-array) ⇝ *integer*
  Index of last element to select.
- ▷ **Selected** (output_control) ..... tuple(-array) ⇝ *integer* / real / string
  Selected tuple elements.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_select, tuple_first_n, tuple_last_n, tuple_select_mask, tuple_str_bit_select, tuple_concat, tuple_select_rank

See also

tuple_remove

Module

Foundation

tuple_select_rank (: : Tuple, RankIndex : Selected)

Select the element of rank n of a tuple.

tuple_select_rank sorts the elements of the tuple Tuple and returns the element of rank n in Selected. RankIndex determines the index of the element to select. Thus, RankIndex may only contain integer values (any floating point number in RankIndex must represent an integer value without fraction). Indices of tuple elements start at 0, i.e. the lowest tuple element has the index 0.

Exception: Empty input tuples

If RankIndex is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_select_rank, which can be used in an expression in the following syntax:

```
Selected := select_rank(Tuple, RankIndex)
```

Parameters

▷ **Tuple** (input_control) ..... number(-array) ⇝ *integer* / real
Input tuple.

▷ **RankIndex** (input_control) ..... number ⇝ *integer* / real
Rank of the element to select.

▷ **Selected** (output_control) ..... number ⇝ *integer* / real
Selected tuple element.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_sort_index, tuple_sort

See also

tuple_median, tuple_select

Module

Foundation

tuple_str_bit_select (: : Tuple, Index : Selected)

Select single character or bit from a tuple.

tuple_str_bit_select selects a single character or bit from a tuple Tuple of integer numbers and/or strings. The input parameter Index determines the character or bit position to select. Index must contain a single number. If Index contains a floating point number, this may only represent an integer value (without fraction). The result tuple Selected contains a new element for each element of Tuple. Let Index contain the number "n" then each element of Selected consists of the "n-th" character (for strings) or "n-th" bit (for integers) of the corresponding element of Tuple.

If Tuple is empty, an exception is raised.

Unicode code points versus bytes

The index reference Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the index should reference the raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_str_bit_select`, which can be used in an expression in the following syntax:

```
Selected := Tuple{Index}
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *string* / integer
Input tuple.

▷ **Index** (input_control) . . . . . integer ⇝ *integer*
Position of character or bit to select.

▷ **Selected** (output_control) . . . . . tuple(-array) ⇝ *string* / integer
Tuple containing the selected characters and bits.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_select`, `tuple_first_n`, `tuple_last_n`, `tuple_concat`, `tuple_strchr`, `tuple_strrchr`, `tuple_str_first_n`, `tuple_str_last_n`, `tuple_substr`, `tuple_and`, `tuple_or`, `tuple_xor`, `tuple_not`

See also

`tuple_remove`

Module

Foundation

tuple_uniq (: : Tuple : Uniq)

Discard all but one of successive identical elements of a tuple.

`tuple_uniq` discards all but one of successive identical elements from the input tuple `Tuple` and returns the remaining elements in `Uniq`. For example, if `Tuple` contains the values [0,0,1,1,1,2,0,1], the output tuple `Uniq` will contain the values [0,1,2,0,1]. It is allowed to mix strings and numbers in the input tuple.

To get a tuple `Uniq` that contains all different entries of `Tuple` exactly once, use the operator `tuple_sort` first. Note however that in this case the output tuple `Uniq` is sorted. The result of the above example then is [0,1,2].

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_uniq`, which can be used in an expression in the following syntax:

```
Uniq := uniq(Tuple)
```

As mentioned above, you can use `tuple_sort` to truly get all unique elements of `Tuple`.

```
Uniq := uniq(sort(Tuple))
```

Parameters

▷ **Tuple** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Input tuple.

▷ **Uniq** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string
Tuple without successive identical elements.

Example

```
Tuple := [0,0,1,1,1,2,0,1]
*
tuple_uniq (Tuple, Uniq)
*
tuple_sort (Uniq, Sorted)
tuple_uniq (Sorted, Uniq1)
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

tuple_inverse, tuple_sort

Alternatives

tuple_intersection

Module

Foundation

28.12 Sets

tuple_difference (: : Set1, Set2 : Difference)

Compute the difference set of two input tuples.

tuple_difference returns the difference set from Set1 and Set2 in Difference. For example, if Set1 contains the values [0,1,3,3,5] and Set2 contains the values [2,3,5,10], the output Difference is [0,1]. The operator also allows mixed types of elements in the input tuples. However, the elements with different types will be considered as different elements, i.e. 1.0 and 1 are different. Also, this means, if Set1 and Set2 have different types of elements, their difference set could be Set1 itself. For example, if Set1 contains the values [2,5,3] and Set2 contains the values [2.0,5.0,3.0], the output Difference is [2,3,5]. Please note that the order of tuple elements resulting from tuple_difference does not necessarily conform to the order in the input tuple.

Exception: Empty input tuples

If both input tuples are empty, the operator returns an empty tuple. If Set1 is empty and Set2 is not, the operator returns an empty tuple as well. If Set2 is empty and Set1 is not, the output corresponds to Set1.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_difference, which can be used in an expression in the following syntax:

```
Difference := difference(Set1, Set2)
```

Parameters

▷ **Set1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **Set2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **Difference** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
The difference set of two input tuples.

Result

If the parameters are valid, the operator tuple_difference returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

tuple_symmdiff

See also

tuple_intersection, tuple_symmdiff, tuple_union

Module

Foundation

tuple_intersection (: : Set1, Set2 : Intersection)

Compute the intersection set of two input tuples.

tuple_intersection returns the intersection set from Set1 and Set2 in Intersection. For example, if Set1 contains the values [0,1,3,3,5] and Set2 contains the values [2,3,5,10], the output Intersection is [3,5]. The operator also allows mixed types of elements in the input tuples. However, the elements with different types will be considered as different elements, i.e. 1.0 and 1 are different. Also, this means, if Set1 and Set2 have different types of elements, their intersection set could be empty. For example, if Set1 contains the values [2,5,3] and Set2 contains the values [2.0,5.0,0,10], the output Intersection is empty. Please note that the order of tuple elements resulting from tuple_intersection does not necessarily conform to the order in the input tuple.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_intersection, which can be used in an expression in the following syntax:

```
Intersection := intersection(Set1, Set2)
```

Parameters

▷ **Set1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **Set2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **Intersection** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
The intersection set of two input tuples.

Result

If the parameters are valid, the operator tuple_intersection returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

tuple_union

See also

tuple_difference, tuple_symmdiff, tuple_union

Module

Foundation

tuple_symmdiff (: : Set1, Set2 : SymmDiff)

Compute the symmetric difference set of two input tuples.

tuple_symmdiff returns the symmetric difference set from Set1 and Set2 in SymmDiff. For example, if Set1 contains the values [0,1,3,3,5] and Set2 contains the values [2,3,5,10], the output SymmDiff is [0,1,2,10]. The operator also allows mixed types of elements in the input tuples. However, the elements with different types will be considered as different elements, i.e. 1.0 and 1 are different. Also, this means, if Set1 and Set2 have different types of elements, their symmetric difference set could be the union. For example, if Set1 contains the values [2,5,3] and Set2 contains the values [2.0,5.0], the output SymmDiff is [2,3,5,2.0,5.0]. Please note that the order of tuple elements resulting from tuple_symmdiff does not necessarily conform to the order in the input tuple.

Exception: Empty input tuples

If both of the input tuples are empty, the operator returns an empty tuple. If one of the input tuples is empty and the other is not, the output corresponds to the input tuple that is not empty.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_symmdiff, which can be used in an expression in the following syntax:

```
SymmDiff := symmdiff(Set1, Set2)
```

Parameters

- ▷ **Set1** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
  Input tuple.
- ▷ **Set2** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
  Input tuple.
- ▷ **SymmDiff** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
  The symmetric difference set of two input tuples.

Result

If the parameters are valid, the operator tuple_symmdiff returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

tuple_difference

See also

tuple_difference, tuple_intersection, tuple_union

Module

Foundation

tuple_union (: : Set1, Set2 : Union)

Compute the union set of two input tuples.

tuple_union returns the union set from Set1 and Set2 in Union. For example, if Set1 contains the values [0,1,3,3,5] and Set2 contains the values [3,4], the output Union is [0,1,3,4,5]. The operator also allows mixed types of elements in the input tuples. However, the elements with different types will be considered as different elements, i.e. 1.0 and 1 are different. For example, the union of [2,5,3] and [4.0,5.0] is [2,3,5,4.0,5.0]. Please note that the order of tuple elements resulting from tuple_union does not necessarily conform to the order in the input tuple.

Exception: Empty input tuples

If both of the input tuples are empty, the operator returns an empty tuple. If one of the input tuples is empty and the other is not, the output corresponds to the input tuple that is not empty.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_union`, which can be used in an expression in the following syntax:

```
Union := union(Set1, Set2)
```

Parameters

▷ **`Set1`** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **`Set2`** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **`Union`** (output_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
The union set of two input tuples.

Result

If the parameters are valid, the operator `tuple_union` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on internal data level.

Alternatives

`tuple_intersection`

28.13 String Operations

This chapter contains operators for string operations.

General Information

The HALCON library encodes strings in UTF-8 by default.

UTF-8 is a Unicode character encoding that can encode all Unicode code points with one to four bytes. 'Unicode' refers to the character set that assigns each character of a string to a code point (for example, 'U + 0041' for 'A'). UTF-8 then translates the Unicode code points into binary data. The memory requirement for all ASCII characters is usually 1 byte. Certain characters, such as German umlauts, or Greek and Cyrillic characters require 2 bytes. Asian characters occupy up to 4 bytes per character.

By default, the HALCON string operators work on the basis of Unicode code points. That is, accessing a character of a string always returns the corresponding Unicode code point of the character, regardless of how many bytes are needed to represent the code point in UTF-8. Thus, multi-byte characters, such as Asian characters or German umlauts can be uniformly translated on all systems. Please note that the Unicode standard also allows you to assemble printable characters from multiple code points (using so-called 'Combining Diacritical Marks'). This is currently not fully supported by HALCON: in HALCON, the code points are processed separately, and when strings are compared, equivalent characters are not set equal if coded with different code points.

If there are compatibility problems during execution of older programs, the string encoding of the HALCON library can be changed from *'utf8'* to *'locale'* (legacy mode). Then strings are stored depending on the locale and the string operators work – as in previous versions of HALCON – not characterwise but bytewise. If bytewise character processing is also required in UTF-8 mode, the operator `set_system` can be used to set the option *'tuple_string_operator_mode'* from *'codepoint'* to *'byte'*. Afterwards, the string operators no longer work on the basis of code points. The byte sequence of a string can be interesting for debugging, for example.

tuple_environment (: : Names : Values)

Read one or more environment variables.

tuple_environment reads the content of all environment variables that are referenced by their names in the input tuple Names and returns the content with the output tuple Values. The input tuple may only contain strings.

For general information about string operations see Tuple / String Operations.

Exception: Empty input tuples

If the input tuple is empty, the operator returns an empty tuple. Additionally, an empty string is returned for every name within Names that does not denote a valid environment variable.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_environment, which can be used in an expression in the following syntax:

```
Values := environment(Names)
```

Parameters

▷ **Names** (input_control) ..... string(-array) ⇝ *string*
Tuple containing name(s) of the environment variable(s).

▷ **Values** (output_control) ..... string(-array) ⇝ *string*
Content of the environment variable(s).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_strstr, tuple_strrstr, tuple_strchr, tuple_strrchr, tuple_strlen, tuple_str_first_n, tuple_str_last_n, tuple_split, tuple_substr

Module

Foundation

tuple_join (: : Strings, Separators : JoinedStrings)

Join strings using separator symbol(s).

tuple_join joins the strings of the input tuple Strings interleaved with the separators defined in the input tuple Separators and returns the result in the tuple JoinedStrings.

For each string element in Separators, there is one corresponding element in JoinedStrings which holds the elements of Strings joined by this separator. Thereby an empty string in Separators corresponds to simple string concatenation.

Example: Strings = *['aaa', 'bbb', 'ccc', 'ddd']* and Separators = *['++', '–', '']*. In this case the operator returns the tuple JoinedStrings = *['aaa++bbb++ccc++ddd', 'aaa–bbb–ccc–ddd', 'aaabbbcccddd']*.

Both input tuples (Strings and Separators) may only consist of strings. Otherwise tuple_join returns an error.

Exception: Empty input tuples

If either or both of the input tuples are empty, the operator returns an empty tuple.

Unicode code points versus bytes

A separator always consists of the entire string. This is true regardless of the system setting of *'tsp_tuple_string_operator_mode'*.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_join`, which can be used in an expression in the following syntax:

```
JoinedStrings := join(Strings, Separators)
```

Parameters

▷ **`Strings`** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with strings to join.

▷ **`Separators`** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with separator symbol(s).

▷ **`JoinedStrings`** (output_control) . . . . . string(-array) ⇝ *string*
Output tuple with the contained strings.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Successors

`tuple_split`

Alternatives

`tuple_strstr`, `tuple_strrstr`, `tuple_strchr`, `tuple_strrchr`, `tuple_strlen`, `tuple_str_first_n`, `tuple_str_last_n`, `tuple_environment`

Module

Foundation

`tuple_regexp_match` (: : Data, Expression : Matches)

Extract substrings using regular expressions.

`tuple_regexp_match` applies the regular expression in `Expression` to one or more input strings in `Data`, and in each case returns the first matching substring in `Matches`. Normally, one output string is returned for each input string, the output string being empty if no match was found. However, if the regular expression contains capturing groups (see below), the behavior depends on the number of input strings: If there is only a single input string, the result is a tuple of all captured submatches. If there are multiple input strings, the output strings represent the matched pattern of the first capturing group.

A summary of regular expression syntax is provided here. Basically, each character in the regular expression represents a literal to match, except for the following symbols which have a special meaning (the described syntax is compatible with Perl):

^	Matches start of string
$	Matches end of string (a trailing newline is allowed)
.	Matches any character except newline
[...]	Matches any character literal listed in the brackets. If the first character is a '^', this matches any character except those in the list. You can use the '-' character as in [A-Z0-9] to select character ranges. Other characters lose their special meaning in brackets, except '\'. Within these brackets it is possible to use the following POSIX character classes (note that the additional brackets are needed): [:alnum:] alphabetic and numeric characters [:alpha:] alphabetic characters [:blank:] space and tab [:cntrl:] control characters [:digit:] digits [:graph:] non-blank (like spaces or control characters) [:lower:] lowercase alphabetic characters [:print:] like [:graph:] but including spaces [:punct:] punctuation characters [:space:] all whitespace characters ([:blank:], newline, ...) [:upper:] uppercase alphabetic characters [:xdigit:] digits allowed in hexadecimal numbers (0-9a-fA-F).
*	Allows 0 or more repetitions of preceding literal or group
+	Allows 1 or more repetitions of preceding literal or group
?	Allows 0 or 1 repetitions of preceding literal or group
{n,m}	Allows n to m repetitions of preceding literal or group
{n}	Allows exactly n repetitions of preceding literal or group
|	Separates alternative matching expressions
()	Groups a subpattern and creates a capturing group. The substrings captured by this group will be stored separately. (?:) Groups a subpattern without creating a capturing group (?=) Positive lookahead (requested condition right to the match) (?!) Negative lookahead (forbidden condition right to the match) (?<=) Positive lookbehind (requested condition left to the match) (?<!) Negative lookbehind (forbidden condition left to the match)
\	Escapes any special symbol to treat it as a literal. *Attention:* Some host languages like HDevelop and C/C++ already use the backslash as a general escape character. In this case, '\.' matches a literal dot while '\\' matches a literal backslash. Furthermore, there are some special codes: \d Matches a digit (Negation: \D) \w Matches a letter, digit or underscore (Negation: \W) \s Matches a white space character (Negation: \S) \b Matches a word boundary (Negation: \B)

The repeat quantifiers listed in the table above are greedy by default, i.e., they attempt to maximize the length of the match. Appending '?' attempts to find a minimal match, e.g., '+?'.

If the specified expression is syntactically incorrect, you will receive an error stating that the value of control parameter 2 is wrong. Additional details are displayed in a message box if set_system('do_low_error', 'true') is set and in HDevelop's Output Console.

Furthermore, you can set some options by passing a string tuple for Expression. In this case, the first element is used as the expression, and each additional element is treated as an option.

- *'ignore_case'*: Perform case-insensitive matching
- *'multiline'*: '^' and '$' match start and end of individual lines
- *'dot_matches_all'*: Allow the '.' character to also match newlines
- *'newline_lf'*, *'newline_crlf'*, *'newline_cr'*: Specify the encoding of newlines in the input data. The default is LF on all systems (even though in Windows files usually CRLF is used as line break, when reading a file into memory the read operators return for every line break just '\n', which is the same as LF).

For general information about string operations see Tuple / String Operations.

If the input parameter `Data` is an empty tuple, the operator returns an empty tuple. If `Expression` is an empty tuple, an exception is raised.

Unicode code points versus bytes

Regular expression matching operates on Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If regular expression matching should only match on bytes, this operator can be switched to byte mode with `set_system('tsp_tuple_string_operator_mode','byte')`. If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_regexp_match`, which can be used in an expression in the following syntax:

```
Matches := regexp_match(Data, Expression)
```

Parameters

- ▷ **`Data`** (input_control) ..... string(-array) ⇝ *string*
  Input strings to match.
- ▷ **`Expression`** (input_control) ..... string(-array) ⇝ *string*
  Regular expression.
  Default: '.*'
  Suggested values: `Expression` ∈ {'.*', 'ignore_case', 'multiline', 'dot_matches_all', 'newline_lf', 'newline_crlf', 'newline_cr'}
- ▷ **`Matches`** (output_control) ..... string(-array) ⇝ *string*
  Found matches.

Example

```
tuple_regexp_match ('abba', 'a*b*', Result)
* Returns 'abb'

tuple_regexp_match ('abba', 'b*a*', Result)
* Returns 'a'

tuple_regexp_match ('abba', 'b+a*', Result)
* Returns 'bba'

tuple_regexp_match ('abba', '.a', Result)
* Returns 'ba'

tuple_regexp_match ('abba', '[ab]*', Result)
* Returns 'abba'

tuple_regexp_match (['img123','img124'], 'img(.*)', Result)
* Returns ['123','124']

tuple_regexp_match ('mydir/img001.bmp', 'img(.*)\\.(.*)', Result)
* Returns ['001','bmp']
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_strstr`

tuple_regexp_replace, tuple_regexp_test, tuple_regexp_select

References

Perl Compatible Regular Expressions (PCRE), http://www.pcre.org/

Module

Foundation

tuple_regexp_replace (: : Data, Expression, Replace : Result)

Replace a substring using regular expressions.

tuple_regexp_replace applies the regular expression in Expression to one or more input strings in Data, and replaces the **first** matching substring using the Replace expression. For each input string, a processed output string is returned in Result.

Please refer to the documentation of tuple_regexp_match for syntax and options of regular expressions. Additionally, tuple_regexp_replace supports the option *'replace_all'*, which causes **all** matches within each individual string to be replaced.

The Replace expression may use the tag *'$0'* to refer to the matched substring in the input data, *'$i'* to refer to the submatch of the i-th capturing group (for $i <= 9$), and *'$$'* to refer to the *'$'* literal.

For general information about string operations see Tuple / String Operations.

If Data is an empty tuple, the operator returns an empty tuple. If Replace is an empty tuple and Data is not empty, an exception is raised.

Unicode code points versus bytes

Regular expression matching operates on Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If regular expression matching should only match on bytes, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_regexp_replace, which can be used in an expression in the following syntax:

```
Result := regexp_replace(Data, Expression, Replace)
```

Parameters

- ▷ **Data** (input_control) ..... string(-array) ⇝ *string*
  Input strings to process.
- ▷ **Expression** (input_control) ..... string(-array) ⇝ *string*
  Regular expression.
  Default: '.*'
  Suggested values: Expression ∈ {'.*', 'replace_all', 'ignore_case', 'multiline', 'dot_matches_all', 'newline_lf', 'newline_crlf', 'newline_cr'}
- ▷ **Replace** (input_control) ..... string ⇝ *string*
  Replacement expression.
- ▷ **Result** (output_control) ..... string(-array) ⇝ *string*
  Processed strings.

Example

```
tuple_regexp_replace(['img10.bmp','img11.bmp','img12.bmp'], \
                     'img(.*).bmp', 'out$1.txt', Result)
* Returns ['out10.txt','out11.txt','out12.txt']
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

tuple_regexp_match, tuple_regexp_test, tuple_regexp_select

Module

Foundation

tuple_regexp_select (: : Data, Expression : Selection)

Select tuple elements matching a regular expression.

tuple_regexp_select applies the regular expression in Expression to one or more input strings in Data, and returns the matching string elements in Selection. This is convenient, e.g., for filtering a list of files obtained using the operator list_files.

Please refer to the documentation of tuple_regexp_match for syntax and options of regular expressions. Additionally, tuple_regexp_select supports the option *'invert_match'*, which causes those input strings to be selected which do **not** match the regular expression.

For general information about string operations see Tuple / String Operations.

If the input tuple is empty, the operator returns an empty tuple.

Unicode code points versus bytes

Regular expression matching operates on Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If regular expression matching should only match on bytes, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_regexp_select, which can be used in an expression in the following syntax:

```
Selection := regexp_select(Data, Expression)
```

Parameters

▷ **Data** (input_control) ..... string(-array) ⇝ *string*
Input strings to match.

▷ **Expression** (input_control) ..... string(-array) ⇝ *string*
Regular expression.
Default: '.*'
Suggested values: Expression ∈ {'.*', 'invert_match', 'ignore_case', 'multiline', 'dot_matches_all', 'newline_lf', 'newline_crlf', 'newline_cr'}

▷ **Selection** (output_control) ..... string(-array) ⇝ *string*
Matching strings

Example

```
tuple_regexp_select (['.','..','mydir','a.png','b.txt','c.bmp','d.dat'], \
                     '.(bmp|png)', Result)
* Returns ['a.png','c.bmp']

tuple_regexp_select (Files, ['training','invert_match'], Matches)
* Returns all file names that do *not* contain the string 'training'
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Alternatives

tuple_select

See also

tuple_regexp_match, tuple_regexp_replace, tuple_regexp_test

Module

Foundation

tuple_regexp_test (: : Data, Expression : NumMatches)

Test if a string matches a regular expression.

tuple_regexp_test applies the regular expression in Expression to one or more input strings in Data, and returns the number of matching strings in NumMatches. In particular, the result for a single input string will be 1 in case of a match, and 0 otherwise.

Please refer to the documentation of tuple_regexp_match for syntax and options of regular expressions. Additionally, tuple_regexp_test supports the option *'invert_match'*, which causes those input strings to be counted which do **not** match the regular expression.

For convenient use in conditional expressions, this functionality is also available as the =~ operation in HDevelop.

For general information about string operations see Tuple / String Operations.

If the input tuple is empty, the operator returns 0.

Unicode code points versus bytes

Regular expression matching operates on Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If regular expression matching should only match on bytes, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_regexp_test, which can be used in an expression in the following syntax:

NumMatches := regexp_test(Data, Expression) or NumMatches := Data =~ Expression

Parameters

▷ **Data** (input_control) ..... string(-array) ⇝ *string*
Input strings to match.

▷ **Expression** (input_control) ..... string(-array) ⇝ *string*
Regular expression.
Default: '.*'
Suggested values: Expression ∈ {'.*', 'invert_match', 'ignore_case', 'multiline', 'dot_matches_all', 'newline_lf', 'newline_crlf', 'newline_cr'}

▷ **NumMatches** (output_control) ..... integer ⇝ *integer*
Number of matching strings

Example

```
tuple_regexp_test ('p10662599755', '[A-Z]*', Result)
* Returns 0

tuple_regexp_test ('p10662599755', ['[A-Z]*','ignore_case'], Result)
* Returns 1
```

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_strstr

See also

tuple_regexp_match, tuple_regexp_replace, tuple_regexp_select

Module

Foundation

tuple_split (: : String, Separator : Substrings)

Split strings into substrings using predefined separator symbol(s).

tuple_split searches within the strings of the input tuple String for the separators defined in the input tuple Separator. tuple_split then splits the examined strings into the substrings divided by the separators and returns them in the tuple Substrings. The behavior depends on the length of the input tuples:

- Separator contains only one string: Every string in String is split up according to the separator symbols in Separator. E.g., String = *['alpha:1', 'beta:2', 'gamma:3']* and Separator = *['a:']*. In this case, the operator returns the tuple Substrings = *['lph', '1', 'bet', '2', 'g', 'mm', '3']*.
- String contains only one string: The single string is split up for every element in Separator. E.g., String = *['alpha:1 beta:2 gamma:3']* and Separator = *[':', '123']*. In this case, the output tuple Substrings will comprise the substrings *'alpha'*, *'1'*, *'beta'*, *'2'*, *'gamma'*, and *'3'*, as the result of splitting the string of String according to the first element of Separator (*':'*) as well as *'alpha:'*, *'beta:'*, and *'gamma:'* as the result of splitting according to the second element of Separator (*'123'*).
- Both tuples consist of the same amount of strings: The search is done elementwise. I.e., tuple_split will split the first string of String according to the separator symbols in the first element of Separator, the second string of String according to the separator symbols in the second element of Separator and so on.
- Either or both of the input tuples are empty: An empty tuple is returned.

Notes to Separator: If an element of Separator contains more than one character, each character defines a separator (see the example given above). Subsequent occurrences of Separator in String are treated as one separator. Separators at the beginning and the end of String will not result in an empty string.

Please consider, both input tuples (String and Separator) may only consist of strings. Otherwise tuple_split returns an error. If both input tuples contain more than one element and the number of elements differs for the input tuples, tuple_split returns an error.

Unicode code points versus bytes

The split characters are interpreted as Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the split characters should be handled as raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_split, which can be used in an expression in the following syntax:

```
Substrings := split(String, Separator)
```

Parameters

▷ **String** (input_control) ..... string(-array) ⇝ *string*
Input tuple with string(s) to split.

▷ **Separator** (input_control) ..... string(-array) ⇝ *string*
Input tuple with separator symbol(s).

▷ **Substrings** (output_control) ..... string(-array) ⇝ *string*
Substrings after splitting the input strings.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_strstr, tuple_strrstr, tuple_strchr, tuple_strrchr, tuple_strlen, tuple_str_first_n, tuple_str_last_n, tuple_environment

Module

Foundation

tuple_str_distance (: : String1, String2, Mode : Distance)

Calculate the distance between strings.

tuple_str_distance computes the edit distance between String1 and String2 and returns the result in Distance. The distance measure used is specified in Mode. Both input tuples may only consist of strings. Otherwise, tuple_str_distance returns an error. As an exception, an empty tuple in String1 or String2 cause Distance to also be empty.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each of the input tuples String1 and String2 can be given as a tuple of length *1* or *'N'*. Parameters with tuple length *1* will be repeated internally such that the number of computed distances is always *'N'*.

Supported distance measures

- *'levenshtein'*: Uses the Levenshtein distance to quantify string distances. The Levenshtein distance is the minimum number of edit operations required to transform String1 into String2. Valid edit operations are insertion, deletion and replacement of characters.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_str_distance, which can be used in an expression in the following syntax:

```
Result := str_distance(String1, String2, Mode)
```

Parameters

▷ **String1** (input_control) ..... string(-array) ⇝ *string*
Input tuple.
Default: 'String1'

▷ **String2** (input_control) ..... string(-array) ⇝ *string*
Input tuple.
Default: 'String2'

▷ **Mode** (input_control) ..... string ⇝ *string*
Distance measure.
Default: 'levenshtein'
List of values: Mode ∈ {'levenshtein'}

▷ **Distance** (output_control) ..... integer(-array) ⇝ *integer*
Element-wise string distance.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`get_text_result`, `find_text`, `do_ocr_word_mlp`

Alternatives

`suggest_lexicon`

Module

Foundation

tuple_str_first_n (: : String, Position : Substring)

Cut the first characters up to position "n" out of a string tuple.

`tuple_str_first_n` cuts the first characters up to position "n" out of each string of the input tuple `String` and returns them as new strings in the output tuple `Substring` (remark: the position within strings starts with 0 for the first character of a string). The number "n" is determined by the second input tuple `Position`. If `Position` only contains one element, this element contains the number "n". If `String` and `Position` have got the same number of elements, the first element of `Position` determines the position "n" for the first string of `String`, the second element of `Position` does so for the second string of `String` and so on. If `Position` contains more than one element and `String` contains only one string, `tuple_str_first_n` cuts more than one substrings out of this string. The elements of `Position` then determine the lengths of these substrings. If both input tuples contain more than one element but differ in the number of elements, `tuple_str_first_n` returns an error.

If both input tuples are empty, the operator returns an empty tuple. Similarly, if `String` is empty and `Position` is not, the operator returns an empty tuple. In contrast, if `Position` is empty and `String` is not, an exception is raised.

Unicode code points versus bytes

The position references Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the position should reference the raw bytes of the string, this operator can be switched to byte mode with `set_system('tsp_tuple_string_operator_mode','byte')`. If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_str_first_n`, which can be used in an expression in the following syntax:

```
Substring := str_firstn(String, Position)
```

Parameters

▷ **String** (input_control) ..... string(-array) ⇝ *string*
Input tuple with string(s) to examine.

▷ **Position** (input_control) ..... number(-array) ⇝ *integer* / real
Input tuple with position(s) "n".

▷ **Substring** (output_control) ..... string(-array) ⇝ *string*
The first characters of the string(s) up to position "n".

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

Module

Foundation

tuple_str_last_n (: : String, Position : Substring)

Cut all characters starting at position "n" out of a string tuple.

tuple_str_last_n cuts all characters from position "n" to the end of the string out of each string of the input tuple String and returns them as new strings in the output tuple Substring. The position "n" is determined by the second input tuple Position. If Position only contains one element, this element contains "n". If String and Position have got the same number of elements, the first element of Position determines the start position for the first string of String, the second element of Position does so for the second string of String and so on. If Position contains more than one element and String contains only one string, tuple_str_last_n cuts more than one substrings out of this string. The elements of Position then determine the start positions for these substrings. If both input tuples contain more than one element but differ in the number of elements, tuple_str_last_n returns an error.

If both input tuples are empty, the operator returns an empty tuple. Similarly, if String is empty and Position is not, the operator returns an empty tuple. In contrast, if Position is empty and String is not, an exception is raised.

Unicode code points versus bytes

The position references Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the position should reference the raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_str_last_n, which can be used in an expression in the following syntax:

```
Substring := str_lastn(String, Position)
```

Parameters

- ▷ **String** (input_control) ..... string(-array) ⇝ *string*
  Input tuple with string(s) to examine.
- ▷ **Position** (input_control) ..... number(-array) ⇝ *integer* / real
  Input tuple with position(s) "n".
- ▷ **Substring** (output_control) ..... string(-array) ⇝ *string*
  The last characters of the string(s) starting at position "n".

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_str_first_n, tuple_substr, tuple_strstr, tuple_strrstr, tuple_strlen, tuple_strchr, tuple_strrchr, tuple_split, tuple_environment

Module

Foundation

tuple_str_replace (: : String, Before, After : Replaced)

Replace all occurrences of a substring within a string.

tuple_str_replace replaces all occurrences of Before in String with After and returns the result in Replaced. All three tuples may only consist of strings. Otherwise, tuple_str_replace returns an error. As an exception, an empty tuple in After corresponds to an empty string. Before and After must contain the same number of elements. They can either contain one element, then Before is replaced with After in all input strings of the tuple String or they can contain exactly the same number of elements as the tuple String, then the n-th entry in Before is replaced with the n-th entry in After in the n-th entry of String. The string with all replacements is returned in Replaced and contains the same number of elements as String in both cases.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_str_replace, which can be used in an expression in the following syntax:

```
Replaced := str_replace(String, Before, After)
```

Parameters

- ▷ **String** (input_control) ..... string(-array) ⇝ *string*
  Input tuple with string(s) to work on.
- ▷ **Before** (input_control) ..... string(-array) ⇝ *string*
  Input tuple with string(s) to search.
- ▷ **After** (input_control) ..... string(-array) ⇝ *string*
  Input tuple with string(s) to replace Before.
- ▷ **Replaced** (output_control) ..... string(-array) ⇝ *string*
  Output tuple with replaced strings.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_regexp_replace

Module

Foundation

tuple_strchr (: : String, ToFind : Position)

Forward search for characters within a string tuple.

tuple_strchr searches within the strings of the input tuple String for the characters of the input tuple ToFind. Both input tuples may only consist of strings. Otherwise tuple_strchr returns an error. If the elements of ToFind contain more than one character, only the first character of each element is considered for searching. If String contains only one string, all the characters defined in ToFind are searched in this string. Thus, the output tuple consists of as many elements as ToFind. Whenever a searched character has been found, the position of its first occurrence gets stored in the output tuple Position (remark: the position starts at 0 for

the first character of a string). If a character can not be found, -1 will be returned instead of its position. If both input tuples show the same number of elements, the search is done elementwise. I.e., the first character of the first element of ToFind is searched within the first string of String, the first character of the second element of ToFind is searched within the second string of String and so on. The results of the elementwise searches are returned with Position that contains as many elements as String and ToFind. If ToFind only contains one string, its first character is searched within all strings of String. Thus, in this case Position consists of as many elements as String. If both input tuples contain more than one element and the number of elements differs for the input tuples, tuple_strchr returns an error.

If either or both of the input tuples are empty, the operator returns an empty tuple.

Unicode code points versus bytes

The position references Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the position should reference the raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_strchr, which can be used in an expression in the following syntax:

```
Position := strchr(String, ToFind)
```

Parameters

- ▷ **String** (input_control) . . . . . string(-array) ⇝ *string*
  Input tuple with string(s) to examine.
- ▷ **ToFind** (input_control) . . . . . string(-array) ⇝ *string*
  Input tuple with character(s) to search.
- ▷ **Position** (output_control) . . . . . integer(-array) ⇝ *integer*
  Position of searched character(s) within the string(s).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_strrchr, tuple_strstr, tuple_strrstr, tuple_strlen, tuple_substr, tuple_str_first_n, tuple_str_last_n, tuple_split, tuple_environment

Module

Foundation

tuple_strlen (: : T1 : Length)

Determine the length of every string within a tuple of strings.

tuple_strlen checks the length of every string within the input tuple T1 and returns the length of each string with the output tuple Length. All elements of T1 may only consist of strings. Otherwise tuple_strlen returns an error.

If the input tuple is empty, the operator returns an empty tuple.

Unicode code points versus bytes

The string length references Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the length should reference the raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_strlen`, which can be used in an expression in the following syntax:

```
Length := strlen(T1)
```

Parameters

▷ **T1** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple.

▷ **Length** (output_control) . . . . . integer(-array) ⇝ *integer*
Lengths of the single strings of the input tuple.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_strstr`, `tuple_strrstr`, `tuple_strchr`, `tuple_strrchr`, `tuple_substr`, `tuple_str_first_n`, `tuple_str_last_n`, `tuple_split`, `tuple_environment`

`tuple_is_string`

Module

Foundation

tuple_strrchr (: : String, ToFind : Position)

Backward search for characters within a string tuple.

`tuple_strrchr` searches within the strings of the input tuple `String` for the characters of the input tuple `ToFind`. Both input tuples may only consist of strings. Otherwise `tuple_strrchr` returns an error. In any case backward search is used, i.e., every string is examined from its last to its first character. If the elements of `ToFind` contain more than one character, only the first character of each element is considered for searching. If `String` contains only one string, all the characters defined in `ToFind` are searched in this string. Thus, the output tuple consists of as many elements as `ToFind`. Whenever a searched character has been found, the position of its first occurrence gets stored in the output tuple `Position` . If a character can not be found, -1 will be returned instead of its position (remark: the position starts at 0 for the first character of a string). If both input tuples show the same number of elements, the search is done elementwise. I.e., the first character of the first element of `ToFind` is searched within the first string of `String`, the first character of the second element of `ToFind` is searched within the second string of `String` and so on. The results of the elementwise searches are returned with `Position` that contains as many elements as `String` and `ToFind`. If `ToFind` only contains one string, its first character is searched within all strings of `String`. Thus, in this case `Position` consists of as many elements as `String`. If both input tuples contain more than one element and the number of elements differs for the input tuples, `tuple_strrchr` returns an error.

If either or both of the input tuples are empty, the operator returns an empty tuple.

Unicode code points versus bytes

The position references Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the position should reference the raw bytes of the string, this operator can be switched to byte mode with `set_system('tsp_tuple_string_operator_mode','byte')`. If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_strrchr`, which can be used in an expression in the following syntax:

```
Position := strrchr(String, ToFind)
```

Parameters

▷ **String** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with string(s) to examine.

▷ **ToFind** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with character(s) to search.

▷ **Position** (output_control) . . . . . integer(-array) ⇝ *integer*
Position of searched character(s) within the string(s).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_strchr, tuple_strstr, tuple_strrstr, tuple_strlen, tuple_substr, tuple_str_first_n, tuple_str_last_n, tuple_split, tuple_environment

Module

Foundation

tuple_strrstr (: : String, ToFind : Position)

Backward search for strings within a string tuple.

tuple_strrstr searches within the strings of the input tuple String for the strings of the input tuple ToFind. Both input tuples may only consist of strings. Otherwise tuple_strrstr returns an error. In any case backward search is used, i.e., every string is examined from its last to its first character. If String contains only one string, all strings of ToFind are searched in it. Thus, the output tuple consists of as many elements as ToFind. Whenever a searched string has been found, the position of its first occurrence gets stored in the output tuple Position (positions in strings are counted starting with 0). If a string can not be found, -1 will be returned instead of its position. If both input tuples show the same number of elements, the strings are searched elementwise. I.e., the first string of ToFind is searched within the first string of String, the second string of ToFind is searched within the second string of String and so on. The results of the elementwise searches are returned with Position that contains as many elements as String and ToFind. If ToFind only contains one string, this is searched within all strings of String. Thus, in this case Position consists of as many elements as String. If both input tuples contain more than one element and the number of elements differs for the input tuples, tuple_strrstr returns an error.

If either or both of the input tuples are empty, the operator returns an empty tuple.

Unicode code points versus bytes

The position references Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the position should reference the raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_strrstr, which can be used in an expression in the following syntax:

```
Position := strrstr(String, ToFind)
```

Parameters

▷ **String** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with string(s) to examine.

▷ **ToFind** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with string(s) to search.

▷ **Position** (output_control) . . . . . integer(-array) ⇝ *integer*
Position of searched string(s) within the examined string(s).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_strstr, tuple_strlen, tuple_strchr, tuple_strrchr, tuple_substr, tuple_str_first_n, tuple_str_last_n, tuple_split, tuple_environment

Module

Foundation

tuple_strstr (: : String, ToFind : Position)

Forward search for strings within a string tuple.

tuple_strstr searches within the strings of the input tuple String for the strings of the input tuple ToFind. Both input tuples may only consist of strings. Otherwise tuple_strstr returns an error. If String contains only one string, all strings of ToFind are searched in it. Thus, the output tuple consists of as many elements as ToFind. Whenever a searched string has been found, the position of its first occurrence gets stored in the output tuple Position (positions in strings are counted starting with 0). If a string can not be found, -1 will be returned instead of its position. If both input tuples show the same number of elements, the strings are searched elementwise. I.e., the first string of ToFind is searched within the first string of String, the second string of ToFind is searched within the second string of String and so on. The results of the elementwise searches are returned with Position that contains as many elements as String and ToFind. If ToFind only contains one string, this is searched within all strings of String. Thus, in this case Position consists of as many elements as String. If both input tuples contain more than one element and the number of elements differs for the input tuples, tuple_strstr returns an error.

If either or both of the input tuples are empty, the operator returns an empty tuple.

Unicode code points versus bytes

The position references Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the position should reference the raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_strstr, which can be used in an expression in the following syntax:

```
Position := strstr(String, ToFind)
```

Parameters

▷ **String** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with string(s) to examine.

▷ **ToFind** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with string(s) to search.

▷ **Position** (output_control) . . . . . integer(-array) ⇝ *integer*
Position of searched string(s) within the examined string(s).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_strrstr, tuple_strlen, tuple_strchr, tuple_strrchr, tuple_substr, tuple_str_first_n, tuple_str_last_n, tuple_split, tuple_environment

Module

Foundation

tuple_substr (: : String, Position1, Position2 : Substring)

Cut characters from position "n1" through "n2" out of a string tuple.

tuple_substr cuts all characters from position "n1" through "n2" out of each string of the input tuple String and returns them as new strings in the output tuple Substring. The positions "n1" and "n2" are determined by the second and third input tuples Position1 and Position2. Their length has to be equal. If Position1 and Position2 only contain one element, this element defines for all strings of String "n1" and "n2", respectively . If String, Position1 and Position2 have got the same number of elements, the first elements of Position1 and Position2 determine the start and end position for the first string of String. The second elements of Position1 and Position2 do so for the second string of String and so on. If Position1 and Position2 contain more than one element and String contains only one string, tuple_substr cuts more than one substring out of this string. The elements of Position1 and Position2 then determine the start and end positions for these substrings. If all input tuples contain more than one element but differ in the number of elements, tuple_substr returns an error.

If String is an empty tuple, the operator returns an empty tuple. If String is not empty and Position1 and/or Position2 are empty tuples, an exception is raised.

Unicode code points versus bytes

The positions reference Unicode code points. One Unicode code point may be composed of multiple bytes in the UTF-8 string. If the positions should reference the raw bytes of the string, this operator can be switched to byte mode with set_system('tsp_tuple_string_operator_mode','byte'). If *'filename_encoding'* is set to *'locale'* (legacy), this operator always uses the byte mode.

For general information about string operations see Tuple / String Operations.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_substr, which can be used in an expression in the following syntax:

```
Substring := String{Position1:Position2}
```

Parameters

▷ **String** (input_control) . . . . . string(-array) ⇝ *string*
Input tuple with string(s) to examine.

▷ **Position1** (input_control) . . . . . number(-array) ⇝ *integer* / real
Input tuple with start position(s) "n1".

▷ **Position2** (input_control) . . . . . number(-array) ⇝ *integer* / real
Input tuple with end position(s) "n2".

▷ **Substring** (output_control) . . . . . string(-array) ⇝ *string*
Characters of the string(s) from position "n1" to "n2".

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_str_first_n, tuple_str_last_n, tuple_strstr, tuple_strrstr, tuple_strlen, tuple_strchr, tuple_strrchr, tuple_split, tuple_environment

Module

Foundation

28.14 Type

tuple_is_handle (: : T : IsHandle)

Test if the internal representation of a tuple is of type handle.

tuple_is_handle tests if the internal representation of the input tuple T is of type handle. In that case the value *1* (true) is returned in IsHandle, otherwise the value *0* (false) is returned. If a tuple consists of handle elements only, IsHandle can nevertheless be 0 in case the internal representation is H_TYPE_MIXED; see tuple_type for details.

Exception: Empty input tuple

If the input tuple is empty, the operator returns *1*.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_is_handle, which can be used in an expression in the following syntax:

```
IsHandle := is_handle(T)
```

Attention

Even if all tuple elements are of type handle, tuple_is_handle returns *0* (false) if the internal representation of the tuple is of type H_TYPE_MIXED. To test if the elements of the tuple are of type handle, the operator tuple_is_handle_elem should be used.

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *handle* / real / integer / string
Input tuple.

▷ **IsHandle** (output_control) . . . . . number ⇝ *integer*
Boolean value indicating if the input tuple is of type handle.

Result

If the parameters are valid, the operator tuple_is_handle returns the value 2 (H_MSG_TRUE).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_type, tuple_is_number, tuple_is_handle_elem, tuple_is_string, tuple_sem_type

See also

tuple_is_int, tuple_is_real, tuple_is_string

Module

Foundation

tuple_is_handle_elem (: : T : IsHandle)

Test whether the elements of a tuple are of type `handle`*.*

`tuple_is_handle_elem` tests the elements of the input tuple `T` separately. For all elements of type `handle` the value *1* (true) is returned in `IsHandle`, else *0* (false) is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_handle_elem`, which can be used in an expression in the following syntax:

```
IsHandle := is_handle_elem(T)
```

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *handle* / real / integer / string
Input tuple.

▷ **IsHandle** (output_control) . . . . . number(-array) ⇝ *integer*
Boolean values indicating if the elements of the input tuple are of type `handle`.

Result

If the parameters are valid, the operator `tuple_is_handle_elem` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_type_elem`, `tuple_is_handle`

See also

`tuple_is_mixed`, `tuple_is_int`, `tuple_is_real`, `tuple_is_string`, `tuple_is_mixed`, `tuple_is_int_elem`, `tuple_is_real_elem`, `tuple_is_number`, `tuple_is_handle`

Module

Foundation

tuple_is_int (: : T : IsInt)

Test if the internal representation of a tuple is of type `integer`*.*

`tuple_is_int` tests if the internal representation of the input tuple `T` is of type `integer`. In that case the value *1* (true) is returned in `IsInt`, otherwise the value *0* (false) is returned. If a tuple consists of `integer` elements only, `IsInt` can nevertheless be 0 in case the internal representation is H_TYPE_MIXED; see `tuple_type` for details.

Exception: Empty input tuple

If the input tuple is empty, the operator returns 1.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_int`, which can be used in an expression in the following syntax:

```
IsInt := is_int(T)
```

Attention

Even if all tuple elements are of type `integer`, `tuple_is_int` returns *0* (false) if the internal representation of the tuple is of type H_TYPE_MIXED. To test if the elements of the tuple are of type `integer` the operator `tuple_is_int_elem` should be used.

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **IsInt** (output_control) . . . . . number ⇝ *integer*
Is the input tuple of type `integer`?

Example

```
tuple_is_int ([3.1416,'pi',3], IsIntA)
* IsIntA = false
tuple_is_int ([1,2,3], IsIntB)
* IsIntB = true
tuple_is_int ([], IsIntC)
* IsIntC = true
```

Result

If the parameters are valid, the operator `tuple_is_int` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_is_number`, `tuple_is_int_elem`

See also

`tuple_is_real`, `tuple_is_string`, `tuple_is_handle`

Module

Foundation

tuple_is_int_elem (: : T : IsInt)

Test whether the types of the elements of a tuple are of type `integer`.

`tuple_is_int_elem` tests the elements of the input tuple `T` separately. For all elements of type `integer` the value *1* (true) is returned in `IsInt`, else *0* (false) is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_int_elem`, which can be used in an expression in the following syntax:

```
IsInt := is_int_elem(T)
```

Attention

`tuple_is_int_elem` returns `2` (`H_MSG_TRUE`) if the internal data type of the elements of the tuple is `integer`. In contrast to `tuple_is_number` it does not return whether the elements of a tuple could be represented as `integer` values.

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *integer* / real / string / handle
Input tuple.

▷ **IsInt** (output_control) . . . . . number(-array) ⇝ *integer*
Are the elements of the input tuple of type `integer`?

Example

```
tuple_is_int_elem ([3.1416,'pi',3,3.0], IsInt)
* IsInt = [false, false, true, false]
```

Result

If the parameters are valid, the operator `tuple_is_int_elem` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_type_elem`, `tuple_is_int`

See also

`tuple_is_mixed`, `tuple_is_int`, `tuple_is_real`, `tuple_is_string`, `tuple_is_mixed`, `tuple_is_real_elem`, `tuple_is_string_elem`, `tuple_is_number`, `tuple_is_handle_elem`, `tuple_is_handle`

Module

Foundation

tuple_is_mixed (: : T : IsMixed)

Test whether a tuple is of type `mixed`.

`tuple_is_mixed` tests the input tuple `T`. If the type is `mixed`, the value *1* (true) is returned in `IsMixed`, else *0* (false) is returned. If a tuple consists of elements with equal data types only, `IsMixed` can nevertheless be 1 in case the internal representation is H_TYPE_MIXED; see `tuple_type` for details.

If the type of the tuple is `mixed` and you need all elements of the tuple `T` to be of one data type only, you can explicitly convert the tuple to a better fitting representation by using `tuple_int`, `tuple_real` or `tuple_string` with Format='s'. This improves processing speed for the converted tuple which is especially useful if the tuple is used many times afterwards.

Exception: Empty input tuple

If the input tuple is empty, the operator returns 1.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_mixed`, which can be used in an expression in the following syntax:

```
IsMixed := is_mixed(T)
```

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *string* / real / integer / handle
Input tuple.

▷ **IsMixed** (output_control) . . . . . number ⇝ *integer*
Is the input tuple of type `mixed`?

Example

```
tuple_is_mixed ([3.1416,'pi',3], IsMixedA)
* IsMixedA = true
tuple_is_mixed (['a','b','111'], IsMixedB)
* IsMixedB = false
tuple_is_mixed ([], IsMixedC)
* IsMixedC = true
```

Result

If the parameters are valid, the operator `tuple_is_mixed` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_is_number`

See also

`tuple_is_int`, `tuple_is_real`

Module

Foundation

tuple_is_nan_elem (: : T : IsNaN)

Check a tuple whether it represents NaNs (Not-a-number).

`tuple_is_nan_elem` checks each element of the input tuple `T` whether it represents a NaN. If it does, 1 is returned for that element, otherwise 0.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_nan_elem`, which can be used in an expression in the following syntax:

```
IsNaN := is_nan_elem(T)
```

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *real* / integer
Input tuple.

▷ **IsNaN** (output_control) . . . . . number ⇝ *integer*
Tuple with Boolean numbers.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_is_number`, `tuple_sem_type`

See also

`tuple_is_int`, `tuple_is_real`, `tuple_is_string`

Module

Foundation

tuple_is_number (: : T : IsNumber)

Check a tuple (of strings) whether it represents numbers.

tuple_is_number checks each element of the input tuple T whether it represents a number. If the element is a number (real or integer), 1 is returned for that element. If the element is a string, it is checked whether the string represents a number. If so, 1 is returned, otherwise 0.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_is_number, which can be used in an expression in the following syntax:

```
IsNumber := is_number(T)
```

Parameters

- ▷ **T** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string
  Input tuple.
- ▷ **IsNumber** (output_control) . . . . . integer(-array) ⇝ *integer*
  Tuple with Boolean numbers.

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

See also

tuple_number

Module

Foundation

tuple_is_real (: : T : IsReal)

Test if the internal representation of a tuple is of type real.

tuple_is_real tests if the internal representation of the input tuple T is of type real. In that case the value *1* (true) is returned in IsReal, otherwise the value *0* (false) is returned. If a tuple consists of real elements only, IsReal can nevertheless be 0 in case the internal representation is H_TYPE_MIXED; see tuple_type for details.

Exception: Empty input tuple

If the input tuple is empty, the operator returns 1.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_is_real, which can be used in an expression in the following syntax:

```
IsReal := is_real(T)
```

Attention

Even if all tuple elements are of type real, tuple_is_real returns *0* (false) if the internal representation of the tuple is of type H_TYPE_MIXED. To test if the elements of the tuple are of type real the operator tuple_is_real_elem should be used.

Parameters

- ▷ **T** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string / handle
  Input tuple.
- ▷ **IsReal** (output_control) . . . . . number ⇝ *integer*
  Is the input tuple of type real?

Example

```
tuple_is_real ([3.1416,'pi',3], IsRealA)
* IsRealA = false
tuple_is_real ([1.0,2.0,3.0], IsRealB)
* IsRealB = true
tuple_is_real ([], IsRealC)
* IsRealC = true
```

Result

If the parameters are valid, the operator `tuple_is_real` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_is_number`, `tuple_is_real_elem`

See also

`tuple_is_int`, `tuple_is_string`, `tuple_is_handle`

Module

Foundation

`tuple_is_real_elem` (: : T : IsReal)

Test whether the types of the elements of a tuple are of type `real`.

`tuple_is_real_elem` tests the elements of the input tuple `T` separately. For all elements of type `real` the value *1* (true) is returned in `IsReal`, else *0* (false) is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_real_elem`, which can be used in an expression in the following syntax:

```
IsReal := is_real_elem(T)
```

Attention

`tuple_is_real_elem` returns `2` (`H_MSG_TRUE`) if the internal data type of the elements of the tuple is `real`. In contrast to `tuple_is_number` it does not return whether the elements of a tuple could be represented as `real` values.

Parameters

▷ **`T`** (input_control) ..... tuple(-array) ⇝ *real* / integer / string / handle
Input tuple.

▷ **`IsReal`** (output_control) ..... number(-array) ⇝ *integer*
Are the elements of the input tuple of type `real`?

Example

```
tuple_is_real_elem ([3.1416,'pi',3,3.0], IsReal)
* IsReal = [true, false, false, true]
```

Result

If the parameters are valid, the operator `tuple_is_real_elem` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_type_elem`, `tuple_is_real`

See also

Module

Foundation

tuple_is_string (: : T : IsString)

Test if the internal representation of a tuple is of type `string`.

`tuple_is_string` tests if the internal representation of the input tuple `T` is of type `string`. In that case the value *1* (true) is returned in `IsString`, otherwise the value *0* (false) is returned. If a tuple consists of `string` elements only, `IsString` can nevertheless be 0 in case the internal representation is H_TYPE_MIXED; see `tuple_type` for details.

Exception: Empty input tuple

If the input tuple is empty, the operator returns 1.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_string`, which can be used in an expression in the following syntax:

```
IsString := is_string(T)
```

Attention

Even if all tuple elements are of type `string`, `tuple_is_string` returns *0* (false) if the internal representation of the tuple is of type H_TYPE_MIXED. To test if the elements of the tuple are of type `string` the operator `tuple_is_string_elem` should be used.

Parameters

▷ **T** (input_control) ..... tuple(-array) ⇝ *string* / real / integer / handle
Input tuple.

▷ **IsString** (output_control) ..... number ⇝ *integer*
Is the input tuple of type `string`?

Example

```
tuple_is_string ([3.1416,'pi',3], IsStringA)
* IsStringA = false
tuple_is_string (['a','b','111'], IsStringB)
* IsStringB = true
tuple_is_string ([], IsStringC)
* IsStringC = true
```

Result

If the parameters are valid, the operator `tuple_is_string` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_type, tuple_is_number, tuple_is_string_elem

tuple_is_int, tuple_is_real, tuple_is_handle

Module

Foundation

tuple_is_string_elem (: : T : IsString)

Test whether the types of the elements of a tuple are of type `string`.

`tuple_is_string_elem` tests the elements of the input tuple `T` separately. For all elements of type `string` the value *1* (true) is returned in `IsString`, else *0* (false) is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_is_string_elem`, which can be used in an expression in the following syntax:

```
IsString := is_string_elem(T)
```

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *string* / real / integer / handle
Input tuple.

▷ **IsString** (output_control) . . . . . number(-array) ⇝ *integer*
Are the elements of the input tuple of type `string`?

Example

```
tuple_is_string_elem ([3.1416,'pi',3], IsString)
* IsString = [false, true, false]
```

Result

If the parameters are valid, the operator `tuple_is_string_elem` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_type, tuple_type_elem, tuple_is_string

See also

tuple_is_mixed, tuple_is_int, tuple_is_real, tuple_is_string, tuple_is_mixed, tuple_is_int_elem, tuple_is_real_elem, tuple_is_number, tuple_is_handle_elem, tuple_is_handle

Module

Foundation

tuple_is_valid_handle (: : Handle : IsValid)

Check if a handle is valid.

tuple_is_valid_handle returns *1* in IsValid if Handle is a valid handle that has not been cleared, and *0* otherwise.

If multiple handles are passed in Handle, a validity value will be returned for each of them in IsValid.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

Parameters

▷ **Handle** (input_control) . . . . . tuple(-array) ⇝ *handle*
The handle to check for validity.

▷ **IsValid** (output_control) . . . . . integer(-array) ⇝ *integer*
The validity of the handle, *1* or *0*.

Result

If the parameters are valid, the operator tuple_is_valid_handle returns the value 2 (H_MSG_TRUE). Otherwise, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

tuple_sem_type (: : T : SemType)

Return the semantic type of a tuple.

tuple_sem_type returns the semantic type of the input tuple T. The type is returned as a string value in the output parameter SemType.

If T contains only valid handles of the same type, the corresponding semantic type of the handles is returned (e.g., *'matrix'*). If it contains only valid or invalid handles, or handles of different type, *'handle'* is returned. If T contains elements of different types, *'any'* is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns *'any'*.

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_sem_type, which can be used in an expression in the following syntax:

```
SemType := sem_type(T)
```

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *handle* / real / integer / string
Input tuple.

▷ **SemType** (output_control) . . . . . string ⇝ *string*
Semantic type of the input tuple as a string.

Example

```
create_matrix (3, 3, 0, MatrixID)
tuple_sem_type (MatrixID, SemType)
```

```
* SemType == 'matrix' (Handle of specific type)
clear_handle (MatrixID)
tuple_sem_type (MatrixID, SemType)
* SemType == 'handle' (Cleared handle)
tuple_sem_type ([MatrixID,123], SemType)
* SemType == 'any' (Mixed types)
```

Result

If the parameters are valid, the operator `tuple_sem_type` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_is_int`, `tuple_is_number`, `tuple_is_real`, `tuple_is_string`, `tuple_type`

See also

`get_obj_class`

Module

Foundation

tuple_sem_type_elem (: : T : SemTypes)

Return the semantic type of the elements of a tuple.

`tuple_sem_type_elem` returns the semantic type of each element of the input tuple `T`. The semantic type is returned as a tuple of string values in the output parameter `SemTypes`.

If an element is a valid handle, the corresponding semantic type of the handle is returned. For an invalid or cleared handle, *'handle'* is returned.

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_sem_type_elem`, which can be used in an expression in the following syntax:

```
SemTypes := sem_type_elem(T)
```

Parameters

- ▷ **T** (input_control) . . . . . tuple(-array) ⇝ *handle* / real / integer / string
  Input tuple.
- ▷ **SemTypes** (output_control) . . . . . string(-array) ⇝ *string*
  Semantic types of the elements of the input tuple as strings.

Example

```
create_matrix (3, 3, 0, MatrixID)
tuple_sem_type_elem ([MatrixID,1,1.0,'HALCON',HNULL], SemTypeElem)
* SemTypeElem == ['matrix','integer','real','string','handle']
```

Result

If the parameters are valid, the operator `tuple_sem_type_elem` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

tuple_type, tuple_is_mixed, tuple_is_int, tuple_is_real, tuple_is_string, tuple_is_mixed, tuple_is_int_elem, tuple_is_real_elem, tuple_is_string_elem, tuple_type_elem, tuple_sem_type

See also

get_obj_class

Module

Foundation

tuple_type (: : T : Type)

Return the type of a tuple.

tuple_type returns the type of the input tuple T. The type is returned as an integer value in the output parameter Type. In HDevelop corresponding constants are defined:

- H_TYPE_INT (1).
- H_TYPE_REAL (2).
- H_TYPE_STRING (4).
- H_TYPE_MIXED (8).
- H_TYPE_HANDLE (16).
- H_TYPE_ANY (31).

H_TYPE_MIXED is returned in the following two cases:

- some elements of the tuple have different data types, e.g., real and integer.
- the tuple T has undergone operations which modified the data type of single elements. Such tuples will generally not be optimized automatically (because of runtime reasons) even if the data types of all elements become equal in subsequent operations. See tuple_is_mixed and the following example on how to optimize such tuples.

Exception: Empty input tuple

If the input tuple is empty, the operator returns 31 (H_TYPE_ANY).

HDevelop In-line Operation

HDevelop provides an in-line operation for tuple_type, which can be used in an expression in the following syntax:

```
Type := type(T)
```

Attention

tuple_type returns the internal data type of the tuple. In contrast to tuple_is_number it does not return whether a tuple could be represented as a tuple of a certain type.

Parameters

▷ **T** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string / handle
Input tuple.

▷ **Type** (output_control) . . . . . number ⇝ *integer*
Type of the input tuple as an integer number.

Example

```
tuple_type ([3.1416,'pi',3], TypeA)
* TypeA = H_TYPE_MIXED
tuple_type (['a','b','111'], TypeB)
* TypeB = H_TYPE_STRING
tuple_type ([], TypeC)
* TypeC = H_TYPE_ANY
tuple_type (HNULL, TypeD)
* TypeD = H_TYPE_HANDLE

TupleInt := [1,2,3,4]
TupleReal := [42.0]
TupleConcat := [TupleInt, TupleReal]
tuple_type (TupleConcat, TypeConcat)
* TypeConcat = H_TYPE_MIXED
* Now set 42.0 to 42
TupleConcat[4] := 42
tuple_type (TupleConcat, TypeConcat2)
* TypeConcat2 = H_TYPE_MIXED
* TupleConcat now consists of integers only, but the
* internal representation hasn't been updated. Optimize
* it by converting the tuple explicitly to an integer
* tuple.
tuple_int (TupleConcat, TupleConcatInt)
tuple_type (TupleConcatInt, TypeConcatInt)
* TypeConcatInt = H_TYPE_INT
```

Result

If the parameters are valid, the operator `tuple_type` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_is_int`, `tuple_is_number`, `tuple_is_real`, `tuple_is_string`, `tuple_sem_type`

`get_obj_class`

Module

Foundation

tuple_type_elem (: : T : Types)

Return the types of the elements of a tuple.

`tuple_type_elem` returns the types of the elements of the input tuple `T`. The types are returned separately as integer values in the output parameter `Types`. In HDevelop the corresponding constants are defined:

- H_TYPE_INT (1).
- H_TYPE_REAL (2).
- H_TYPE_STRING (4).
- H_TYPE_HANDLE (16).

Exception: Empty input tuple

If the input tuple is empty, the operator returns an empty tuple.

HDevelop In-line Operation

HDevelop provides an in-line operation for `tuple_type_elem`, which can be used in an expression in the following syntax:

```
Types := type_elem(T)
```

Parameters

▷ **`T`** (input_control) . . . . . tuple(-array) ⇝ *real* / integer / string / handle
Input tuple.

▷ **`Types`** (output_control) . . . . . number(-array) ⇝ *integer*
Types of the elements of the input tuple as integer values.

Example

```
tuple_type_elem ([3.1416,'pi',3], Types)
* Types = [H_TYPE_REAL, H_TYPE_STRING, H_TYPE_INT]
```

Result

If the parameters are valid, the operator `tuple_type_elem` returns the value `2` (`H_MSG_TRUE`).

Execution Information

- Multithreading type: independent (runs in parallel even with exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Alternatives

`tuple_type`, `tuple_is_mixed`, `tuple_is_int`, `tuple_is_real`, `tuple_is_string`, `tuple_is_mixed`, `tuple_is_int_elem`, `tuple_is_real_elem`, `tuple_is_string_elem`

XLD

29.1 Access

get_contour_xld (Contour : : : Row, Col)

Return the coordinates of an XLD contour.

get_contour_xld returns the following values of the XLD contour Contour:

Row	Row coordinate of the contour's points
Col	Column coordinate of the contour's points

Parameters

▷ **Contour** (input_object) . . . . . xld_cont ⇝ *object*
Input XLD contour.

▷ **Row** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinate of the contour's points.

▷ **Col** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinate of the contour's points.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Module

Foundation

get_lines_xld (Polygon : : : BeginRow, BeginCol, EndRow, EndCol, Length, Phi)

Return an XLD polygon's data (as lines).

get_lines_xld returns the XLD polygon Polygon as a set of lines. The following values are returned:

BeginRow:	Rows coordinates of the lines' start points
BeginCol:	Columns coordinates of the lines' start points
EndRow:	Row coordinates of the lines' end points
EndCol:	Column coordinates of the lines' end points
Length:	Lengths of the line segments
Phi:	Angles to the normal vectors of the line segments

Parameters

- ▷ **Polygon** (input_object) ..... xld_poly(-array) ⇝ *object*
  Input XLD polygons.
- ▷ **BeginRow** (output_control) ..... line.begin.y-array ⇝ *real*
  Row coordinates of the lines' start points.
- ▷ **BeginCol** (output_control) ..... line.begin.x-array ⇝ *real*
  Column coordinates of the lines' start points.
- ▷ **EndRow** (output_control) ..... line.end.y-array ⇝ *real*
  Column coordinates of the lines' end points.
- ▷ **EndCol** (output_control) ..... line.end.x-array ⇝ *real*
  Column coordinates of the lines' end points.
- ▷ **Length** (output_control) ..... real-array ⇝ *real*
  Lengths of the line segments.
- ▷ **Phi** (output_control) ..... angle.rad-array ⇝ *real*
  Angles to the normal vectors of the line segments.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

gen_polygons_xld

Alternatives

get_polygon_xld

Module

Foundation

get_parallels_xld (Parallels : : : Row1, Col1, Length1, Phi1, Row2, Col2, Length2, Phi2)

Return an XLD parallel's data (as lines).

get_parallels_xld returns for the first XLD parallel in Parallels the following values:

Row1:	Row coordinates of the points on polygon P1
Col1:	Column coordinates of the points on polygon P1
Length1:	Lengths of the line segments on polygon P1
Phi1:	Angles to the normal vectors of the line segments on polygon P1
Row2:	Row coordinates of the points on polygon P2
Col2:	Column coordinates of the points on polygon P2
Length2:	Lengths of the line segments on polygon P2
Phi2:	Angles to the normal vectors of the line segments on polygon P2

Parameters

▷ **Parallels** (input_object) . . . . . xld ⇝ *object*
Input XLD parallels.

▷ **Row1** (output_control) . . . . . polygon.y-array ⇝ *real*
Row coordinates of the points on polygon P1.

▷ **Col1** (output_control) . . . . . polygon.x-array ⇝ *real*
Column coordinates of the points on polygon P1.

▷ **Length1** (output_control) . . . . . real-array ⇝ *real*
Lengths of the line segments on polygon P1.

▷ **Phi1** (output_control) . . . . . angle.rad-array ⇝ *real*
Angles to the normal vectors of the line segments on polygon P1.

▷ **Row2** (output_control) . . . . . polygon.y-array ⇝ *real*
Row coordinates of the points on polygon P2.

▷ **Col2** (output_control) . . . . . polygon.x-array ⇝ *real*
Column coordinates of the points on polygon P2.

▷ **Length2** (output_control) . . . . . real-array ⇝ *real*
Lengths of the line segments on polygon P2.

▷ **Phi2** (output_control) . . . . . angle.rad-array ⇝ *real*
Angles to the normal vectors of the line segments on polygon P2.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

get_polygon_xld (Polygon : : : Row, Col, Length, Phi)

Return an XLD polygon's data.

get_polygon_xld returns the following values of the XLD polygon Polygon:

Row	Row coordinates of the polygons' points
Col	Column coordinates of the polygons' points
Length	Lengths of the line segments between points i and $i+1$, respectively
Phi	Angles to the normal vectors of the line segments between points i and $i+1$, respectively

Parameters

▷ **Polygon** (input_object) . . . . . xld_poly ⇝ *object*
Input XLD polygon.

▷ **Row** (output_control) . . . . . point.y-array ⇝ *real*
Row coordinates of the polygons' points.

▷ **Col** (output_control) . . . . . point.x-array ⇝ *real*
Column coordinates of the polygons' points.

▷ **Length** (output_control) . . . . . real-array ⇝ *real*
Lengths of the line segments.

▷ **Phi** (output_control) . . . . . angle.rad-array ⇝ *real*
Angles to the normal vectors of the line segments.

Execution Information

29.2 Creation

gen_circle_contour_xld (: ContCircle : Row, Column, Radius, StartPhi, EndPhi, PointOrder, Resolution :)

Create XLD contours corresponding to circles or circular arcs.

gen_circle_contour_xld creates one or more circular arcs or closed circles. Circles are specified by their center (Row, Column) and their Radius. In addition to that, circular arcs are characterized by the angle of the start point StartPhi, the angle of the end point EndPhi, and the PointOrder along the boundary. The resolution of the resulting contours ContCircle is controlled via Resolution containing the Euclidean distance in pixel between neighboring contour points. In general, the distance between the second to last and the last point is smaller than Resolution.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **ContCircle** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Resulting contours.

▷ **Row** (input_control) . . . . . circle.center.y(-array) ⇝ *real*
Row coordinate of the center of the circles or circular arcs.
Default: 200.0

▷ **Column** (input_control) . . . . . circle.center.x(-array) ⇝ *real*
Column coordinate of the center of the circles or circular arcs.
Default: 200.0

▷ **Radius** (input_control) . . . . . circle.radius(-array) ⇝ *real*
Radius of the circles or circular arcs.
Default: 100.0
Restriction: Radius > 0

▷ **StartPhi** (input_control) . . . . . angle.rad(-array) ⇝ *real*
Angle of the start points of the circles or circular arcs [rad].
Default: 0.0

▷ **EndPhi** (input_control) . . . . . angle.rad(-array) ⇝ *real*
Angle of the end points of the circles or circular arcs [rad].
Default: 6.28318

▷ **PointOrder** (input_control) . . . . . string(-array) ⇝ *string*
Point order along the circles or circular arcs.
Default: 'positive'
List of values: PointOrder ∈ {'positive', 'negative'}

▷ **Resolution** (input_control) . . . . . real ⇝ *real*
Distance between neighboring contour points.
Default: 1.0
Restriction: Resolution >= 0.00001

Example

```
draw_circle (WindowHandle, Row, Column, Radius)
gen_circle_contour_xld (ContCircle, Row, Column, Radius, 0, \
                        rad(360) , 'positive', 1.0)
gen_region_contour_xld (ContCircle, Region, 'filled')
```

Result

`gen_circle_contour_xld` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

Possible Successors

`disp_xld`

Alternatives

`gen_ellipse_contour_xld`

Module

Foundation

gen_contour_nurbs_xld (: Contour : Rows, Cols, Knots, Weights, Degree, MaxError, MaxDistance :)

Transform a NURBS curve into an XLD contour.

`gen_contour_nurbs_xld` generates an XLD `Contour` that approximates a NURBS curve (non-uniform rational B-Spline curve). The NURBS curve is specified by its `Degree`, a control polygon (via `Rows` and `Cols`), a `Weights` vector and a `Knots` vector.

The `Degree` of the curve determines the grade of differentiability of the curve. The curve lies within the convex hull of its control polygon (`Rows`,`Cols`). The weights in `Weights` determine how much the curve is attracted by the individual control points (`Rows`,`Cols`). A `Weights` vector with equal weights for all control points is generated if *'auto'* is chosen. The `Knots` vector describes the domain of the curve. Typically, this parameter can be set to *'auto'*.

The accuracy of the generated `Contour` depends on the two parameters `MaxDistance` and `MaxError`. `MaxDistance` limits the maximum distance of two subsequent `Contour` points. The maximum distance between the generated `Contour` and the actual NURBS curve is limited to `MaxError`. By default the approximation must fulfill both constraints, but it is possible to set one of these parameters to *'omit'*. The lower `MaxError` and `MaxDistance` are chosen the better is the approximation of the curve. Note that all `Contour` points lie exactly on the curve (except for numerical inaccuracies).

Definition

A NURBS curve C of degree p is given by

$$C(u) = \frac{\sum_{i=0}^{n} N_{i,p}(u) w_i P_i}{\sum_{i=0}^{n} N_{i,p}(u) w_i}, u \in [u_p, u_n].$$

The basis functions $N_{i,p}$ are defined by

$$N_{i,0}(u) = \begin{cases} 1 & \text{if } u_i \leq u < u_{i+1} \\ 0 & \text{otherwise} \end{cases}$$

$$N_{i,p}(u) = \frac{u - u_i}{u_{i+p} - u_i} N_{i,p-1}(u) + \frac{u_{i+p+1} - u}{u_{i+p+1} - u_{i+1}} N_{i+1,p-1}(u)$$

Thus, each NURBS curve is determined by its `Degree` p, its control Polygon $P_0, ..., P_{n-1}$ (`Rows` and `Cols`), its weight vector $w = (w_0, ..., w_{n-1})$ (`Weights`), and its knot vector $u = (u_0, ..., u_{n+p})$ (`Knots`).

The grade of differentiability of the curve is set via the degree p. At least $p + 1$ control points P_i are required to form a valid curve. The knot vector u describes the domain of the curve. Its length must be $n + p + 1$ and its entries must be monotonically increasing. Every entry u_i stands for a knot between the curve segments $[u_{i-1}, u_i)$ and $[u_i, u_{i+1})$. Each curve segment $[u_i, u_{i+1})$ lies within the convex hull of the control points $P_{i-p}, .., P_i$. For every curve segment of length zero, the differentiability at knot k decreases. The number of occurrences of each knot in the knot vector is called multiplicity. The maximum multiplicity of one knot is p. Only the start and the end point's multiplicity can be $p + 1$ (which in fact is the case for most curves, because in this case start and end point of the curve correspond to the first respectively last point of the control polygon). If start and/or end point do not have full multiplicity, the domain of the curve is restricted to $[u_p, u_n]$. The weights w_i determine the influence of the individual control points P_i on the curve.

Closed Curves: If start and end point are equal ($P_0 = P_{n-1}$) and `Knots` is set to *'auto'*, the curve is closed automatically such that all knots feature multiplicity one. Note that in this case the length of `Weights` is required to be $n - 1$.

Parameters

▷ **`Contour`** (output_object) . . . . . xld_cont ⇝ *object*
The contour that approximates the NURBS curve.

▷ **`Rows`** (input_control) . . . . . coordinates.y-array ⇝ *real*
Row coordinates of the control polygon.
Number of elements: Rows == Cols && Rows >= Degree + 1

▷ **`Cols`** (input_control) . . . . . coordinates.x-array ⇝ *real*
Column coordinates of the control polygon.
Number of elements: Cols == Rows && Cols >= Degree + 1

▷ **`Knots`** (input_control) . . . . . string(-array) ⇝ *string* / real
The knot vector u.
Default: 'auto'
Suggested values: `Knots` ∈ {'auto'}

▷ **`Weights`** (input_control) . . . . . string(-array) ⇝ *string* / real
The weight vector w.
Number of elements: Weights == Rows
Default: 'auto'
Suggested values: `Weights` ∈ {'auto'}
Restriction: Weights > 0.0

▷ **`Degree`** (input_control) . . . . . integer ⇝ *integer*
The degree p of the NURBS curve.
Default: 3
Suggested values: `Degree` ∈ {2, 3, 4, 5}
Restriction: Degree >= 2

▷ **`MaxError`** (input_control) . . . . . real ⇝ *real* / string
Maximum distance between the NURBS curve and its approximation.
Default: 1.0
Suggested values: `MaxError` ∈ {'omit', 1.0, 2.0, 3.0, 4.0, 5.0}
Restriction: MaxError > 0.0

▷ **`MaxDistance`** (input_control) . . . . . real ⇝ *real* / string
Maximum distance between two subsequent `Contour` points.
Default: 5.0
Suggested values: `MaxDistance` ∈ {'omit', 1.0, 2.0, 3.0, 4.0, 5.0}
Restriction: MaxDistance > 0.0

Example

```
* use a polygon XLD contour as control polygon and approximate
* the NURBS curve as contour

get_contour_xld(Polygon, Row, Col)
gen_contour_nurbs_xld(NURBSContour, Row, Col, 'auto', 'auto', 3, 1.0, 10.0)
```

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_contour_polygon_rounded_xld (: Contour : Row, Col, Radius, SamplingInterval :)

Generate an XLD contour with rounded corners from a polygon (given as tuples).

gen_contour_polygon_rounded_xld generates an XLD contour Contour with rounded corners from a polygon given in the tuples Row and Col. The rounded corners are created in form of arcs defined by Radius. For every specified point of the polygon there must be a corresponding rounding radius defined. In case of a closed polygon the first and the last point have to be defined identical with the radii of these points being equal. In contrast, the radii of the first and last point of open polygons are ignored. Finally, the SamplingInterval parameter defines the distance of the control points of the formed contour Contour.

Parameters

▷ **Contour** (output_object) . . . . . xld_cont ⇝ *object*
Resulting contour.

▷ **Row** (input_control) . . . . . coordinates.y-array ⇝ *real* / integer
Row coordinates of the polygon.
Default: [20,80,80,20,20]
Suggested values: Row ∈ {0, 1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500}

▷ **Col** (input_control) . . . . . coordinates.x-array ⇝ *real* / integer
Column coordinates of the polygon.
Default: [20,20,80,80,20]
Suggested values: Col ∈ {0, 1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500}

▷ **Radius** (input_control) . . . . . number-array ⇝ *real* / integer
Radii of the rounded corners.
Default: [20,20,20,20,20]
Suggested values: Radius ∈ {0, 1, 2, 5, 10, 20, 50}

▷ **SamplingInterval** (input_control) . . . . . number ⇝ *real* / integer
Distance of the samples.
Default: 1.0
Suggested values: SamplingInterval ∈ {0.5, 1.0, 2.0, 5.0}

gen_contour_polygon_xld (: Contour : Row, Col :)

Generate an XLD contour from a polygon (given as tuples).

gen_contour_polygon_xld generates an XLD contour Contour from a polygon given in the tuples Row and Col. This operator is useful if contours have been obtained from routines outside the core library, but higher level operators, e.g., polygon approximation and extraction of parallels, are to be performed on the contours.

Parameters

▷ **Contour** (output_object) ..... xld_cont ⇝ *object*
Resulting contour.

▷ **Row** (input_control) ..... coordinates.y-array ⇝ *real* / integer
Row coordinates of the polygon.
Default: [0,1,2,2,2]
Suggested values: Row ∈ {0, 1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500}

▷ **Col** (input_control) ..... coordinates.x-array ⇝ *real* / integer
Column coordinates of the polygon.
Default: [0,0,0,1,2]
Suggested values: Col ∈ {0, 1, 2, 3, 4, 5, 10, 20, 50, 100, 200, 500}

Module

Foundation

gen_contour_region_xld (Regions : Contours : Mode :)

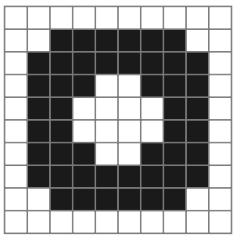
Generate XLD contours from regions.

gen_contour_region_xld generates XLD contours Contours from the regions given in Regions. This operator is useful if regions have been obtained from segmentation operations, but higher level operators, e.g.,

polygon approximation and extraction of parallels, are to be performed on their boundaries. For each connected component of the input regions a closed contour of the boundary is generated. The parameter Mode can take on the following values:

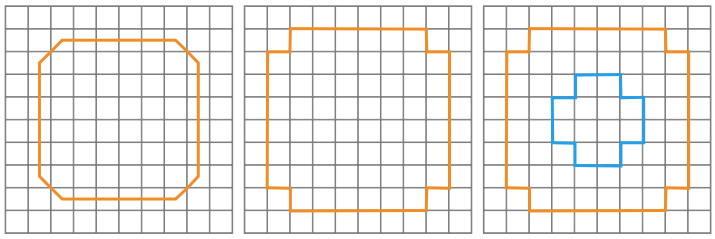
- *'center'*: The centers of the border pixels are used as contour points.
- *'border'*: The outer border of the border pixels is used as contour points.
- *'border_holes'*: In addition to the outer border of the input region you get the contours of all holes.

The difference between the modes is demonstrated using the following region:



Example region.

Computing the contour with the different values available for Mode returns the following result contours:



(1) (2) (3)

Result for *'center'* (1), *'border'* (2), and *'border_holes'* mode (3).

This means, for example, that contours generated with *'border'* will in general have a much larger Euclidean length (see length_xld) than contours generated with *'center'*. This results from the fact that for diagonal border elements *'border'* uses two contour segments of length 1 each, whereas *'center'* uses a single segment of length $\sqrt{2}$. Other features, e.g., the area (see area_center_xld), will obviously also have different values.

Parameters

▷ **Regions** (input_object) . . . . . region(-array) ⇝ *object*
Input regions.

▷ **Contours** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Resulting contours.

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Mode of contour generation.
Default: 'border'
List of values: Mode ∈ {'border', 'border_holes', 'center'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_contours_skeleton_xld

Module

Foundation

gen_contours_skeleton_xld (Skeleton : Contours : Length, Mode :)

Convert a skeleton into XLD contours.

gen_contours_skeleton_xld converts the input skeleton (e.g., edges) Skeleton, which is assumed to contain mostly one pixel wide regions (see skeleton), into XLD contours.

The algorithm first attempts to transform the regions to contain only line segments in 8-neighborhood. In a second step, the junction points are labeled. After this, gen_contours_skeleton_xld tries to generate contours which end in junction or end points, in particular for junction points of the following configurations (in all four possible rotations):

1	0	1	1	0	1	1	0	0	1	0	0	0	1	0	0	1	0
0	2	0	0	2	0	0	2	1	0	2	1	0	2	1	1	2	1
0	0	1	1	0	1	0	1	0	1	0	0	0	1	0	0	1	0

where 0 = background, 1 = foreground, and 2 = junction point.

After this, all contours having at least Length points are returned. Since contours are split at junction points, possibly long contours may be split into several short segments because of short adjacent lines, even if they are longer than Length points, if Mode = *'filter'* was selected. This can be avoided by setting Mode = *'generalize1'*. In this case, the contours are generated as if the segments shorter than Length were not contained in the input region. In order to preserve line segments, which are split into very short segments by the crossing of short lines, Mode = *'generalize2'* can be selected. In this case, line segments are preserved if they end in two junction points, even if they are shorter than Length.

Parameters

▷ **Skeleton** (input_object) . . . . . region ⇝ *object*
Skeleton of which the contours are to be determined.

▷ **Contours** (output_object) . . . . . xld_cont-array ⇝ *object*
Resulting contours.

▷ **Length** (input_control) . . . . . integer ⇝ *integer*
Minimum number of points a contour has to have.
Default: 1
Suggested values: Length ∈ {1, 2, 3, 5, 10, 20}

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Contour filter mode.
Default: 'filter'
List of values: Mode ∈ {'filter', 'generalize1', 'generalize2'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

gen_cross_contour_xld (: Cross : Row, Col, Size, Angle :)

Generate one XLD contour in the shape of a cross for each input point.

gen_cross_contour_xld generates an XLD contour in the shape of a cross for each input point (Row,Col). Conceptually, the contour consists of two lines of length Size, which intersect exactly in the input point. Their orientation is determined by Angle. The cross is returned in Cross.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **Cross** (output_object) ..... xld_cont(-array) ⇝ *object*
Generated XLD contours.

▷ **Row** (input_control) ..... point.y(-array) ⇝ *real* / integer
Row coordinates of the input points.

▷ **Col** (input_control) ..... point.x(-array) ⇝ *real* / integer
Column coordinates of the input points.
Restriction: number(Col) == number(Row)

▷ **Size** (input_control) ..... number ⇝ *real* / integer
Length of the cross bars.
Default: 6.0
Suggested values: Size ∈ {4.0, 6.0, 8.0, 10.0}
Restriction: 0.0 <= Size

▷ **Angle** (input_control) ..... angle.rad ⇝ *real*
Orientation of the crosses.
Default: 0.785398
Suggested values: Angle ∈ {0.0, 0.785398}

Result

gen_cross_contour_xld returns 2 (H_MSG_TRUE) if all parameters are correct and no error occurs during execution.

gen_ellipse_contour_xld (: ContEllipse : Row, Column, Phi, Radius1, Radius2, StartPhi, EndPhi, PointOrder, Resolution :)

Create an XLD contour that corresponds to an elliptic arc.

gen_ellipse_contour_xld creates one or more elliptic arcs or closed ellipses. Ellipses are specified by their center (Row, Column), the orientation of the main axis Phi, the length of the larger half axis Radius1, and the length of the smaller half axis Radius2. In addition to that, elliptic arcs are characterized by the angle of the start point StartPhi, the angle of the end point EndPhi, and the point order PointOrder along the boundary. Both the angle of the start point and the angle of the end point are measured from the positive main

axis specified with Phi. They correspond to the smallest surrounding circle of the ellipse. The actual start and end point of the ellipse is the intersection of the ellipse with the orthogonal projection of the corresponding circle point onto the main axis. Both angles refer to the coordinate system of the ellipse, i.e. relative to the main axis and in a mathematical positive direction. Thus, the two main poles correspond to the angles 0 and π, the two minor poles to the angles $\pi/2$ and $3\pi/2$. To create a closed ellipse the values 0 and 2π (with positive point order) have to be passed to the operator. All angles Phi, StartPhi, EndPhi take arbitrary values and are mapped internally to the interval $[0, 2\pi]$. The resolution of the resulting contours ContEllipse is controlled via Resolution containing the maximum Euclidean distance between neighboring contour points. The resolution is set to the smallest valid value, if the input value falls below this value.

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

- ▷ **ContEllipse** (output_object) ..... xld_cont(-array) ⇝ *object*
  Resulting contour.
- ▷ **Row** (input_control) ..... ellipse.center.y(-array) ⇝ *real*
  Row coordinate of the center of the ellipse.
  Default: 200.0
- ▷ **Column** (input_control) ..... ellipse.center.x(-array) ⇝ *real*
  Column coordinate of the center of the ellipse.
  Default: 200.0
- ▷ **Phi** (input_control) ..... ellipse.angle.rad(-array) ⇝ *real*
  Orientation of the main axis [rad].
  Default: 0.0
- ▷ **Radius1** (input_control) ..... ellipse.radius1(-array) ⇝ *real*
  Length of the larger half axis.
  Default: 100.0
  Restriction: Radius1 > 0
- ▷ **Radius2** (input_control) ..... ellipse.radius2(-array) ⇝ *real*
  Length of the smaller half axis.
  Default: 50.0
  Restriction: Radius2 >= 0 && Radius2 <= Radius1
- ▷ **StartPhi** (input_control) ..... angle.rad(-array) ⇝ *real*
  Angle of the start point on the smallest surrounding circle [rad].
  Default: 0.0
- ▷ **EndPhi** (input_control) ..... angle.rad(-array) ⇝ *real*
  Angle of the end point on the smallest surrounding circle [rad].
  Default: 6.28318
- ▷ **PointOrder** (input_control) ..... string(-array) ⇝ *string*
  point order along the boundary.
  Default: 'positive'
  List of values: PointOrder ∈ {'positive', 'negative'}
- ▷ **Resolution** (input_control) ..... real ⇝ *real*
  Resolution: Maximum distance between neighboring contour points.
  Default: 1.5
  Restriction: Resolution >= 1.192e-7

Example

```
draw_ellipse(WindowHandle,Row,Column,Phi,Radius1,Radius2)
gen_ellipse_contour_xld(Ellipse,Row,Column,Phi,Radius1,Radius2,0,6.28319, \
                        'positive',1.5)
length_xld(Ellipse,Length)
* Transform StartPhi so that the start point of the ellipse actually
* intersects the line through origin at the angle StartPhi measured from
* the positive main axis
affine_trans_point_2d ([1.0,0.0,0.0,0.0,1.0*Radius2/Radius1,0.0], \
```

```
                        sin(StartPhi), cos(StartPhi), Qx, Qy)
StartPhiEllipse := atan2(Qx,Qy)
```

Result

`gen_ellipse_contour_xld` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

gen_nurbs_interp (: : Rows, Cols, Tangents, Degree : CtrlRows, CtrlCols, Knots)

Create control data of a NURBS curve that interpolates given points.

`gen_nurbs_interp` creates the NURBS control data `CtrlRows`, `CtrlCols`, and `Knots` of a NURBS curve that interpolates the input points (`Rows`, `Cols`). If the input point list is not closed (i.e., the first point is identical to the last point), the tangents of the first and last point must be given in `Tangents` in the order $[drow\_0, dcol\_0, drow\_n - 1, dcol\_n - 1]$ (for closed point lists, `Tangents` must be an empty tuple). Furthermore the `Degree` of the NURBS curve must be specified.

The output of `gen_nurbs_interp` can be used directly with `gen_contour_nurbs_xld` with the weights vector set to *'auto'*.

See the documentation of `gen_contour_nurbs_xld` for more information on NURBS curves.

Parameters

▷ **Rows** (input_control) . . . . . coordinates.y-array ⇝ *real*
Row coordinates of input point list.
Number of elements: Rows == Cols

▷ **Cols** (input_control) . . . . . coordinates.x-array ⇝ *real*
Column coordinates of input point list.
Number of elements: Cols == Rows

▷ **Tangents** (input_control) . . . . . real-array ⇝ *real*
Tangents at first and last point.
Default: []

▷ **Degree** (input_control) . . . . . integer ⇝ *integer*
Order of the output curve.
Default: 3
Suggested values: `Degree` ∈ {2, 3, 4, 5}
Restriction: Degree >= 2

▷ **CtrlRows** (output_control) . . . . . coordinates.y-array ⇝ *real*
Row coordinates of the control polygon.

▷ **CtrlCols** (output_control) . . . . . coordinates.x-array ⇝ *real*
Column coordinates of the control polygon.
Number of elements: Cols == Rows

▷ **Knots** (output_control) . . . . . real-array ⇝ *real*
The knot vector of the output curve.

Result

If all input parameters are correct `gen_nurbs_interp` returns the value `2` (`H_MSG_TRUE`).

Execution Information

gen_parallels_xld (Polygons : Parallels : Len, Dist, Alpha, Merge :)

Extract parallel XLD polygons.

`gen_parallels_xld` examines the XLD polygons passed in `Polygons` for parallelism. The resulting parallel polygons are returned in `Parallels`. If the parameter `Merge` is set to *'true'*, adjacent parallel polygons are returned in a single parallel relation. Otherwise, one parallel relation is returned for each pair of parallel line segments.

Only polygon segments longer than `Len` are taken into account. Whether two polygon segments are parallel depends on a maximum allowed angle difference `Alpha` (in radians). Furthermore, the projections of the two segments onto their angle bisector have to overlap. Finally, the overlap on the angle bisector is reprojected onto the two segments. If the maximal distance of the reprojections is smaller than `Dist`, the segments are stored in `Parallels`.

As a side effect, a quality factor is calculated for each pair of parallels, compare `mod_parallels_xld`. It is based on the normalized angular difference and the normalized length of the overlap:

$$q = \frac{\pi/2 - \delta\alpha}{\pi/2} \frac{2overlap}{len_1 + len_2} \qquad \text{with} \quad 0 \leq q \leq 1$$

Here, $\delta\alpha$ is the angle difference of the polygon segments, $overlap$ is the length of the overlap, len_1 and len_2 the lengths of the polygon segments, and q the resulting quality factor. The quality factor is a measure of parallelism (the larger its value, the "more parallel" the polygons). Finally, the quality factors of all parallel polygon segments contained in a single polygon are added, weighted with their length of the overlapping area. Note that you can query the range for the quality factor with `info_parallels_xld`.

Parameters

▷ **Polygons** (input_object) . . . . . xld_poly-array ⇝ *object*
Input polygons.

▷ **Parallels** (output_object) . . . . . xld_para-array ⇝ *object*
Parallel polygons.

▷ **Len** (input_control) . . . . . number ⇝ *real* / integer
Minimum length of the individual polygon segments.
Default: 10.0
Suggested values: `Len` ∈ {5.0, 10.0, 15.0, 20.0}
Restriction: Len > 0.0

▷ **Dist** (input_control) . . . . . number ⇝ *real* / integer
Maximum distance between the polygon segments.
Default: 30.0
Suggested values: Dist ∈ {20.0, 25.0, 30.0, 40.0, 50.0, 75.0}
Restriction: Dist > 0.0

▷ **Alpha** (input_control) . . . . . number ⇝ *real* / integer
Maximum angle difference of the polygon segments.
Default: 0.15
Suggested values: Alpha ∈ {0.05, 0.10, 0.15, 0.20, 0.30}
Restriction: 0 <= Alpha && Alpha <= pi / 2

▷ **Merge** (input_control) . . . . . string ⇝ *string*
Should adjacent parallel relations be merged?
Default: 'true'
List of values: Merge ∈ {'true', 'false'}

gen_rectangle2_contour_xld (: Rectangle : Row, Column, Phi, Length1, Length2 :)

Create an XLD contour in the shape of a rectangle.

gen_rectangle2_contour_xld creates one or more XLD contours in the shape of a rectangle with arbitrary orientation. The rectangle has the center (Row, Column), the orientation Phi, and the half edge lengths Length1 and Length2. The angle Phi must be given in radians and specifies the angle between the horizontal axis and the edge with the half length Length1 in the mathematically positive direction (counterclockwise).

Parameter Broadcasting

This operator supports parameter broadcasting. This means that each parameter can be given as a tuple of length *1* or *N*. Parameters with tuple length *1* will be repeated internally such that the number of created items is always *N*.

Parameters

▷ **Rectangle** (output_object) ..... xld_cont(-array) ⇝ *object*
Rectangle contour.

▷ **Row** (input_control) ..... rectangle2.center.y(-array) ⇝ *real*
Row coordinate of the center of the rectangle.
Default: 300.0

▷ **Column** (input_control) ..... rectangle2.center.x(-array) ⇝ *real*
Column coordinate of the center of the rectangle.
Default: 200.0

▷ **Phi** (input_control) ..... rectangle2.angle.rad(-array) ⇝ *real*
Orientation of the main axis of the rectangle [rad].
Default: 0.0
Restriction: - pi / 2 < Phi && Phi <= pi / 2

▷ **Length1** (input_control) ..... rectangle2.hwidth(-array) ⇝ *real*
First radius (half length) of the rectangle.
Default: 100.5

▷ **Length2** (input_control) ..... rectangle2.hheight(-array) ⇝ *real*
Second radius (half width) of the rectangle.
Default: 20.5

Result

gen_rectangle2_contour_xld returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

mod_parallels_xld (Parallels, Image : ModParallels, ExtParallels : Quality, MinGray, MaxGray, MaxStandard :)

Extract parallel XLD polygons enclosing a homogeneous area.

mod_parallels_xld selects XLD parallels enclosing homogeneous areas from the input parallels Parallels. The parameter Image contains the corresponding gray value image.

Only parallels having a quality factor larger than Quality are examined. The algorithm performs parallel cross sections one pixel apart, and parallel to the line segments in the area of overlap between two parallel line segments.

In the first iteration, the mean gray value for each of the lines in the cross section is calculated. In the second iteration, the standard deviations of the gray values along each line are computed.

If the mean gray value of an area between parallels lies in the interval [MinGray,MaxGray], and if the mean of all standard deviations is smaller than the upper threshold MaxStandard, the corresponding parallels are returned as modified parallels in ModParallels.

In a second step, all polygon segments adjacent to parallels bordering homogeneous areas are checked for homogeneity. To do so, a rectangle having the width of the last area enclosed by a modified parallel is constructed, and checked for homogeneity using the algorithm described above. This process is continued as long as there are adjacent polygon segments. The polygons thus found are returned as extended parallels in ExtParallels.

Parameters

- ▷ **Parallels** (input_object) ..... xld_para-array ⇝ *object*
  Input XLD parallels.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object : byte*
  Corresponding gray value image.
- ▷ **ModParallels** (output_object) ..... xld_mod_para-array ⇝ *object*
  Modified XLD parallels.
- ▷ **ExtParallels** (output_object) ..... xld_ext_para-array ⇝ *object*
  Extended XLD parallels.
- ▷ **Quality** (input_control) ..... number ⇝ *real / integer*
  Minimum quality factor (measure of parallelism).
  Default: 0.4
  Suggested values: Quality ∈ {0.1, 0.2, 0.3, 0.4, 0.5, 0.6}
  Restriction: 0.0 <= Quality && Quality <= 1.0
- ▷ **MinGray** (input_control) ..... integer ⇝ *integer*
  Minimum mean gray value.
  Default: 160
  Suggested values: MinGray ∈ {80, 100, 120, 140, 160, 180}
  Restriction: 0 <= MinGray && MinGray <= 255
- ▷ **MaxGray** (input_control) ..... integer ⇝ *integer*
  Maximum mean gray value.
  Default: 220
  Suggested values: MaxGray ∈ {140, 160, 180, 200, 220, 240}
  Restriction: 0 <= MaxGray && MaxGray <= 255 && MaxGray >= MinGray

▷ **MaxStandard** (input_control) . . . . . number ⇝ *real / integer*
Maximum allowed standard deviation.
Default: 10.0
Suggested values: MaxStandard ∈ {5.0, 10.0, 15.0, 20.0}
Restriction: MaxStandard >= 0.0

29.3 Features

area_center_points_xld (XLD : : : Area, Row, Column)

Area and center of gravity (centroid) of contours and polygons treated as point clouds.

area_center_points_xld calculates the area and center of gravity (centroid) of the point clouds given by contours or polygons XLD (i.e., the order of the points in the contour or polygon is not taken into account). The area corresponds to the number of points in the point cloud. The centroid is given by the arithmetic mean of all points. If the contour or polygon is closed (end point = start point), the end point of the contour or polygon is not taken into account to avoid that it receives twice the weight of the other points.

area_center_points_xld should be used if the contour XLD intersects itself or if it is not possible to close the contour using a line from end to start point without self-intersection, because in this case area_center_xld does not produce useful results. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used.

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Attention

Even if the contour or polygon XLD is not intersecting itself, the result of area_center_points_xld significantly differs from the result of area_center_xld as it is calculated from the point cloud and not from the enclosed region.

Parameters

▷ **XLD** (input_object) . . . . . xld(-array) ⇝ *object*
Point clouds to be examined in form of contours or polygons.

▷ **Area** (output_control) . . . . . real(-array) ⇝ *real*
Area of the point cloud.

▷ **Row** (output_control) . . . . . point.y(-array) ⇝ *real*
Row coordinate of the centroid.

▷ **Column** (output_control) . . . . . point.x(-array) ⇝ *real*
Column coordinate of the centroid.

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

area_center_points_xld returns 2 (H_MSG_TRUE) if the input is not empty. If the input is empty the behavior can be set via set_system('no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

area_center_xld (XLD : : : Area, Row, Column, PointOrder)

Area and center of gravity (centroid) of contours and polygons.

area_center_xld calculates the area and center of gravity (centroid) of the regions enclosed by the contours or polygons XLD as well as the order of the points along the boundary. The area and centroid are computed by applying Green's theorem using only the points on the contour or polygon, i.e., no region is generated explicitly for the purpose of calculating the features. If the points are arranged counterclockwise (i.e., in a positive mathematical sense) in the contour or polygon, PointOrder will be *'positive'*. It is assumed that the contours or polygons are closed. If this is not the case area_center_xld will artificially close the contour respectively polygon.

It should be noted that area_center_xld only returns useful results if the contour or polygon encloses a region in the plane. In particular, the contour or polygon must not intersect itself. This is particularly important if open contours or polygons are passed because they are closed automatically, which can produce a self-intersection. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used. If the contour or polygon intersects itself, a useful value for the center of gravity can be calculated with area_center_points_xld.

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Area** (output_control) ..... real(-array) ⇝ *real*
Area enclosed by the contour or polygon.

▷ **Row** (output_control) ..... point.y(-array) ⇝ *real*
Row coordinate of the centroid.

▷ **Column** (output_control) ..... point.x(-array) ⇝ *real*
Column coordinate of the centroid.

▷ **PointOrder** (output_control) ..... string(-array) ⇝ *string*
point order along the boundary ('positive'/'negative').

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

area_center_xld returns 2 (H_MSG_TRUE) if the input is not empty. If the input is empty the behavior can be set via set_system('no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

circularity_xld (XLD : : : Circularity)

Shape factor for the circularity (similarity to a circle) of contours or polygons.

The operator circularity_xld calculates the similarity of each input contour or polygon with a circle. The input contour or polygon must not intersect itself, otherwise the resulting parameter is not meaningful (Whether the input contour or polygon intersects itself or not can be determined with test_self_intersection_xld). If the input contour or polygon is not closed it will be closed automatically.

Calculation: If F is the enclosed area of the contour or polygon and max is the maximum distance from the center to all contour or polygon pixels, the shape factor Circularity is defined as:

$$\text{Circularity} = \frac{F}{(max^2 * \pi)}$$

The shape factor Circularity of a circle is 1. If the contour or polygon encloses an elongated area Circularity is smaller than 1. The operator circularity_xld especially responds to large bulges.

If more than one contour or polygon is passed, the numerical values of the shape factor are stored in a tuple in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Circularity** (output_control) ..... real(-array) ⇝ *real*
Roundness of the input contours or polygons.
Assertion: 0 <= Circularity && Circularity <= 1.0

Result

The operator circularity_xld returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input contour available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

compactness_xld (XLD : : : Compactness)

Shape factor for the compactness of contours or polygons.

The operator compactness_xld calculates the compactness of each input contour or polygon in XLD. The input contour or polygon must not intersect itself, otherwise the resulting parameter is not meaningful (Whether the input contour or polygon intersects itself or not can be determined with test_self_intersection_xld). If the input contour or polygon is not closed it will be closed automatically.

Calculation: If L is the length and F the enclosed area of the contour or polygon the shape factor Compactness is defined as:

$$\text{Compactness} = \frac{L^2}{4F\pi}$$

The shape factor Compactness of a circle is 1. If the contour or polygon encloses an elongated area Compactness is larger than 1. The operator compactness_xld responds to the course of the contour or polygon (roughness). If more than one contour or polygon is passed, the shape factors are stored in a tuple in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Compactness** (output_control) ..... real(-array) ⇝ *real*
Compactness of the input contours or polygons.
Assertion: Compactness >= 1.0 || Compactness == 0

Result

The operator compactness_xld returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input contours available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

contour_point_num_xld (Contour : : : Length)

Return the number of points in an XLD contour.

contour_point_num_xld returns the length of the input contour Contour, i.e., its number of points, in Length.

Parameters

▷ **Contour** (input_object) ..... xld_cont(-array) ⇝ *object*
Input XLD contour.

▷ **Length** (output_control) ..... integer(-array) ⇝ *integer*
Number of contour points.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

Foundation

convexity_xld (XLD : : : Convexity)

Shape factor for the convexity of contours or polygons.

The operator convexity_xld calculates the convexity for each input contour or polygon. The input contour or polygon must not intersect itself, otherwise the resulting parameter is not meaningful (Whether the input contour or polygon intersects itself or not can be determined with test_self_intersection_xld). If the input contour or polygon is not closed it will be closed automatically.

Calculation: If F_c is the area of the convex hull and F_o the area enclosed by the original contour or polygon the shape factor Convexity is defined as:

$$\texttt{Convexity} = \frac{F_o}{F_c}$$

The shape factor Convexity is 1 if the contour or polygon is convex (e.g., a rectangle, circle, etc.). If there are indentations Convexity is smaller than 1.

If more than one contour or polygon is passed, the numerical results of the shape factor are stored in a tuple in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Convexity** (output_control) ..... real(-array) ⇝ *real*
Convexity of the input contours or polygons.
Assertion: Convexity <= 1

Result

The operator convexity_xld returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input contour available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

diameter_xld (XLD : : : Row1, Column1, Row2, Column2, Diameter)

Maximum distance between two contour or polygon points.

The operator diameter_xld calculates the maximum distance between two points of each input contour or polygon. The coordinates of these two extremes and the distance between them will be returned. The input contour or polygon must not intersect itself, otherwise the resulting parameters are not meaningful (Whether the input contour or polygon intersects itself or not can be determined with test_self_intersection_xld). If the input contour or polygon is not closed it will be closed automatically. If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Attention

If the contour or polygon is empty, the results of Row1, Column1, Row2 and Column2 (all of them = 0) may lead to confusion.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Row1** (output_control) ..... line.begin.y(-array) ⇝ *real*
Row coordinate of the first extreme point of the contours or polygons.

▷ **Column1** (output_control) ..... line.begin.x(-array) ⇝ *real*
Column coordinate of the first extreme point of the contours or polygons.

▷ **Row2** (output_control) ..... line.end.y(-array) ⇝ *real*
Row coordinate of the second extreme point of the contour or polygons.

▷ **Column2** (output_control) ..... line.end.x(-array) ⇝ *real*
Column coordinate of the second extreme point of the contours or polygons.

▷ **Diameter** (output_control) ..... number(-array) ⇝ *real*
Distance of the two extreme points of the contours or polygons.

Result

The operator diameter_xld returns the value 2 (H_MSG_TRUE), if the input is not empty. The reaction to empty input (no input contours are available) may be determined with the help of the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Automatically parallelized on tuple level.

Module

Foundation

dist_ellipse_contour_points_xld (Contour : : DistanceMode, ClippingEndPoints, Row, Column, Phi, Radius1, Radius2 : Distances)

Compute the distances of all contour points to an ellipse.

The operator dist_ellipse_contour_points_xld determines the distances between points of a contour Contour and an ellipse specified by the center (Row, Column), the orientation of the main axis Phi, the length of the larger half axis Radius1, and the length of the smaller half axis Radius2.

The distance measure is the geometric distance, sometimes also called orthogonal distance. The distances Distances are returned for all points of the contour. Normally, the distance is a positive value. In this case DistanceMode equal to *'unsigned'* must be chosen. If this option is switched to *'signed'* the distances can take positive or negative sign, depending on whether the contour points lie outside or inside the ellipse respectively.

Because of artifacts in the preprocessing, the start and end points of a contour might be faulty. In this case, the operator fit_ellipse_contour_xld is typically called with the parameter ClippingEndPoints set to a value greater than zero to exclude points at the beginning and the end of the contour from the computation. In order to get the geometric distances of the same set of points as used in the fitting process ClippingEndPoints should take the same value.

Parameters

▷ **Contour** (input_object) . . . . . xld_cont ⇝ *object*
Input contours.

▷ **DistanceMode** (input_control) . . . . . string ⇝ *string*
Mode for unsigned or signed distance values.
Default: 'unsigned'
List of values: DistanceMode ∈ {'unsigned', 'signed'}

▷ **ClippingEndPoints** (input_control) . . . . . integer ⇝ *integer*
Number of points at the beginning and the end of the contours to be ignored for the computation of distances.
Default: 0
Restriction: ClippingEndPoints >= 0

▷ **Row** (input_control) . . . . . ellipse.center.y ⇝ *real*
Row coordinate of the center of the ellipse.

▷ **Column** (input_control) . . . . . ellipse.center.x ⇝ *real*
Column coordinate of the center of the ellipse.

▷ **Phi** (input_control) . . . . . ellipse.angle.rad ⇝ *real*
Orientation of the main axis in radian.
Restriction: Phi >= 0 && Phi <= 6.283185307

▷ **Radius1** (input_control) . . . . . ellipse.radius1 ⇝ *real*
Length of the larger half axis.
Restriction: Radius1 > 0

▷ **Radius2** (input_control) . . . . . ellipse.radius2 ⇝ *real*
Length of the smaller half axis.
Restriction: Radius2 >= 0 && Radius2 <= Radius1

▷ **Distances** (output_control) . . . . . real-array ⇝ *real*
Distances of the contour points to the ellipse.

Result

`dist_ellipse_contour_points_xld` returns `2` (`H_MSG_TRUE`) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`fit_ellipse_contour_xld`

Alternatives

`dist_ellipse_contour_xld`

Module

Foundation

dist_ellipse_contour_xld (Contours : : Mode, MaxNumPoints, ClippingEndPoints, Row, Column, Phi, Radius1, Radius2 : MinDist, MaxDist, AvgDist, SigmaDist)

Compute the distance of contours to an ellipse.

`dist_ellipse_contour_xld` determines the distance between the contours in `Contours` and an ellipse specified by the center (`Row`, `Column`), the orientation of the main axis `Phi`, the length of the larger half axis `Radius1`, and the length of the smaller half axis `Radius2`. Different measures for the distance of a contour point $X = (x_i, y_i)$ to the ellipse are available (`Mode`):

'geometric' The underlying distance measure is the geometric distance between a point on the contour and the ellipse. This measure is also called orthogonal or Euclidean distance.

'algebraic' The distance is measured by the algebraic distance
$ax_i^2 + bx_iy_i + cy_i^2 + dx_i + ey_i + f$, where the parameters a - f describing the ellipse are normalized in order to obtain `Radius2` as distance of the center of the ellipse. This measure shows a *high curvature bias*: Near points of high curvature on the ellipse (like the poles on the main axis) the distance is smaller than near points with low curvature.

'focpoints' The distance is measured by the deviation $XF_1 + XF_2 - 2a$, where F_1,F_2 are the focal points and a corresponds to `Radius1`. This measure shows a *low curvature bias*: Near points of high curvature on the ellipse (like the poles on the main axis) the distance is larger than near points with low curvature.

'bisec' The distance is measured by the distance between X and the intersection of the angular bisector of the two lines through X and the focal points with the ellipse. This is a good approximation of the orthogonal distance from X to the ellipse. The accuracy of the approximation depends on both the aspect ratio of the ellipse and the distance.

The operator returns the minimum absolute distance `MinDist`, the maximum absolute distance `MaxDist`, the average absolute distance `AvgDist`, and the standard deviation of the absolute distances `SigmaDist` of all contour points.

To reduce the computational load, the computation of the distances can be restricted to a subset of the contour points: If a value other than -1 is assigned to `MaxNumPoints`, only up to `MaxNumPoints` points - uniformly distributed over the contour - are used. Due to artifacts in the pre-processing the start and end points of a contour might be faulty. Therefore, it is possible to exclude `ClippingEndPoints` points at the beginning and at the end of a contour from the computation.

Parameters

- ▷ **Contours** (input_object) . . . . . xld_cont(-array) ⇝ *object*
  Input contours.
- ▷ **Mode** (input_control) . . . . . string ⇝ *string*
  Method for the determination of the distances.
  Default: 'geometric'
  List of values: Mode ∈ {'geometric', 'algebraic', 'focpoints', 'bisec'}
- ▷ **MaxNumPoints** (input_control) . . . . . integer ⇝ *integer*
  Maximum number of contour points used for the computation (-1 for all points).
  Default: -1
  Restriction: MaxNumPoints >= 3
- ▷ **ClippingEndPoints** (input_control) . . . . . integer ⇝ *integer*
  Number of points at the beginning and the end of the contours to be ignored for the computation of distances.
  Default: 0
  Restriction: ClippingEndPoints >= 0
- ▷ **Row** (input_control) . . . . . ellipse.center.y ⇝ *real*
  Row coordinate of the center of the ellipse.
- ▷ **Column** (input_control) . . . . . ellipse.center.x ⇝ *real*
  Column coordinate of the center of the ellipse.
- ▷ **Phi** (input_control) . . . . . ellipse.angle.rad ⇝ *real*
  Orientation of the main axis in radian.
  Restriction: Phi >= 0 && Phi <= 6.283185307
- ▷ **Radius1** (input_control) . . . . . ellipse.radius1 ⇝ *real*
  Length of the larger half axis.
  Restriction: Radius1 > 0
- ▷ **Radius2** (input_control) . . . . . ellipse.radius2 ⇝ *real*
  Length of the smaller half axis.
  Restriction: Radius2 >= 0 && Radius2 <= Radius1
- ▷ **MinDist** (output_control) . . . . . real(-array) ⇝ *real*
  Minimum distance.
- ▷ **MaxDist** (output_control) . . . . . real(-array) ⇝ *real*
  Maximum distance.
- ▷ **AvgDist** (output_control) . . . . . real(-array) ⇝ *real*
  Mean distance.
- ▷ **SigmaDist** (output_control) . . . . . real(-array) ⇝ *real*
  Standard deviation of the distance.

Example

```

Module

Foundation

dist_rectangle2_contour_points_xld (
Contour : : ClippingEndPoints, Row, Column, Phi, Length1,
Length2 : Distances)

Compute the distances of all contour points to a rectangle.

dist_rectangle2_contour_points_xld determines the Euclidean distances between the points of a contour Contour and a rectangle of arbitrary orientation specified by the center (Row, Column), the orientation Phi, and the half edge lengths Length1 and Length2. The angle Phi must be given in radians and specifies the angle between the horizontal axis and the edge with the half length Length1 in the mathematically positive direction (counterclockwise).

Depending on the processing used to create Contour, the start and end points of a contour may contain positional errors. In this case, the operator fit_rectangle2_contour_xld is typically called with the parameter ClippingEndPoints set to a value greater than zero to exclude points at the beginning and the end of the contour from the computation. To compute the distances of the same set of points as used in the fitting process, ClippingEndPoints should be set to the same value as in fit_rectangle2_contour_xld.

Parameters

▷ **Contour** (input_object) . . . . . xld_cont ⇝ *object*
Input contour.

▷ **ClippingEndPoints** (input_control) . . . . . integer ⇝ *integer*
Number of points at the beginning and the end of the contours to be ignored for the computation of distances.
Default: 0
Suggested values: ClippingEndPoints ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: ClippingEndPoints >= 0

▷ **Row** (input_control) . . . . . rectangle2.center.y ⇝ *real*
Row coordinate of the center of the rectangle.

▷ **Column** (input_control) . . . . . rectangle2.center.x ⇝ *real*
Column coordinate of the center of the rectangle.

▷ **Phi** (input_control) . . . . . rectangle2.angle.rad ⇝ *real*
Orientation of the main axis of the rectangle [rad].

▷ **Length1** (input_control) . . . . . rectangle2.hwidth ⇝ *real*
First radius (half length) of the rectangle.
Restriction: Length1 > 0

▷ **Length2** (input_control) . . . . . rectangle2.hheight ⇝ *real*
Second radius (half width) of the rectangle.
Restriction: Length2 >= 0

▷ **Distances** (output_control) . . . . . real-array ⇝ *real*
Distances of the contour points to the rectangle.

Result

dist_rectangle2_contour_points_xld returns 2 (H_MSG_TRUE) if all parameter values are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

fit_rectangle2_contour_xld

Module

Foundation

eccentricity_points_xld (XLD : : : Anisometry)

Anisometry of contours or polygons treated as point clouds.

The operator eccentricity_points_xld calculates the shape feature Anisometry derived from the geometric moments of the point cloud given by the contour or polygon XLD (i.e., the order of the points in the contour or polygon is not taken into account). If the contour or polygon is closed (end point = start point), the end point of the contour or polygon is not taken into account to avoid that it receives twice the weight of the other points.

Calculation: If the ellipse radii Ra, Rb (elliptic_axis_points_xld) are given, the following applies:

$$\texttt{Anisometry} = \frac{Ra}{Rb}$$

The anisometry of a circle is 1.0.

eccentricity_points_xld should be used if the contour XLD intersects itself or if it is not possible to close the contour using a line from end to start point without self-intersection, because in this case eccentricity_xld does not produce useful results. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used.

If more than one contour or polygon is passed, the values of the anisometry are stored in a tuple in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Anisometry** (output_control) ..... real(-array) ⇝ *real*
Anisometry of the contours or polygons.
Assertion: Anisometry >= 1.0

Result

The operator eccentricity_points_xld returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input contours available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

eccentricity_xld (XLD : : : Anisometry, Bulkiness, StructureFactor)

Shape features derived from the ellipse parameters of contours or polygons.

The operator eccentricity_xld calculates the three shape features Anisometry, Bulkiness, and StructureFactor derived from the geometric moments for each input contour or polygon. If the input contour or polygon is not closed it will be closed automatically.

Calculation: If the ellipse radii Ra, Rb (elliptic_axis_xld) and the enclosed area A of the contour or polygon are given, the following applies:

$$\begin{aligned} \texttt{Anisometry} &= \frac{Ra}{Rb} \\ \texttt{Bulkiness} &= \frac{\pi \cdot Ra \cdot Rb}{F} \\ \texttt{StructureFactor} &= \texttt{Anisometry} \cdot \texttt{Bulkiness} - 1 \end{aligned}$$

The anisometry of a circle is 1.0.

It should be noted that eccentricity_xld only returns useful results if the contour or polygon encloses a region in the plane. In particular, the contour or polygon must not intersect itself. This is particularly important if open contours or polygons are passed because they are closed automatically, which can produce a self-intersection. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used. If the contour or polygon intersects itself, a useful value for the anisometry can be calculated with eccentricity_points_xld.

If more than one contour is passed the results are stored in tuples, the index of a value in the tuple corresponding to the index of a contour in the input.

Parameters

- ▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **Anisometry** (output_control) ..... real(-array) ⇝ *real*
  Anisometry of the contours or polygons.
  Assertion: Anisometry >= 1.0
- ▷ **Bulkiness** (output_control) ..... real(-array) ⇝ *real*
  Bulkiness of the contours or polygons.
- ▷ **StructureFactor** (output_control) ..... real(-array) ⇝ *real*
  Structure factor of the contours or polygons.

Result

The operator eccentricity_xld returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input contours available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

elliptic_axis_points_xld (XLD : : : Ra, Rb, Phi)

Parameters of the equivalent ellipse of contours or polygons treated as point clouds.

The operator elliptic_axis_points_xld calculates the radii (Ra, Rb) and the orientation (Phi, in radians) of the ellipse having the same orientation and the same aspect ratio as the point cloud given by the contour or polygon XLD (i.e., the order of the points in the contour or polygon is not taken into account). If the contour or polygon is closed (end point = start point), the end point of the contour or polygon is not taken into account to avoid that it receives twice the weight of the other points.

Calculation: If the moments M_{20}, M_{02} and M_{11} are normalized to the area (see moments_points_xld), the major radius Ra and the minor radius Rb are calculated as:

$$\mathtt{Ra} = \frac{\sqrt{8(M_{20} + M_{02} + \sqrt{(M_{20} - M_{02})^2 + 4M_{11}^2})}}{2}$$

$$\mathtt{Rb} = \frac{\sqrt{8(M_{20} + M_{02} - \sqrt{(M_{20} - M_{02})^2 + 4M_{11}^2})}}{2}$$

The orientation Phi, i.e., the angle between the major axis and the x (column) axis, is defined by:

$$\mathtt{Phi} = -0.5 \operatorname{atan2}(2M_{11}, M_{02} - M_{20})$$

elliptic_axis_points_xld should be used if the contour XLD intersects itself or if it is not possible to close the contour using a line from end to start point without self-intersection, because in this case elliptic_axis_xld does not produce useful results. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used.

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Parameters

- ▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **Ra** (output_control) ..... real(-array) ⇝ *real*
  Major radius.
  Assertion: Ra >= 0.0
- ▷ **Rb** (output_control) ..... real(-array) ⇝ *real*
  Minor radius.
  Assertion: Rb >= 0.0 && Rb <= Ra
- ▷ **Phi** (output_control) ..... angle.rad(-array) ⇝ *real*
  Angle between the major axis and the column axis (radians).
  Assertion: - pi / 2 < Phi && Phi <= pi / 2

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

elliptic_axis_points_xld returns 2 (H_MSG_TRUE) if the input is not empty. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

elliptic_axis_xld (XLD : : : Ra, Rb, Phi)

Parameters of the equivalent ellipse of contours or polygons.

The operator elliptic_axis_xld calculates the radii and the orientations of the ellipses having the same orientation and the same aspect ratio as the input contours or polygons. The length of the major radius Ra and the minor radius Rb as well as the orientation of the main axis with regard to the horizontal (Phi) are determined. The angle is indicated in radians. It is assumed that the contours or polygons are closed. If this is not the case elliptic_axis_xld will artificially close the contours or polygons.

Calculation: If the moments M_{20}, M_{02} and M_{11} are normalized and passed to the area (see moments_xld), the radii Ra and Rb are calculated as:

$$\texttt{Ra} = \frac{\sqrt{8(M_{20}+M_{02}+\sqrt{(M_{20}-M_{02})^2+4M_{11}^2})}}{2}$$

$$\texttt{Rb} = \frac{\sqrt{8(M_{20}+M_{02}-\sqrt{(M_{20}-M_{02})^2+4M_{11}^2})}}{2}$$

The orientation Phi is defined by:

$$\texttt{Phi} = -0.5\text{atan2}(2M_{11}, M_{02}-M_{20})$$

It should be noted that elliptic_axis_xld only returns useful results if the contour or polygon encloses a region in the plane. In particular, the contour or polygon must not intersect itself. This is particularly important if open contours or polygons are passed because they are closed automatically, which can produce a self-intersection. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used. If the contour or polygon intersects itself, useful values for the ellipse parameters can be calculated with elliptic_axis_points_xld.

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Ra** (output_control) ..... real(-array) ⇝ *real*
Major radius.
Assertion: Ra >= 0.0

▷ **Rb** (output_control) ..... real(-array) ⇝ *real*
Minor radius.
Assertion: Rb >= 0.0 && Rb <= Ra

▷ **Phi** (output_control) ..... angle.rad(-array) ⇝ *real*
Angle between the major axis and the x axis (radians).
Assertion: - pi / 2 < Phi && Phi <= pi / 2

Complexity

If N is the number of contour or polygon points, the runtime complexity is $O(N)$.

Result

`elliptic_axis_xld` returns `2` (`H_MSG_TRUE`) if the input is not empty. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

fit_circle_contour_xld (Contours : : Algorithm, MaxNumPoints, MaxClosureDist, ClippingEndPoints, Iterations, ClippingFactor : Row, Column, Radius, StartPhi, EndPhi, PointOrder)

Approximate XLD contours by circles.

`fit_circle_contour_xld` approximates the XLD contours `Contours` by circles. It does not perform a segmentation of the input contours. Thus, one has to make sure that each contour corresponds to one and only one circle. The operator returns for each contour the center (`Row`, `Column`), and the `Radius`.

The algorithm used for the fitting of circles can be selected via `Algorithm`:

'algebraic' This approach minimizes the algebraic distance between the contour points and the resulting circle.

'ahuber' Similar to *'algebraic'*. Here the contour points are weighted to decrease the impact of outliers based on the approach of Huber (see below).

'atukey' Similar to *'algebraic'*. Here the contour points are weighted and outliers are ignored based on the approach of Tukey (see below).

'geometric' This approach minimizes the geometric distance between the contour points and the resulting circle. The distance measure is statistically optimal, but takes more computational time. This option is recommended if the contour points are considerably distorted by noise.

'geohuber' Similar to *'geometric'*. Here the contour points are weighted to decrease the impact of outliers based on the approach of Huber (see below).

'geotukey' Similar to *'geometric'*. Here the contour points are weighted and outliers are ignored based on the approach of Tukey (see below).

For '*huber' and '*tukey' a robust error statistics is used to estimate the standard deviation of the distances from the contour points *without* outliers from the approximating circle. The parameter `ClippingFactor` (a scaling factor for the standard deviation) controls the amount of outliers: the smaller the value chosen for `ClippingFactor` the more outliers are detected. In the Tukey algorithm outliers are removed, whereas in the Huber algorithm outliers are only damped, or more precisely they are weighted linearly. Without any robust weighting the squares of the distances are taken as error values in the optimization, i.e., a least square formulation. In practice, the approach of Tukey is recommended.

The parameter `Iterations` specifies the number of iterations for the algorithms *'algebraic'*, *'ahuber'* and *'atukey'*. This parameter is ignored for the algorithms *'geometric'*, *'geohuber'* and *'geotukey'*. If `Iterations` is set to zero, the algorithm does not perform iterative improvements on the fitted circle, but only checks if the initial guess was already close enough depending on the chosen treatment of outliers.

To reduce the computational load, the fitting of circles can be restricted to a subset of the contour points: If a value other than *-1* is assigned to `MaxNumPoints`, only up to `MaxNumPoints` points - uniformly distributed over the contour - are used.

For circular arcs, the points on the circle closest to the start points and end points of the original contours are chosen as start and end points. The corresponding angles referring to the X-axis are returned in `StartPhi` and `EndPhi`, see also `gen_ellipse_contour_xld`. Contours, for which the distance between their start points and their end points is less or equal `MaxClosureDist` are considered to be closed. Thus, they are approximated by circles instead of circular arcs. Due to artifacts in the pre-processing the start and end points of a contour might be faulty. Therefore, it is possible to exclude `ClippingEndPoints` points at the beginning and at the end of a contour from the fitting of circles. However, they are still used for the determination of `StartPhi` and `EndPhi`.

The minimum necessary number of contour points for fitting a circle is three. Therefore, it is required that the number of contour points is at least $3 + 2 \cdot$ `ClippingEndPoints`.

Parameters

▷ **`Contours`** (input_object) ..... xld_cont(-array) ⇝ *object*
Input contours.

▷ **`Algorithm`** (input_control) ..... string ⇝ *string*
Algorithm for the fitting of circles.
Default: 'algebraic'
List of values: `Algorithm` ∈ {'algebraic', 'ahuber', 'atukey', 'geometric', 'geohuber', 'geotukey'}

▷ **`MaxNumPoints`** (input_control) ..... integer ⇝ *integer*
Maximum number of contour points used for the computation (-1 for all points).
Default: -1
Restriction: MaxNumPoints >= 3

▷ **`MaxClosureDist`** (input_control) ..... real ⇝ *real*
Maximum distance between the end points of a contour to be considered as 'closed'.
Default: 0.0
Restriction: MaxClosureDist >= 0.0

▷ **`ClippingEndPoints`** (input_control) ..... integer ⇝ *integer*
Number of points at the beginning and at the end of the contours to be ignored for the fitting.
Default: 0
Restriction: ClippingEndPoints >= 0

▷ **`Iterations`** (input_control) ..... integer ⇝ *integer*
Maximum number of iterations for the robust weighted fitting.
Default: 3
Restriction: Iterations >= 0

▷ **ClippingFactor** (input_control) ..... real ⇝ *real*
Clipping factor for the elimination of outliers (typical: 1.0 for Huber and 2.0 for Tukey).
Default: 2.0
Suggested values: ClippingFactor ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
Restriction: ClippingFactor > 0

▷ **Row** (output_control) ..... circle.center.y(-array) ⇝ *real*
Row coordinate of the center of the circle.

▷ **Column** (output_control) ..... circle.center.x(-array) ⇝ *real*
Column coordinate of the center of the circle.

▷ **Radius** (output_control) ..... circle.radius(-array) ⇝ *real*
Radius of circle.

▷ **StartPhi** (output_control) ..... angle.rad(-array) ⇝ *real*
Angle of the start point [rad].

▷ **EndPhi** (output_control) ..... angle.rad(-array) ⇝ *real*
Angle of the end point [rad].

▷ **PointOrder** (output_control) ..... string(-array) ⇝ *string*
Point order along the boundary.
List of values: PointOrder ∈ {'positive', 'negative'}

Result

fit_circle_contour_xld returns 2 (H_MSG_TRUE) if all parameter values are correct, and circles could be fitted to the input contours. If the input is empty the behavior can be set via set_system ('no_object_result',<Result>). If necessary, an exception is raised. If the parameter ClippingFactor is chosen too small, i.e., all points are classified as outliers, the error 3264 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

fit_ellipse_contour_xld (Contours : : Algorithm, MaxNumPoints, MaxClosureDist, ClippingEndPoints, VossTabSize, Iterations, ClippingFactor : Row, Column, Phi, Radius1, Radius2, StartPhi, EndPhi, PointOrder)

Approximate XLD contours by ellipses or elliptic arcs.

fit_ellipse_contour_xld approximates the XLD contours Contours by elliptic arcs or closed ellipses. It does not perform a segmentation of the input contours. Thus, one has to make sure that each contour corresponds to one and only one elliptic structure. The operator returns for each contour the center (Row, Column), the orientation of the main axis Phi, the length of the larger half axis Radius1, and the length of the smaller half axis Radius2 of the underlying ellipse. In addition to that, the angle corresponding to the start point and the end point StartPhi, EndPhi, and the point order along the boundary PointOrder is returned for elliptic arcs. These parameters are set to 0, 2π, and 'positive' for closed ellipses. The algorithm used for the fitting of ellipses can be selected via Algorithm:

'fitzgibbon' This approach minimizes the algebraic distance $ax_i^2+bx_iy_i+cy_i^2+dx_i+ey_i+f$ between the contour points (x_i, y_i) and the resulting ellipse. The constraint $4ac-b^2=1$ guarantees that the resulting polynomial characterizes an ellipse (instead of a hyperbola or a parabola).

'fhuber' Similar to *'fitzgibbon'*. Here the contour points are weighted to decrease the impact of outliers based on the approach of Huber (see below).

'ftukey' Similar to *'fitzgibbon'*. Here the contour points are weighted and outliers are ignored based on the approach of Tukey (see below).

'geometric' This approach minimizes the geometric distance between the contour points and the resulting ellipse. The distance measure is statistically optimal, but takes more computational time, because the computation is an iterative process. This option is recommended if the contour points are considerably distorted by noise.

'geohuber' Similar to *'geometric'*. Here the contour points are weighted to decrease the impact of outliers based on the approach of Huber (see below).

'geotukey' Similar to *'geometric'*. Here the contour points are weighted and outliers are ignored based on the approach of Tukey (see below).

'voss' Each input contour is transformed in an affine standard position. Based on the moments of the transformed contour (that is of the enclosed image region) the standard circular segment is chosen whose standard position matches best with the standard position of the contour. The ellipse corresponding to the standard position of the selected circular segment is re-transformed based on the affine transformation which produced the standard position of the contour resulting in the ellipse matching the original contour. `VossTabSize` standard circular segments are used for this computation. To speed up the process the corresponding moments and other data is stored in a table which is created during the first call (with a specific value for `VossTabSize`) to `fit_ellipse_contour_xld`.

'focpoints' Each point P on an ellipse satisfies the constraint that the sum of distances to the focal points F_1,F_2 equals twice the length of the larger half axis a. In this approach, the deviation PF_1+PF_2-2a is minimized for all contour points by a least squares optimization.

'fphuber' Similar to *'focpoints'*. Here a *weighted* least squares optimization is done to decrease the impact of outliers based on the approach of Huber (see below).

'fptukey' Similar to *'focpoints'*. Here a *weighted* least squares optimization is done and outliers are ignored based on the approach of Tukey (see below).

For *'*huber'* and *'*tukey'* a robust error statistics is used to estimate the standard deviation of the distances from the contour points *without* outliers from the approximating ellipse. The parameter `ClippingFactor` (a scaling factor for the standard deviation) controls the amount of outliers: the smaller the value chosen for `ClippingFactor` the more points are classified as outliers. Every contour point is individually weighted and contributes according to its weight in the fitting process. The bundle of robust weighting and fitting can be iterated. The overall number of iterations is given by `Iterations`. This parameter is of relevance for all algorithms except the two based on the geometric distance, i.e., *'geohuber'* and *'geotukey'*, where this parameter is ignored. If the algorithm does not find a fitting ellipse within this number of iterations, it fits a line; in this case `Radius2` is zero. In the Tukey algorithm outliers are removed, whereas in the Huber algorithm outliers are only damped, or more precisely they are weighted linearly. Without any robust weighting the squares of the distances are taken as error values in the optimization, i.e., a least square formulation. In practice, the approach of Tukey is recommended.

To reduce the computational load, the fitting of ellipses can be restricted to a subset of the contour points: If a value other than *-1* is assigned to `MaxNumPoints`, only up to `MaxNumPoints` points - uniformly distributed over the contour - are used.

For elliptic arcs, the points on the ellipse closest to the start points and end points of the original contours are chosen as start and end points. The corresponding angles referring to the main axis of the ellipse are returned in `StartPhi` and `EndPhi`, see also `gen_ellipse_contour_xld`. Contours, for which the distance between their start points and their end points is less or equal `MaxClosureDist` are considered to be closed. Thus, they are approximated by ellipses instead of elliptic arcs. The *'focpoints'* algorithms determine the initial parameters for the optimization for closed contours in a faster and less accurate way than for open contours. As a result, in some cases more `Iterations` may be necessary when applied to closed contours. Due to artifacts in the pre-processing the start and end points of a contour might be faulty. Therefore, it is possible to exclude `ClippingEndPoints` points at the beginning and at the end of a contour from the fitting of ellipses. However, they are still used for the determination of `StartPhi` and `EndPhi`.

The minimum necessary number of contour points for fitting an ellipse is five. Therefore, it is required that the number of contour points is at least $5 + 2 \cdot$ `ClippingEndPoints`.

Parameters

▷ **`Contours`** (input_object) . . . . . xld_cont(-array) ⇝ *object*
Input contours.

▷ **`Algorithm`** (input_control) . . . . . string ⇝ *string*
Algorithm for the fitting of ellipses.
Default: 'fitzgibbon'
List of values: `Algorithm` ∈ {'fitzgibbon', 'fhuber', 'ftukey', 'geometric', 'geohuber', 'geotukey', 'voss', 'focpoints', 'fphuber', 'fptukey'}

▷ **`MaxNumPoints`** (input_control) . . . . . integer ⇝ *integer*
Maximum number of contour points used for the computation (-1 for all points).
Default: -1
Restriction: MaxNumPoints >= 5

▷ **`MaxClosureDist`** (input_control) . . . . . real ⇝ *real*
Maximum distance between the end points of a contour to be considered as 'closed'.
Default: 0.0
Restriction: MaxClosureDist >= 0.0

▷ **`ClippingEndPoints`** (input_control) . . . . . integer ⇝ *integer*
Number of points at the beginning and at the end of the contours to be ignored for the fitting.
Default: 0
Restriction: ClippingEndPoints >= 0

▷ **`VossTabSize`** (input_control) . . . . . integer ⇝ *integer*
Number of circular segments used for the Voss approach.
Default: 200
Restriction: VossTabSize >= 25 && VossTabSize <= 5000

▷ **`Iterations`** (input_control) . . . . . integer ⇝ *integer*
Maximum number of iterations for the robust weighted fitting.
Default: 3
Restriction: Iterations >= 0

▷ **`ClippingFactor`** (input_control) . . . . . real ⇝ *real*
Clipping factor for the elimination of outliers (typical: 1.0 for '*huber' and 2.0 for '*tukey').
Default: 2.0
Suggested values: `ClippingFactor` ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
Restriction: ClippingFactor > 0

▷ **`Row`** (output_control) . . . . . ellipse.center.y(-array) ⇝ *real*
Row coordinate of the center of the ellipse.

▷ **`Column`** (output_control) . . . . . ellipse.center.x(-array) ⇝ *real*
Column coordinate of the center of the ellipse.

▷ **`Phi`** (output_control) . . . . . ellipse.angle.rad(-array) ⇝ *real*
Orientation of the main axis [rad].

▷ **`Radius1`** (output_control) . . . . . ellipse.radius1(-array) ⇝ *real*
Length of the larger half axis.

▷ **`Radius2`** (output_control) . . . . . ellipse.radius2(-array) ⇝ *real*
Length of the smaller half axis.

▷ **`StartPhi`** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Angle of the start point [rad].

▷ **`EndPhi`** (output_control) . . . . . angle.rad(-array) ⇝ *real*
Angle of the end point [rad].

▷ **`PointOrder`** (output_control) . . . . . string(-array) ⇝ *string*
point order along the boundary.
List of values: `PointOrder` ∈ {'positive', 'negative'}

Example

```
read_image (Image, 'caltab')
```

```
find_caltab (Image, CalPlate, 'caltab_800mm.descr', 3, 112, 5)
reduce_domain (Image, CalPlate, ImageReduced)
edges_sub_pix (ImageReduced, Edges, 'lanser2', 0.5, 20, 40)
select_contours_xld (Edges, EdgesClosed, 'closed', 0, 2.0, 0, 0)
select_contours_xld (EdgesClosed, EdgesMarks, 'length', 20, 80, 0, 0)
fit_ellipse_contour_xld (EdgesMarks, 'fitzgibbon', -1, 2, 0, 200, 3, 2.0, \
                         Row, Column, Phi, Radius1, Radius2, StartPhi, \
                         EndPhi, PointOrder)
gen_ellipse_contour_xld (EllMarks, Row, Column, Phi, Radius1, Radius2, \
                         StartPhi, EndPhi, PointOrder, 1.5)
length_xld(EllMarks,Length)
```

Result

`fit_ellipse_contour_xld` returns `2` (`H_MSG_TRUE`) if all parameter values are correct, and ellipses could be fitted to the input contours. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised. If the parameter `ClippingFactor` is chosen too small, i.e., all points are classified as outliers, the error 3264 is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

fit_line_contour_xld (Contours : : Algorithm, MaxNumPoints, ClippingEndPoints, Iterations, ClippingFactor : RowBegin, ColBegin, RowEnd, ColEnd, Nr, Nc, Dist)

Approximate XLD contours by line segments.

`fit_line_contour_xld` approximates the XLD contours `Contours` by line segments. It does not perform a segmentation of the input contours. Thus, one has to make sure that each contour corresponds to one and only one line segment. The operator returns for each contour the start point (`RowBegin`, `ColBegin`), the end point (`RowEnd`, `ColEnd`), and the regression line to the contour given by the normal vector (`Nr`, `Nc`) of the line and its distance `Dist` from the origin, i.e., the line equation is given by $r \cdot \mathtt{Nr} + c \cdot \mathtt{Nc} - \mathtt{Dist} = 0$.

The algorithm used for the fitting of lines can be selected via `Algorithm`:

'regression': Standard 'least squares' line fitting.

'huber': Weighted 'least squares' line fitting, where the impact of outliers is decreased based on the approach of Huber (see below).

'tukey': Weighted 'least squares' line fitting, where outliers are ignored based on the approach of Tukey (see below).

'drop': 'least squares' line fitting, where outliers are ignored. In particular, all contour points further away from the contour than the mean distance to the regression line multiplied with the `ClippingFactor` (see below) are ignored for the calculation of the undistorted regression line.

'gauss': Weighted 'least squares' line fitting, where the impact of outliers is decreased based on the mean value and the standard deviation of the distances of all contour points from the approximating line.

For *'huber'*, *'tukey'*, and *'drop'* a robust error statistics is used to estimate the standard deviation of the distances from the contour points *without* outliers from the approximating line. The parameter `ClippingFactor` (a scaling factor for the standard deviation) controls the amount of outliers: The smaller the value chosen for `ClippingFactor` the more outliers are detected. The detection of outliers is repeated. The parameter `Iterations` specifies the number of iterations. In the mode *'regression'* this value is ignored. Note that in the approach of Tukey (*'tukey'*), the outliers are removed before performing the approximation and all other points are weighted, whereas in the approach of Huber (*'huber'*), the outliers still have a small influence. Particularly, for outliers the optimization is influenced linearly and for points with a smaller distance it is influenced to the square. In practice, the approach of Tukey is recommended.

To reduce the computational load, the fitting of lines can be restricted to a subset of the contour points: If a value other than -1 is assigned to `MaxNumPoints`, only up to `MaxNumPoints` points - uniformly distributed over the contour - are used.

The start point and the end point of a line segment is determined by projecting the first and the last point of the corresponding contour to the approximating line. Due to artifacts in the pre-processing the start and end points of a contour might be faulty. Therefore, it is possible to exclude `ClippingEndPoints` points at the beginning and at the end of a contour from the line fitting. However, they are still used for the determination of the start point and the end point of the line segment.

The minimum necessary number of contour points for fitting a line is two. Therefore, it is required that the number of contour points is at least $2 + 2 \cdot$ `ClippingEndPoints`.

Parameters

- ▷ **`Contours`** (input_object) ..... xld_cont(-array) ⇝ *object*
  Input contours.
- ▷ **`Algorithm`** (input_control) ..... string ⇝ *string*
  Algorithm for the fitting of lines.
  Default: 'tukey'
  List of values: `Algorithm` ∈ {'regression', 'huber', 'tukey', 'gauss', 'drop'}
- ▷ **`MaxNumPoints`** (input_control) ..... integer ⇝ *integer*
  Maximum number of contour points used for the computation (-1 for all points).
  Default: -1
  Restriction: MaxNumPoints >= 2
- ▷ **`ClippingEndPoints`** (input_control) ..... integer ⇝ *integer*
  Number of points at the beginning and at the end of the contours to be ignored for the fitting.
  Default: 0
  Restriction: ClippingEndPoints >= 0
- ▷ **`Iterations`** (input_control) ..... integer ⇝ *integer*
  Maximum number of iterations (unused for *'regression'*).
  Default: 5
  Restriction: Iterations >= 0
- ▷ **`ClippingFactor`** (input_control) ..... real ⇝ *real*
  Clipping factor for the elimination of outliers (typical values: *1.0* for *'huber'* and *'drop'* and *2.0* for *'tukey'*).
  Default: 2.0
  Suggested values: `ClippingFactor` ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
  Restriction: ClippingFactor > 0
- ▷ **`RowBegin`** (output_control) ..... line.begin.y(-array) ⇝ *real*
  Row coordinates of the starting points of the line segments.
- ▷ **`ColBegin`** (output_control) ..... line.begin.x(-array) ⇝ *real*
  Column coordinates of the starting points of the line segments.
- ▷ **`RowEnd`** (output_control) ..... line.end.y(-array) ⇝ *real*
  Row coordinates of the end points of the line segments.
- ▷ **`ColEnd`** (output_control) ..... line.end.x(-array) ⇝ *real*
  Column coordinates of the end points of the line segments.
- ▷ **`Nr`** (output_control) ..... number(-array) ⇝ *real*
  Line parameter: Row coordinate of the normal vector

▷ **Nc** (output_control) . . . . . number(-array) ⇝ *real*
Line parameter: Column coordinate of the normal vector

▷ **Dist** (output_control) . . . . . number(-array) ⇝ *real*
Line parameter: Distance of the line from the origin

Example

```
read_image (Image, 'mreut')
edges_sub_pix (Image, Edges, 'lanser2', 0.5, 20, 40)
gen_polygons_xld (Edges, Polygons, 'ramer', 2)
split_contours_xld (Polygons, Contours, 'polygon', 1, 5)
fit_line_contour_xld (Contours, 'regression', -1, 0, 5, 2, RowBegin, \
                      ColBegin, RowEnd, ColEnd, Nr, Nc, Dist)
```

Result

`fit_line_contour_xld` returns `2` (`H_MSG_TRUE`) if all parameter values are correct, and line segments could be fitted to the input contours. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised. If the parameter `ClippingFactor` is chosen too small, i.e., all points are classified as outliers, the error 3264 is raised.

fit_rectangle2_contour_xld (Contours : : Algorithm, MaxNumPoints, MaxClosureDist, ClippingEndPoints, Iterations, ClippingFactor : Row, Column, Phi, Length1, Length2, PointOrder)

Fit rectangles to XLD contours.

`fit_rectangle2_contour_xld` fits rectangles to the rectangular XLD contours given by `Contours` and returns the parameters of the rectangles in `Row`, `Column` (center), `Phi` (orientation), as well as `Length1` and `Length2` (half edge lengths). The angle `Phi` is returned in radians and specifies the angle between the horizontal axis and the edge with the half length `Length1` in the mathematically positive direction (counterclockwise). In addition, the point order of the contour is returned in `PointOrder`. `PointOrder` = *'positive'* means that the contour is traversed in the mathematically positive direction (counterclockwise).

The algorithm used for the fitting of the rectangles can be selected via `Algorithm`:

'regression' Standard least-squares line fitting.

'huber' Weighted least-squares line fitting, where the impact of outliers is decreased based on the approach of Huber (see below).

'tukey' Weighted least-squares line fitting, where outliers are ignored based on the approach of Tukey(see below).

For *'huber'* and *'tukey'*, a robust error statistics is used to estimate the standard deviation of the distances of the contour points from the approximating sides of the rectangle while ignoring outliers. The standard deviation is computed separately for each side of the rectangle to allow the processing of rectangles whose sides are not exactly perpendicular to each other. The parameter `ClippingFactor` (a scaling factor relative to the standard deviation) controls the amount of outliers: The smaller the value chosen for `ClippingFactor` the more outliers are detected. The detection of outliers is iterated. The parameter `Iterations` specifies the number of iterations. For `Algorithm` = *'regression'*, the values of the last two parameters are ignored. Note that in the approach of Tukey (*'tukey'*), the outliers are removed before performing the approximation and all other points are weighted, whereas in the approach of Huber (*'huber'*), the outliers still have a small influence. Particularly, for outliers the optimization is influenced linearly and for points with a smaller distance it is influenced to the square. For the algebraic approach, all distances of the points influence the optimization to the square and thus are not robust against outliers. In practice, the approach of Tukey is recommended.

To reduce the computational load, the fitting of rectangles can be restricted to a subset of the contour points: If a value other than *-1* is assigned to `MaxNumPoints`, only up to `MaxNumPoints` points, uniformly distributed across the contour, are used.

Depending on the processing used to create `Contours`, the start and end points of a contour may contain positional errors. Therefore, it is possible to exclude `ClippingEndPoints` points at the beginning and at the end of a contour from the rectangle fitting.

Contours, for which the distance between their start points and their end points is $\leq$ `MaxClosureDist` are considered to be closed. For closed contours, the end point of the contour is not used for the rectangle fitting because it would receive twice the weight of the remaining points in the fit.

The fitting of the rectangle to the contour is based on finding the correspondence between the contour points and the four sides of the rectangle. To enable a successful fit, there must be at least one point that lies in the interior of the line segment that represents the respective rectangle side, i.e., the point must not lie at the ends of the line segment. Because of this, at least eight contour points are necessary to fit the rectangle. A point is internally assigned to the side of the rectangle to which it has the minimum distance. For this, the currently optimal rectangle parameters, i.e., the parameters used for the current iteration step, are used internally. If no corresponding points are found for at least one side of the rectangle, the rectangle parameters cannot be determined uniquely. In this case, the error 3266 is returned. Because of this, the caller of `fit_rectangle2_contour_xld` must ensure that the input contours sufficiently resemble a rectangle. In particular, none of the interior angles of the contour, if the contour was approximated by four lines, should be smaller than 45 degrees or larger than 135 degrees. Because of the assignment of contour points to the closest side of the rectangle this would mean that at least one side of the rectangle would have no corresponding points. Furthermore, `ClippingFactor` should not be chosen too small to avoid that the outlier suppression creates rectangle sides without corresponding contour points. This can only happen for `Algorithm` = *'tukey'*. If the above conditions are observed, `fit_rectangle2_contour_xld` returns highly accurate rectangle parameters. If the outlier suppression according to Tukey is used, `fit_rectangle2_contour_xld` can be used to robustly fit rectangles, e.g., to rectangular contours with rounded corners.

Parameters

▷ **`Contours`** (input_object) ..... xld_cont(-array) ⇝ *object*
Input contours.

▷ **`Algorithm`** (input_control) ..... string ⇝ *string*
Algorithm for fitting the rectangles.
Default: 'regression'
List of values: `Algorithm` ∈ {'regression', 'huber', 'tukey'}

▷ **`MaxNumPoints`** (input_control) ..... integer ⇝ *integer*
Maximum number of contour points used for the computation (-1 for all points).
Default: -1
Restriction: MaxNumPoints == -1 || MaxNumPoints >= 8

▷ **`MaxClosureDist`** (input_control) ..... real ⇝ *real*
Maximum distance between the end points of a contour to be considered as closed.
Default: 0.0
Restriction: MaxClosureDist >= 0.0

▷ **ClippingEndPoints** (input_control) . . . . . integer ⇝ *integer*
Number of points at the beginning and at the end of the contours to be ignored for the fitting.
Default: 0
Suggested values: ClippingEndPoints ∈ {0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10}
Restriction: ClippingEndPoints >= 0

▷ **Iterations** (input_control) . . . . . integer ⇝ *integer*
Maximum number of iterations (not used for *'regression'*).
Default: 3
Restriction: Iterations >= 0

▷ **ClippingFactor** (input_control) . . . . . real ⇝ *real*
Clipping factor for the elimination of outliers (typical values: *1.0* for *'huber'* and *2.0* for *'tukey'*).
Default: 2.0
Suggested values: ClippingFactor ∈ {1.0, 1.5, 2.0, 2.5, 3.0}
Restriction: ClippingFactor > 0

▷ **Row** (output_control) . . . . . rectangle2.center.y(-array) ⇝ *real*
Row coordinate of the center of the rectangle.

▷ **Column** (output_control) . . . . . rectangle2.center.x(-array) ⇝ *real*
Column coordinate of the center of the rectangle.

▷ **Phi** (output_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real*
Orientation of the main axis of the rectangle [rad].

▷ **Length1** (output_control) . . . . . rectangle2.hwidth(-array) ⇝ *real*
First radius (half length) of the rectangle.

▷ **Length2** (output_control) . . . . . rectangle2.hheight(-array) ⇝ *real*
Second radius (half width) of the rectangle.

▷ **PointOrder** (output_control) . . . . . string(-array) ⇝ *string*
Point order of the contour.
List of values: PointOrder ∈ {'positive', 'negative'}

Result

fit_rectangle2_contour_xld returns 2 (H_MSG_TRUE) if all parameter values are correct, and rectangles could be fitted to the input contours. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised. If the parameter ClippingFactor is chosen too small, i.e., all points are classified as outliers, the error 3266 is raised. If no points could be found for at least one side of the rectangle, the error 3266 is raised as well.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

get_contour_angle_xld (Contour : : AngleMode, CalcMode, Lookaround : Angles)

Calculate the direction of an XLD contour for each contour point.

get_contour_angle_xld calculates for each point of the XLD contour Contour the direction of its tangent. Two modes for the output values can be chosen: By passing *'abs'* for AngleMode, the resulting angles are returned relative to the horizontal axis as angles between 0 and 2π (counter-clockwise). By passing *'rel'*, the angle difference to the previous contour point is returned. In this case the range of values is between $-\pi$ and π, where negative values indicate a right turn and positive values indicate a left turn.

There are three different ways of calculating the tangent direction (CalcMode) of the contour point i using the contour points in the interval from $i -$ Lookaround to $i +$ Lookaround. By using *'range'*, the angle of the line segment between the first and last point of the interval is used. For *'mean'*, the average of all angles between consecutive points of the contour is used. Finally, for *'regress'*, the direction of the regression line (the least squares fit of a line to the contour points in the interval) is used. Lookaround is a measure of how strongly the contour is smoothed. The angles are returned in Angles in radians.

Due to the interval given by Lookaround, the input contour must have at least $2 *$ Lookaround $+ 2$ points. This minimum number of points is required so that the operator always delivers reasonable output values for the different parameter settings.

Parameters

▷ **Contour** (input_object) ..... xld_cont ⇝ *object*
Input contour.

▷ **AngleMode** (input_control) ..... string ⇝ *string*
Return type of the angles.
Default: 'abs'
List of values: AngleMode ∈ {'abs', 'rel'}

▷ **CalcMode** (input_control) ..... string ⇝ *string*
Method for computing the angles.
Default: 'range'
List of values: CalcMode ∈ {'range', 'mean', 'regress'}

▷ **Lookaround** (input_control) ..... integer ⇝ *integer*
Number of points to take into account.
Default: 3
Restriction: Lookaround > 0

▷ **Angles** (output_control) ..... real-array ⇝ *real*
Direction of the tangent to the contour points.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Processed without parallelization.

Possible Predecessors

gen_contours_skeleton_xld, lines_gauss, lines_facet, edges_sub_pix

See also

get_contour_xld, get_contour_attrib_xld

Module

Foundation

get_contour_attrib_xld (Contour : : Name : Attrib)

Return point attribute values of an XLD contour.

get_contour_attrib_xld returns the values of the attribute Name of the XLD contour Contour in Attrib. Contour point attributes are additional values defined for each contour point and describe local features. query_contour_attribs_xld can be used to query which attributes are set for a particular contour.

The following list contains information about the different contour point attributes and the operators that add them to XLD contours (for exceptions see the respective operator references):

'angle'

The direction of the normal vectors of the contour is described by *'angle'* [rad] (see image below). It is oriented such that the normal vectors point to the right side of the contour as the contour is traversed from start to end point (the angles are defined counterclockwise with respect to the row axis of the image).

The attribute *'angle'* is added by the following operators:

edges_color_sub_pix, edges_sub_pix, lines_color, lines_facet, lines_gauss

'response'

'response' contains the magnitude of the edge gradient (see image below).

The attribute *'response'* is added by the following operators:

edges_color_sub_pix, edges_sub_pix, lines_color, lines_facet, lines_gauss

'width_right'

The line width to the right of the line (as the contour is traversed from start to end point) is described by *'width_right'* [px] (see image below).

The attribute *'width_right'* is added by the following operators:

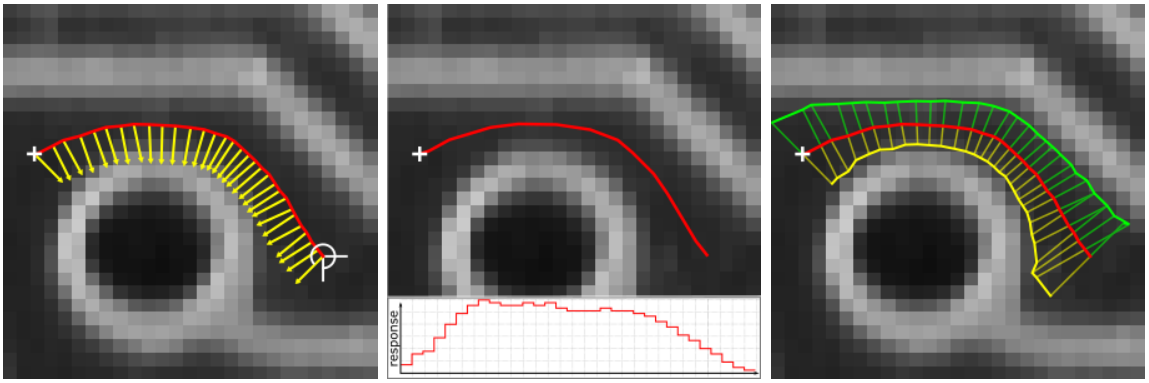
lines_color, lines_gauss

'width_left'

The line width to the left of the line (as the contour is traversed from start to end point) is described by *'width_left'* [px] (see image below).

The attribute *'width_left'* is added by the following operators:

lines_color, lines_gauss



(1) (2) (3)

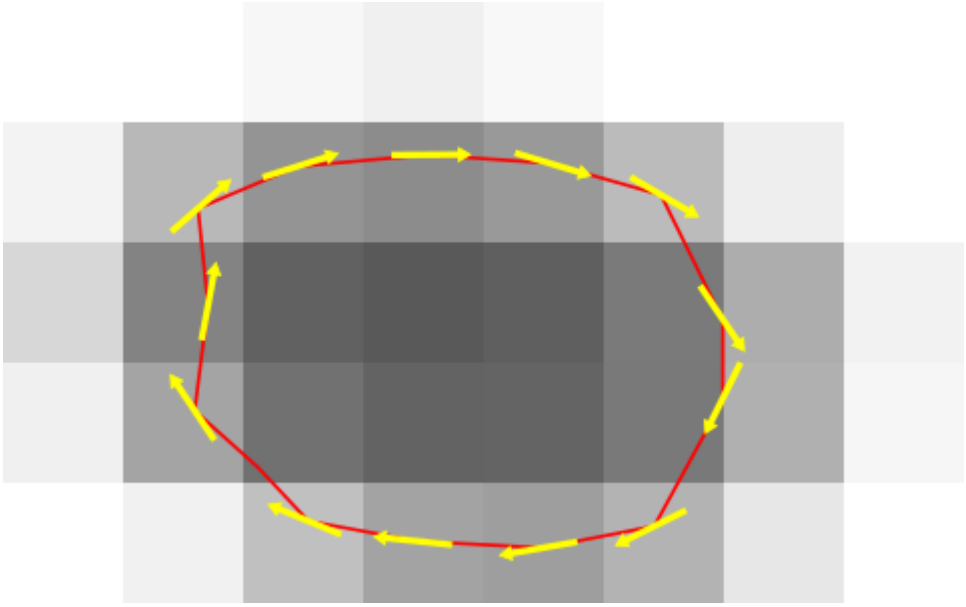
Visualization of different point attributes of a contour (red). The starting point of the contour is marked with a white cross. (1) Vectors (yellow), plotted at *'angle'* (with respect to the row axis), representing the normal for every point of the contour, (2) behavior of the attribute *'response'* along a contour, and (3) visualization of the calculated attributes *'width_right'* (yellow) and *'width_left'* (green).

'edge_direction'

Gives the direction of the edge (not of the XLD contour), calculated from image gradients in direction of rows and columns. The angles are given with respect to the column axis of the image.

The attribute *'edge_direction'* [rad] is added by the following operators:

edges_color_sub_pix, edges_sub_pix



Vectors plotted in *'edge_direction'* (yellow) for every point of a contour (red).

'asymmetry'

The contour attribute *'asymmetry'* describes the image gradient on both sides of the edge. It is positive if the asymmetric part, i.e., the part with the weaker gradient, is on the right side of the line, while it is negative if the asymmetric part is on the left side of the line (see image below).

The attribute *'asymmetry'* is added by the following operator:

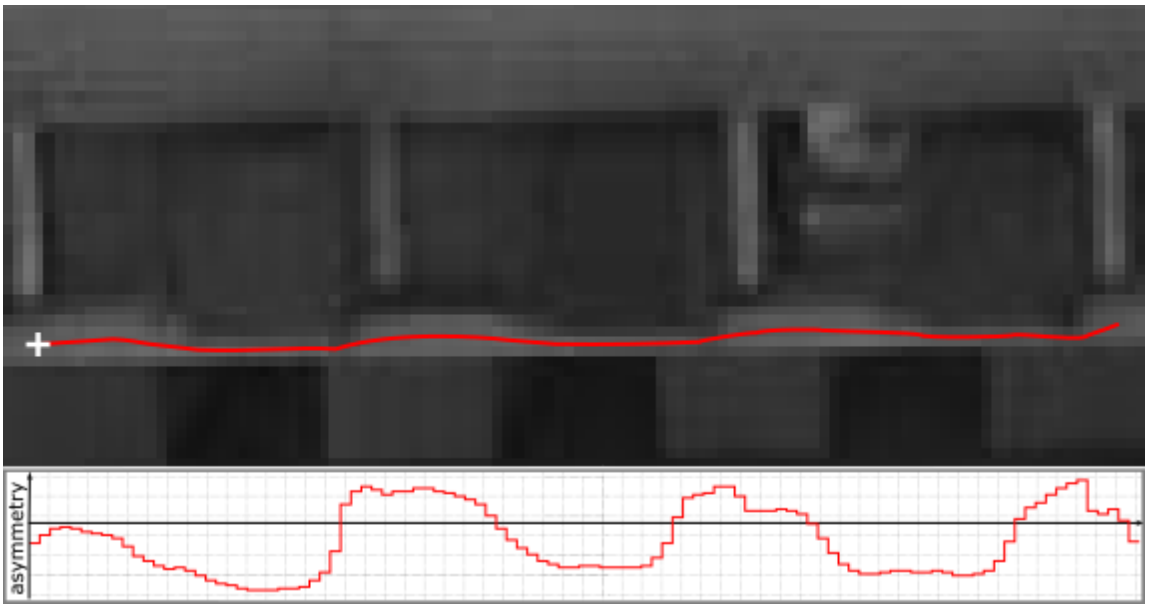
`lines_gauss`

'contrast'

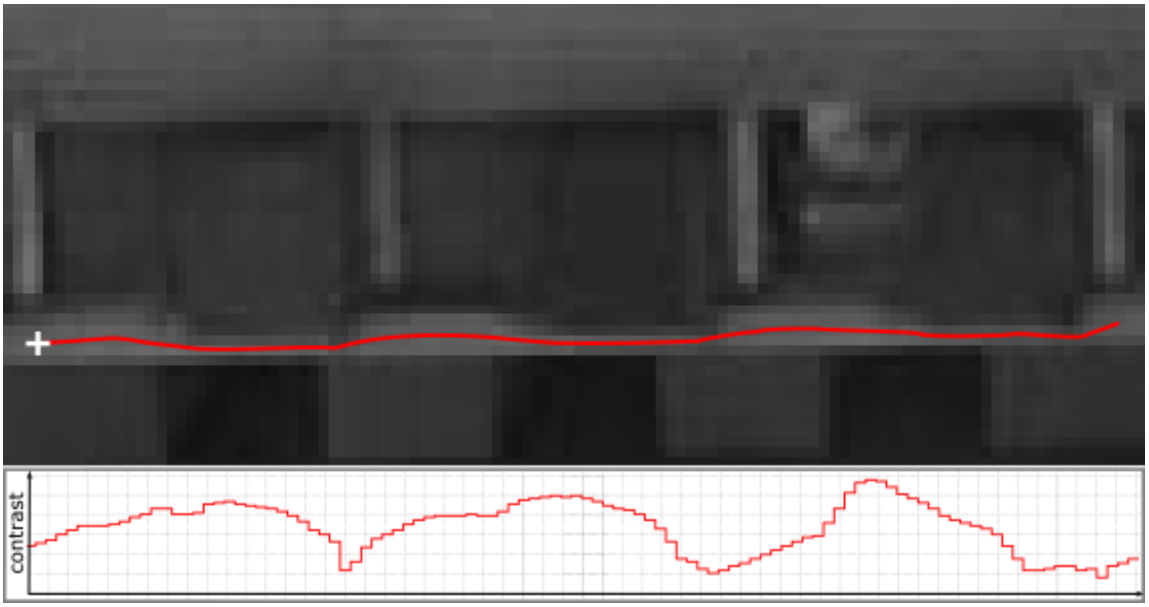
The contrast of a contour describes the difference between the gray values of the line and the gray values of the local background. It is positive if bright lines are extracted, while it is negative for dark lines (see image below).

The attribute *'contrast'* is added by the following operator:

`lines_gauss`



(1)



(2)

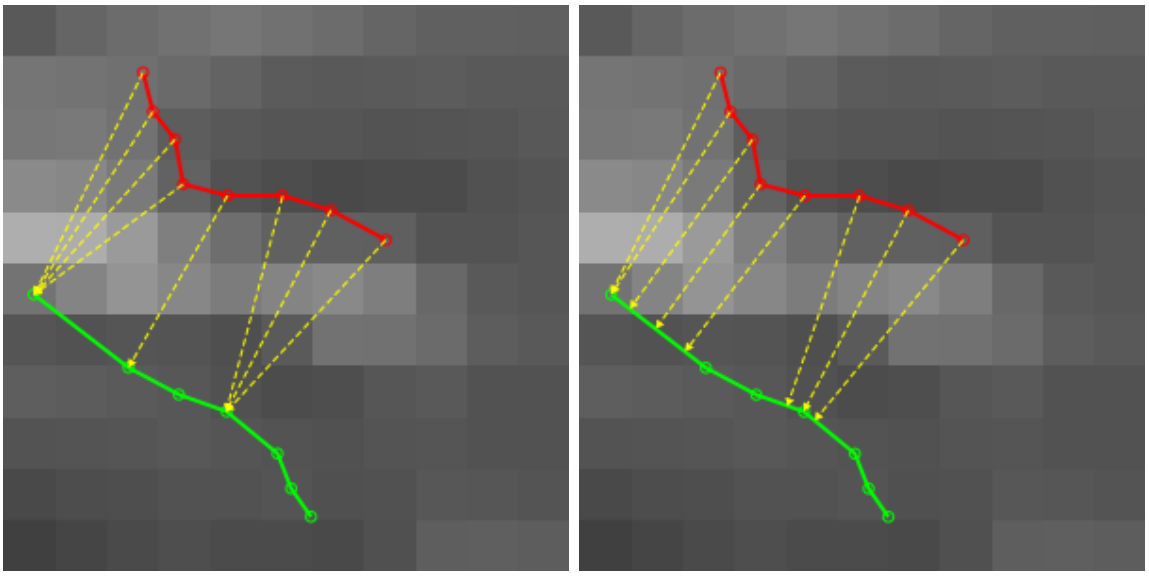
behavior of the attributes (1) *'asymmetry'* and (2) *'contrast'* for a contour along an image structure (the starting point of the contour is marked with a white cross).

'distance'

The minimum distance to any point or segment of the reference contour (depending on the mode chosen for the calculation) is given in the attribute *'distance'* [px] for all points of a contour.

The attribute *'distance'* is added by the following operators:

`apply_distance_transform_xld`, `distance_contours_xld`



(1) (2)

(1) *'distance'* of a contour (red) to the points of a reference contour (green) and (2) *'distance'* to any segment of a reference contour (green).

For information about global contour attributes see the operator reference of `get_contour_global_attrib_xld`.

Parameters

▷ **`Contour`** (input_object) ..... xld_cont ⇝ *object*
Input XLD contour.

▷ **`Name`** (input_control) ..... string ⇝ *string*
Name of the attribute.
Default: 'angle'
Suggested values: `Name` ∈ {'angle', 'edge_direction', 'width_right', 'width_left', 'response', 'contrast', 'asymmetry', 'distance'}

▷ **`Attrib`** (output_control) ..... real-array ⇝ *real*
Attribute values.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

`lines_gauss`, `lines_facet`, `edges_sub_pix`, `distance_contours_xld`, `apply_distance_transform_xld`

See also

`query_contour_attribs_xld`, `get_contour_global_attrib_xld`, `query_contour_global_attribs_xld`

Module

Foundation

`get_contour_global_attrib_xld` (`Contour` : : `Name` : `Attrib`)

Return global attributes values of an XLD contour.

`get_contour_global_attrib_xld` returns the values of the global attribute `Name` of the XLD contour `Contour` in `Attrib`. Global attributes are additional values defined for each contour.

query_contour_global_attribs_xld can be used to query which global attributes are set for a particular contour.

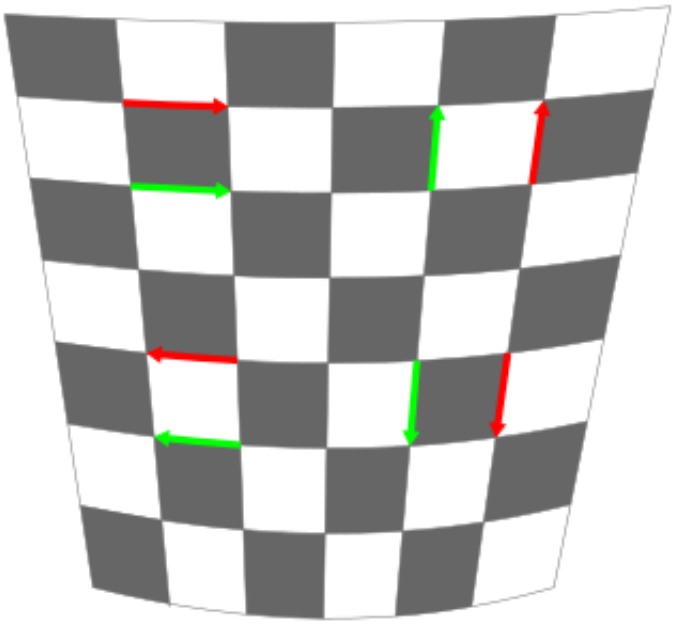
The following list contains information about the different global contour attributes and the operators that add them to XLD contours:

'bright_dark'

The type of transition for each output XLD contour is stored in the attribute *'bright_dark'*. It is set to *1.0*, if the connecting line forms a bright-dark transition (left to right, viewed from start point to end point), otherwise it is set to *0.0*.

The attribute *'bright_dark'* is added by the following operator:

connect_grid_points



Exemplary XLD contours (red and green) along the edges of a rectification grid (direction from start to end point indicated by arrow head). The transition type, stored in the attribute *'bright_dark'*, is *1.0* for red contours and *0.0* for green contours.

'cont_approx'

The best way to approximate a contour is stated by the attribute *'cont_approx'*: for *'cont_approx'=-1.0*, the contour is best approximated by a line segment, for *'cont_approx'=0.0*, by an elliptic arc, and for *'cont_approx'=1.0*, by a circular arc.

The attribute *'cont_approx'* is added by the following operator:

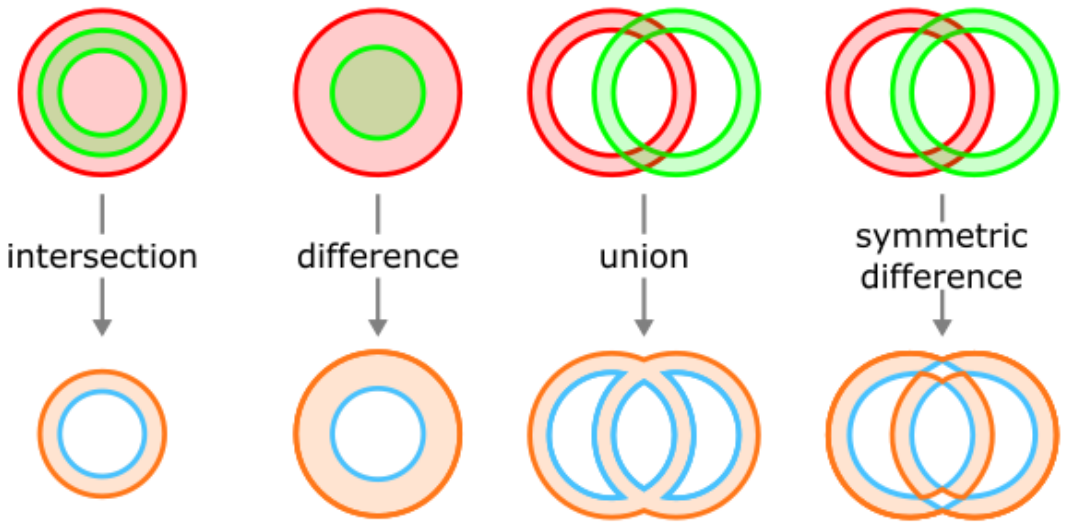
segment_contours_xld

'is_hole'

For boundaries that enclose holes, the global contour attribute *'is_hole'* is set to *1.0*, otherwise, it is set to *0.0*.

The attribute *'is_hole'* is added by the following operators:

symm_difference_closed_contours_xld, difference_closed_contours_xld, intersection_closed_contours_xld, union2_closed_contours_xld



Applying different set operations to XLD contours or contour sets adds the global attribute *'is_hole'* to the resulting contour(s). In the example above, for two sets (red and green) of closed contours different set operations are performed. If a resulting boundary encloses a hole (blue contours), *'is_hole'* is set to *1.0*, otherwise the value of *'is_hole'* is *0.0* (orange contours).

'regr_dev_dist'

'regr_dev_dist' [px] gives the standard deviation of the (Euclidean) distances between the contour points and the regression line (see image below).

The attribute *'regr_dev_dist'* is added by the following operator:

`regress_contours_xld`

'regr_dist'

'regr_dist' [px] gives the minimal distance of the regression line from the origin of the image coordinate system (see image below).

The attribute *'regr_dist'* is added by the following operator:

`regress_contours_xld`

'regr_mean_dist'

The attribute *'regr_mean_dist'* [px] contains the mean of the Euclidean distances between each contour point and the regression line (see image below).

The attribute *'regr_mean_dist'* is added by the following operator:

`regress_contours_xld`

'regr_norm_col'

'regr_norm_col' [px] is the column coordinate of the unit normal vector of the regression line with the normal vector pointing from the origin to the line (see image below).

The attribute *'regr_norm_col'* is added by the following operator:

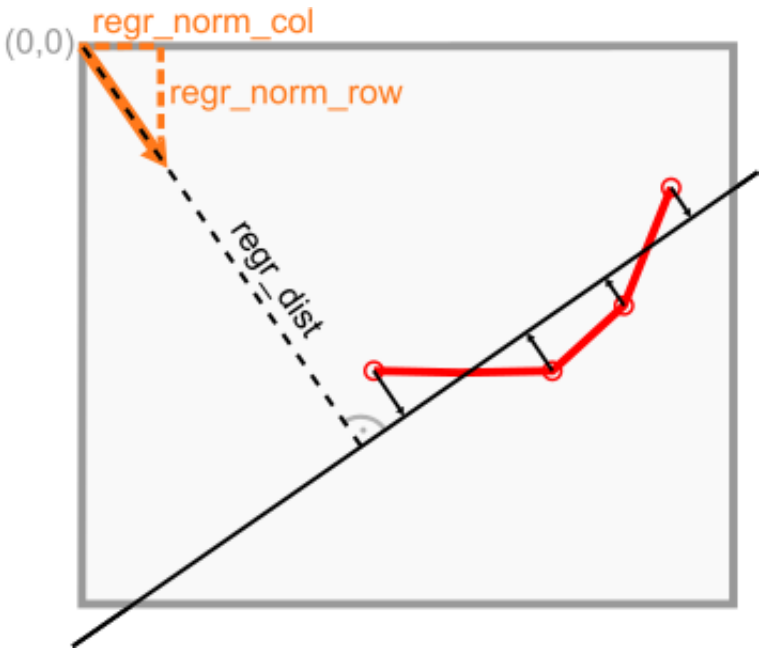
`regress_contours_xld`

'regr_norm_row'

'regr_norm_row' [px] is the row coordinate of the unit normal vector of the regression line with the normal vector pointing from the origin to the line (see image below).

The attribute *'regr_norm_row'* is added by the following operator:

`regress_contours_xld`



Sketch of the attributes *'regr_dist'*, *'regr_norm_col'*, *'regr_norm_row'* for the regression of an XLD contour (red). *'regr_mean_dist'* and *'regr_dev_dist'* are computed from the distances (black arrows) between the contour points and the regression line (solid black line).

Parameters

▷ **Contour** (input_object) ..... xld_cont ⇝ *object*
Input XLD contour.

▷ **Name** (input_control) ..... string(-array) ⇝ *string*
Name of the attribute.
Default: 'regr_norm_row'
Suggested values: Name ∈ {'regr_norm_row', 'regr_norm_col', 'regr_mean_dist', 'regr_dev_dist', 'cont_approx', 'bright_dark', 'is_hole'}

▷ **Attrib** (output_control) ..... real-array ⇝ *real*
Attribute values.

Execution Information

get_regress_params_xld (Contours : : : Length, Nx, Ny, Dist, Fpx, Fpy, Lpx, Lpy, Mean, Deviation)

Return XLD contour parameters.

get_regress_params_xld returns the following parameters for all XLD contours given in Contours:

- the number of contour points Length,
- the coordinates Nx and Ny of the normal vector of the regression line (i.e., least-squares approximating line),
- the distance Dist of the regression line to the origin
- the sub-pixel precise coordinates Fpx and Fpy of the perpendicular projection of the start point of the contour onto the regression line,
- the sub-pixel precise coordinates Lpx and Lpy of the perpendicular projection of the end point of the contour onto the regression line,
- the mean of the Euclidean distance of the contour points from the regression line,
- the standard deviation of these distances.

Attention

Before the contour parameters can be returned by get_regress_params_xld, the parameters of the regression line to the contour must be calculated by calling regress_contours_xld.

Parameters

▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
Input XLD contours.

▷ **Length** (output_control) ..... integer-array ⇝ *integer*
Number of contour points.

▷ **Nx** (output_control) ..... point.x-array ⇝ *real*
X-coordinate of the normal vector of the regression line.

▷ **Ny** (output_control) ..... point.y-array ⇝ *real*
Y-coordinate of the normal vector of the regression line.

▷ **Dist** (output_control) ..... number-array ⇝ *real*
Distance of the regression line from the origin.

▷ **Fpx** (output_control) ..... point.x-array ⇝ *real*
X-coordinate of the projection of the start point of the contour onto the regression line.

▷ **Fpy** (output_control) ..... point.y-array ⇝ *real*
Y-coordinate of the projection of the start point of the contour onto the regression line.

▷ **Lpx** (output_control) ..... point.x-array ⇝ *real*
X-coordinate of the projection of the end point of the contour onto the regression line.

▷ **Lpy** (output_control) ..... point.y-array ⇝ *real*
Y-coordinate of the projection of the end point of the contour onto the regression line.

▷ **Mean** (output_control) ..... real-array ⇝ *real*
Mean distance of the contour points from the regression line.

▷ **Deviation** (output_control) ..... real-array ⇝ *real*
Standard deviation of the distances from the regression line.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

height_width_ratio_xld (XLD : : : Height, Width, Ratio)

Compute the width, height, and aspect ratio of the enclosing rectangle parallel to the coordinate axes of contours or polygons.

The operator height_width_ratio_xld calculates the enclosing rectangle (parallel to the coordinate axes) for each input contour or polygon. The enclosing rectangle is described by the coordinates of the corner pixels (Row1,Column1,Row2,Column2) (see smallest_rectangle1_xld). Based on these values, height_width_ratio_xld computes the width, height, and aspect ratio of the smallest surrounding rectangle as follows:

$$\begin{aligned} \texttt{Width} &= \texttt{Column2} - \texttt{Column1} \\ \texttt{Height} &= \texttt{Row2} - \texttt{Row1} \\ \texttt{Ratio} &= \texttt{Height}/\texttt{Width} \end{aligned}$$

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD. In case of an empty contour all parameters have the value 0 if no other behavior was set (see set_system).

Attention

If Width = 0, Ratio is set to DBL_MAX (1.797e308).

Parameters

- ▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **Height** (output_control) ..... extent.y(-array) ⇝ *real*
  Height of the enclosing rectangle.
- ▷ **Width** (output_control) ..... extent.x(-array) ⇝ *real*
  Width of the enclosing rectangle.
- ▷ **Ratio** (output_control) ..... real(-array) ⇝ *real*
  Aspect ratio of the enclosing rectangle.

Complexity

If N is the number of contour points, the runtime complexity is $O(N)$.

Result

height_width_ratio_xld returns 2 (H_MSG_TRUE) if the input is not empty. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

info_parallels_xld (Parallels, Image : : : QualityMin, QualityMax, GrayMin, GrayMax, StandardMin, StandardMax)

Return information about the gray values of the area enclosed by XLD parallels.

info_parallels_xld calculates various gray value features of the area enclosed by the XLD parallels Parallels. The input image Image is used to get the gray values needed for this. The algorithm used in this operator is very similar to the one used in mod_parallels_xld. The operator returns ranges for the quality factor (QualityMin and QualityMax, see gen_parallels_xld for the corresponding calculation), the mean gray value (GrayMin and GrayMax), and the standard deviation with respect to the mean gray value (StandardMin and StandardMax).

This operator serves to determine appropriate thresholds for mod_parallels_xld.

Parameters

- ▷ **Parallels** (input_object) ..... xld_para-array ⇝ *object*
  Input XLD Parallels.
- ▷ **Image** (input_object) ..... singlechannelimage ⇝ *object :* byte
  Corresponding gray value image.
- ▷ **QualityMin** (output_control) ..... real ⇝ *real*
  Minimum quality factor.
- ▷ **QualityMax** (output_control) ..... real ⇝ *real*
  Maximum quality factor.
- ▷ **GrayMin** (output_control) ..... integer ⇝ *integer*
  Minimum mean gray value.
- ▷ **GrayMax** (output_control) ..... integer ⇝ *integer*
  Maximum mean gray value.
- ▷ **StandardMin** (output_control) ..... real ⇝ *real*
  Minimum standard deviation.
- ▷ **StandardMax** (output_control) ..... real ⇝ *real*
  Maximum standard deviation.

Execution Information

Module

Foundation

length_xld (XLD : : Length)

Length of contours or polygons.

length_xld calculates the length of the contours or polygons XLD. The length is calculated as the sum of the Euclidean distances of successive points on the contour or polygon. If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) . . . . . xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Length** (output_control) . . . . . real(-array) ⇝ *real*
Length of the contour or polygon.
Assertion: Length >= 0

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

`length_xld` returns `2` (`H_MSG_TRUE`) if the input is not empty. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

local_max_contours_xld (Contours, Image : LocalMaxContours : MinPercent, MinDiff, Distance :)

Select XLD contours with a local maximum of gray values.

`local_max_contours_xld` selects XLD contours from the contours passed in `Contours`, which have a local maximum in gray values across the direction of the contour. In order to be selected, at least `MinPercent` of the contour points must have a local maximum perpendicular to the direction of the contour. The contours' direction is determined by fitting a regression line through five neighboring points of the contour. In order to decide whether there is a local maximum for a contour point, a gray value profile that is `Distance` points wide and perpendicular to the contour is computed on both sides of the contour. If the gray value at the contour point is at least `MinDiff` larger than the gray value at at least one point on each side of the profile, the contour point is labeled as a local maximum. The selected contours are returned in `LocalMaxContours`.

Parameters

▷ **Contours** (input_object) . . . . . xld_cont-array ⇝ *object*
XLD contours to be examined.

▷ **Image** (input_object) . . . . . singlechannelimage ⇝ *object :* byte
Corresponding gray value image.

▷ **LocalMaxContours** (output_object) . . . . . xld_cont-array ⇝ *object*
Selected contours.

▷ **MinPercent** (input_control) . . . . . number ⇝ *integer* / real
Minimum percentage of maximum points.
Default: 70
Suggested values: `MinPercent` ∈ {60, 70, 75, 80, 85, 90, 95}
Restriction: 0.0 <= MinPercent && MinPercent <= 100.0

▷ **MinDiff** (input_control) . . . . . integer ⇝ *integer*
Minimum amount by which the gray value at the maximum must be larger than in the profile.
Default: 15
Suggested values: `MinDiff` ∈ {5, 8, 10, 12, 15, 20}
Restriction: 0 <= MinDiff && MinDiff <= 255

▷ **Distance** (input_control) . . . . . integer ⇝ *integer*
Maximum width of profile used to check for maxima.
Default: 4
Suggested values: Distance ∈ {2, 3, 4, 5, 6}
Restriction: Distance >= 1

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

max_parallels_xld (ExtParallels : MaxPolygons : :)

Join modified XLD parallels lying on the same polygon.

max_parallels_xld joins all modified XLD parallels in ExtParallels into a polygon if they lie on the same original polygon segment. This means that polygons exhibiting parallelism and enclosing homogeneous areas in several places are joined into one long polygon (from the first parallel line to the last parallel line). The resulting polygons are returned in MaxPolygons.

Parameters

▷ **ExtParallels** (input_object) . . . . . xld_ext_para-array ⇝ *object*
Extended XLD parallels.
▷ **MaxPolygons** (output_object) . . . . . xld_poly-array ⇝ *object*
Maximally extended parallels.

Module

Foundation

moments_any_points_xld (XLD : : Mode, Area, CenterRow, CenterCol, P, Q : M)

Arbitrary geometric moments of contours or polygons treated as point clouds.

moments_any_points_xld calculates arbitrary moments M of the point clouds given by the contours or polygons XLD (i.e., the order of the points in the contour or polygon is not taken into account).

The computed moments are normalized depending on the desired mode Mode:

'unnormalized': No normalization. The computed moment $M_{p,q}$ is:

$$M_{p,q} = \sum_{i=0}^{n-1} r_i^p c_i^q$$

'unnormalized_central': Shift the contour points by their centroid $[\bar{r}, \bar{c}] = [\texttt{CenterRow}, \texttt{CenterCol}]$:

$$M_{p,q} = \sum_{i=0}^{n-1} (r_i - \bar{r})^p (c_i - \bar{c})^q$$

'normalized': Normalization by the area $A = \texttt{Area}$ from XLD:

$$M_{p,q} = \frac{1}{A} \sum_{i=0}^{n-1} r_i^p c_i^q$$

'central': Normalization by the area $A = \texttt{Area}$ and a shift of the contour points by their centroid $[\bar{r}, \bar{c}] = [\texttt{CenterRow}, \texttt{CenterCol}]$:

$$M_{p,q} = \frac{1}{A} \sum_{i=0}^{n-1} (r_i - \bar{r})^p (c_i - \bar{c})^q$$

For the normalization of the moments three specific values are used: The area Area and the coordinates CenterRow,CenterCol of it's centroid (this values can be computed with area_center_points_xld).

If the contour or polygon is closed (end point = start point), the end point of the contour or polygon is not taken into account to avoid that it receives twice the weight of the other points.

moments_any_xld should be used if the contour XLD intersects itself or if it is not possible to close the contour using a line from end to start point without self-intersection, because in this case moments_any_xld does not produce useful results. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used.

If more than one contour or polygon is passed, M contains all desired moments of the first contour/polygon followed by all the moments of the second contour/polygon and so forth.

Parameters

- ▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **Mode** (input_control) ..... string ⇝ *string*
  Computation mode.
  Default: 'unnormalized'
  Suggested values: Mode ∈ {'unnormalized', 'unnormalized_central', 'normalized', 'central'}
- ▷ **Area** (input_control) ..... real(-array) ⇝ *real*
  Area enclosed by the contour or polygon.
- ▷ **CenterRow** (input_control) ..... point.y(-array) ⇝ *real*
  Row coordinate of the centroid.
- ▷ **CenterCol** (input_control) ..... point.x(-array) ⇝ *real*
  Column coordinate of the centroid.
- ▷ **P** (input_control) ..... point.x(-array) ⇝ *integer*
  First index of the desired moments $M_{p,q}$.
  Default: 1
  Suggested values: P ∈ {0, 1, 2, 3, 4}
- ▷ **Q** (input_control) ..... point.x(-array) ⇝ *integer*
  Second index of the desired moments $M_{p,q}$.
  Default: 1
  Suggested values: Q ∈ {0, 1, 2, 3, 4}
- ▷ **M** (output_control) ..... real(-array) ⇝ *real*
  The computed moments.

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

`moments_any_points_xld` returns `2` (`H_MSG_TRUE`) if the input is not empty. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

moments_any_xld (XLD : : Mode, PointOrder, Area, CenterRow, CenterCol, P, Q : M)

Arbitrary geometric moments of contours or polygons.

`moments_any_xld` calculates arbitrary moments `M` of the regions enclosed by the contours or polygons `XLD`. The moments are computed by applying Green's theorem using only the points on the contour or polygon, i.e., no region is generated explicitly for the purpose of calculating the features. It is assumed that the contours or polygons are closed. If this is not the case `moments_any_xld` will artificially close the contours or polygons.

It should be noted that `moments_any_xld` only returns useful results if the contour or polygon encloses a region in the plane. In particular, the contour or polygon must not intersect itself. This is particularly important if open contours or polygons are passed because they are closed automatically, which can produce a self-intersection. To test whether the contours or polygons intersect themselves, `test_self_intersection_xld` can be used. If the contour or polygon intersects itself, useful values for the moments can be calculated with `moments_any_points_xld`.

The computed moments are normalized depending on the desired mode `Mode`:

'unnormalized': No normalization. Let R be the enclosed image region. Then the computed moment $M_{p,q}$ is equivalent to:

$$M_{p,q} = \int_R r^p c^q \, dr \, dc$$

'unnormalized_central': Shift the region by its centroid $[\bar{r}, \bar{c}] = $ [`CenterRow`, `CenterCol`]:

$$M_{p,q} = \int_R (r - \bar{r})^p (c - \bar{c})^q \, dr \, dc$$

'normalized': Normalization by the area $A = $ `Area` of the enclosed image region:

$$M_{p,q} = \frac{1}{A} \int_R r^p c^q \, dr \, dc$$

'central': Normalization by the area $A = $ `Area` of the enclosed image region and a shift of the region by it's centroid $[\bar{r}, \bar{c}] = $ [`CenterRow`, `CenterCol`]:

$$M_{p,q} = \frac{1}{A} \int_R (r - \bar{r})^p (c - \bar{c})^q \, dr \, dc$$

For the normalization of the moments three specific moments are used: The area `Area` of the enclosed image region and the coordinates `CenterRow`,`CenterCol` of it's centroid (this values can be calculated with `area_center_xld`). In addition to that `moments_any_xld` expects information about the point order of the input contours/polygons in `PointOrder`, see `area_center_xld` again.

If more than one contour or polygon is passed, `M` contains all desired moments of the first contour/polygon followed by all the moments of the second contour/polygon and so forth.

Parameters

- ▷ **`XLD`** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **`Mode`** (input_control) ..... string ⇝ *string*
  Computation mode.
  Default: 'unnormalized'
  Suggested values: `Mode` ∈ {'unnormalized', 'unnormalized_central', 'normalized', 'central'}
- ▷ **`PointOrder`** (input_control) ..... string(-array) ⇝ *string*
  Point order along the boundary.
  Default: 'positive'
  Suggested values: `PointOrder` ∈ {'positive', 'negative'}
- ▷ **`Area`** (input_control) ..... real(-array) ⇝ *real*
  Area enclosed by the contour or polygon.
- ▷ **`CenterRow`** (input_control) ..... point.y(-array) ⇝ *real*
  Row coordinate of the centroid.
- ▷ **`CenterCol`** (input_control) ..... point.x(-array) ⇝ *real*
  Column coordinate of the centroid.
- ▷ **`P`** (input_control) ..... point.x(-array) ⇝ *integer*
  First index of the desired moments $M_{p,q}$.
  Default: 1
  Suggested values: `P` ∈ {0, 1, 2, 3, 4}
- ▷ **`Q`** (input_control) ..... point.x(-array) ⇝ *integer*
  Second index of the desired moments $M_{p,q}$.
  Default: 1
  Suggested values: `Q` ∈ {0, 1, 2, 3, 4}
- ▷ **`M`** (output_control) ..... real(-array) ⇝ *real*
  The computed moments.

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

`moments_any_xld` returns `2` (`H_MSG_TRUE`) if the input is not empty. If the input is empty the behavior can be set via `set_system(::'no_object_result',<Result>:)`. If necessary, an exception is raised.

Module

Foundation

moments_points_xld (XLD : : : M11, M20, M02)

Geometric moments M_{20}, M_{02}, and M_{11} of contours or polygons treated as point clouds.

moments_points_xld calculates the moments (M20, M02, and M11) of a point cloud given by a contour or a polygon XLD (i.e., the order of the points in the contour or polygon is not taken into account). Therefore, the moments are given by

$$M_{p,q} = \sum_{i=0}^{n-1} (r_i - \bar{r})^p (c_i - \bar{c})^q.$$

. Here, $(\bar{r}, \bar{c})$ is the centroid and n the number of points.

If the contour or polygon is closed (end point = start point), the end point of the contour or polygon is not taken into account to avoid that it receives twice the weight of the other points.

moments_points_xld should be used if the contour XLD intersects itself or if it is not possible to close the contour using a line from end to start point without self-intersection, because in this case moments_xld does not produce useful results. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used.

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Parameters

- ▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **M11** (output_control) ..... real(-array) ⇝ *real*
  Mixed second order moment.
- ▷ **M20** (output_control) ..... real(-array) ⇝ *real*
  Second order moment along the row axis.
- ▷ **M02** (output_control) ..... real(-array) ⇝ *real*
  Second order moment along the column axis.

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

moments_points_xld returns 2 (H_MSG_TRUE) if the input is not empty. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

moments_xld (XLD : : : M11, M20, M02)

Geometric moments M_{20}, M_{02}, and M_{11} of contours or polygons.

moments_xld calculates the moments (M20, M02, and M11) of the region enclosed by the contours or polygons XLD. See moments_region_2nd for the definition of these features. The moments are computed by applying Green's theorem using only the points on the contour or polygon, i.e., no region is generated explicitly for the purpose of calculating the features. It is assumed that the contours or polygons are closed. If this is not the case moments_xld will artificially close the contours or polygons.

It should be noted that moments_xld only returns useful results if the contour or polygon encloses a region in the plane. In particular, the contour or polygon must not intersect itself. This is particularly important if open contours or polygons are passed because they are closed automatically, which can produce a self-intersection. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used. If the contour or polygon intersects itself, useful values for the moments can be calculated with moments_points_xld.

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **M11** (output_control) ..... real(-array) ⇝ *real*
Mixed second order moment.

▷ **M20** (output_control) ..... real(-array) ⇝ *real*
Second order moment along the row axis.

▷ **M02** (output_control) ..... real(-array) ⇝ *real*
Second order moment along the column axis.

Complexity

Let n be the number of points of the contour or polygon. Then the run time is $O(n)$.

Result

moments_xld returns 2 (H_MSG_TRUE) if the input is not empty. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

Foundation

orientation_points_xld (XLD : : : Phi)

Calculate the orientation of contours or polygons treated as point clouds.

The operator orientation_points_xld calculates the orientation Phi of the point clouds given by the contours or polygons XLD (the order of the points in the contour or polygon is not taken into account). The orientation Phi is calculated the same way as in elliptic_axis_points_xld. If the contour or polygon is closed (end point = start point), the end point of the contour or polygon is not taken into account to avoid that it receives twice the weight of the other points.

In addition, the contour point p_m with maximum distance to the center of gravity c is calculated. If the angle between the vector $\overrightarrow{p_m c}$ and the vector given by Phi is greater than π, the value of π is added to the angle. If XLD consists of only two points, Phi is given by the direction from the first point towards the second point.

orientation_points_xld should be used if the contour XLD intersects itself or if it is not possible to close the contour using a line from end to start point without self-intersection, because in this case orientation_xld does not produce useful results. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used.

If more than one contour or polygon is passed, the values of the orientations are stored in a tuple in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Phi** (output_control) ..... angle.rad(-array) ⇝ *real*
Orientation of the contours or polygons (radians).
Assertion: - pi < Phi && Phi <= pi

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

orientation_xld (XLD : : : Phi)

Calculate the orientation of contours or polygons.

The operator orientation_xld calculates the orientation (Phi) of each input contour or polygon (XLD). The operator is based on elliptic_axis_xld. In addition, the contour respectively polygon point with maximum distance to the center of gravity is calculated. If the column coordinate of this point is less than the column coordinate of the center of gravity the value of π is added to the angle. It is assumed that the contours or polygons are closed. If this is not the case orientation_xld will artificially close the contours or polygons.

It should be noted that orientation_xld only returns useful results if the contour or polygon encloses a region in the plane. In particular, the contour or polygon must not intersect itself. This is particularly important if open contours or polygons are passed because they are closed automatically, which can produce a self-intersection. To test whether the contours or polygons intersect themselves, test_self_intersection_xld can be used. If the contour or polygon intersects itself, useful values for the orientation can be calculated with orientation_points_xld.

If more than one contour or polygon is passed, the values of the orientations are stored in a tuple in the same order as the respective contours or polygons in XLD.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Phi** (output_control) ..... angle.rad(-array) ⇝ *real*
Orientation of the contours or polygons (radians).
Assertion: - pi < Phi && Phi <= pi

Result

The operator orientation_xld returns the value 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input contours available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

query_contour_attribs_xld (Contour : : : Attribs)

Return the names of the defined attributes of an XLD contour.

query_contour_attribs_xld returns the names of the defined attributes of an XLD contour Contour in Attribs. Attributes are additional values defined for each contour point, e.g., the direction perpendicular to the contour (*'angle'*). Operators which define contour point attributes contain a description of the name and semantics of the defined values. The operator get_contour_attrib_xld can be used to access the values of a particular attribute.

For an overview of the different contour point attributes and the operators that add them to XLD contours see the operator reference of get_contour_attrib_xld.

Parameters

▷ **Contour** (input_object) ..... xld_cont ⇝ *object*
Input contour.

▷ **Attribs** (output_control) ..... string-array ⇝ *string*
List of the defined contour attributes.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

Foundation

query_contour_global_attribs_xld (Contour : : : Attribs)

Return the names of the defined global attributes of an XLD contour.

query_contour_global_attribs_xld returns the names of the globally defined attributes that are set for an XLD Contour in Attribs. Global attributes are additional values defined for each contour, e.g., the normal vector of the regression line of a contour (*'regr_norm_row'* and *'regr_norm_col'*). Operators which define global attributes contain a description of the name and semantics of the defined values. The operator get_contour_global_attrib_xld can be used to access the value of a particular attribute.

For an overview of the different global contour attributes and the operators that add them to XLD contours see the operator reference of get_contour_global_attrib_xld.

Parameters

▷ **Contour** (input_object) ..... xld_cont ⇝ *object*
Input contour.

▷ **Attribs** (output_control) ..... string-array ⇝ *string*
List of the defined global contour attributes.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

lines_gauss, lines_facet, edges_sub_pix

Module

Foundation

rectangularity_xld (XLD : : : Rectangularity)

Shape factor for the rectangularity of contours or polygons.

The operator rectangularity_xld calculates the rectangularity of each input contour or polygon in XLD. The input contour or polygon must not intersect itself, otherwise the resulting parameter is not meaningful (Whether the input contour or polygon intersects itself or not can be determined with test_self_intersection_xld). If the input contour or polygon is not closed it will be closed automatically.

To determine the rectangularity, first a rectangle is computed that has the same first and second order moments as the input contour or polygon. The computation of the rectangularity measure is finally based on the area of the difference between the computed rectangle and the input contour or polygon normalized with respect to the area of the rectangle.

For rectangles rectangularity_xld returns the value 1. The more the input contour or polygon deviates from a perfect rectangle, the less the returned value for Rectangularity will be. If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD.

Attention

For input contours or polygons which orientation cannot be computed by using second order moments (as it is the case for squares, for example), the returned Rectangularity is underestimated by up to 10% depending on the orientation of the input contour or polygon.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Rectangularity** (output_control) ..... real(-array) ⇝ *real*
Rectangularity of the input contours or polygons.
Assertion: 0 <= Rectangularity && Rectangularity <= 1.0

Result

The operator `rectangularity_xld` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input contours or polygons available) is set via the operator `set_system ('no_object_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

select_contours_xld (Contours : SelectedContours : Feature, Min1, Max1, Min2, Max2 :)

Select XLD contours according to several features.

`select_contours_xld` selects XLD contours from the input contours `Contours` according to the following features (parameter `Feature`):

'contour_length': all contours whose length is smaller than `Min1` or larger than `Max1` are not returned (`Min2` and `Max2` have no influence here).

'maximum_extent': all contours whose maximum extent (as measured by their eight extremal points in row and column direction, according to Haralick and Shapiro: Computer and Robot Vision, Addison-Wesley 1992, chapter 3.2) is smaller than `Min1` or larger than `Max1` are not returned (`Min2` and `Max2` have no influence here).

'direction': only contours for which the direction of the regression line is between `Min1` and `Max1` (in radians, counter-clockwise) are returned. `Min1` and `Max1` are mapped to the range of [0,2*PI[. (`Min2` and `Max2` have no influence here).

'curvature': only contours for which the mean distance from the regression line lies between `Min1` and `Max1`, and for which the standard deviation of the distances is between `Min2` and `Max2` are returned.

'closed': only contours for which the distance between their start point and their end point is less or equal `Max1` pixels are returned. (`Min1`, `Min2` and `Max2` have no influence here.)

'open': only contours for which the distance between their start point and their end point is greater than `Min1` pixels are returned. (`Max1`, `Min2` and `Max2` have no influence here).

If Min1 = Max1 = 0 or Min2 = Max2 = 0 is used for the selection according to curvature, the respective feature has no influence on the selection.

Attention

Before contour can be filtered by select_contours_xld according to *'direction'* or *'curvature'*, the parameters of the regression lines to the contours must be calculated with regress_contours_xld. If this has not been done, select_contours_xld calls regress_contours_xld internally with the parameters Mode = *'no'* and Iterations = *1*. If a different mode should be used, regress_contours_xld must be called explicitly.

Parameters

- ▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
  Input XLD contours.
- ▷ **SelectedContours** (output_object) ..... xld_cont-array ⇝ *object*
  Output XLD contours.
- ▷ **Feature** (input_control) ..... string ⇝ *string*
  Feature to select contours with.
  Default: 'contour_length'
  List of values: Feature ∈ {'contour_length', 'maximum_extent', 'direction', 'curvature', 'closed', 'open'}
- ▷ **Min1** (input_control) ..... real ⇝ *real*
  Lower threshold.
  Default: 0.5
- ▷ **Max1** (input_control) ..... real ⇝ *real*
  Upper threshold.
  Default: 200.0
- ▷ **Min2** (input_control) ..... real ⇝ *real*
  Lower threshold.
  Default: -0.5
- ▷ **Max2** (input_control) ..... real ⇝ *real*
  Upper threshold.
  Default: 0.5

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

select_shape_xld (XLD : SelectedXLD : Features, Operation, Min, Max :)

Select contours or polygons using shape features.

The operator select_shape_xld selects contours or polygons according to their shape. For each input contour or polygon in XLD the indicated features (Features) are calculated. If each (Operation = *'and'*) or at least one (Operation = *'or'*) of the calculated features is within the limits (Min,Max) the contour respectively polygon is

copied into the output. The parameters Min and Max can be set to *'min'* or *'max'* in order to leave bottom and top limits, respectively, open.

Condition:

$$\texttt{Min}_i \leq \texttt{Features}_i(Object) \leq \texttt{Max}_i$$

Possible values for Features:

(all features can be used with polygons as well)

'area': Area of the contour (see area_center_xld)

'area_points': Area of the contour points (see area_center_points_xld)

'row': Row index of the center of gravity (see area_center_xld)

'column': Column index of the center of gravity (see area_center_xld)

'row_points': Row index of the center of gravity of the contour points (see area_center_points_xld)

'column_points': Column index of the center of gravity of the contour points (see area_center_points_xld)

'width': Width of the contour (see height_width_ratio_xld)

'height': Height of the contour (see height_width_ratio_xld)

'ratio': Ratio of the height and the width of the contour (see height_width_ratio_xld)

'row1': Row coordinate of upper left corner (see smallest_rectangle1_xld)

'column1': Column coordinate of upper left corner (see smallest_rectangle1_xld)

'row2': Row coordinate of lower right corner (see smallest_rectangle1_xld)

'column2': Column coordinate of lower right corner (see smallest_rectangle1_xld)

'circularity': Circularity (see circularity_xld)

'compactness': Compactness (see compactness_xld)

'rectangularity': Rectangularity (see rectangularity_xld)

'contlength': Total length of contour (see length_xld)

'convexity': Convexity (see convexity_xld)

'ra': Major radius of the equivalent ellipse (see elliptic_axis_xld)

'rb': Minor radius of the equivalent ellipse (see elliptic_axis_xld)

'phi': Orientation of the equivalent ellipse (see elliptic_axis_xld)

'ra_points': Major radius of the equivalent ellipse of the contour points (see elliptic_axis_points_xld)

'rb_points': Minor radius of the equivalent ellipse of the contour points (see elliptic_axis_points_xld)

'phi_points': Orientation of the equivalent ellipse of the contour points (see elliptic_axis_points_xld)

'anisometry:' Anisometry (see eccentricity_xld)

'anisometry_points:' Anisometry of the contour points (see eccentricity_points_xld)

'bulkiness:' Bulkiness (see eccentricity_xld)

'struct_factor:' Structure factor (see eccentricity_xld)

'outer_radius': Radius of smallest enclosing circle (see smallest_circle_xld)

'max_diameter': Maximum diameter of the contour (see diameter_xld)

'orientation': Orientation of the contour (see orientation_xld)

'orientation_points': Orientation of the contour points (see orientation_points_xld)

'rect2_phi': Orientation of the smallest surrounding rectangle (see smallest_rectangle2_xld)

'rect2_len1': Half the length of the smallest surrounding rectangle (see smallest_rectangle2_xld)

'rect2_len2': Half the width of the smallest surrounding rectangle (see smallest_rectangle2_xld)

'moments_m11', 'moments_m20', 'moments_m02': Geometric moments of the contour (see moments_region_2nd)

'moments_m11_points', 'moments_m20_points', 'moments_m02_points': Geometric moments of the contour points (see `moments_points_xld`)

If only one feature (`Features`) is used the value of `Operation` is meaningless. Several features are processed in the sequence in which they are entered.The use of some features requires that the input contour respectively polygon must not intersect itself, otherwise the results are not meaningful (Whether the input contour or polygon intersects itself or not can be determined with `test_self_intersection_xld`).

Parameters

▷ **`XLD`** (input_object) . . . . . xld-array ⇝ *object*
Contours or polygons to be examined.

▷ **`SelectedXLD`** (output_object) . . . . . xld-array ⇝ *object*
Contours or polygons fulfilling the condition(s).

▷ **`Features`** (input_control) . . . . . string(-array) ⇝ *string*
Shape features to be checked.
Default: 'area'
List of values: `Features` ∈ {'area', 'area_points', 'row', 'row_points', 'column', 'column_points', 'width', 'height', 'ratio', 'row1', 'column1', 'row2', 'column2', 'circularity', 'compactness', 'contlength', 'convexity', 'rectangularity', 'ra', 'ra_points', 'rb', 'rb_points', 'phi', 'phi_points', 'anisometry', 'anisometry_points', 'bulkiness', 'struct_factor', 'outer_radius', 'max_diameter', 'orientation', 'orientation_points', 'rect2_phi', 'rect2_len1', 'rect2_len2', 'moments_m11', 'moments_m11_points', 'moments_m20', 'moments_m20_points', 'moments_m02', 'moments_m02_points'}

▷ **`Operation`** (input_control) . . . . . string ⇝ *string*
Operation type between the individual features.
Default: 'and'
List of values: `Operation` ∈ {'and', 'or'}

▷ **`Min`** (input_control) . . . . . real(-array) ⇝ *real* / integer / string
Lower limits of the features or 'min'.
Default: 150.0
Minimum increment: 0.001
Recommended increment: 1.0

▷ **`Max`** (input_control) . . . . . real(-array) ⇝ *real* / integer / string
Upper limits of the features or 'max'.
Default: 99999.0
Minimum increment: 0.001
Recommended increment: 1.0
Restriction: Max >= Min

Result

The operator `select_shape_xld` returns the value `2` (`H_MSG_TRUE`) if the input is not empty. The behavior in case of empty input (no input objects available) is set via the operator `set_system ('no_object_result',<Result>)`. If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

select_xld_point (XLDs : DestXLDs : Row, Column :)

Choose all contours or polygons containing a given point.

The operator select_xld_point selects all contours or polygons from XLDs containing the test point (Row,Column). If the contours or polygons overlap, more than one contour or polygon might contain the point. In this case, all these contours or polygons are returned. If no contour or polygon contains the indicated point, an empty object is returned. It is assumed that the contours or polygons are closed. If this is not the case, select_xld_point will artificially close the contours or polygons. Nevertheless, it is strongly recommended to pass only meaningful and closed contours or polygons in XLDs by calling select_contours_xld with the parameter *'closed'* before calling select_xld_point.

Attention

If the test point is on the border of a contour or polygon, select_xld_point will deliver unpredictable results, i.e., the contour or polygon may be or may not be added to DestXLDs, depending on arbitrary factors such as how the polygon is oriented with respect to the coordinate system. Note further that for points in the near proximity of the contour or polygon sides, a reliable classification is practically impossible because of numerical inaccuracies.

Parameters

- ▷ **XLDs** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **DestXLDs** (output_object) ..... xld(-array) ⇝ *object*
  All contours or polygons containing the test point.
- ▷ **Row** (input_control) ..... point.y ⇝ *real* / integer
  Line coordinate of the test point.
  Default: 100.0
- ▷ **Column** (input_control) ..... point.x ⇝ *real* / integer
  Column coordinate of the test point.
  Default: 100.0

Result

The operator select_xld_point returns the value 2 (H_MSG_TRUE) if the parameters are correct. The behavior in case of empty input (no input contours or polygons available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Possible Predecessors

select_contours_xld, close_contours_xld, threshold_sub_pix

Alternatives

test_xld_point

Module

Foundation

smallest_circle_xld (XLD : : : Row, Column, Radius)

Smallest enclosing circle of contours or polygons.

The operator smallest_circle_xld determines the smallest enclosing circle of contours or polygons, i.e., the circle with the smallest area of all circles containing the contour. For this circle the center (Row,Column) and the radius (Radius) are calculated.

If several contours or polygons are passed in XLD corresponding tuples are returned as output parameter. In case of empty contours all parameters have the value 0.0 if no other behavior was set (see set_system).

Parameters

- ▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be examined.
- ▷ **Row** (output_control) ..... circle.center.y(-array) ⇝ *real*
  Row coordinate of the center of the enclosing circle.
- ▷ **Column** (output_control) ..... circle.center.x(-array) ⇝ *real*
  Column coordinate of the center of the enclosing circle.
- ▷ **Radius** (output_control) ..... circle.radius(-array) ⇝ *real*
  Radius of the enclosing circle.
  Assertion: Radius >= 0

Complexity

If N is the number of contour points then the runtime complexity is $O(N * ln(N))$.

Result

The operator smallest_circle_xld returns the value 2 (H_MSG_TRUE) if the input is not empty. If the input is empty the behavior can be set via set_system(::'no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

smallest_rectangle1_xld (XLD : : : Row1, Column1, Row2, Column2)

Enclosing rectangle parallel to the coordinate axes of contours or polygons.

The operator smallest_rectangle1_xld calculates the enclosing rectangle (parallel to the coordinate axes) for each input contour or polygon. The enclosing rectangle is described by the coordinates of the corner pixels (Row1,Column1,Row2,Column2)

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in XLD. In case of an empty contour all parameters have the value 0 if no other behavior was set (see set_system).

Attention

In case of empty contours the result of Row1,Column1, Row2 and Column2 (all are 0) can lead to confusion.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Row1** (output_control) ..... rectangle.origin.y(-array) ⇝ *real*
Row coordinate of upper left corner point of the enclosing rectangle.

▷ **Column1** (output_control) ..... rectangle.origin.x(-array) ⇝ *real*
Column coordinate of upper left corner point of the enclosing rectangle.

▷ **Row2** (output_control) ..... rectangle.corner.y(-array) ⇝ *real*
Row coordinate of lower right corner point of the enclosing rectangle.

▷ **Column2** (output_control) ..... rectangle.corner.x(-array) ⇝ *real*
Column coordinate of lower right corner point of the enclosing rectangle.

Complexity

If N is the number of contour points, the runtime complexity is $O(N)$.

Result

`smallest_rectangle1_xld` returns `2` (`H_MSG_TRUE`) if the input is not empty. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

smallest_rectangle2_xld (XLD : : : Row, Column, Phi, Length1, Length2)

Smallest enclosing rectangle with arbitrary orientation of contours or polygons.

The operator `smallest_rectangle2_xld` determines the smallest enclosing rectangle of each input contour or polygon, i.e., the rectangle with the smallest area of all rectangles containing the contour. For this rectangle the center, the inclination, and the two radii are calculated.

If more than one contour or polygon is passed, the results are stored in tuples in the same order as the respective contours or polygons in `XLD`. In case of an empty contour all parameters have the value 0.0 if no other behavior was set (see `set_system`).

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be examined.

▷ **Row** (output_control) ..... rectangle2.center.y(-array) ⇝ *real*
Row coordinate of the center point of the enclosing rectangle.

▷ **Column** (output_control) . . . . . rectangle2.center.x(-array) ⇝ *real*
Column coordinate of the center point of the enclosing rectangle.

▷ **Phi** (output_control) . . . . . rectangle2.angle.rad(-array) ⇝ *real*
Orientation of the enclosing rectangle (arc measure)
Assertion: - pi / 2 < Phi && Phi <= pi / 2

▷ **Length1** (output_control) . . . . . rectangle2.hwidth(-array) ⇝ *real*
First radius (half length) of the enclosing rectangle.
Assertion: Length1 >= 0.0

▷ **Length2** (output_control) . . . . . rectangle2.hheight(-array) ⇝ *real*
Second radius (half width) of the enclosing rectangle.
Assertion: Length2 >= 0.0 && Length2 <= Length1

Complexity

If N is the number of contour points and C is the number of points in the convex hull, the runtime complexity is $O(N * ln(N) + C^2)$.

Result

`smallest_rectangle2_xld` returns `2` (`H_MSG_TRUE`) if the input is not empty. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

test_closed_xld (XLD : : : IsClosed)

Test whether contours or polygons are closed.

`test_closed_xld` tests each contour or polygon in `XLD`, whether it is closed and returns the result in `IsClosed`. If the contour contour or polygon is closed, the respective return value is 1, otherwise 0. A contour or polygon is closed, if its last point is equal to its first point.

Parameters

▷ **XLD** (input_object) . . . . . xld(-array) ⇝ *object*
Contours or polygons to be tested.

▷ **IsClosed** (output_control) . . . . . integer(-array) ⇝ *integer*
Tuple with Boolean numbers.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

- Processed without parallelization.

Possible Predecessors

gen_contour_region_xld, edges_sub_pix

Module

Foundation

test_self_intersection_xld (XLD : : CloseXLD : DoesIntersect)

Test XLD contours or polygons for self intersection.

test_self_intersection_xld tests whether the input contours or polygons in XLD intersect or touch themselves. The output array DoesIntersect contains a *1* if the corresponding input contour or polygon intersects or touches itself and *0* otherwise.

If the input parameter CloseXLD is set to *'true'*, open contours or polygons are closed before the check is performed by simply connecting the first and the last contour or polygon point with a line segment.

Attention

A contour or polygon touches itself if a contour or polygon point lies exactly on a contour or polygon segment. However, whether a point lies exactly on a contour or polygon segment or not can practically not be decided because of numerical reasons.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Input contours or polygons.

▷ **CloseXLD** (input_control) ..... string ⇝ *string*
Should the input contours or polygons be closed first?
Default: 'true'
List of values: CloseXLD ∈ {'true', 'false'}

▷ **DoesIntersect** (output_control) ..... number(-array) ⇝ *integer*
1 for contours or polygons with self intersection and 0 otherwise.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

Module

Foundation

test_xld_point (XLD : : Row, Column : IsInside)

Test whether one or more contours or polygons enclose the given point(s).

test_xld_point tests whether a test point (Row, Column) is enclosed by a contour or polygon XLD and returns the result in IsInside. If the input point is enclosed by the contour or polygon, the return value is *1*, otherwise *0*. In the case of a single test point and multiple contours or polygons, the (i-1)-th element of the resulting tuple IsInside indicates, whether the point is enclosed by the i-th contour or polygon. In the case of multiple test points and a single contour or polygon, the i-th element of the resulting tuple IsInside indicates, whether the i-th point is enclosed by the contour or polygon. In the case of multiple test points and multiple contours or polygons, the (i-1)-th element of the resulting tuple IsInside indicates, whether the (i-1)-th point is enclosed by the i-th contour or polygon (the subscription differs, because the indexing of the results tuple starts with 0 in contrast to the indexing of object tuples). In this case the number of input points must be equal to the number of contours or polygons. It is assumed that the contours or polygons are closed. If this is not the case test_xld_point will artificially close the contour. Nevertheless it is strongly recommended to pass only meaningful and closed contours or polygons in XLD.

Attention

If a test point is on the border of the contour or polygon, `test_xld_point` will deliver unpredictable results, i.e. the result may be *0* or *1* depending on arbitrary factors such as how the polygon is oriented with respect to the coordinate system. Note further that for points in the near proximity of the contour or polygon sides, a reliable classification is practically impossible because of numerical inaccuracies.

Parameters

- ▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
  Contours or polygons to be tested.
- ▷ **Row** (input_control) ..... point.y(-array) ⇝ *real*
  Row coordinates of the points to be tested.
- ▷ **Column** (input_control) ..... point.x(-array) ⇝ *real*
  Column coordinates of the points to be tested.
  Number of elements: Column == Row
- ▷ **IsInside** (output_control) ..... integer(-array) ⇝ *integer*
  Tuple with Boolean numbers.

Result

`test_xld_point` returns `2` (`H_MSG_TRUE`) if the input is not empty. If the input is empty the behavior can be set via `set_system('no_object_result',<Result>:)`. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

29.4 Geometric Transformations

affine_trans_contour_xld (
Contours : ContoursAffineTrans : HomMat2D :)

Apply an arbitrary affine 2D transformation to XLD contours.

`affine_trans_contour_xld` applies an arbitrary affine 2D transformation, i.e., scaling, rotation, translation, and slant (skewing), to the XLD contours given in `Contours` and returns the transformed contours in `ContoursAffineTrans`. The affine transformation is described by the homogeneous transformation matrix given in `HomMat2D`, which can be created using the operators `hom_mat2d_identity`, `hom_mat2d_scale`, `hom_mat2d_rotate`, `hom_mat2d_translate`, etc., or be the result of operators like `vector_angle_to_rigid`.

The components of the homogeneous transformation matrix are interpreted as follows: The *row* coordinate of the image corresponds to x and the *column* coordinate corresponds to y of the coordinate system in which the transformation matrix was defined. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

Attention

`affine_trans_contour_xld` does not use the HALCON standard coordinate system (with the origin in the center of the upper left pixel), but instead uses the same coordinate system as in `affine_trans_pixel`, i.e., the origin lies in the upper left corner of the upper left pixel. Therefore, applying `affine_trans_contour_xld` corresponds to a chain of transformations (see `affine_trans_pixel`), which is applied to each point of the contour (input and output pixels as homogeneous vectors). As an effect, you might get unexpected results when creating affine transformations based on coordinates that are derived from the contour, e.g., by operators like

area_center_xld. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric XLD contour and then rotate the contour around this point using hom_mat2d_rotate, the resulting contour will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to HomMat2D before using it in affine_trans_contour_xld:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
affine_trans_contour_xld(Contours, ContoursAffineTrans,
HomMat2DAdapted)
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- ▷ **Contours** (input_object) ..... xld_cont(-array) ⇝ *object*
  Input XLD contours.
- ▷ **ContoursAffineTrans** (output_object) ..... xld_cont(-array) ⇝ *object*
  Transformed XLD contours.
- ▷ **HomMat2D** (input_control) ..... hom_mat2d ⇝ *real*
  Input transformation matrix.

Result

If the matrix HomMat2D represents an affine transformation (i.e., not a projective transformation), affine_trans_contour_xld returns 2 (H_MSG_TRUE). If the input is empty the behavior can be set via set_system('no_object_result',<Result>:). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

affine_trans_polygon_xld (Polygons : PolygonsAffineTrans : HomMat2D :)

Apply an arbitrary affine transformation to XLD polygons.

affine_trans_polygon_xld applies an arbitrary affine transformation, i.e., scaling, rotation, translation, and slant (skewing), to the XLD polygons given in Polygons and returns the transformed polygons in PolygonsAffineTrans. The affine transformation is described by the homogeneous transformation matrix given in HomMat2D. This matrix can be created using the operators hom_mat2d_identity, hom_mat2d_scale, hom_mat2d_rotate, hom_mat2d_translate, etc., or be the result of operators like vector_angle_to_rigid.

The components of the homogeneous transformation matrix are interpreted as follows: The *row* coordinate of the image corresponds to x and the *column* coordinate corresponds to y of the coordinate system in which the transformation matrix was defined. This is necessary to obtain a right-handed coordinate system for the image. In particular, this assures that rotations are performed in the correct direction. Note that the (x,y) order of the matrices quite naturally corresponds to the usual (row,column) order for coordinates in the image.

Attention

The XLD contours that are possibly referenced by `Polygons` are neither transformed nor stored with the output polygons, since this is generally impossible without creating inconsistencies for the attributes of the XLD contours. Hence, operators that access the contours associated with a polygon, e.g., `split_contours_xld` will not work correctly.

`affine_trans_polygon_xld` does not use the HALCON standard coordinate system (with the origin in the center of the upper left pixel), but instead uses the same coordinate system as in `affine_trans_pixel`, i.e., the origin lies in the upper left corner of the upper left pixel. Therefore, applying `affine_trans_polygon_xld` corresponds to a chain of transformations (see `affine_trans_pixel`), which is applied to each point of the polygon (input and output pixels as homogeneous vectors). As an effect, you might get unexpected results when creating affine transformations based on coordinates that are derived from the polygon, e.g., by operators like `area_center_xld`. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric XLD polygon and then rotate the polygon around this point using `hom_mat2d_rotate`, the resulting polygon will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to `HomMat2D` before using it in `affine_trans_polygon_xld`:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
affine_trans_polygon_xld(Polygons, PolygonsAffineTrans,
HomMat2DAdapted)
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

- ▷ **`Polygons`** (input_object) ..... xld_poly(-array) ⇝ *object*
  Input XLD polygons.
- ▷ **`PolygonsAffineTrans`** (output_object) ..... xld_poly(-array) ⇝ *object*
  Transformed XLD polygons.
- ▷ **`HomMat2D`** (input_control) ..... hom_mat2d ⇝ *real*
  Input transformation matrix.

Result

If the matrix `HomMat2D` represents an affine transformation (i.e., not a projective transformation), `affine_trans_polygon_xld` returns `2` (`H_MSG_TRUE`). If the input is empty the behavior can be set via `set_system('no_object_result',<Result>)`. If necessary, an exception is raised.

`gen_parallel_contour_xld` (Contours : ParallelContours : Mode, Distance :)

Compute the parallel contour of an XLD contour.

gen_parallel_contour_xld computes for each of the input contours Contours a parallel contour with distance Distance. The resulting contours are returned in ParallelContours. To calculate the parallel contour, the normal vector of the input contour is needed in every contour point. The parameter Mode determines how these normal vectors are computed. If Mode = *'gradient'*, it is assumed that the input contours are edges, and the normal information is obtained from the gradient direction of the edge (see edges_sub_pix). For this, the attribute *'edge_direction'* must exist for the input contour (see get_contour_attrib_xld). If Mode = *'contour_normal'*, a possibly existing normal information is used to determine the normals. For this, the contour attribute *'angle'* must exist (see lines_gauss or edges_sub_pix). Finally, if Mode = *'regression_normal'*, the normal vectors are determined from a local line fit to each contour point. Here, the normal vectors are oriented such that they point to the right side of the contour when the contour is traversed from start to end. In contrast to the first two modes, this mode can be used for all XLD contours, no matter how they were generated.

Parameters

▷ **Contours** (input_object) . . . . . xld_cont-array ⇝ *object*
Contours to be transformed.

▷ **ParallelContours** (output_object) . . . . . xld_cont-array ⇝ *object*
Parallel contours.

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Mode, with which the direction information is computed.
Default: 'regression_normal'
Suggested values: Mode ∈ {'gradient', 'contour_normal', 'regression_normal'}

▷ **Distance** (input_control) . . . . . number ⇝ *real* / integer
Distance of the parallel contour.
Default: 1
Suggested values: Distance ∈ {0.2, 0.4, 0.6, 0.8, 1, 2, 3, 4, 5, 7, 10, 15, 20, 30, 40, 50}

polar_trans_contour_xld (Contour : PolarTransContour : Row, Column, AngleStart, AngleEnd, RadiusStart, RadiusEnd, Width, Height :)

Transform a contour in an annular arc to polar coordinates.

polar_trans_contour_xld transforms the Contour in the annular arc specified by the center point (Row, Column), the radii RadiusStart and RadiusEnd and the angles AngleStart and AngleEnd to its polar coordinate version PolarTransContour in the virtual image of the dimensions Width × Height. The output contour is cropped at the borders of this virtual image.

The coordinate (0,0) in the output contour always corresponds to the contour point specified by RadiusStart and AngleStart. Analogously, the coordinate (Height − 1,Width − 1) in the output contour always corresponds to the point in the contour that is specified by RadiusEnd and AngleEnd, even if the contour does not contain these points. In the usual mode (AngleStart < AngleEnd and RadiusStart < RadiusEnd),

the polar transformation is performed in the mathematically positive orientation (counterclockwise). Furthermore, contour points with smaller radii lie in the upper part of the output contour. By suitably exchanging the values of these parameters (e.g., AngleStart > AngleEnd or RadiusStart > RadiusEnd), any desired orientation of the output contour PolarTransContour can be achieved.

The angles can be chosen from all real numbers. Center point and radii can be real as well.

Note that PolarTransContour can consist of more than one contour because Contour may be split at AngleStart respectively AngleEnd or the size of the angle interval [AngleStart, AngleEnd] may be greater than one $2pi$ period.

If more than one contour is passed in Contour, their polar transformations are computed individually and stored as a tuple in PolarTransContour. However, since one contour may be transformed into several contours, there is no relation between the indices of the contours in the input tuple Contour and the indices in the output tuple PolarTransContour.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

Only the contour points are transformed. As the polar transformation is not affine, polar_trans_contour_xld only produces reliable results if the spacing of the contour points is small. Existing attributes are not transformed.

Parameters

▷ **Contour** (input_object) ..... xld_cont(-array) ⇝ *object*
Input contour.

▷ **PolarTransContour** (output_object) ..... xld_cont(-array) ⇝ *object*
Output contour.

▷ **Row** (input_control) ..... number ⇝ *real* / integer
Row coordinate of the center of the arc.
Default: 256
Suggested values: Row ∈ {0, 16, 32, 64, 128, 240, 256, 480, 512}

▷ **Column** (input_control) ..... number ⇝ *real* / integer
Column coordinate of the center of the arc.
Default: 256
Suggested values: Column ∈ {0, 16, 32, 64, 128, 256, 320, 512, 640}

▷ **AngleStart** (input_control) ..... angle.rad ⇝ *real*
Angle of the ray to be mapped to the column coordinate *0* of PolarTransContour.
Default: 0.0
Suggested values: AngleStart ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853, 12.566370616}
Value range: -6.2831853 ≤ AngleStart ≤ 6.2831853

▷ **AngleEnd** (input_control) ..... angle.rad ⇝ *real*
Angle of the ray to be mapped to the column coordinate Width − 1 of PolarTransContour to.
Default: 6.2831853
Suggested values: AngleEnd ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853, 12.566370616}
Value range: -6.2831853 ≤ AngleEnd ≤ 6.2831853

▷ **RadiusStart** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to be mapped to the row coordinate *0* of PolarTransContour.
Default: 0
Suggested values: RadiusStart ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusStart ≤ 32767

▷ **RadiusEnd** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to be mapped to the row coordinate Height − 1 of PolarTransContour.
Default: 100
Suggested values: RadiusEnd ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ RadiusEnd ≤ 32767

▷ **Width** (input_control) . . . . . extent.x ⇝ *integer*
Width of the virtual output image.
Default: 512
Suggested values: Width ∈ {256, 320, 512, 640, 800, 1024}
Value range: 0 ≤ Width ≤ 32767

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the virtual output image.
Default: 512
Suggested values: Height ∈ {240, 256, 480, 512, 600, 1024}
Value range: 0 ≤ Height ≤ 32767

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

Module

Foundation

polar_trans_contour_xld_inv (PolarContour : XYTransContour : Row, Column, AngleStart, AngleEnd, RadiusStart, RadiusEnd, WidthIn, HeightIn, Width, Height :)

Transform a contour in polar coordinates back to Cartesian coordinates

polar_trans_contour_xld_inv transforms the polar coordinate representation of a contour, stored in PolarContour, back onto an annular arc in Cartesian coordinates, described by the radii RadiusStart and RadiusEnd and the angles AngleStart and AngleEnd with the center point located at (Row, Column). All of these values can be chosen as real numbers. In addition, the dimensions of the virtual image containing the contour PolarContour must be given in WidthIn and HeightIn. WidthIn − 1 is the column coordinate corresponding to AngleEnd and HeightIn − 1 is the row coordinate corresponding to RadiusEnd. AngleStart and RadiusStart correspond to column and row coordinate *0*. Furthermore, the dimensions Width and Height of the virtual output image containing the transformed contour XYTransContour are required. The output contour is cropped at the borders of this virtual output image.

polar_trans_contour_xld_inv is the inverse function of polar_trans_contour_xld.

The call sequence:

```
polar_trans_contour_xld(Contour, PolarContour, Row, Column,
rad(360)
polar_trans_contour_xld_inv(PolarContour, XYTransContour,
Row, Column, rad(360), 0, 0, Radius, Width, Height, WidthOut,
HeightOut)
```

returns the contour Contour, restricted to the circle around (Row, Column) with radius Radius, as its output contour XYTransContour.

Note that XYTransContour can consist of more than one contour because PolarContour may be cropped at the borders of the virtual output image given by Width and Height.

If more than one contour is passed in PolarContour, their transformations are computed individually and stored as a tuple in XYTransContour. However, since one contour may be transformed into several contours, there is no relation between the indices of the contours in the input tuple PolarContour and the indices in the output tuple XYTransContour.

Further Information

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Attention

Only the contour points are transformed. As the polar transformation is not affine, `polar_trans_contour_xld_inv` only produces reliable results if the spacing of the contour points is small. Existing attributes are not transformed.

Parameters

▷ **`PolarContour`** (input_object) ..... xld_cont(-array) ⇝ *object*
Input contour.

▷ **`XYTransContour`** (output_object) ..... xld_cont(-array) ⇝ *object*
Output contour.

▷ **`Row`** (input_control) ..... number ⇝ *real* / integer
Row coordinate of the center of the arc.
Default: 256
Suggested values: `Row` ∈ {0, 16, 32, 64, 128, 240, 256, 480, 512}

▷ **`Column`** (input_control) ..... number ⇝ *real* / integer
Column coordinate of the center of the arc.
Default: 256
Suggested values: `Column` ∈ {0, 16, 32, 64, 128, 256, 320, 512, 640}

▷ **`AngleStart`** (input_control) ..... angle.rad ⇝ *real*
Angle of the ray to map the column coordinate *0* of `PolarContour` to.
Default: 0.0
Suggested values: `AngleStart` ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853}
Value range: -6.2831853 ≤ `AngleStart` ≤ 6.2831853

▷ **`AngleEnd`** (input_control) ..... angle.rad ⇝ *real*
Angle of the ray to map the column coordinate `WidthIn` − 1 of `PolarContour` to.
Default: 6.2831853
Suggested values: `AngleEnd` ∈ {0.0, 0.78539816, 1.57079632, 3.141592654, 6.2831853}
Value range: -6.2831853 ≤ `AngleEnd` ≤ 6.2831853

▷ **`RadiusStart`** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to map the row coordinate *0* of `PolarContour` to.
Default: 0
Suggested values: `RadiusStart` ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ `RadiusStart` ≤ 32767

▷ **`RadiusEnd`** (input_control) ..... number ⇝ *real* / integer
Radius of the circle to map the row coordinate `HeightIn` − 1 of `PolarContour` to.
Default: 100
Suggested values: `RadiusEnd` ∈ {0, 16, 32, 64, 100, 128, 256, 512}
Value range: 0 ≤ `RadiusEnd` ≤ 32767

▷ **`WidthIn`** (input_control) ..... extent.x ⇝ *integer*
Width of the virtual input image.
Default: 512
Suggested values: `WidthIn` ∈ {256, 320, 512, 640, 800, 1024}
Value range: 0 ≤ `WidthIn` ≤ 32767

▷ **`HeightIn`** (input_control) ..... extent.y ⇝ *integer*
Height of the virtual input image.
Default: 512
Suggested values: `HeightIn` ∈ {240, 256, 480, 512, 600, 1024}
Value range: 0 ≤ `HeightIn` ≤ 32767

▷ **`Width`** (input_control) ..... extent.x ⇝ *integer*
Width of the virtual output image.
Default: 512
Suggested values: `Width` ∈ {256, 320, 512, 640, 800, 1024}
Value range: 0 ≤ `Width` ≤ 32767

▷ **Height** (input_control) . . . . . extent.y ⇝ *integer*
Height of the virtual output image.
Default: 512
Suggested values: Height ∈ {240, 256, 480, 512, 600, 1024}
Value range: 0 ≤ Height ≤ 32767

projective_trans_contour_xld (Contours : ContoursProjTrans : HomMat2D :)

Apply a projective transformation to an XLD contour.

projective_trans_contour_xld applies the projective transformation specified by the homogeneous matrix HomMat2D on the contours in Contours and returns the transformed contours in ContoursProjTrans.

For creation and interpretation details of this matrix see also projective_trans_image.

Attention

The used coordinate system is the same as in affine_trans_pixel. This means that in fact not HomMat2D is applied but a modified version. Therefore, applying projective_trans_contour_xld corresponds to the following chain of transformations, which is applied to each point (Row_i, Col_i) of the contour (input and output pixels as homogeneous vectors):

$$\begin{pmatrix} RowTrans_i \\ ColTrans_i \\ 1 \end{pmatrix} = \begin{bmatrix} 1 & 0 & -0.5 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \text{HomMat2D} \cdot \begin{bmatrix} 1 & 0 & +0.5 \\ 0 & 1 & +0.5 \\ 0 & 0 & 1 \end{bmatrix} \cdot \begin{pmatrix} Row_i \\ Col_i \\ 1 \end{pmatrix}$$

As an effect, you might get unexpected results when creating projective transformations based on coordinates that are derived from the contour, e.g., by operators like area_center_xld. For example, if you use this operator to calculate the center of gravity of a rotationally symmetric XLD contour and then rotate the contour around this point using hom_mat2d_rotate, the resulting contour will not lie on the original one. In such a case, you can compensate this effect by applying the following translations to HomMat2D before using it in projective_trans_contour_xld:

```
hom_mat2d_translate(HomMat2D, 0.5, 0.5, HomMat2DTmp)
hom_mat2d_translate_local(HomMat2DTmp, -0.5, -0.5,
HomMat2DAdapted)
projective_trans_contour_xld(Contours, ContoursAffineTrans,
HomMat2DAdapted)
```

For an explanation of the different 2D coordinate systems used in HALCON, see the introduction of chapter Transformations / 2D Transformations.

Parameters

▷ **Contours** (input_object) . . . . . xld_cont(-array) ⇝ *object*
Input contours.

▷ **ContoursProjTrans** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Output contours.

▷ **HomMat2D** (input_control) . . . . . hom_mat2d ⇝ *real*
Homogeneous projective transformation matrix.

29.5 Sets

```
difference_closed_contours_xld ( Contours,
    Sub :  ContoursDifference :  :  )
```

Compute the difference of closed contours.

The operator difference_closed_contours_xld calculates the difference of the regions enclosed by the contours Contours and Sub. The boundaries of this difference are returned in ContoursDifference.

If the individual input contours are not closed, they are closed automatically by connecting their start and end points.

Internally, first, the regions enclosed by each set of contours (Contours and Sub, respectively) are determined as described below. Then, the difference of these two regions is calculated.

In the following, the two sets of input contours are referred to as *boundary sets*. A boundary set consists of an arbitrary number of boundaries (the individual contours of Contours and Sub, respectively). Each boundary may be convex or concave and self-intersecting. Internal holes may be formed by the nesting of boundaries.

The region enclosed by such a boundary set is defined by the so-called Even-Odd-Rule. Thus, it consists of all points with the following property: The line constructed by connecting the point with another reference point that lies outside of the region has an odd number of intersections with boundaries.

More descriptive, this means that a boundary defines a hole in the region enclosed by another boundary if it lies completely inside that region. Similarly, the overlapping area of two separate boundaries of one boundary set is taken as a "hole", i.e., it does not belong to the region enclosed by the two boundaries. Note that the region enclosed by a boundary does not depend on the orientation of the boundary.

A self-intersecting boundary may be split at the intersection point or it is reordered such that it touches itself at the intersection point. The resulting boundaries are treated as separate boundaries.

The resulting boundaries ContoursDifference are automatically classified into boundaries that enclose regions and boundaries that enclose holes. This information is stored in the global contour attribute *'is_hole'*. For further information about global contour attributes see get_contour_global_attrib_xld.

Note that subsequent points whose row and column coordinates differ by less than 1e-06 pixels are considered as one point.

Parameters

▷ **Contours** (input_object) . . . . . xld_cont(-array) ⇝ *object*
Contours enclosing the region from which the second region is subtracted.

▷ **Sub** (input_object) . . . . . xld_cont(-array) ⇝ *object*
Contours enclosing the region that is subtracted from the first region.

▷ **ContoursDifference** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Contours enclosing the difference.

Result

`difference_closed_contours_xld` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

difference_closed_polygons_xld (Polygons, Sub : PolygonsDifference : :)

Compute the difference of closed polygons.

The operator `difference_closed_polygons_xld` calculates the difference of the regions enclosed by the polygons `Polygons` and `Sub`. The boundaries of this difference are returned in `PolygonsDifference`.

If the individual input polygons are not closed, they are closed automatically by connecting their start and end points.

Internally, first, the regions enclosed by each set of polygons (`Polygons` and `Sub`, respectively) are determined as described below. Then, the difference of these two regions is calculated.

In the following, the two sets of input polygons are referred to as *boundary sets*. A boundary set consists of an arbitrary number of boundaries (the individual polygons of `Polygons` and `Sub`, respectively). Each boundary may be convex or concave and self-intersecting. Internal holes may be formed by the nesting of boundaries.

The region enclosed by such a boundary set is defined by the so-called Even-Odd-Rule. Thus, it consists of all points with the following property: The line constructed by connecting the point with another reference point that lies outside of the region has an odd number of intersections with boundaries.

More descriptive, this means that a boundary defines a hole in the region enclosed by another boundary if it lies completely inside that region. Similarly, the overlapping area of two separate boundaries of one boundary set is taken as a "hole", i.e., it does not belong to the region enclosed by the two boundaries. Note that the region enclosed by a boundary does not depend on the orientation of the boundary.

A self-intersecting boundary may be split at the intersection point or it is reordered such that it touches itself at the intersection point. The resulting boundaries are treated as separate boundaries.

Attention

The resulting polygons `PolygonsDifference` contain no references to the XLD contours that are possibly referenced by `Polygons` and `Sub`. Hence, operators that access the contours associated with a polygon, e.g., `split_contours_xld` will not work correctly.

Parameters

▷ **Polygons** (input_object) . . . . . xld_poly(-array) ⇝ *object*
Polygons enclosing the region from which the second region is subtracted.

▷ **Sub** (input_object) . . . . . xld_poly(-array) ⇝ *object*
Polygons enclosing the region that is subtracted from the first region.

▷ **PolygonsDifference** (output_object) . . . . . xld_poly(-array) ⇝ *object*
Polygons enclosing the difference.

Result

`difference_closed_polygons_xld` returns `2` (`H_MSG_TRUE`) if all parameters are correct. If necessary, an exception is raised.

Execution Information

intersection_region_contour_xld (Region, Contour : ContourIntersection : Mode :)

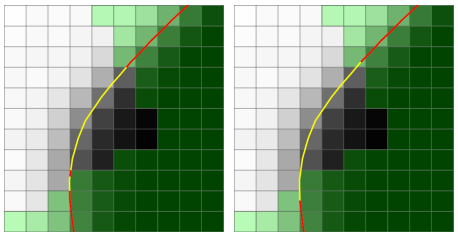
Intersect a contour with a region.

The operator intersection_region_contour_xld intersects the contour Contour with the region Region and returns the parts of the contour that are within the region in ContourIntersection.

The type of intersection can be specified with Mode. The following values are possible:

'lines' **(Default):** In *'lines'* mode, each line segment of the input contour is intersected with the region with subpixel accuracy. This mode is usually slower than *'points'* but more accurate. Line segments that are only partially within the region are split into multiple segments if necessary.

*'points'***:** In *'points'* mode, entire line segments from Contour are tested against the region using their start and end point. If both the start and end point of a line segment are within the region, that line segment is included in the output. This mode is faster than *'lines'* but less accurate, especially if the contour is coarsely sampled. For example, line segments might leave the region between their start and end point, but are still included in the output. Further, a line segment might be contained in the region for the most part but is not included in the output if the start or end point are not in the region.



(1) (2)

Result for *'lines'* (1) and *'points'* mode (2) when intersecting a contour with a region (green). The red sections of the contour will be returned as the result.

Parameters

▷ **Region** (input_object) . . . . . region ⇝ *object*
Input region.

▷ **Contour** (input_object) . . . . . xld_cont-array ⇝ *object*
Input contour.

▷ **ContourIntersection** (output_object) . . . . . xld_cont-array ⇝ *object*
Selected part of the input contour.

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Intersection mode.
Default: 'lines'
List of values: Mode ∈ {'points', 'lines'}

add_noise_white_contour_xld (
Contours : NoisyContours : NumRegrPoints, Amp :)

Add noise to XLD contours.

add_noise_white_contour_xld adds noise to the input XLD contours Contours and returns the noisy contours in NoisyContours. For each point along the original contours the local regression line (i.e., a least-squares approximating line) based on NumRegrPoints neighboring points is determined. Then the point is shifted perpendicular to this line. The length of the shifts corresponds to white noise, equally distributed in the interval [-Amp,Amp].

The random noise is generated using the C function "drand48()". See the parameter *'seed_rand'* of set_system for information on the used random seed.

Parameters

- ▷ **Contours** (input_object) ..... xld_cont(-array) ⇝ *object*
  Original contours.
- ▷ **NoisyContours** (output_object) ..... xld_cont(-array) ⇝ *object*
  Noisy contours.
- ▷ **NumRegrPoints** (input_control) ..... integer ⇝ *integer*
  Number of points used to calculate the regression line.
  Default: 5
  Suggested values: NumRegrPoints ∈ {3, 5, 7, 9}
  Restriction: NumRegrPoints >= 3 && odd(NumRegrPoints)
- ▷ **Amp** (input_control) ..... real ⇝ *real*
  Maximum amplitude of the added noise (equally distributed in [-Amp,Amp]).
  Default: 1.0
  Suggested values: Amp ∈ {0.25, 0.5, 1.0, 1.5, 2.0, 3.0, 4.0, 5.0, 10.0}
  Restriction: Amp > 0

Example

```
draw_ellipse(WindowHandle,Row,Column,Phi,Radius1,Radius2)
gen_ellipse_contour_xld(Ellipse,Row,Column,Phi,Radius1,Radius2,0,6.28319, \
                        'positive', 1.5)
add_noise_white_contour_xld(Ellipse,NoisyEllipse,5,0.5)
fit_ellipse_contour_xld (NoisyEllipse, 'fitzgibbon', -1, 2, 0, 200, 3, 2.0, \
                         ERow, EColumn, EPhi, ERadius1, ERadius2, \
                         EStartPhi, EEndPhi, EPointOrder)
```

Result

add_noise_white_contour_xld returns 2 (H_MSG_TRUE) if all parameter values are correct. If the input is empty the behavior can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).

clip_contours_xld (Contours : ClippedContours : Row1, Column1, Row2, Column2 :)

Clip an XLD contour.

clip_contours_xld clips all XLD contours given in Contours, i.e., only contour points contained in the rectangle given by Row1, Column1, Row2, and Column2 are returned on output. Note, that the rectangle behaves like a region, i.e., the rectangle encloses the pixels completely. If necessary, contours are split, and several new contours are produced. The resulting contours are returned in ClippedContours.

Parameters

- ▷ **Contours** (input_object) . . . . . xld_cont(-array) ⇝ *object*
  Contours to be clipped.
- ▷ **ClippedContours** (output_object) . . . . . xld_cont(-array) ⇝ *object*
  Clipped contours.
- ▷ **Row1** (input_control) . . . . . rectangle.origin.y ⇝ *integer*
  Row coordinate of the upper left corner of the clip rectangle.
  Default: 0
  Suggested values: Row1 ∈ {0, 500, 1000, 1500, 2000}
- ▷ **Column1** (input_control) . . . . . rectangle.origin.x ⇝ *integer*
  Column coordinate of the upper left corner of the clip rectangle.
  Default: 0
  Suggested values: Column1 ∈ {0, 500, 1000, 1500, 2000}
- ▷ **Row2** (input_control) . . . . . rectangle.corner.y ⇝ *integer*
  Row coordinate of the lower right corner of the clip rectangle.
  Default: 512
  Suggested values: Row2 ∈ {512, 1024, 1536, 2048}
- ▷ **Column2** (input_control) . . . . . rectangle.corner.x ⇝ *integer*
  Column coordinate of the lower right corner of the clip rectangle.
  Default: 512
  Suggested values: Column2 ∈ {512, 1024, 1536, 2048}

clip_end_points_contours_xld (Contours : ClippedContours : Mode, Length :)

Clip the end points of an XLD contour.

The operator clip_end_points_contours_xld clips the end points of an XLD contour. The parameter Mode determines the measure used to determine which part of the contour is clipped.

If Mode = *'length'*, the Euclidean length of the part to be clipped is passed in Length. If Mode = *'num_points'*, the number of points to be clipped is passed in Length.

The clipped contour is returned in ClippedContours. If all points of the input contour are clipped, no contour is returned. Therefore, the number of returned contours is less or equal to the number of input contours.

Parameters

▷ **Contours** (input_object) ..... xld_cont(-array) ⇝ *object*
Input contour

▷ **ClippedContours** (output_object) ..... xld_cont(-array) ⇝ *object*
Clipped contour

▷ **Mode** (input_control) ..... string ⇝ *string*
Clipping mode.
Default: 'num_points'
List of values: Mode ∈ {'num_points', 'length'}

▷ **Length** (input_control) ..... number ⇝ *real* / integer
Clipping length in unit pixels (Mode = *'length'*) or number (Mode = *'num_points'*)
Default: 3
Suggested values: Length ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10}

Result

clip_end_points_contours_xld returns 2 (H_MSG_TRUE) if the input is not empty. The behavior in case of empty input (no input contour available) is set via the operator set_system ('no_object_result',<Result>). If necessary an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

close_contours_xld (Contours : ClosedContours : :)

Close an XLD contour.

close_contours_xld closes all XLD contours given in Contours. The resulting contours are returned in ClosedContours. To obtain meaningful results, it is strongly recommended to select contours with select_contours_xld that have end points that are not further apart than a certain maximum distance before passing them to close_contours_xld.

Parameters

▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
Contours to be closed.

▷ **ClosedContours** (output_object) ..... xld_cont(-array) ⇝ *object*
Closed contours.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

combine_roads_xld (EdgePolygons, ModParallels, ExtParallels, CenterLines : RoadSides : MaxAngleParallel, MaxAngleColinear, MaxDistanceParallel, MaxDistanceColinear :)

Combine road hypotheses from two resolution levels.

`combine_roads_xld` combines road hypotheses obtained from two different resolution levels. The algorithm selects only those hypotheses which mutually support each other in both resolution levels. The parameters `EdgePolygons`, `ModParallels` and `ExtParallels` correspond to the road hypotheses from the highest resolution level. The parameter `CenterLines` is the result of road extraction in a lower resolution level. Those of the polygons `EdgePolygons` are returned for which evidence of being roadsides is found in both resolution levels. The parameters `MaxAngleParallel` and `MaxAngleColinear` determine the angle, that may be formed by two parallel collinear line segments, respectively. The parameters `MaxDistanceParallel` and `MaxDistanceColinear` determine the maximum allowed distance of two parallel or collinear line segments, respectively. The combination is done using a number of rules.

Parameters

▷ **EdgePolygons** (input_object) ..... xld_poly-array ⇝ *object*
XLD polygons to be examined.

▷ **ModParallels** (input_object) ..... xld_mod_para-array ⇝ *object*
Modified parallels obtained from `EdgePolygons`.

▷ **ExtParallels** (input_object) ..... xld_ext_para-array ⇝ *object*
Extended parallels obtained from `EdgePolygons`.

▷ **CenterLines** (input_object) ..... xld_poly-array ⇝ *object*
Road-center-line polygons to be examined.

▷ **RoadSides** (output_object) ..... xld_poly-array ⇝ *object*
Roadsides found.

▷ **MaxAngleParallel** (input_control) ..... angle.rad ⇝ *real* / integer
Maximum angle between two parallel line segments.
Default: 0.523598775598
Suggested values: `MaxAngleParallel` ∈ {0.349065850399, 0.523598775598, 0.6981317008}
Restriction: 0 <= MaxAngleParallel <= pi / 2

▷ **MaxAngleColinear** (input_control) ..... angle.rad ⇝ *real* / integer
Maximum angle between two collinear line segments.
Default: 0.261799387799
Suggested values: `MaxAngleColinear` ∈ {0.174532925199, 0.261799387799, 0.349065850399}
Restriction: 0 <= MaxAngleColinear <= pi / 2

▷ **MaxDistanceParallel** (input_control) ..... real ⇝ *real* / integer
Maximum distance between two parallel line segments.
Default: 40
Suggested values: `MaxDistanceParallel` ∈ {20, 30, 40, 50, 60}
Restriction: MaxDistanceParallel > 0

▷ **MaxDistanceColinear** (input_control) ..... real ⇝ *real* / integer
Maximum distance between two collinear line segments.
Default: 40
Suggested values: MaxDistanceColinear ∈ {20, 30, 40, 50, 60}
Restriction: MaxDistanceColinear > 0

Execution Information

- Multithreading type: mutually exclusive (runs in parallel with other non-exclusive operators, but not with itself).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

crop_contours_xld (Contours : CroppedContours : Row1, Col1, Row2, Col2, CloseContours :)

Crop an XLD contour.

crop_contours_xld crops all XLD contours given in Contours, i.e., only contour segments contained in the rectangle given by Row1, Col1, Row2 and Col2 are returned on output. While in clip_contours_xld all contour segments that intersect a boundary line are omitted, here they are cropped at the exact intersection point with the cropping rectangle. If necessary, contours are split and several new contours are produced. Closed contours can, however, be closed again using the parameter CloseContours. If it is set to *'true'*, a closed contour is transformed into one or several contours that are closed via segments on the cropping rectangle. If it is *'false'*, all contours end at the points where they leave the cropping rectangle. The resulting contours are returned in CroppedContours.

Parameters

▷ **Contours** (input_object) ..... xld_cont(-array) ⇝ *object*
Input contours.

▷ **CroppedContours** (output_object) ..... xld_cont(-array) ⇝ *object*
Output contours.

▷ **Row1** (input_control) ..... number ⇝ *real* / integer
Upper border of the cropping rectangle.
Default: 0
Suggested values: Row1 ∈ {0, 500, 1000, 1500, 2000}

▷ **Col1** (input_control) ..... number ⇝ *real* / integer
Left border of the cropping rectangle.
Default: 0
Suggested values: Col1 ∈ {0, 500, 1000, 1500, 2000}

▷ **Row2** (input_control) ..... number ⇝ *real* / integer
Lower border of the cropping rectangle.
Default: 512
Suggested values: Row2 ∈ {512, 1024, 1536, 2048}

▷ **Col2** (input_control) ..... number ⇝ *real* / integer
Right border of the cropping rectangle.
Default: 512
Suggested values: Col2 ∈ {512, 1024, 1536, 2048}

▷ **CloseContours** (input_control) ..... string ⇝ *string*
Should closed contours produce closed output contours?
Default: 'true'
List of values: CloseContours ∈ {'true', 'false'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

merge_cont_line_scan_xld (CurrConts, PrevConts : CurrMergedConts, PrevMergedConts : ImageHeight, Margin, MergeBorder, MaxImagesCont :)

Merge XLD contours from successive line scan images.

The operator merge_cont_line_scan_xld connects adjacent XLD contours, which were extracted from adjacent images with the height ImageHeight. This operator was especially designed to connect contours that were extracted from images grabbed by a line scan camera. CurrConts contains the contours from the current image and PrevConts the contours from the previous one.

With the help of the parameter MergeBorder two cases can be distinguished: If the top (first) line of the current image touches the bottom (last) line of the previous image, MergeBorder must be set to *'top'*, otherwise set MergeBorder to *'bottom'*. MergeBorder defines a margin to the border. Only those end points of the contours which are inside this margin are considered for the following merging process.

If the operator merge_cont_line_scan_xld is used recursively, the parameter MaxImagesCont determines the maximum number of images which are covered by a merged contour. All points of the merged contour from an older image are removed.

The operator merge_cont_line_scan_xld returns two contour arrays. PrevMergedConts contains all those contours from the previous input contours PrevConts, which could not be merged with a current contour. CurrMergedConts collects all current contours together with the merged parts from the previous images. Merged contours will exceed the original image, because the previous contours are moved upward (MergeBorder=*'top'*) or downward (MergeBorder=*'bottom'*) according to the image height.

Parameters

▷ **CurrConts** (input_object) ..... xld_cont(-array) ⇝ *object*
Current input contours.

▷ **PrevConts** (input_object) ..... xld_cont(-array) ⇝ *object*
Merged contours from the previous iteration.

▷ **CurrMergedConts** (output_object) ..... xld_cont(-array) ⇝ *object*
Current contours, merged with old ones where applicable.

▷ **PrevMergedConts** (output_object) . . . . . xld_cont(-array) ⇝ *object*
Contours from the previous iteration which could not be merged with the current ones.

▷ **ImageHeight** (input_control) . . . . . integer ⇝ *integer*
Height of the line scan images.
Default: 512
Suggested values: ImageHeight ∈ {240, 480, 512}

▷ **Margin** (input_control) . . . . . real ⇝ *real* / integer
Maximum distance of contours from the image border.
Default: 0.0
Suggested values: Margin ∈ {0.0, 1.0, 2.0, 3.0, 4.0, 5.0}

▷ **MergeBorder** (input_control) . . . . . string ⇝ *string*
Image line of the current image, which touches the previous image.
Default: 'top'
List of values: MergeBorder ∈ {'top', 'bottom'}

▷ **MaxImagesCont** (input_control) . . . . . integer ⇝ *integer*
Maximum number of images covered by one contour.
Default: 3
Suggested values: MaxImagesCont ∈ {1, 2, 3, 4, 5}

Result

The operator merge_cont_line_scan_xld returns the value 2 (H_MSG_TRUE) if the given parameters are correct. Otherwise, an exception will be raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Module

regress_contours_xld (Contours : RegressContours : Mode, Iterations :)

Calculate the parameters of a regression line to an XLD contour.

regress_contours_xld calculates the following parameters for the input XLD contours Contours, and stores them with the resulting contours as global attributes:

- the coordinates of the normal vector of the regression line, i.e., the least-squares approximating line, of all contour points; the normal vector always points from the origin to the line (attributes: *'regr_norm_row'*, *'regr_norm_col'*),
- the mean of the Euclidean distance of the contour points from the regression line (attribute: *'regr_mean_dist'*),
- the standard deviation of these distances to the regression line (attribute: *'regr_dev_dist'*),
- the distance of the regression line from the origin (attribute: *'regr_dist'*).

See get_contour_global_attrib_xld for further information about global contour attributes.

For Mode = *'no'*, the parameters of the regression line are calculated for all points of the contour. In addition, three different kinds of outlier treatment can be applied. Outliers are contour points which do not lie on the general contour direction in an "obvious" manner, and thus "distort" the resulting regression line.

Mode =

- *'drop'*: All contour points further away from the contour than the mean distance to the regression line are ignored for the calculation of the undistorted regression line.

- *'gauss'*: The distances of the contour points are weighted according to their probability of occurrence in a Gaussian distribution around the normal regression line.
- *'median'*: Here, also a normal distribution is assumed for the distances to the normal regression line, however with the outlier-independent standard deviation $\frac{M_d}{0.6745}$, with M_d: median of all distances. Again, the distances are weighted, and points further away than a certain distance are ignored for the undistorted regression line.

The calculation of the undistorted regression line can be iterated several times (`Iterations`).

Parameters

▷ **`Contours`** (input_object) ..... xld_cont-array ⇝ *object*
Input XLD contours.

▷ **`RegressContours`** (output_object) ..... xld_cont-array ⇝ *object*
Resulting XLD contours.

▷ **`Mode`** (input_control) ..... string ⇝ *string*
Type of outlier treatment.
Default: 'no'
List of values: `Mode` ∈ {'no', 'drop', 'gauss', 'median'}

▷ **`Iterations`** (input_control) ..... integer ⇝ *integer*
Number of iterations for the outlier treatment.
Default: 1
Suggested values: `Iterations` ∈ {1, 2, 3, 5, 10, 20}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

`segment_contour_attrib_xld` (Contour : ContourPart : Attribute, Operation, Min, Max :)

Segment XLD contour parts whose local attributes fulfill given conditions.

`segment_contour_attrib_xld` segments the contour in `Contour` into contour parts `ContourPart`. The segmentation of the contour depends on the values of its attributes `Attribute` (see the possible values for `Attribute` below). The operator checks which attribute values lie within the given limits (`Min`, `Max`) and returns the corresponding contour segments with its attributes in `ContourPart`.

If `Operation` is set to *'and'*, each of the given attributes must lie within the limits. If `Operation` is set to *'or'*, at least one of the attributes has to be within the limits. The attributes are processed in the same order as they are given in `Attribute`. If only one attribute is used, the value of `Operation` is ignored. The parameters `Min` and `Max` can be set to *'min'* or *'max'* in order to leave bottom and top limit, respectively, open.

Note that not all attributes are defined in all contours per default. Which attributes are defined for a contour depends on how the contour was instantiated, and whether some operations have been previously performed on it. For example, the attributes *'width_right'* and *'width_left'* are only defined, if the contour was created with the operator `lines_gauss`. Likewise, the attribute *'distance'* is only present if the distances to some other contour was previously calculated with `distance_contours_xld` or `apply_distance_transform_xld`.

Condition: $Min_i \leq Attribute_i(Object) \leq Max_i$

Possible values for `Attribute`:

'edge_direction': Edge direction

'angle': Angle of the direction perpendicular to the contour

'response': Magnitude of the second derivative

'width_right': Line width to the right of the line

'width_left': Line width to the left of the line

'contrast': Contrast of the line point

'asymmetry': Asymmetry of the line point

'distance': Minimum pointwise distance to a reference contour

To find out which operators add the attributes above to contours and further details about those attributes, see `get_contour_attrib_xld`.

Parameters

▷ **`Contour`** (input_object) ..... xld_cont(-array) ⇝ *object*
Contour to be segmented.

▷ **`ContourPart`** (output_object) ..... xld_cont-array ⇝ *object*
Segmented contour parts.

▷ **`Attribute`** (input_control) ..... string(-array) ⇝ *string*
Contour attributes to be checked.
Default: 'distance'
List of values: `Attribute` ∈ {'distance', 'angle', 'edge_direction', 'width_right', 'width_left', 'response', 'contrast', 'asymmetry'}

▷ **`Operation`** (input_control) ..... string ⇝ *string*
Linkage type of the individual attributes.
Default: 'and'
List of values: `Operation` ∈ {'and', 'or'}

▷ **`Min`** (input_control) ..... real(-array) ⇝ *real* / integer / string
Lower limits of the attribute values.
Default: 150.0
Minimum increment: 0.001
Recommended increment: 1.0

▷ **`Max`** (input_control) ..... real(-array) ⇝ *real* / integer / string
Upper limits of the attribute values.
Default: 99999.0
Minimum increment: 0.001
Recommended increment: 1.0
Restriction: Max >= Min

Example

```
read_image (Image, 'fabrik')
edges_sub_pix (Image, Edges, 'canny', 1, 20, 40)
* select 'vertical' edges:
segment_contour_attrib_xld (Edges, ContourPart, 'edge_direction', \
                            'and', rad(90-20), rad(90+20))
```

Result

The operator `segment_contour_attrib_xld` returns the value `2` (`H_MSG_TRUE`) if the input is not

empty. The behavior in case of empty input (no input objects available) is set via the operator set_system ('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

segment_contours_xld (Contours : ContoursSplit : Mode, SmoothCont, MaxLineDist1, MaxLineDist2 :)

Segment XLD contours into line segments and circular or elliptic arcs.

segment_contours_xld segments the input contours Contours into lines if Mode='*lines*', into lines and circular arcs if Mode='*lines_circles*', or into lines and elliptic arcs if Mode='*lines_ellipses*'. The segmented contours are returned in ContoursSplit. The information on whether an output contour represents a line or a circular or elliptic arc is done via the global contour attribute *'cont_approx'* (see get_contour_global_attrib_xld for further information).

segment_contours_xld first approximates the input contours by polygons. With this, the contours are oversegmented in curved areas. After this, the contours are approximated according to the modes Mode given below. If SmoothCont is set to a value > 0, the input contours are first smoothed (see smooth_contours_xld). This can be necessary to prevent very short segments in the polygonal approximation and to achieve a more robust fit with circular or elliptic arcs, because the smoothing suppresses outliers on the contours.

The calculation of the segmentation depends on the respective selected method in Mode:

'lines' The Ramer algorithm is used to perform a polygon approximation with a maximum distance of MaxLineDist1 (see gen_polygons_xld). If Mode='*lines*', the parameter MaxLineDist2 is ignored.

'lines_circles' **or** *'lines_ellipses'* The initial polygonal approximation is done by using the Ramer algorithm (see gen_polygons_xld) with a maximum distance of MaxLineDist1. If the maximum distance of the resulting arc to the contour is smaller than the maximum distance of the two line segments, the two line segments are replaced with the arc. This procedure is iterated until no more changes occur. After this, the parts of the contour that are still approximated by line segments are again segmented with a polygonal approximation with maximum distance MaxLineDist2, and the newly created line segments are merged to circular or elliptical arcs where possible. This changes the output only if MaxLineDist2 differs from MaxLineDist1. This two-step approach is more efficient than a one-step approach with MaxLineDist2, since fewer line segments are generated in the first step, and hence the circle or ellipse fit has to be performed less often. Therefore, parts of the input contours that can be approximated by long arcs can be found more efficiently. In the second step, parts of the input contours that can be approximated by short arcs are found and the end parts of long arcs are refined. In order to benefit from this two-step approach it is recommended to set MaxLineDist2 $<$ MaxLineDist1.

The resulting contours are at least 3 pixel long and contain at least 6 successive points of the input contour. All input contours with a length less than 3 pixel or with less than 6 contour points are copied to the output contours without modifications.

Parameters

- ▷ **Contours** (input_object) . . . . . xld_cont(-array) ⇝ *object*
  Contours to be segmented.
- ▷ **ContoursSplit** (output_object) . . . . . xld_cont-array ⇝ *object*
  Segmented contours.
- ▷ **Mode** (input_control) . . . . . string ⇝ *string*
  Mode for the segmentation of the contours.
  Default: 'lines_circles'
  List of values: Mode ∈ {'lines', 'lines_circles', 'lines_ellipses'}
- ▷ **SmoothCont** (input_control) . . . . . integer ⇝ *integer*
  Number of points used for smoothing the contours.
  Default: 5
  Suggested values: SmoothCont ∈ {0, 3, 5, 7, 9}
  Restriction: SmoothCont == 0 || SmoothCont >= 3 && odd(SmoothCont)
- ▷ **MaxLineDist1** (input_control) . . . . . real ⇝ *real*
  Maximum distance between a contour and the approximating line (first iteration).
  Default: 4.0
  Suggested values: MaxLineDist1 ∈ {1.0, 1.5, 2.0, 2.5, 3.0, 3.5}
  Restriction: MaxLineDist1 >= 0.0
- ▷ **MaxLineDist2** (input_control) . . . . . real ⇝ *real*
  Maximum distance between a contour and the approximating line (second iteration).
  Default: 2.0
  Suggested values: MaxLineDist2 ∈ {1.0, 1.5, 2.0, 2.5, 3.0, 3.5}
  Restriction: MaxLineDist2 >= 0.0

Example

```
read_image (Image, 'pumpe')

shape_trans_xld (XLD : XLDTrans : Type :)

Transform the shape of contours or polygons.

shape_trans transforms the input contours or polygons depending on the parameter Type:

'convex' Convex hull.

'ellipse' Ellipse with the same moments and area as the input contour or polygon. The closed input contour or polygon must not intersect itself, otherwise the resulting ellipse is not meaningful(Whether the input contour or polygon intersects itself or not can be determined with test_self_intersection_xld).

'outer_circle' Smallest enclosing circle.

'rectangle1' Smallest enclosing rectangle parallel to the coordinate axes.

'rectangle2' Smallest enclosing rectangle.

Parameters

▷ **XLD** (input_object) ..... xld(-array) ⇝ *object*
Contours or polygons to be transformed.

▷ **XLDTrans** (output_object) ..... xld(-array) ⇝ *object*
Transformed contours respectively polygons.

▷ **Type** (input_control) ..... string ⇝ *string*
Type of transformation.
Default: 'convex'
List of values: Type ∈ {'convex', 'ellipse', 'outer_circle', 'rectangle1', 'rectangle2'}

Result

shape_trans_xld returns 2 (H_MSG_TRUE) if all parameters are correct. The behavior in case of empty input (no contours given) can be set via set_system('no_object_result',<Result>). If necessary, an exception is raised.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Automatically parallelized on tuple level.

smooth_contours_xld (Contours : SmoothedContours : NumRegrPoints :)

Smooth an XLD contour.

smooth_contours_xld smooths the input XLD contours Contours and returns the smoothed contours in SmoothedContours. The smoothing is done by projecting the contours' points onto a local regression line (i.e., a least-squares approximating line), which is computed from NumRegrPoints on each side of the current contour point. This operator should be called, for example, before contours are scaled.

Parameters

▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
Contour to be smoothed.

▷ **SmoothedContours** (output_object) ..... xld_cont-array ⇝ *object*
Smoothed contour.

▷ **NumRegrPoints** (input_control) ..... integer ⇝ *integer*
Number of points used to calculate the regression line.
Default: 5
Suggested values: NumRegrPoints ∈ {3, 5, 7, 9}
Restriction: NumRegrPoints >= 3 && odd(NumRegrPoints)

sort_contours_xld (Contours : SortedContours : SortMode, Order, RowOrCol :)

Sort contours with respect to their relative position.

The operator sort_contours_xld sorts the contours with respect to their relative position. RowOrCol specifies the sorting criteria: *'row'* sorts the contours with respect to the row coordinate of their position first and, if the row coordinates are identical, with respect to the column coordinate. In contrast, *'column'* sorts contours according to the column coordinate first. SortMode defines the position of a contour by individual reference points. The following parameter values are available:

'upper_left': The position is determined by the upper left corner of the surrounding rectangle.

'upper_right': The position is determined by the upper right corner of the surrounding rectangle.

'lower_left': The position is determined by the lower left corner of the surrounding rectangle.

'lower_right': The position is determined by the lower right corner of the surrounding rectangle.

'character': The position is determined by the upper left corner of the surrounding rectangle. In contrast to *'upper_left'*, the contours are also sorted according to the remaining coordinate, if they overlap in the direction of the coordinate which is specified by the parameter RowOrCol.

The parameter Order determines whether the sorting order is increasing or decreasing: using *'true'* the order will be increasing, using *'false'* the order will be decreasing.

Parameters

▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
Contours to be sorted.

▷ **SortedContours** (output_object) ..... xld_cont-array ⇝ *object*
Sorted contours.

▷ **SortMode** (input_control) ..... string ⇝ *string*
Kind of sorting.
Default: 'upper_left'
List of values: SortMode ∈ {'character', 'upper_left', 'lower_left', 'upper_right', 'lower_right'}

▷ **Order** (input_control) ..... string ⇝ *string*
Increasing or decreasing sorting order.
Default: 'true'
List of values: Order ∈ {'true', 'false'}

▷ **RowOrCol** (input_control) ..... string ⇝ *string*
Sorting first with respect to row, then to column.
Default: 'row'
List of values: RowOrCol ∈ {'row', 'column'}

Result

If the parameters are correct, the operator sort_contours_xld returns the value 2 (H_MSG_TRUE). Otherwise an exception will be raised.

Execution Information

split_contours_xld (Polygons : Contours : Mode, Weight, Smooth :)

Split XLD contours at dominant points.

split_contours_xld splits the contours which were used to generate the polygons Polygons at prominent points. If the mode *'polygon'* is selected, the contours are split at the polygons' control points. In mode *'dominant'*, they are split at dominant points, i.e., at points for which the calculated change of direction is larger than the (empirically determined) threshold 2πWeight$/$*contour length*, and for which in the (empirically determined) neighborhood of $\sqrt{\text{Smooth}} * \log(\textit{contour length})$ points no larger change of direction occurs. The contour direction is determined from the direction of the regression line (i.e., the least-squares approximating line) through all points in a neighborhood of Smooth points around a contour point. The directions thus determined are smoothed with a Gaussian of width Smooth. Weight is a weighting factor for the sensitiveness of the operator. The larger Weight is selected, the less dominant points are found.

Each polygon needs a reference to a contour. If the reference is missing, because the polygon is e.g., read from a DXF-File, split_contours_xld returns an error.

Parameters

▷ **Polygons** (input_object) ..... xld_poly(-array) ⇝ *object*
Polygons for which the corresponding contours are to be split.

▷ **Contours** (output_object) ..... xld_cont(-array) ⇝ *object*
Split contours.

▷ **Mode** (input_control) ..... string ⇝ *string*
Mode for the splitting of the contours.
Default: 'polygon'
List of values: Mode ∈ {'polygon', 'dominant'}

▷ **Weight** (input_control) ..... integer ⇝ *integer*
Weight for the sensitiveness.
Default: 1

▷ **Smooth** (input_control) ..... integer ⇝ *integer*
Width of the smoothing mask.
Default: 5

union_adjacent_contours_xld (Contours : UnionContours : MaxDistAbs, MaxDistRel, Mode :)

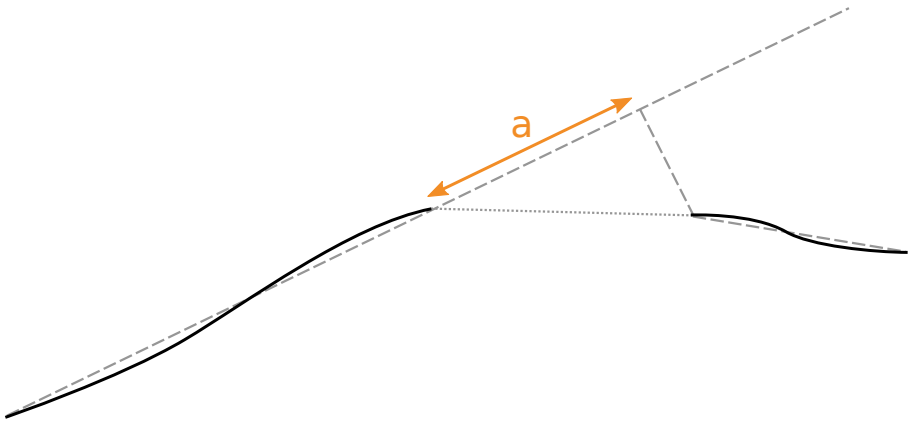
Compute the union of contours whose end points are close together.

The operator union_adjacent_contours_xld unifies all contours of the input XLD contour array (Contours) whose end points are close together. The unified contour consists of the concatenation of the contour points of the input contours. If necessary, the order of these input contour points is flipped, so that the end points of the contours that have to be connected are direct neighbors in the resulting point list. This operation is repeated until there are no more unconnected adjacent contours left. As a result all the contours that are newly created by unification, as well as the input contours that could not be connected with any other contour, are returned in UnionContours.

Parameters

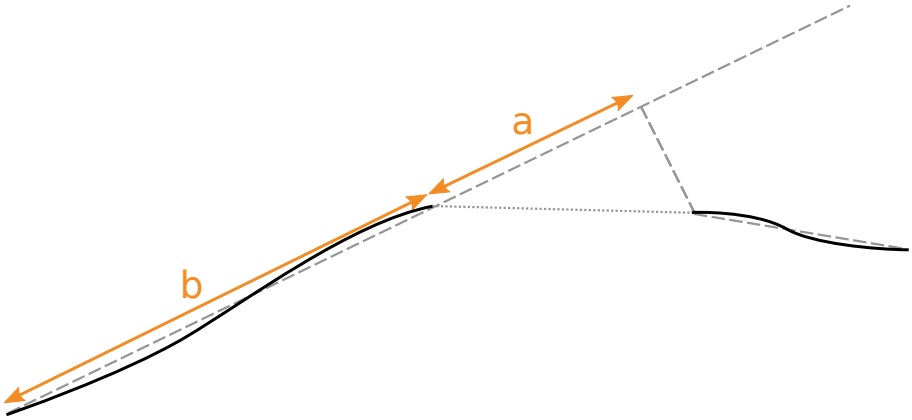
The parameters MaxDistAbs and MaxDistRel are used to define the conditions for the proximity of two contours. In principle, the measures for these parameters depend on the order in which each pair of contours is evaluated, i.e., which contour is used as reference contour that is to be joined with the second contour. To avoid this dependency, the respective measures are evaluated in both directions and the order of contours is chosen that results in the smaller value for these measures. Note that in the illustrations below, the contour on the left is always used as the reference contour. The parameter Mode controls the handling of the attributes of the input contours.

MaxDistAbs The parameter MaxDistAbs defines the maximum accepted absolute distance between the two contours. The distance is measured along the regression line of the reference contour. Thus, it is the length of the projection of the gap between the two contours onto the regression line of the reference contour.



$a \leq$ MaxDistAbs

MaxDistRel The parameter MaxDistRel defines the maximum accepted relative distance between the two contours. The relative distance is calculated by dividing the distance a (see the description of the parameter MaxDistAbs) by the length b of the reference contour.



$\frac{a}{b} \leq$ MaxDistRel

The order for connecting adjacent contours depends mainly on the distance of the neighbored end points: the contours with the smallest distance are connected first. If there are two pairs of contours with the same distance, first the contour pair that does not contain the shortest contour is connected.

Mode Finally, by the parameter Mode it is possible to control how to handle the attributes that may come with input contours. For example, the operator edges_sub_pix attaches to every contour point attributes like the local orientation, the edge response, and the edge direction. Choosing the default value *'attr_keep'*, all attributes are copied to the output, and – if a contour has to be flipped for connecting it with another one – they are adapted to the new orientation. With a great number of input contours, however, it may be sensible to ignore the attributes for performance reasons, if they are not needed for further calculations. For this the value *'attr_forget'* has to be passed.

Parameters

▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
Input XLD contours.

▷ **UnionContours** (output_object) ..... xld_cont-array ⇝ *object*
Output XLD contours.

▷ **MaxDistAbs** (input_control) ..... real ⇝ *real*
Maximum distance of the contours' end points.
Default: 10.0
Value range: 0.0 ≤ MaxDistAbs

▷ **MaxDistRel** (input_control) ..... real ⇝ *real*
Maximum distance of the contours' end points in relation to the length of the longer contour.
Default: 1.0
Value range: 0.0 ≤ MaxDistRel

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Mode describing the treatment of the contours' attributes.
Default: 'attr_keep'
List of values: Mode ∈ {'attr_keep', 'attr_forget'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).

```
union_cocircular_contours_xld ( Contours : UnionContours : MaxArcAngleDiff, MaxArcOverlap,
    MaxTangentAngle, MaxDist, MaxRadiusDiff, MaxCenterDist,
    MergeSmallContours, Iterations : )
```

Compute the union of contours that belong to the same circle.

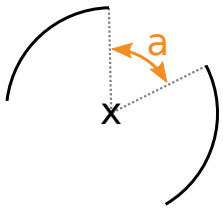
The operator union_cocircular_contours_xld merges all contours that belong to the same circle. The result is a set of contours in which contours on the same circle are connected.

The algorithm tries to merge contours by first fitting circles to each contour and then examining the result by means of radius, circle center, and gap on the circular arc. The list of contours is processed in sequence of increasing radii. Contours to which no circle could be fitted are optionally merged in a second pass.

The threshold parameters are used to define whether contours belong to the same circle. All thresholds must be fulfilled simultaneously for two contours to be merged.

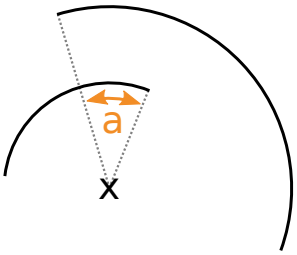
Parameters

MaxArcAngleDiff The parameter MaxArcAngleDiff defines the maximum angular distance in radians between the end point of one contour and the start point of a second contour on a circle.



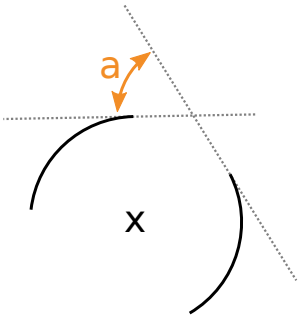
$a \leq$ MaxArcAngleDiff

MaxArcOverlap MaxArcOverlap denotes the maximum angle by which contours may overlap.



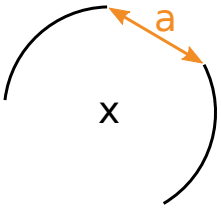
$a \leq$ MaxArcOverlap

MaxTangentAngle MaxTangentAngle describes the maximum angle between circle tangents and the connecting line of two contours.



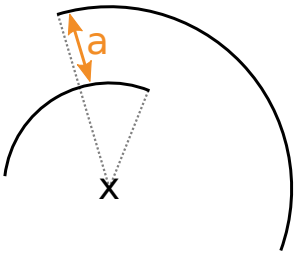
$a \leq$ MaxTangentAngle

MaxDist MaxDist denotes the maximum absolute distance in pixels of the end and start points of two contours.



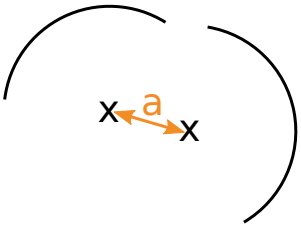
$a \leq$ MaxDist

MaxRadiusDiff MaxRadiusDiff is the maximum absolute difference of the radii of circles fitted to the contours.



$a \leq$ MaxRadiusDiff

MaxCenterDist MaxCenterDist is the limit of the Euclidean distance of the circle centers.



$a \leq$ MaxCenterDist

MergeSmallContours If the parameter MergeSmallContours is set to *'true'*, contours without fitted circles are also merged. For a small contour to match, each point of the contour needs to have a distance to

the circle center which differs from the radius by not more then MaxRadiusDiff. The angle between a line between two consecutive points on the contour and the circle tangent must be within MaxTangentAngle. Additionally, the condition for MaxDist must be fulfilled for two contours to be merged.

Iterations Merging of contours leads to new circle parameters. Therefore, an iteration can lead to further merges. The parameter Iterations controls the number of iterations. More than two iterations are seldom needed.

For each possible merge of two contours a cost is calculated by summing up the distances corresponding to the different threshold values. For comparability, the distances are scaled by the thresholds to a value between 0.0 and 1.0. If two or more contour start points match to the same end point of another contour, the contour with the lower cost is merged.

You should make sure that the input contours can be approximated by lines and circular arcs, for example by preprocessing them with split_contours_xld.

Attention

Note that already closed contours are not considered for a union anymore. That is, even if a contour and the already closed contour share the same circle, they are returned as separate contours.

Parameters

- ▷ **Contours** (input_object) . . . xld_cont-array ⇝ *object*
  Contours to be merged.
- ▷ **UnionContours** (output_object) . . . xld_cont-array ⇝ *object*
  Merged contours.
- ▷ **MaxArcAngleDiff** (input_control) . . . angle.rad ⇝ *real* / integer
  Maximum angular distance of two circular arcs.
  Default: 0.5
  Suggested values: MaxArcAngleDiff ∈ {0.25, 0.5, 0.75, 1.0}
- ▷ **MaxArcOverlap** (input_control) . . . angle.rad ⇝ *real* / integer
  Maximum overlap of two circular arcs.
  Default: 0.1
  Suggested values: MaxArcOverlap ∈ {0.0, 0.1, 0.2}
- ▷ **MaxTangentAngle** (input_control) . . . angle.rad ⇝ *real* / integer
  Maximum angle between the connecting line and the tangents of circular arcs.
  Default: 0.2
  Suggested values: MaxTangentAngle ∈ {0.1, 0.2, 0.3, 0.4, 0.5}
- ▷ **MaxDist** (input_control) . . . number ⇝ *real* / integer
  Maximum length of the gap between two circular arcs in pixels.
  Default: 30
  Suggested values: MaxDist ∈ {10, 30, 50, 70}
- ▷ **MaxRadiusDiff** (input_control) . . . number ⇝ *real* / integer
  Maximum radius difference of the circles fitted to two arcs.
  Default: 10
  Suggested values: MaxRadiusDiff ∈ {10, 20, 30}
- ▷ **MaxCenterDist** (input_control) . . . number ⇝ *real* / integer
  Maximum center distance of the circles fitted to two arcs.
  Default: 10
  Suggested values: MaxCenterDist ∈ {10, 20, 30}
- ▷ **MergeSmallContours** (input_control) . . . string ⇝ *string*
  Determine whether small contours without fitted circles should also be merged.
  Default: 'true'
  List of values: MergeSmallContours ∈ {'true', 'false'}
- ▷ **Iterations** (input_control) . . . integer ⇝ *integer*
  Number of iterations.
  Default: 1
  Suggested values: Iterations ∈ {1, 2}

Complexity

$O(n^2)$ for n contours.

Result

union_cocircular_contours_xld returns 2 (H_MSG_TRUE) if all parameters are correct.

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

split_contours_xld, select_contours_xld

Alternatives

union_collinear_contours_xld, union_cotangential_contours_xld, union_straight_contours_xld, union_adjacent_contours_xld, union_collinear_contours_ext_xld

Module

Foundation

```
union_collinear_contours_ext_xld ( Contours : UnionContours : MaxDistAbs, MaxDistRel, MaxShift,
    MaxAngle, MaxOverlap, MaxRegrError, MaxCosts, WeightDist,
    WeightShift, WeightAngle, WeightLink, WeightRegr, Mode : )
```

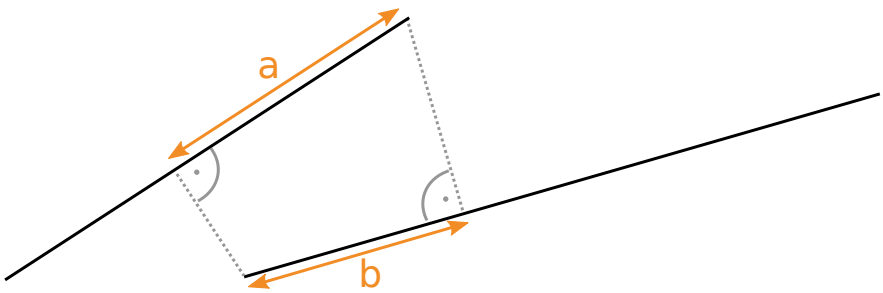
Compute the union of collinear contours (operator with extended functionality).

Like union_collinear_contours_xld, the operator union_collinear_contours_ext_xld detects all the collinear contours within the input array containing straight contours (Contours) and returns the results in UnionContours. The basic behavior is identical to the operator union_collinear_contours_xld and is described there. union_collinear_contours_ext_xld, however, provides several additional parameters to control the process of contour unification more precisely.

Parameters

The parameters MaxDistAbs, MaxDistRel, MaxShift, and MaxAngle operate as described for the operator union_collinear_contours_xld.

MaxOverlap In addition, the parameter MaxOverlap allows to define an overlap between two contours, in order to connect contours which slightly overlap. Internally, the operator assures – irrespective of the passed value for MaxOverlap – that the overlap is not bigger than a third of the length of both contours.



$min(a, b) \leq$ MaxOverlap

MaxRegrError The parameter MaxRegrError is not used at the moment. Its aim is to assure that after the unification of two contours, the resulting contour does not deviate too much from its regression line. This parameter is by default switched off (*-1*), because of its high time consumption and because of the fact that it is normally not necessary. In some cases, however, result contours may be created with points diverging to much from the regression line (winding input contours, shift and angle differences close to the – quite high adjusted – thresholds, recursive unification of a lot of small contours).

MaxCosts With the help of the parameter MaxCosts it is possible to limit the maximum costs for connecting two contours. So, not only contour pairs with one value beyond a certain threshold may be excluded from unification, but also contour pairs where all values are quite close to the limits. The costs are always normalized at a value between 0 and 1, where 1 means that all values exactly meet the threshold.

WeightDist, WeightShift, WeightAngle, WeightLink, and WeightRegr The influence of the different values on the total costs is adjusted by passing appropriate weights with the parameters WeightDist, WeightShift, WeightAngle, WeightLink, WeightRegr. Any positive number can be chosen for these weights, the resulting costs are always automatically normalized to fit the range from 0 to 1. The parameter WeightRegr is not used.

Mode The parameter Mode controls – as for union_collinear_contours_xld – how to handle the attributes of the input contours.

Parameters

▷ **Contours** (input_object) ..... xld_cont-array ⇝ *object*
Input XLD contours.

▷ **UnionContours** (output_object) ..... xld_cont-array ⇝ *object*
Output XLD contours.

▷ **MaxDistAbs** (input_control) ..... real ⇝ *real*
Maximum distance of the contours' end points in the direction of the reference regression line.
Default: 10.0
Value range: 0.0 ≤ MaxDistAbs

▷ **MaxDistRel** (input_control) ..... real ⇝ *real*
Maximum distance of the contours' end points in the direction of the reference regression line in relation to the length of the contour which is to be elongated.
Default: 1.0
Value range: 0.0 ≤ MaxDistRel

▷ **MaxShift** (input_control) ..... real ⇝ *real*
Maximum distance of the contour from the reference regression line (i.e., perpendicular to the line).
Default: 2.0
Value range: 0.0 ≤ MaxShift

▷ **MaxAngle** (input_control) ..... real ⇝ *real*
Maximum angle difference between the two contours.
Default: 0.1
Value range: 0.0 ≤ MaxAngle ≤ 0.78539816339

▷ **MaxOverlap** (input_control) ..... real ⇝ *real*
Maximum range of the overlap.
Default: 0.0
Value range: 0.0 ≤ MaxOverlap

▷ **MaxRegrError** (input_control) ..... real ⇝ *real*
Maximum regression error of the resulting contours (NOT USED).
Default: -1.0

▷ **MaxCosts** (input_control) ..... real ⇝ *real*
Threshold for reducing the total costs of unification.
Default: 1.0
Value range: 0.0 ≤ MaxCosts

▷ **WeightDist** (input_control) ..... real ⇝ *real*
Influence of the distance in the line direction on the total costs.
Default: 1.0
Value range: 0.0 ≤ WeightDist

▷ **WeightShift** (input_control) ..... real ⇝ *real*
Influence of the distance from the regression line on the total costs.
Default: 1.0
Value range: 0.0 ≤ WeightShift

▷ **WeightAngle** (input_control) ..... real ⇝ *real*
Influence of the angle difference on the total costs.
Default: 1.0
Value range: 0.0 ≤ WeightAngle

▷ **WeightLink** (input_control) . . . . . real ⇝ *real*
Influence of the line disturbance by the linking segment (overlap and angle difference) on the total costs.
Default: 1.0
Value range: 0.0 ≤ WeightLink

▷ **WeightRegr** (input_control) . . . . . real ⇝ *real*
Influence of the regression error on the total costs (NOT USED).
Default: 0.0
Value range: 0.0 ≤ WeightRegr

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Mode describing the treatment of the contours' attributes
Default: 'attr_keep'
List of values: Mode ∈ {'attr_keep', 'attr_forget'}

```
union_collinear_contours_xld ( Contours : UnionContours : MaxDistAbs, MaxDistRel, MaxShift,
    MaxAngle, Mode : )
```

Unite approximately collinear contours.

The operator union_collinear_contours_xld unites all contours of the input XLD contour array Contours that are approximately collinear, i.e., which lie approximately on the same straight line. The united contours consist of the concatenation of the contour points of the respective input contours. They are returned, together with the contours that could not be united with any other contour, in the output XLD contour array UnionContours.

Typical applications

union_collinear_contours_xld can be used to bridge gaps in extracted edges or lines, which may be caused, e.g., by locally low image contrast. It can also be used to unite collinear edge or line segments that are separated, e.g., because of junctions. Typically, union_collinear_contours_xld is part of the process of grouping and selecting extracted edges or lines to achieve meaningful entities.

Example

The following example shows the effect of union_collinear_contours_xld. On the left hand side, a set of disconnected input contours is shown. The contours that lie on the same border of the rectangle are approximately collinear. On the right hand side, the result of union_collinear_contours_xld shows that the contours that were approximately collinear have been united. Note that the contours that are approximately perpendicular to each other have not been united.

(1) (2)

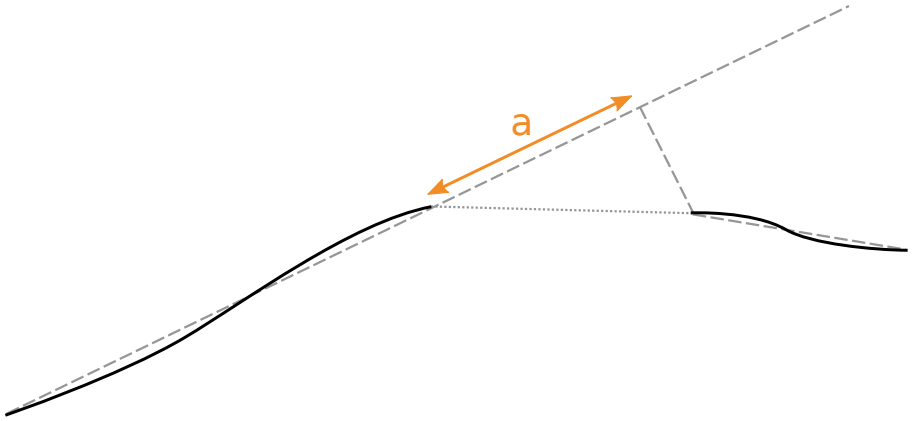
(1) Disconnected input contours. (2) Resulting contours, where approximately collinear contours have been united.

Parameters

The parameters MaxDistAbs, MaxDistRel, MaxShift, and MaxAngle are used to define the conditions for the collinearity of two contours. The parameter Mode controls the handling of the attributes of the input contours.

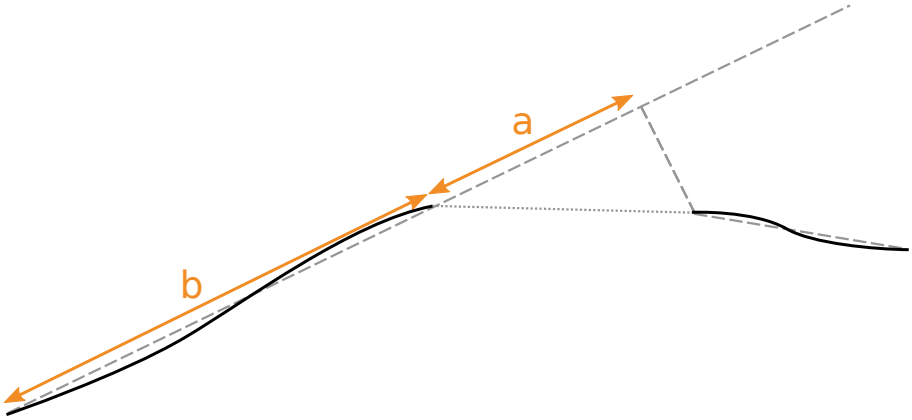
In principle, the measures for the first three parameters depend on the order in which each pair of contours is evaluated, i.e., which contour is used as reference contour that is to be joined with the second contour. To avoid this dependency, the respective measures are evaluated in both directions and the order of contours is chosen that results in the smaller value for these measures. Note that in the illustrations below, the contour on the left is always used as the reference contour.

MaxDistAbs The parameter MaxDistAbs defines the maximum accepted absolute distance between the two contours. The distance is measured along the regression line of the reference contour. Thus, it is the length of the projection of the gap between the two contours onto the regression line of the reference contour.



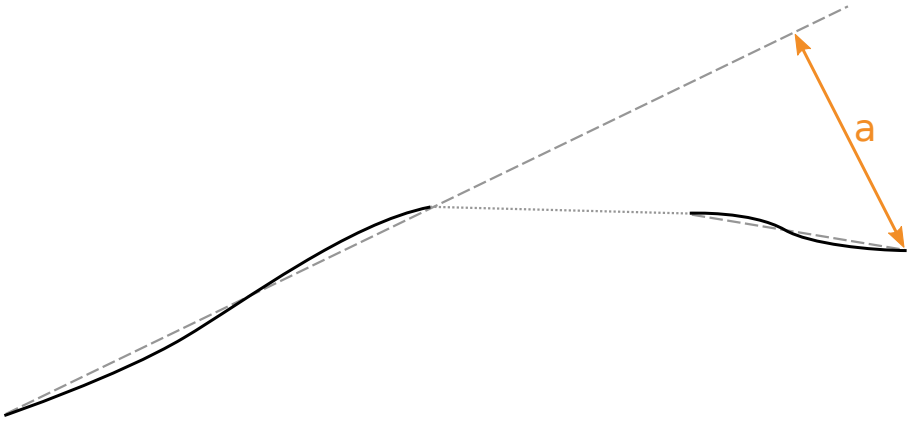
$a \leq$ MaxDistAbs

MaxDistRel The parameter MaxDistRel defines the maximum accepted relative distance between the two contours. The relative distance is calculated by dividing the distance a (see the description of the parameter MaxDistAbs) by the length b of the reference contour.



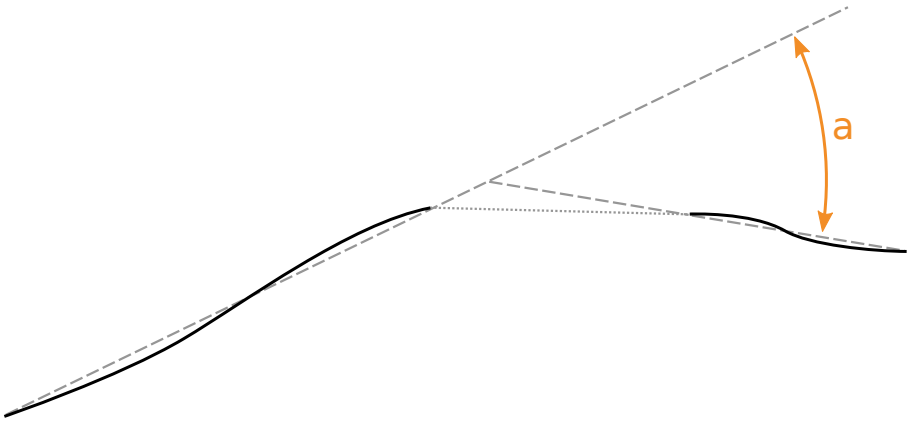
$\frac{a}{b} \leq$ MaxDistRel

MaxShift The parameter MaxShift defines the maximum distance of the second contour from the regression line of the reference contour. This distance is measured perpendicular to the regression line of the reference contour.



$a \leq$ MaxShift

MaxAngle The parameter MaxAngle defines the maximum angle (in radians) between the regression lines of the two contours.



$a \leq$ MaxAngle

Mode The parameter Mode controls the handling of the attributes that may be available for the input contours, e.g., if the contours have been created by edges_sub_pix.

'attr_keep' All attributes are copied to the output contours.
Global attributes are only kept for those contours that are not united with other contours. In general, it is not possible to determine the global attributes of a united contour from the global attributes of the individual contours.

'attr_forget' The output contours will not contain any attributes. This mode may be chosen for performance reasons if the attributes will not be required for further calculations.

To query, which attributes are available, query_contour_attribs_xld can be used.

Implementation details

The input contours are analyzed and united pairwise. This pairwise process is repeated until there are no more unconnected collinear contours left. If necessary, the order of the input contour points is flipped, so that the end points of the contours that have been connected are direct neighbors in the resulting point list.

Two contours are united only if all criteria are fulfilled, i.e., all values must be lower than the specified thresholds. As another precondition, contours must not overlap each other significantly (see union_collinear_contours_ext_xld for an illustration of overlap). An overlap of at most 0.5 pixels is tolerated. To allow a larger overlap, union_collinear_contours_ext_xld can be used.

Besides finding pairs of contours to be united, it is important for the behavior of union_collinear_contours_xld to determine the order in which contours are united. For this, all contour pairs that may be united are rated by calculating costs for their unification. The costs are the sum of the measures, each normalized by the respective threshold, defined by the parameters MaxDistAbs, MaxDistRel,

MaxShift, and MaxAngle. The contour pair with the lowest costs is united first. Then, the costs are updated with respect to the newly created contour and the contour list is searched for the next best pair of contours to be united.

Note that the definition of collinearity as used in union_collinear_contours_xld depends on the regression lines of the input contours. To avoid unexpected results, make sure that the input contours are approximately straight lines, e.g., by splitting them into line segments with segment_contours_xld. Note also that closed contours are not united with any other contour.

Limitations and alternatives

union_collinear_contours_xld can only be used if the contours that should be joined lie approximately on a straight line. If the contours lie approximately on a circle, union_cocircular_contours_xld can be used instead. If the contours represent a free-form, union_cotangential_contours_xld can be used. If only very small gaps between the contours should be closed, regardless of the orientation of the contours, union_adjacent_contours_xld can be used.

If the parameter adjustments available with union_collinear_contours_xld are not sufficient, union_collinear_contours_ext_xld can be used to define the criteria for the unification more specifically. Among others, union_collinear_contours_ext_xld allows to set the tolerance for the overlap of contours as well as a limit for the total costs to avoid the connection of contours that are close to the limits of all criteria.

Parameters

▷ **Contours** (input_object) . . . . . xld_cont-array ⇝ *object*
Input XLD contours.

▷ **UnionContours** (output_object) . . . . . xld_cont-array ⇝ *object*
Output XLD contours.

▷ **MaxDistAbs** (input_control) . . . . . real ⇝ *real*
Maximum length of the gap between two contours, measured along the regression line of the reference contour.
Default: 10.0
Value range: 0.0 ≤ MaxDistAbs

▷ **MaxDistRel** (input_control) . . . . . real ⇝ *real*
Maximum length of the gap between two contours, relative to the length of the reference contour, both measured along the regression line of the reference contour.
Default: 1.0
Value range: 0.0 ≤ MaxDistRel

▷ **MaxShift** (input_control) . . . . . real ⇝ *real*
Maximum distance of the second contour from the regression line of the reference contour.
Default: 2.0
Value range: 0.0 ≤ MaxShift

▷ **MaxAngle** (input_control) . . . . . real ⇝ *real*
Maximum angle between the regression lines of two contours.
Default: 0.1
Value range: 0.0 ≤ MaxAngle ≤ 0.78539816339

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Mode that defines the treatment of contour attributes, i.e., if the contour attributes are kept or discarded.
Default: 'attr_keep'
List of values: Mode ∈ {'attr_keep', 'attr_forget'}

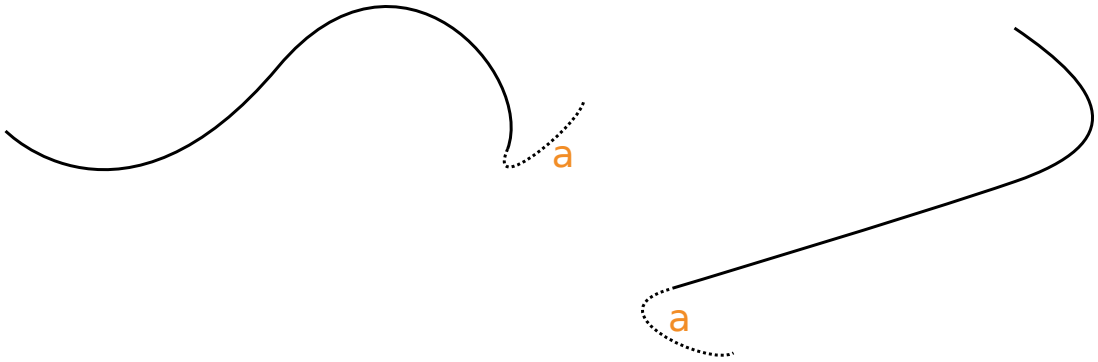
union_cotangential_contours_xld (Contours : UnionContours : FitClippingLength, FitLength, MaxTangAngle, MaxDist, MaxDistPerp, MaxOverlap, Mode :)

Compute the union of cotangential contours.

The operator union_cotangential_contours_xld unifies contours of the input XLD contour array Contours according to the local curvatures at their endpoints.

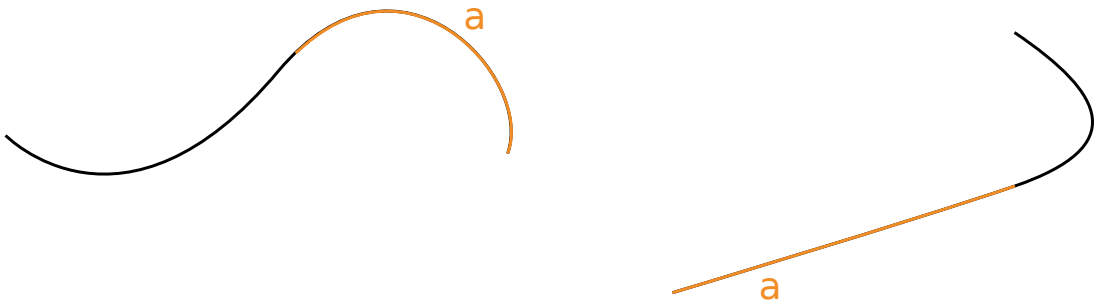
Parameters

FitClippingLength How does the union work? First, end pieces for each input contour in Contours are determined. The parameter FitClippingLength specifies the Euclidean length that is temporarily clipped at both ends of a contour. With this parameter, it is possible to ignore artifacts at the endings of the input contours.



$a \leq$ FitClippingLength

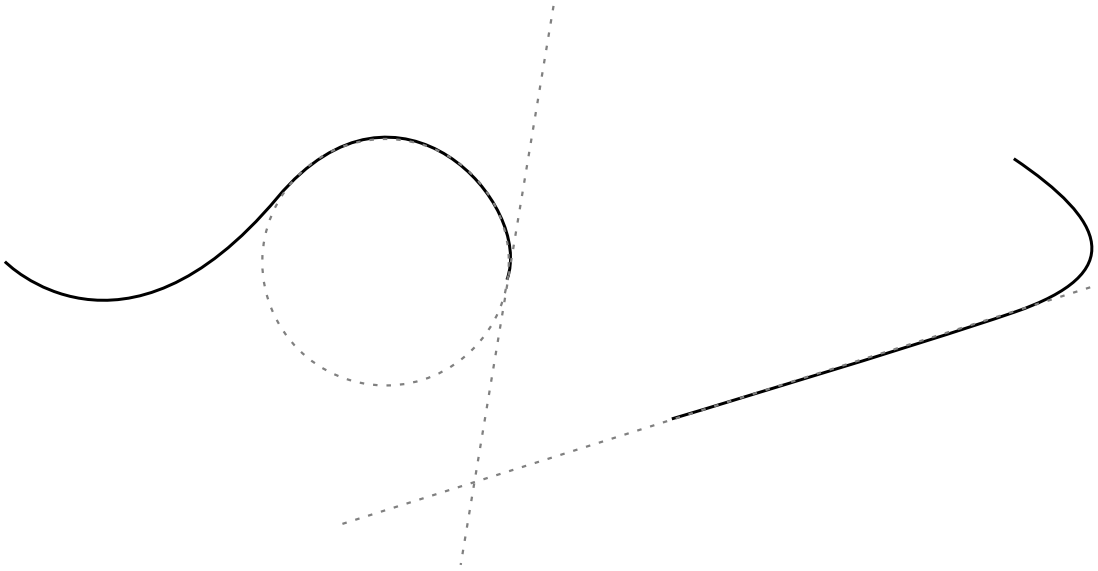
FitLength With the parameter FitLength the Euclidean length of the end pieces that will be examined for the union is given. At each end of a contour at least that many points are assigned to an end piece that its length is greater or equal to FitLength. The value *'auto'* can be used here. The operator then tries to segment the contours into straights and arcs and takes the first and last segment as end pieces. As this is computationally intensive, it is recommended to use numerically specified values for the lengths whenever possible.



$a \leq$ FitLength

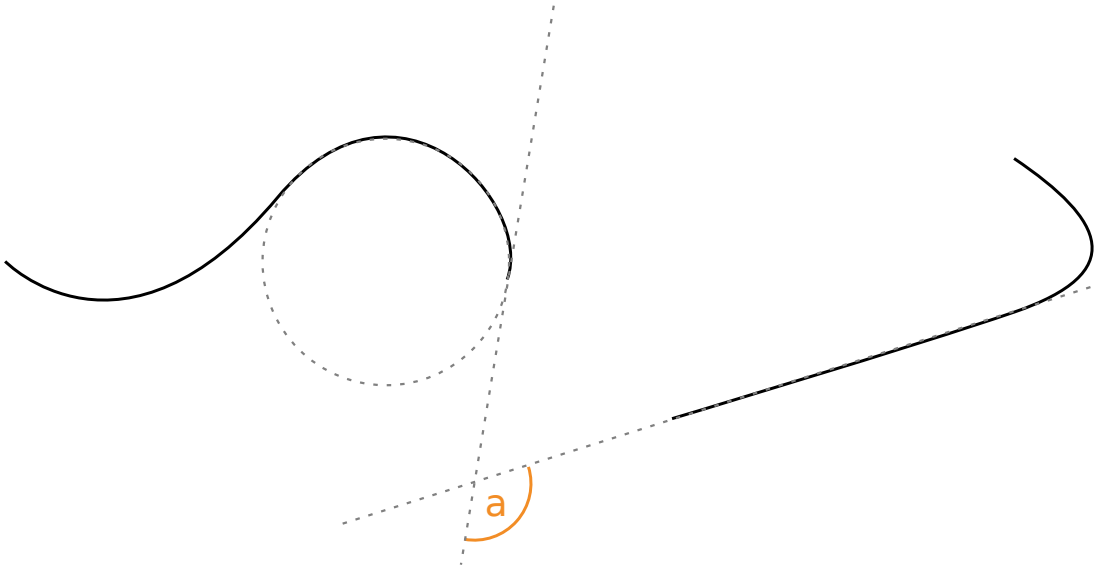
The operator tries to fit a circle into each end piece. Then, the endpoints of the input contours are determined that lie near enough to these circles (measured against the root mean square error of the circle fit). The tangents at these points correspond to the local curvature at the endings of the input contours.

If a circle fit fails, the operator tries to fit a regression line. Then, the local curvature of the endings of a contour corresponds to the direction of the regression line through the points of the end pieces.



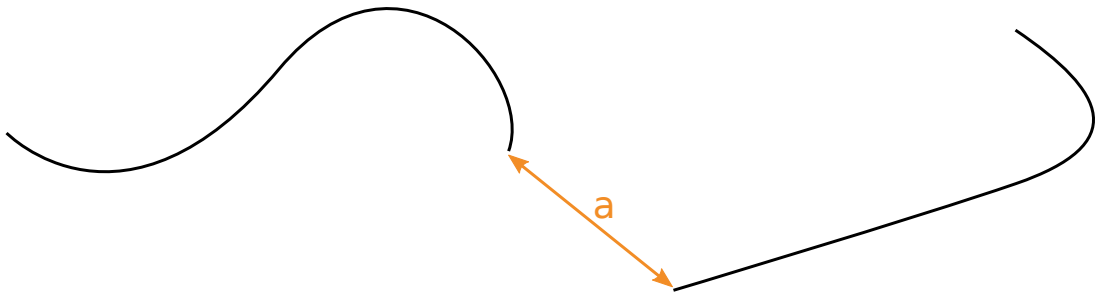
The input contours are going to be unified according to the calculated local curvatures at their endpoints. Two contours are considered for the union if multiple thresholds are fulfilled at the same time:

MaxTangAngle The parameter MaxTangAngle specifies the maximum angle between the tangents of two contours.



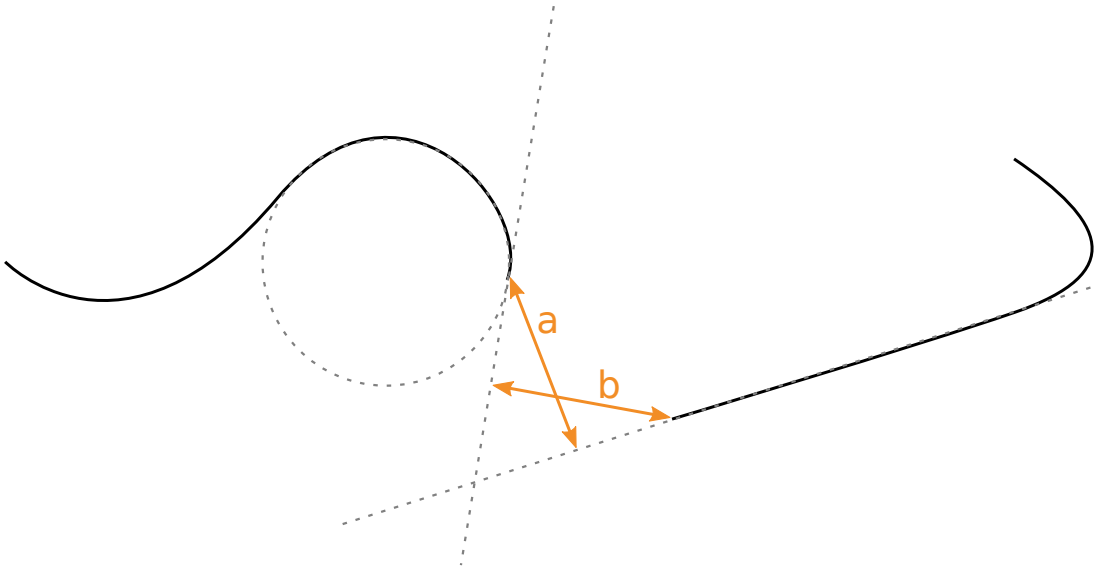
$a \leq$ MaxTangAngle

MaxDist The maximum distance of two endpoints is given with the parameter MaxDist.



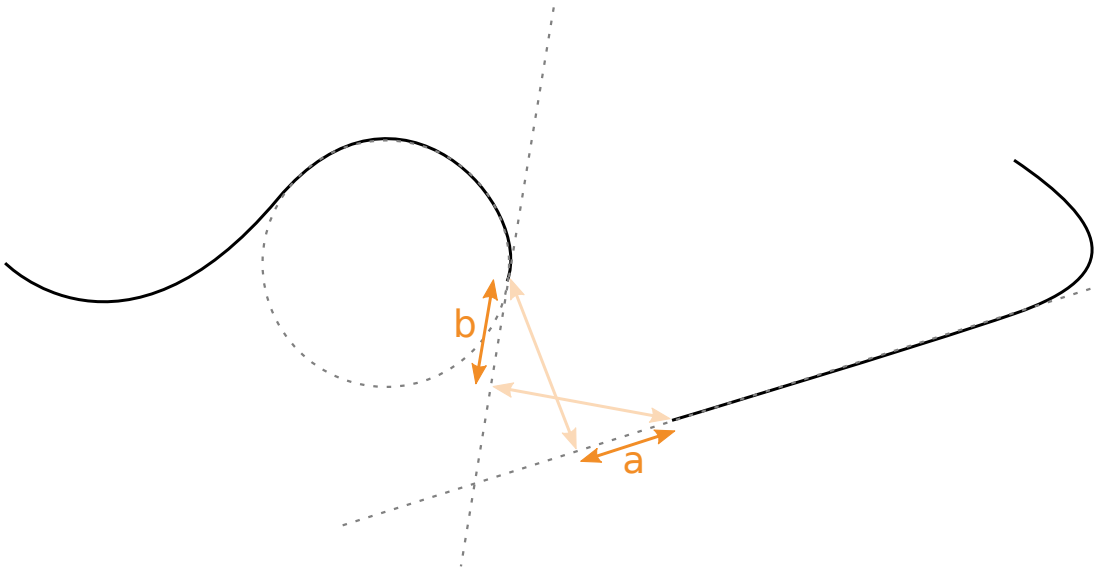
$a \leq$ MaxDist

MaxDistPerp The maximum distance perpendicular to the tangents is specified with the parameter MaxDistPerp. This distance is the minimum of the distances of the endpoints of the contours perpendicular to the other contour.



$min(a, b) \leq$ MaxDistPerp

MaxOverlap As a last threshold, the overlap of the contours is considered. The amount of the overlap is determined by the projection of one endpoint onto the tangent of another contour and vice versa. The distances between the endpoints and their projections must be shorter than MaxOverlap. Contrary to the other threshold values, MaxOverlap can become negative. Negative values denote the minimum distance of the endpoints in the direction of the tangents.



$min(a, b) \leq$ MaxOverlap. In this case, a and b are negative. See the reference manual entry of union_collinear_contours_ext_xld for an illustration with positive values for a and b.

It is possible, that a single contour is closed by this operator or multiple contours are merged into a single closed contour, if the criteria named above are fulfilled for the end pieces. Be aware that already closed contours are not considered for a union anymore.

If all thresholds are fulfilled between contours, a score value is calculated. The closer the calculated values for the angles and distances are to 0, the higher is the score value. The unification is then executed in the order of the score values. Thus, if there are multiple candidates for the unification, the best fitting contours are merged first.

The parameter Mode states, whether existing attributes of the input contours should be copied to the output contours. *'attr_keep'* copies the attributes, which can have negative impacts on the performance of the operator.

'attr_forget' causes the operator to ignore existing attributes. For further details see the description of the parameter Mode of the operator union_adjacent_contours_xld.

Parameters

▷ **Contours** (input_object) . . . . . xld_cont-array ⇝ *object*
Input XLD contours.

▷ **UnionContours** (output_object) . . . . . xld_cont-array ⇝ *object*
Output XLD contours.

▷ **FitClippingLength** (input_control) . . . . . real ⇝ *real*
Length of the part of a contour to skip for the determination of tangents.
Default: 0.0
Value range: 0.0 ≤ FitClippingLength

▷ **FitLength** (input_control) . . . . . real ⇝ *real* / string
Length of the part of a contour to use for the determination of tangents.
Default: 30.0
Suggested values: FitLength ∈ {10.0, 20.0, 30.0, 'auto'}
Value range: 0.0 ≤ FitLength

▷ **MaxTangAngle** (input_control) . . . . . angle.rad ⇝ *real*
Maximum angle difference between two contours' tangents.
Default: 0.78539816
Value range: 0.0 ≤ MaxTangAngle ≤ 3.1415926

▷ **MaxDist** (input_control) . . . . . real ⇝ *real*
Maximum distance of the contours' end points.
Default: 25.0
Suggested values: MaxDist ∈ {5.0, 10.0, 25.0, 50.0}
Value range: 0.0 ≤ MaxDist

▷ **MaxDistPerp** (input_control) . . . . . real ⇝ *real*
Maximum distance of the contours' end points perpendicular to their tangents.
Default: 10.0
Suggested values: MaxDistPerp ∈ {2.0, 5.0, 10.0, 20.0}
Value range: 0.0 ≤ MaxDistPerp

▷ **MaxOverlap** (input_control) . . . . . real ⇝ *real*
Maximum overlap of two contours.
Default: 2.0
Suggested values: MaxOverlap ∈ {2.0, 5.0, 10.0, 20.0}

▷ **Mode** (input_control) . . . . . string ⇝ *string*
Mode describing the treatment of the contours' attributes.
Default: 'attr_forget'
List of values: Mode ∈ {'attr_keep', 'attr_forget'}

Execution Information

- Multithreading type: reentrant (runs in parallel with non-exclusive operators).
- Multithreading scope: global (may be called from any thread).
- Processed without parallelization.

Possible Predecessors

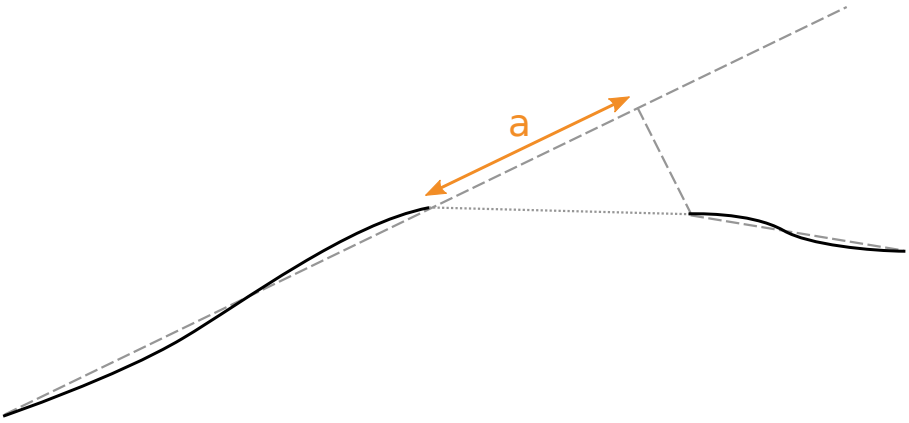
union_straight_contours_xld (Contours : UnionContours : MaxDist, MaxDiff, Percent, Mode, Iterations :)

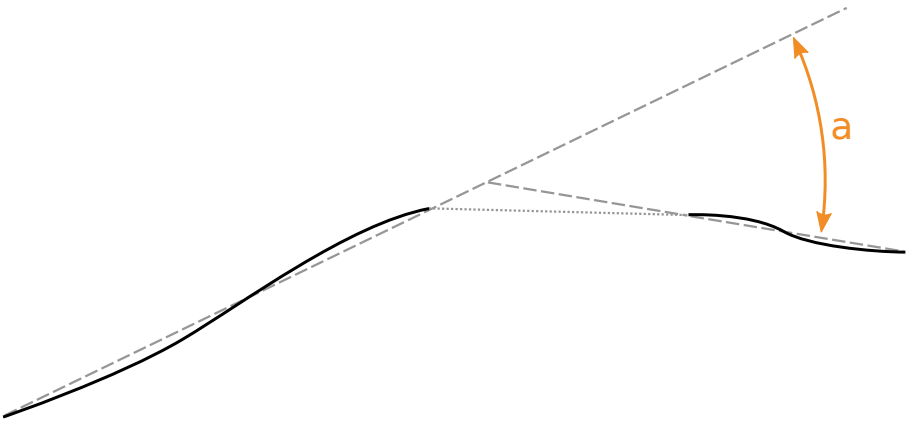
Compute the union of neighboring straight contours that have a similar direction.

union_straight_contours_xld merges neighboring XLD contours Contours if certain criteria are fulfilled. At each iteration, at most two contours that fulfill the given criteria are merged. The parameter Iterations controls how often this step is executed.

Two contours are merged if the shortest distance between their end points (end points are the projections of the contours' first and last points onto its regression line) is smaller than MaxDist, and if the difference in direction (i.e., the regression lines' direction) is smaller than MaxDiff (radians).



$a \leq$ MaxDist



$a \leq$ MaxDiff

If only one of the criteria is fulfilled, the decision on merging can be influenced by the weighting factor Percent, which allows the exceeding of one limit to be balanced by the other value remaining below the limit by the same amount. The end point distance is weighted by Percent, while the directional difference is weighted by $100 -$ Percent.

This means that two contours are merged if they fulfill the following condition:

$$\frac{shortest\ distance}{\texttt{MaxDist}} \cdot \texttt{Percent} + \frac{direction\ difference}{\texttt{MaxDiff}} \cdot (100 - \texttt{Percent}) \leq 100$$

If, for example, two contours have an end point distance of 5.0 and a directional difference of 0.5 (with the limits chosen being MaxDist = *4.0* and MaxDiff = *0.625*), both values differ from the limits by 25%. By choosing Percent = *60%*, the larger end point distance is weighted more than the smaller directional difference, and thus the contours are not merged. Contrary, if Percent = *40%* is chosen, the contours are merged.

For Percent = *100%*, only the end point distance is taken into account, while for Percent = *0%* only the difference of direction is used. If Percent = *50%* both criteria are equally valid.

In case there are parallel contours, there is a danger of merging neighboring contours. If this is to be avoided, Mode = *'noparallel'* has to be chosen, while otherwise Mode = *'paralleltoo'* suffices. For Mode = *'every'*, contours are merged unconditionally. All other parameters have no influence in this case.

The parameters of the regression line are calculated anew for merged contours.

Attention

Before contours can be united by `union_straight_contours_xld`, the parameters of the regression lines to the contours must be calculated by calling `regress_contours_xld`.

Furthermore, note that `union_straight_contours_xld` can not compute the union of contours with different contour point attributes. This can be the case if different operators are used for the contour extraction (e.g., `lines_gauss` and `lines_facet`). For information on the contour attributes and when they are defined, see the respective operator reference. You can query the point attributes of your contour using `query_contour_attribs_xld`.

Parameters

- ▷ **`Contours`** (input_object) ..... xld_cont-array ⇝ *object*
  Input XLD contours.
- ▷ **`UnionContours`** (output_object) ..... xld_cont-array ⇝ *object*
  Output XLD contours.
- ▷ **`MaxDist`** (input_control) ..... real ⇝ *real*
  Maximum distance of the contours' endpoints.
  Default: 5.0
- ▷ **`MaxDiff`** (input_control) ..... angle.rad ⇝ *real*
  Maximum difference in direction.
  Default: 0.5
- ▷ **`Percent`** (input_control) ..... real ⇝ *real*
  Weighting factor for the two selection criteria.
  Default: 50.0
- ▷ **`Mode`** (input_control) ..... string ⇝ *string*
  Should parallel contours be taken into account?
  Default: 'noparallel'
  List of values: `Mode` ∈ {'noparallel', 'paralleltoo', 'every'}
- ▷ **`Iterations`** (input_control) ..... string ⇝ *string* / integer
  Number of iterations or 'maximum'.
  Default: 'maximum'
  Suggested values: `Iterations` ∈ {1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 'maximum'}
  Value range: 1 ≤ `Iterations` ≤ 500 (lin)
  Minimum increment: 1
  Recommended increment: 1
